Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

It was very wet particularly along the Norwegian west coast and in northern Fennoscandia; locally, it was the wettest September in at least 100 years.

In the first half of the month, some thunderstorms with hail were recorded in central Europe.

Another wet area was to be found in the southern parts of Austria (up to more than 200% of the normal precipitation) and in northern Slovenia. Most of the precipitation here fell during the first half of the month.

In the south, it also was between twice as high and even four times higher over large parts of the Mediterranean, around the Black Sea and in the Middle East, where the high September rainfall brought an end to the preceding drought period. Heavy rain with flooding was especially seen in south-eastern France, south-east Spain, southern Italy, eastern Romania, Greece, Cyprus and Turkey.

Marseilles in southern France received 214 mm of precipitation, which was 455% of the 1961-1990 normal; similar records for Palma de Mallorca in the Mediterranean (222 mm, 444%) and even more in Alicante in Spain (309 mm, 754%). Although convective episodes are well typical for this time of the year in Spain, monthly totals broke previous records in some locations. Lajes on the Azores Islands (North Atlantic) received 126 mm (229%).

September also brought exceptional rainfall totals to the eastern parts of the Mediterranean region, the Caucasus region and the Middle East. Athens in Greece received 48 mm or 480% of the 1961-1990 average. Monthly rainfall in Cyprus was eight times higher than normal. Antalya in Turkey recorded 79 mm, Yerevan in Armenia 72 mm, both more than seven times the 1961-1990 normal. Places in Azerbaijan had similar amounts and much flooding, especially in the second half of the month. On the Black Sea coast in Georgia, very high monthly totals of up to 665 mm were measured. The northern Caucasus region (southern European Russia) was also very rainy. Israel, too, saw significant rainfall (30-80 mm in northern and north-eastern parts) which is unusual for this time of year and marked new records for that area.

Snow

Short snowfalls occurred in the mountain areas in Slovenia and Romania. Apart from that, only smaller areas in Scandinavia and the Alps had snow as usual.

Significant weather events

September 03-04:	Storm with gust near hurricane force (ex-tropical storm Danny) and heavy rain over the North Sea. Daily precipitation totals exceeded 120 mm in north-east Scotland. Parts of Aberdeen city centre were flooded with disruptions to road traffic and rail services.
September 04-05:	A low pressure system with heavy precipitation caused damage in north-western Slovenia. An intense cold front passed Hungary; an extended storm system developed in the frontal zone, causing serious damage to property and power lines.
September 07-09:	Flash floods seriously affected north-western Turkey, especially the city of Istanbul after the heaviest rain in 80 years. 80 mm of rain in 48 hours were measured at the airport in Istanbul; 67 mm fell within one hour on 9 September in Duzce. The return period for such rainfall events has been found to be once in 500 years. This event occurred during a season which is normally very dry since the rainy season starts only at the end of September. More than 100 fatalities, hundreds of buildings were destroyed.
September 09:	A new national September record of mean wind speed on mountain stations in Sweden was measured at 148 km/h.
September 12:	Heavy rain in Lower Austria in the morning caused flooding of homes.

September 12: Torrential rain on the island of Evvoia in Greece caused flooding of buildings, roads and a bridge to collapse. More heavy rain and flooding in north-western Turkey.

September 12: Extreme Sharav event in Israel with temperatures up to 38-41°C.

September 15-17: A violent storm crossed southern Italy, with the city of Palermo (Sicily) flooded due to heavy rain. Naples and Rome were also affected.

September 16-18: Heavy rain in southern Spain with thunderstorms and hail caused a mudslide in the city of Ibros with much damage. Locally, 300 mm of precipitation fell within 48 hours. Heavy rain (more than 160 mm) also fell in south-western France in the area of Bayonne (Pyrénées Atlantiques).

September 17: Heavy rain in south-east Latvia due to showers in connection with a cold front passage (locally 105 mm in 9 hours, more than 150% of the monthly normal).

September 18-19: Accompanied by heavy precipitation and hailstorms, tornadoes and large-sized hail affected several areas in Cyprus, causing injuries and significant damage. Israel, too, saw heavy precipitation.

September 20-21: Heavy rain in Dagestan (north Caucasus, European Russia), locally 100 mm or more precipitation in about 3 hours, causing mudflows, river flooding and significant economic damage.

September 20-24: Heavy rain in north-eastern Turkey caused flooding and mudslides.

September 26-29: Intense precipitation was recorded in many locations on the southern Mediterranean coast in Spain (in the region Alicante – Valencia) and on the Balearic Islands. Total rainfall of locally more than 300 mm was recorded within these 4 days. The normal annual precipitation is 450 mm.

September 28-30: Heavy rainfall (or snowfall in the mountains) throughout Armenia. Storm affected agriculture during the harvest season, causing significant damage to the crop.

October

- **Cold in Fennoscandia and Central Europe, milder in the Arctic, the Middle East, in Iberia and over the North Atlantic**
- **Wetter in central, eastern and south-eastern Europe, dry in northern and western Europe as well as in the Caucasian region**

Atmospheric circulation characteristics

Large areas of low pressure dominated over much of the North Atlantic, the Arctic and northern Europe. Especially in the middle of the month, cold polar air spread over northern, occasionally also central Europe, the Alpine region and the central Mediterranean, while milder air masses moved to the Arctic.

Western Europe including the western Mediterranean and the Caucasian region in the east were mostly and frequently influenced by high pressure. The Azores high, however, was rather weak.

South-eastern Europe and the central and eastern Mediterranean region often lay at the south flank of a high pressure zone, and intense low pressure activity continued there.

Temperature

In October, the temperature pattern changed considerably compared to the previous month. Large parts of Europe experienced colder-than-normal conditions, especially Fennoscandia, north-western European Russia, the Baltic countries and central Europe, with monthly mean anomalies partly around or below -2°C (Fig. 10.1), in Fennoscandia locally even below -3°C. It

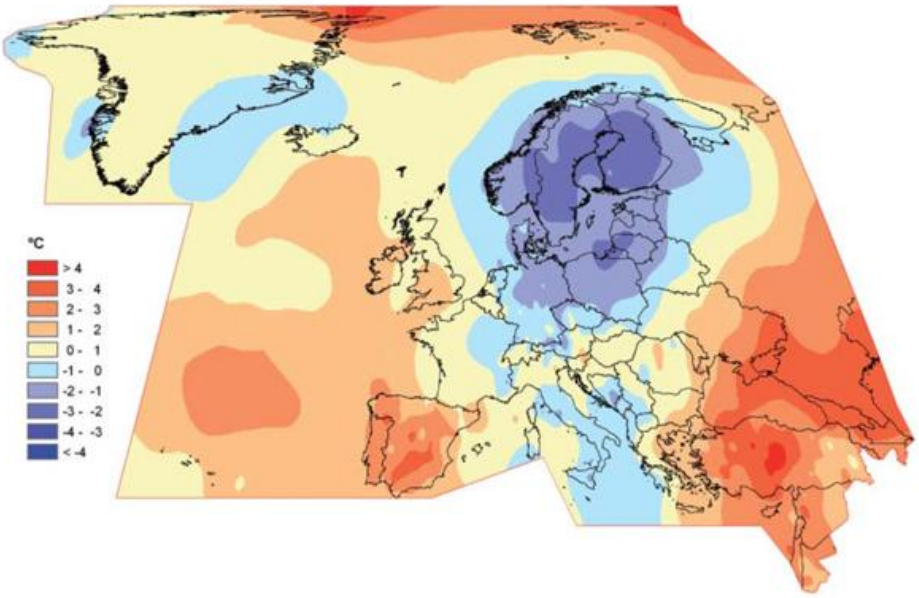

Fig. 10.1: *Monthly mean temperature anomalies in October 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

was the first time in more than 3 years that a month was colder than normal in all parts of Sweden. October had brought a quite early wintry spell from northern to central Europe. In the south, the central Mediterranean region was colder than normal.

The Arctic, the Middle East including the eastern Mediterranean and the Caucasian region, large parts of eastern Europe, particularly the eastern Ukraine, west Kazakhstan and southern European Russia, Iberia, most of western Europe and the North Atlantic were warmer than normal. Mean anomalies exceeded +4°C in the Arctic and in places in southern European Russia and central Turkey.

The last 10 days of October were very mild in the United Kingdom, with the result that the month on the whole was warmer than normal (+1.0 to +1.5°C).

Places in the Alpine region experienced a near normal October mean temperature. This was, however, an average of a very warm start of the month and of a wintry spell later.

The beginning of the month was still very warm in central and south-eastern Europe. Places in Austria saw their highest October daily maximum temperature in many years, e.g. 28.6°C in Vienna on 7 October was the highest in 50 years. In south-western Germany, a maximum of

30.9°C marked a new national October record for that day of the year. Northern and western parts of Serbia recorded a tropical day (maximum >=30°C) on 8 October, which is rare in that area for that time of the year. Even northern Italy recorded a temperature of up to 27°C.

After a very warm first decade, however, very cold air masses from the north crossed central Europe and reached the Alpine region on 12 October, bringing wintry conditions to large parts of central Europe, the Alps and even the central Mediterranean until 20 October. Temperatures showed a sharp decrease, e.g. the maximum temperature dropped by 20°C within one week in the Czech Republic. At -17.9°C, the Zugspitze (Germany's highest mountain, approx. 3000 m a.s.l.) set a new October minimum temperature record. Several lowland stations in Germany also experienced new records of lowest maximum and minimum temperatures for mid-October.

Iberia and southern France experienced some quite hot periods, with maxima above 30°C, and most of Portugal and Spain were more than +2°C warmer than normal based on the monthly average. Portugal had a 9-day heat wave on 10-18 October, with maximum temperatures of 30°C or more in the south of the country.

Israel had a 5-day heat wave on 15-20 October, with maximum temperatures continuously above 35°C in many places. This was the first heat wave of such duration in October since at least 1964. Jordan, too, was affected by this heat wave; the highest maximum there was 41°C on 18 October, +8°C above the normal maximum for this time of the year.

Precipitation

Northern and western Europe, Switzerland, Monaco, northern Italy and Slovenia, most of Iberia (except the north-west), southern European Russia, large areas of Turkey and the Caucasian region were very dry, with less than 80% of the normal monthly total over large areas. Some places received even much less precipitation (Fig. 10.2). Norway, on the whole, received 60% of its monthly normal.

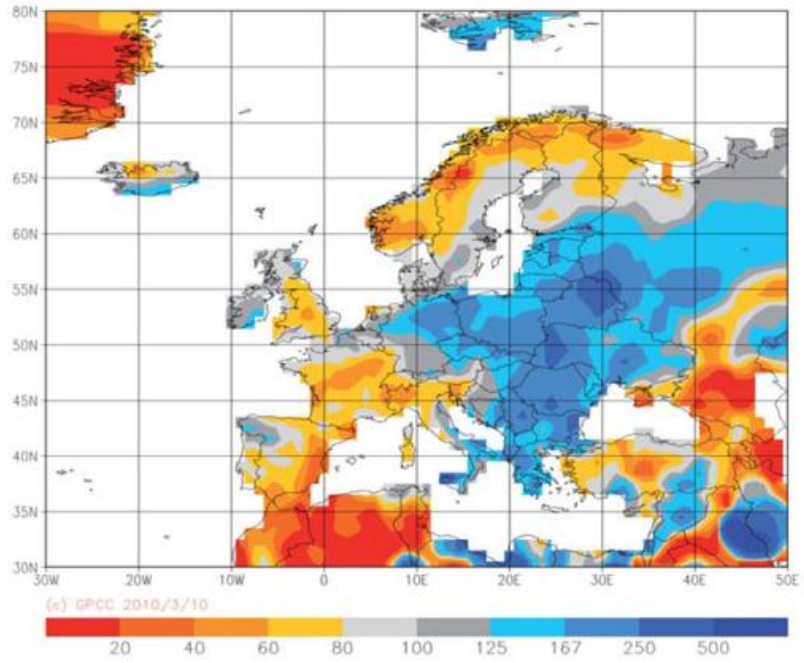

Fig. 10.2: *Monthly precipitation amounts for October 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

October was a wet month in central, eastern and south-eastern Europe (including parts of the central Mediterranean) and in places of the Middle East. 200% of the normal monthly totals were exceeded in various places, e.g. in Estonia, Belarus, European Russia, west Kazakhstan, the Ukraine, Romania, Bulgaria, Serbia, Hungary, Slovakia, Poland and Germany. In northern Germany, unusually heavy thunderstorms occurred due to a sharp temperature contrast between the north and the south. More than 300% of the precipitation normal was received in places and local records were broken, e.g. on mountains in Serbia (Kopaonik mountain had a monthly total of 193.7 mm).

It also was rainy over the North Atlantic. In Horta on one of the Azores Islands, monthly mean precipitation was around twice the normal.

Thunderstorms with heavy rain occurred over large parts of the Mediterranean; daily totals above 200 mm or 200% of the normal were particularly recorded over Sicily, but also in Greece.

Rainfall totals in northern and central Israel were 50-150 mm, compared to a long-term average of 20-40 mm. Most of the rainfall occurred at the end of the month. It was one of the rainiest October months in the last 60-70 years, although not record-breaking.

Snow

Early snow affected large areas of northern and central Europe including the Alps in the middle of the month following a cold front passage on 12-13 October.

On 14-26 October, a snow cover formed in eastern Germany even at altitudes below 1000 m; locally, it was the highest snow cover in October since at least 1971. Other countries in eastern central Europe also saw heavy and exceptionally early snowfall in the middle of the month. The Czech Republic reported a snow depth of 103 cm on 18 October for the mountain station Lysa Hora (altitude 1324 m). Poland also had heavy snowfall.

The Alps, too, received a lot of snow during that period. In Germany, the Zugspitze mountain (approx. 3000 m a.s.l.) recorded a snow depth of 160 cm while the Wendelstein mountain (approx. 1800 m a.s.l.) had accumulated 82 cm of snow until 19 October. A snow depth of 45 cm was recorded at a station near Salzburg in Austria at 2000 m a.s.l.; Switzerland reported similar values. The Austrian Sonnblick mountain (3106 m a.s.l.) had 75 cm of snow, although only two weeks before it had been completely free of snow. High mountains of the Italian Alps had a snow cover of 100-120 cm and Kredarica in Slovenia reached a maximum depth of 40 cm on 24 October. Even Serbia had up to 32 cm of snow in the second decade in mountainous areas, locally also in lower altitudes (3 cm).

Significant weather events

October 01:	Ball lightning in Mustjala, Saaremaa Island in Estonia.
October 01-02:	A storm dropped 70 mm of rain within six hours in Messina, Sicily. Civil protection measurement stations recorded up to 300 mm of precipitation in the mountains, causing severe mudslides, collapsing of buildings and cut-off roads. Thunderstorms in Malta with a daily total of 42 mm at Luqa Airport.
October 03:	Storm moving from the United Kingdom to southern Scandinavia. Gusts up to hurricane force over the North Sea.
October 03-07:	Heavy rain up to 200 mm on coastal areas of south Galicia (north-west Spain).
October 05-07:	Tropical storm Grace formed near the Azores developing to an

extratropical cyclone; it came near to England, but weakened before reaching it. Intense rainfalls of 20-40 mm in 24 hours occurred in England on 6-7 October.

October 07-08: Heavy thunderstorms with more than 50 mm of rain in 12 hours in northern Germany, especially in the night from 7 to 8 October, when the temperature contrast between hot subtropical air in the south and cold polar air in the north became very strong. The intensity of thunderstorms was unusually high for October. Heavy rain occurred also in Belgium.

October 07-08: Heavy rain in Azerbaijan due to a distinct low pressure system. Floods damaged bridges, roads, houses; 2 houses were destroyed completely.

October 10: Heavy precipitation and strong winds in eastern and south-eastern Iceland, with local daily totals of more than 180 mm within a strong Icelandic low.

October 12-26: Early heavy snowfall in large areas of northern and central Europe including the Alps.

October 13: An extended low pressure area affected the central Mediterranean and its surroundings. Heavy storm in Italy (especially in Rome and on the Adriatic coast). A small tornado hit Rome, causing falling trees and traffic chaos. Wind gusts up to 150 km/h were reported from Lower Austria. Heavy precipitation, especially in western and northern Romania. Storm and heavy rain in Turkey.

October 20-22: Heavy rain in southern France in the Rhone delta and the Provence region. Locally up to 157.5 mm within 8 hours. Heavy rain in Portugal (60 mm in 24 hours) during a front passage.

October 25: A storm with heavy rain caused flooding of homes and farms across Greece. The national road between Athens and the Peloponnese was blocked due to mudslides.

October 25-26: Gusts up to 108 km/h during 10 hours under strong low pressure influence in west Kazakhstan.

October 27-31: Heavy rainfall in Israel. Daily totals of more than 120 mm were recorded in the Sharon Plain (north of Tel Aviv) on 30 October, making it one of the three rainiest days since the beginning of measurements in that area. Heavy rain and flooding also in Turkey and Cyprus.

November

- **Very mild in Europe and the Arctic**
- **Mostly wet, dry along the north European coasts and over the western and central Mediterranean**

Atmospheric circulation characteristics

The Icelandic low became much stronger than normal whereas the Azores high retreated southwards. Intense low pressure activity and a mild flow of marine air from the south-west mainly affected north-western and northern Europe, and occasionally other parts of the Region.

Iberia, the western Mediterranean and the easternmost parts of the Region were dominated by high pressure most of the month. Only in the first decade two intense low pressure systems crossed the Mediterranean region.

Eastern central Europe, too, experienced a change after the first ten days. At the beginning of the month, it was under east European high pressure influence with cold air masses near the ground. Later in the month, the area came under the influence of a mild south-westerly airflow.

Temperature

November was a very mild month in Europe and in the Arctic. Monthly mean anomalies exceeded +4°C not only over large parts of the Arctic Sea, but also in places in northern and central Europe (Fig. 11.1); in northern Scandinavia the anomaly went up to +5°C, in northern Svalbard even to +9°C, which was a new record. Most of the European continent was +2 to +4°C warmer than normal.

The United Kingdom had a mean anomaly of +1.8°C and there were notably few days with air frost. Many places in western and northern central Europe were without frost. Monthly mean temperatures for November across the United Kingdom, Netherlands, Belgium, France, and Germany were among the three warmest in the last century. Daily maxima in France ranged up to 25°C, and minima to 12–15°C. In southern Germany, Switzerland and Austria, maximum temperatures of around 20°C were reached in the middle of the month, as a result of foehn winds; however these were not record-breaking temperatures.

The Baltic countries had anomalies between +1.5 and +2°C; the final third of the month was particularly mild there. Latvia reported the highest November temperatures since 1926, which were around 11°C in some areas on 21 November.

Most of the southern Caucasus region was +1 to +2°C warmer than normal; maximum temperatures of up to 23°C were measured in Azerbaijan and in south-eastern Europe (e.g. in Serbia). The station Antalya in southern Turkey even reached 32.5°C.

Some stations with long histories in southern and eastern Spain reported record-breaking monthly mean temperatures, for example at Valencia, with observations dating back 141 years. Daily maxima exceeded 25°C on several occasions. In Monaco, it was the mildest November since 1994 (15.1°C, +1.4°C above the 1969-1998 average).

The central North Atlantic and a few places over the eastern Mediterranean and in the Middle East were slightly colder than normal.

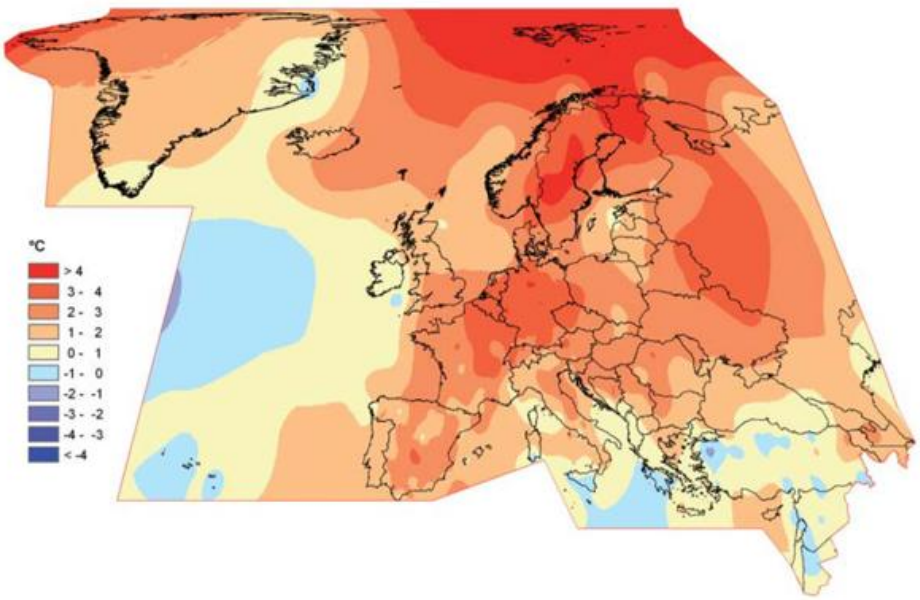

Fig. 11.1: *Monthly mean temperature anomalies in November 2009 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Precipitation

November was wet over large areas of Europe, in Turkey, northern Israel and in most parts of the southern Caucasus countries (Fig. 11.2). It was much drier than normal along north European coasts, in most of the Czech Republic, Austria and Slovenia, over most of the Mediterranean and Iberia (except the north and west), west of the Black Sea and in central and eastern European Russia and western Kazakhstan.

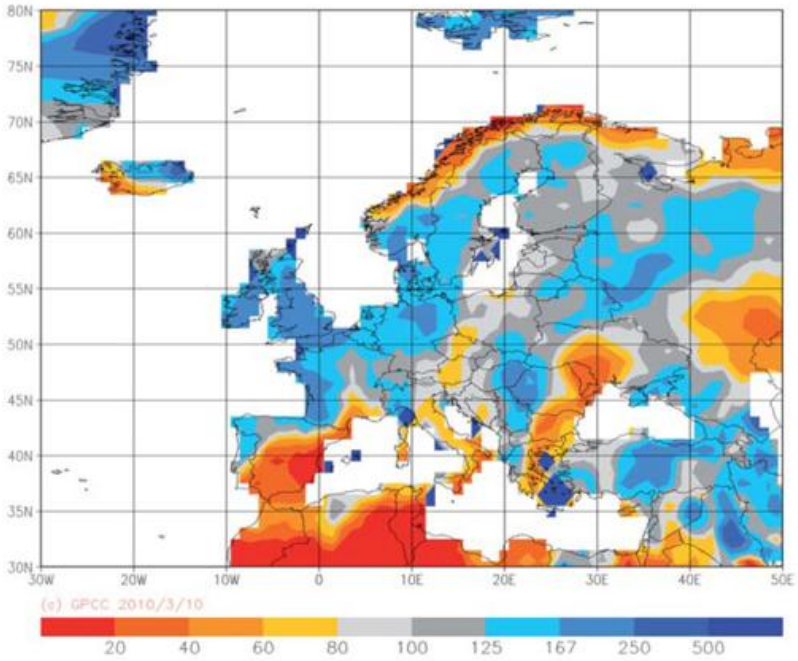

Fig. 11.2: *Monthly precipitation amounts for November 2009 as percentages of the normal in 1951–2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Some areas of northern Norway saw less than 20% of the normal precipitation. Other parts of Scandinavia, in contrast, were much wetter than normal. In southern Scandinavia and Denmark, the 90th percentile of the 1961–90 distribution was exceeded. It was the second wettest November ever registered in parts of southern Norway. A new November record of 27 precipitation days was registered for Denmark.

There was more than 200% of the normal monthly precipitation in Ireland and some parts of the United Kingdom. It was the wettest November on record in the United Kingdom since 1914 and in parts of Ireland, with an average of 217 mm of rain across the UK. For Scotland alone, average monthly rainfall totals rose to record-breaking 256 mm. Much of that rain was due to a heavy rain event on 18–20 November. Ireland had no days without rain every day somewhere and 24–29 rain days (i.e. 0.2 mm or more of rainfall) at most stations, compared to a November normal of 16–22 rain days.

High precipitation was recorded also over various parts of the Balkan Peninsula (except the eastern parts), with locally more than 200% of the normal, e.g. on the southern coast of Montenegro.

Parts of the northern Caucasus region in southern European Russia received up to more than 5 times the monthly normal in places. In Azerbaijan, monthly precipitation was between twice and four times the normal. Several stations in Turkey received around twice the normal monthly precipitation with flooding in the north. Exceptional rainfalls were recorded in Greece during the first half of the month, causing flooding in many parts of the Greek mainland and islands.

In contrast, it was extremely dry in parts of eastern Spain, especially in Barcelona with only 3 mm in the whole month (4% of the normal). However, heavy rains fell in northern and western Iberia during the first ten days of November, with up to 300 mm in some locations such as San Sebastián.

Snow

November started with a temporary snow cover in north-eastern Germany and Denmark. Brief snowstorms occurred sporadically in Lithuania.

The mild conditions during November were sufficient to melt all the snow that had fallen in October up to high altitudes in the Alps. However, heavy snowfalls occurred during the course of November, even at low altitudes on the northern side. Up to 90 cm within 24 hours fell on the southern slope of the Alps in Switzerland. It also snowed on the mountains in Serbia and Romania, and in eastern Slovenia even in the lowlands.

Heavy snowfalls caused avalanching in the northern Caucasus mountain areas. First snowfalls also occurred on high mountains in Georgia and Azerbaijan in the final third of the month.

Significant weather events

November 01–02: Rivers in the United Kingdom (Scotland and Wales) burst their banks after heavy rain (daily totals of up to more than 50 mm) and caused flooding in towns. In Scotland, the river Deveron hit its highest level since records began in 1959.

November 06–11: There was abundant rainfall in western Romania and eastern Serbia; with local levels of up to 80–90 mm of daily precipitation in the mountains. Later, heavy rain and flooding occurred in Turkey.

November 18–20: Record rainfall and widespread flooding affected north-western England, Scotland and Ireland after the passage of frontal systems enforced by a

strong wind shear and orographic lifting. A new 24-hour record of 316 mm of rainfall was noted in the UK in the county of Cumbria (north-western England). Parts of the high ground received more than 400 mm in 72 hours. The flooding problems became worse due to water-saturated soil following wet weather earlier in the month. Many rivers in the Lake District exceeded their previous maximum flows by a wide margin, and exceptionally high flows were also reported across north Wales and southern Scotland. Several road bridges collapsed or were damaged, and some 1,500 properties were flooded (Fig. 11.3). Several places in Ireland were also exceptionally wet, receiving more precipitation during these three days than during a whole November ever, e.g. more than 50 mm on Valentia Island and at Cork Airport and over 100 mm in other places in the west and south-west of the country.

Fig. 11.3: *Aerial view of the River Derwent and the remains of Northside Bridge in Workington, Cumbria (England) in November 2009. Photo provided courtesy of the UK Environment Agency*
Source: Met Office Hadley Centre, United Kingdom

November 18–20: The same low pressure system hit Denmark with wind gusts of up to hurricane force (132 km/h) on 18 November. The strong winds considerably raised the sea level along the west coast, uprooted trees and caused minor damage to buildings. There were also strong winds in northern Germany. In Norway, a precipitation station recorded a daily total of 143 mm on 20 November.

November 21–22: Landslides and flooding occurred in northern Turkey during and after a cold front passage with heavy precipitation.

November 23–24: The passage of a cold front brought gusts of up to hurricane force to lower mountain areas in Central Europe and heavy storms and rain to the lowlands.

December

- **Cold over the northern half of Europe, much milder in the Arctic, the Mediterranean and in the south-east**
- **Mostly wet, but dry along the north-west coasts of Ireland, the United Kingdom and Norway**

Atmospheric circulation characteristics

At the beginning of the month, a large cold trough extended from northern Europe to the central Mediterranean, whereas eastern Europe was under a mild southerly airflow. This situation changed very soon to a zonal circulation with low pressure systems and a generally mild airflow moving from the Atlantic to western, central and northern Europe.

In the middle of the month, however, a strong blocking high moved from eastern to northern Europe, and later to Greenland. Cold air from the north-east spread over the whole of Europe, particularly its northern half. A large low pressure complex developed over the Mediterranean and extended almost to the whole of Europe. During the same period, mild air from the North Atlantic moved to the Arctic region.

At the end of the month, many Atlantic low pressure systems again crossed the European continent. Warm subtropical air masses and a persistent high pressure system over Africa led to mild weather especially over the central and eastern Mediterranean and south-eastern Europe.

Temperature

It was very mild in the Arctic (monthly anomalies more than +4°C above normal (Fig. 12.1), with some places in Greenland and Svalbard at least +7°C warmer than average, and parts of Svalbard even +8 to +9°C) and in Iceland. Daily maxima at the west coast of Greenland and in Iceland were around 10–12°C on several days, and in the north-east of Iceland locally over 14°C because of the foehn. However, the last week of December was cold in Iceland. In Greenland, the beginning of the month was particularly cold. The peak station Eismitte (ice centre) in Greenland (3200 m a.s.l.) recorded -13.1°C in the middle of the month, which was very mild compared to -55.3°C at the beginning of December.

December was a cold month in the northern half of Europe and in the Alps. Monthly mean anomalies below -1°C were recorded over large parts particularly in northern Europe. In eastern European Russia and some areas of the highlands in southern Norway, they were even below -4°C. Ice days were unusually frequent in Scandinavia and in the Alps. Ireland experienced its coldest December in 28 years, the United Kingdom since 1995.

December temperatures in many parts of Europe differed largely between the start and the end of the month. The beginning of the month was unusually warm in the northern and eastern parts of Europe, e.g. in Belarus with temperatures ranging between +5°C and +10°C above average. On 2 December, several locations in Lithuania, Belarus and European Russia set new records for this day, including Minsk (Belarus) (where temperatures reached 9.3°C) and Moscow (9.0°C), while in Moldova, the night of 2 December was the warmest for that day of the year in the last 65 years. The warmest day in Moscow in December 2009, however, was the 6 December, with 9.4°C. Remarkably, this value had been measured in the early morning and was a local record for December.

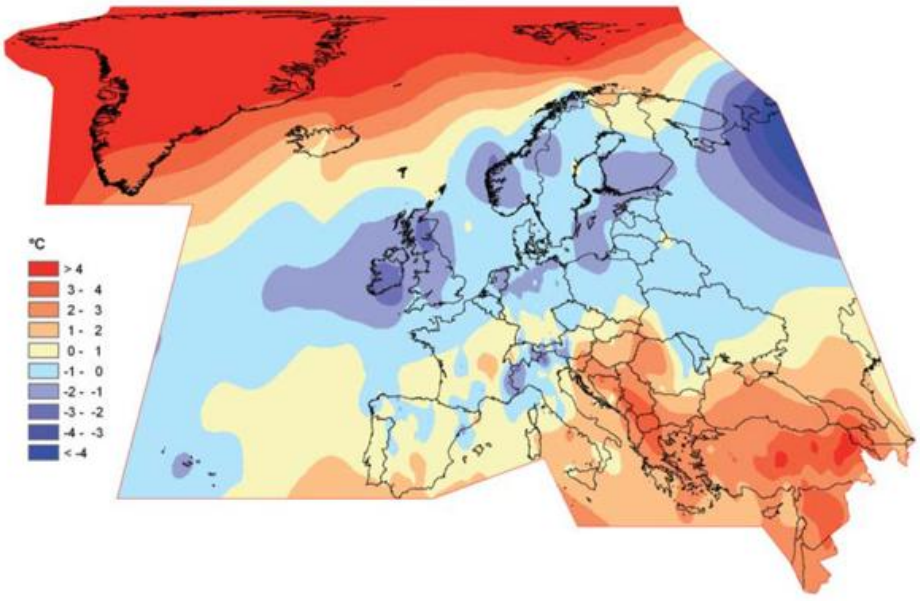

Fig. 12.1: *Monthly mean temperature anomalies in December 2009 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

In the middle of the month, a severe cold snap caused by the dominance of arctic air affected many places in Europe and caused serious traffic problems and loss of life due to freezing. Daily minimum temperatures dropped to around -20°C and below in many places in northern, western, central and eastern Europe and in the higher Alps; in eastern European Russia temperatures dropped below -30°C. In the city of Kazan in European Russia, a new absolute minimum temperature was recorded for the entire 138-year observation series. New daily minimum temperature records compared with the last 60 years or more were also set at several locations in Germany. In Switzerland, Geneva recorded -12.6°C, the lowest temperature for December since 1968. Eurostar trains between Brussels, Paris and London were cancelled over a three-day period. Temperatures across England and Wales, in some places in Ireland (station Mullingar on 25 December) as well as in Belgium and Hungary fell as low as -10°C and below. The last occurrence of a minimum temperature below -10°C in December in Belgium was registered in 1996. In Scandinavia, minima as low as -40°C were recorded, in southern Europe -17°C in northern Italy, and on lower mountains in Spain. Burgos (northern Spain) recorded a new daily minimum record on 20 December since the start of measurements in 1943.

The month started cold in Austria, but the second third of the month was mild, resulting in near normal monthly mean temperatures. In Switzerland, a rapid warming in the final third of the month took place on the northern side of the Alps due to the south foehn.

On average, it was very mild over much of the Mediterranean (including southern and north-eastern Spain, Malta, the Balkan Peninsula, Turkey and Cyprus) and in the Middle East (including the southern Caucasus countries) with anomalies > +2°C (locally > +4°C) over large land areas in south-eastern parts of the Region.

The second half of the month was particularly warm in the south-eastern parts of the Region. Local records for daily maximum temperatures for 23–31 December were broken in Hungary (up to 21.8°C) and Serbia (23.8°C). In Bulgaria, several stations registered record high temperatures on Christmas Day (e.g. 21.2°C in Vratsa). It was the warmest December of the decade 2000–2009 in the whole of Greece; maximum temperatures between 15 and 20°C were

reached in many places. On 25–30 December, record high temperatures were also recorded across central and southern Italy, with temperatures exceeding 25°C. In Azerbaijan, it was particularly warm at the end of the month with maxima of up to 20°C in the highlands.

Precipitation

The high pressure over Scandinavia caused a dry December in much of northern Europe, while most of the rest of Europe, particularly the south, experienced a very wet end of the year (Fig. 12.2).

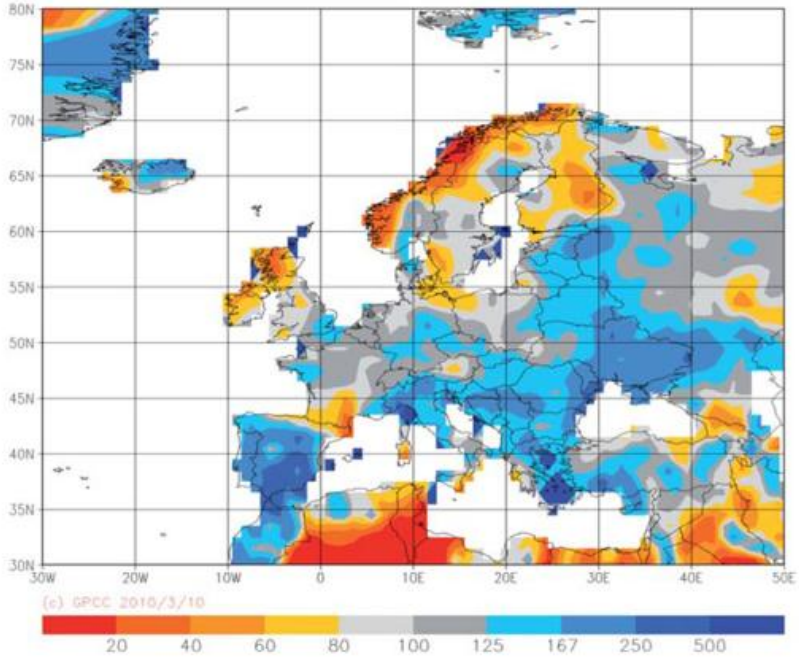

Fig. 12.2: *Monthly precipitation amounts for December 2009 in per cent of the 1951-2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

The Arctic region including parts of eastern Greenland and Iceland was very wet. December rainfall total in Akureyri (northern Iceland) was the highest since the start of continuous measurements in 1927.

Most parts of northern and north-western Europe were very dry. It was much drier than normal particularly along the west coast of Norway, in Ireland and Scotland. In many places there, less than half the normal monthly totals were reached. Parts of the Norwegian west coast received less than 15% of its December precipitation normal 1961–90, owing to the low frequency of westerly airflows. All parts of Finland, too, were much drier than normal. Some northern and central areas of European Russia also received only low precipitation.

Most of the other parts of the Region saw a wet December. The Baltic countries were wet due to several heavy precipitation events; December precipitation levels in Estonia and Latvia were 130–140% of the 1961–1990 normal.

In western Europe, France saw some heavy precipitation in various parts of the country, but monthly totals were mainly not much above normal; in southern France, totals were even much below. Most of central Europe had levels of precipitation slightly above-normal.

It was particularly wet in southern Spain, due to heavy rain events in the second half of the month. Local rain record amounts fell over the month in many places. Large parts of western and southern Iberia received 200 mm of precipitation or more, while extended areas over Andalucía received more than 300 mm, causing widespread flooding. In most of Iberia, December precipitation was more than twice the normal. Portugal had the wettest December of the century, and even the Azores Islands had totals well above the normal (230–250 mm).

Several stations in northern Italy recorded their wettest or second wettest December in nearly 90 years, mainly due to intense precipitation around Christmas. Monaco saw its wettest December since 1983 (175 mm), receiving more than twice the long-term average 1969-1998. Slovenia and Croatia, too, received well above normal precipitation, more than twice the normal in several places, as did Malta; western Slovenia received three times the normal. It was the second wettest December ever recorded on the mountain Kredarica and at the coast of Slovenia. Local records for monthly totals were broken in Serbia. Due to frequent rain and snow melting during the last days of December, high water levels were recorded for rivers in parts of south-eastern Europe, e.g. in Slovenia, northern Hungary and eastern Serbia.

Another area of high precipitation during the month was the north-west coast of the Black Sea, where precipitation exceeded 250% of the normal. The Ukraine received heavy precipitation particularly in the first half of the month.

An exceptional local 24-hour precipitation record was set in Makrinitsa in central Greece, where 417.2 mm fell on 10 December. This is equivalent to nearly half of the total rainfall for 2009 at this station. Some other places in Greece also saw exceptional precipitation on that day, resulting in significant flooding and widespread damage. Cyprus experienced heavy precipitation several times during the month, including a heavy hailstorm on 16 December, resulting in a monthly average total of almost 150% of the normal. Similar levels were recorded in parts of the southern coast of Turkey.

Georgia in the southern Caucasus was very dry; some parts had only half of the normal total and eastern parts had rain on only 5–7 days. North-eastern Turkey was also much drier than normal, in contrast to the rest of the country.

Snow

December was particularly snowy in northern Iceland; Akureyri reached a December record depth of 90 cm.

Snowfall was widespread and locally heavy, especially in the middle of the month in western and central Europe, but also in the south. Deep snow accumulated over high ground from Spain to central and eastern France, northern England and southern Scotland. The Netherlands also experienced unusually heavy snowfall, with depths of up to 30 cm on 17–20 December; road and rail transport were seriously affected. At the German North Sea coast, depths up to 25 cm on 22 December partly were new local records for December. The United Kingdom and the Netherlands including some coastal areas of the North Sea experienced a white Christmas for the first time in nearly 30 years in some places, but a following mild period caused a rapid melting of the snow cover before the end of the year.

High snow depths were also recorded in eastern parts of the Region including the Baltic countries. In Estonia, snow depths of 43 cm at the end of December set a new record for this month. A snowstorm in north-west Latvia in the middle of the month caused considerable increases in snow depth. Heavy snowfall at the end of December was also experienced in Moscow, when 19 cm fell within 24 hours. The Ukraine saw heavy snow storms in the first half of December and again at the end of the year, causing widespread damage to buildings, traffic and electricity lines.

The Alps already had above normal snow depths at the beginning of the month due to snowfall in late November. Further snowfalls occurred during the month, particularly on the southern side of the Alps in the final third.

The Lombardy region in northern Italy had deep snow in the cities Milan and Piacenza. About 30% of the land area of Italy was covered by snow. However, subsequent warming and continuous rainfall in northern Italy resulted in rapid melting causing extensive flooding in Tuscany just before Christmas.

The Balkan Peninsula received snowfall locally to depths of half a metre or more. There was even some snow in coastal regions of Slovenia on 19 December (Fig. 12.3). In some parts, e.g. in Montenegro, the snowfalls caused disruptions of electricity, road and air traffic.

Fig. 12.3: *High tide and a little bit of snow on the Slovenian coast on 19 December 2009*
Source: Environmental Agency of the Republic of Slovenia

Later, just as in Italy, in parts of south-eastern Europe, e.g. in northern Hungary, large accumulations of snow which had fallen in mid-December melted away rapidly and caused rivers to flood. Eastern Serbia recorded the highest river water levels in history for that time of the year and widespread flooding occurred in several parts of the country.

Snow even fell in Cyprus, over the highest parts of the mountain Troodos.

Significant weather events

December 10–12:	A large eastern Mediterranean low pressure system caused thunderstorms with heavy rain on the southern Turkish coast. 186 mm of rain fell in Antalya in 24 hours, mostly during the night 10–11 December. Greece, too, had heavy rain with flooding.
December 14:	There was a violent thunderstorm with funnel clouds over Catania (Sicily, Italy).
December 16:	A winter storm caused 89 cm of snow at Vindafjord in Norway.
December 16:	Heavy rain, hail and strong winds affected all areas of Cyprus. Trees were uprooted and buildings damaged, mainly around Larnaka. Storms and hail also occurred in Turkey.
December 16–17:	There was a snowstorm in north-west Latvia. Snow cover increased by 70 cm and more in places due to this event (Fig. 12.4).

December 18-20: Severe cold spell over large parts of Europe. People died by the cold. 7 victims were reported by Germany around the 20th, overall perhaps more than 80 people died across Europe.

Fig. 12.4: *Snowed-up residential house in Kolka (north-west Latvia) on 17 December 2009 Source: http://weatherfoto.wordpress.com, provided by Latvian Environment, Geology and Meteorology Centre*

December 18: Severe glaze and rime (up to 60 mm thick) was experienced over a 20-hour period in southern European Russia (Stavropol region).

December 18–25: Snowstorm with heavy precipitation in northern Italy, followed by a sudden sharp increase in temperature and further precipitation including freezing rain. Roads and railways were severely affected. Locally more than 600 mm of precipitation fell during this event. The city of Venice was flooded.

December 19–22: An Atlantic storm affected Iberia with torrential rain near the strait of Gibraltar.

December 21–31: Persistent heavy rain left hundreds of homes flooded around Andalucía, southern Spain. The record rainfall, which saw over 400 mm falling in many areas in a week, caused dozens of rivers to burst their banks. The highest local rainfall was 709 mm during 10 days starting on December 21. In total, over two cubic kilometres of water entered the reservoirs in Andalucía over these ten days. This is 20% of the total capacity for the region.

December 21–27: Extremely high precipitation levels were experienced in Slovakia, causing flooding in the Hron river basin. 100 mm within two days fell in Banská Bystrica. There was also abundant precipitation in Slovenia and several rivers were flooded. Summer-like showers and rainstorms were reported in all parts of Hungary, particularly on 26 December.

December 21–31: Extended period of rain in Romania, with particularly heavy rain on the last two days of the year in the western parts of the country. Rainfall levels locally exceeded 150 mm during the final third of the month (Fig. 12.5)

ECSN Activities Report 2009

Support and co-operation in best climate practices

Responsible Member: KNMI; Programme Manager: Aryan van Engelen

The objective of ECSN, the **European Climate Support Network**, an optional Programme of EIG EUMETNET (in 2009, EUMETNET was transformed into an Economic Interest Group, a legal entity), is to support its 25 members in their climate practices in order to provide better products and services to the European user community for the benefit of the environment, safety, economy and health.

In 2009, this objective was realised by a range of activities: running new **programmes** and **projects** (ECA&D, S-EUROGRID/EUMETGRID, ECSM/EuCLIS, PEP725, Climate Change Services and HIST-EU), focusing on a better understanding of Europe's past, present and future climate and the provision of data and products, **participating** in or collaborating with major EU research projects: ENSEMBLES, MILLENNIUM and EURO4M, **communicating** and **co-operating** with other parties such as WMO, WMO-RAVI, EEA, ESA, EUMETSAT, EUMETNET-EUCOS, EUMETNET-SRNWP and **co-ordinating** activities: preparing and organizing the climatology programme of the EMS-ECAM 2009, the ECSN Data Management Workshop 2009 and the EMS-European Conference on Applied Climatology 2010.

S-EUROGRID (SMHI) & **EUMETGRID** (Met.no, http://eumetgrid.eu)

The main objective of EUMETGRID is to develop and maintain a sustainable pan-European data infrastructure for accessing and distributing gridded climate information, based on the NMHS's sustainable observational network, databases and meteorological infrastructure. The EUMETGRID programme aims to build an operational platform for the production and distribution of high-resolution gridded climate data based on the best available national and international high-resolution gridded data sets in Europe. Given that the activity is based on already existing and planned national operations and national and international infrastructure, this project will provide crucial input to climate change/variability assessments, decision support and adaptation. EUMETGRID will develop specifications and implement a data infrastructure for the exchange of gridded climate data based on national contributions through distributed databases. This will ensure access to the best available gridded climate information for any point in Europe.

Highlights:

- S-EUROGRID, the preceding pilot of EUMETGRID, successfully completed.
- EUMETGRID proposal accepted by EIG EUMETNET GA.

EuCLIS/ECSM (DWD, http://www.dwd.de/ecsm)

The aim of EuCLIS/ECSM is to build a sustained operational Web-platform for climate monitoring products in WMO-RA VI. These efforts complement successful regional climate monitoring activities such as the RA VI Bulletin, the European contribution to the annual BAMS Article on the State of the Climate, European contributions to the annual WMO Statement on the Status of the global Climate, ECA&D etc. All these activities together provide basic components of a systems-approach for a co-ordinated operational climate monitoring in WMO

RA VI. Based on the analysis of a questionnaire on RA VI operational climate monitoring requirements (Gocheva, Hechler, Dec 2007), the systems-approach aims at implementing a RA VI RCC (Regional Climate Centre) node for climate monitoring.

Highlights

- 20 countries contribute to ECSM.
- EuCLIS will be the future technical platform of the RCC on Climate Monitoring, currently is in the official pilot phase.

ECA&D-ENSEMBLES/MILLENNIUM/EURO4M (KNMI, http://eca.knmi.nl)

The European Climate Assessment and Data set (ECA&D) aims to create and maintain a pan-European data set of high-quality daily observational series and, on the basis of derived climate change indices, to produce assessments of Europe's changing climate. ECA&D is based on a dataset (E-OBS) which currently comprises approx. 3300 stations and over 12.700 time series. E-OBS is the baseline dataset serving the EU FP projects EMSEMBLES, MILLENNIUM and EURO4M. Like EuCLIS, it will serve as a platform for a RA VI Regional Centre on Climate Data.

Highlights

- EURO4M, an EU FP7 proposal, received funding, the project started in January 2010.
- When the ECA&D became operational, “The European Climate Assessment & Dataset (ECA&D) Report 2008 - towards an operational system for assessing observed changes in climate extremes” was published and disseminated among project participants.
- ECA&D will be the technical platform of the RCC on Climate Data, currently in the official pilot phase.

PEP725 (ZAMG, www.zamg.ac.at/cost725)

Phenology is the study of the timing of recurring biological events in the animal and plant world, such as leaf unfolding and flowering of plants in spring, fruit ripening, colour changing and leaf fall in autumn, as well as the arrival and departure of migrating birds and the timing of animal mating. During the past decade, phenology has rapidly become an important tool for climate change impact studies.

Under Cost Action 725, a prototype database of European phenological records was set up. An ECSN project proposal under the name PEP725 aims at the establishment and sustainable management of a full-scale phenological database.

Highlights

- PEP725 proposal accepted by EUMETNET GA.

EIG EUMETNET Framework for Climate Services on Climate (Change) Information (KNMI)

EUMETNET GA decided to commission a review (to be co-ordinated by ECSN) in the context of a growing European requirement for providing climate services across EIG EUMETNET Members, taking account of the outcomes of the following events:

- The initiative to establish a Global Framework for Climate Services, announced by WMO and discussed and elaborated at the third World Climate Conference (WCC3), early September in Geneva.
- An international workshop "Climate change information services for decision making and adaptation" (KNMI, De Bilt, 10-11 Sept.).
- The RA VI-XV meeting (Brussels, 18-24 Sept.), where the establishment of RCCs was discussed.

The Assembly agreed to establish the Climate Change Services Working Group, co-ordinated by KNMI and ECSN, which should work in close co-operation with WMO and take into account the capabilities of EIG EUMETNET Members, including the Regional Climate Centres, in order to assess how to improve the co-ordination of existing institutions and infrastructure in the domain of Climate Services in Europe.

HIST-EU (ZAMG)

The responsible member of the successfully completed HRT-GAR project (ZAMG) launched this initiative in order to extend the current HIST-ALP project (aiming at the creation of a database of long-term monthly homogenised series over the Greater Alpine Region) to the whole of Europe, with the following two main objectives:

- To extend HIST-ALP to HIST-EU with a climatological network described as long-term, of appropriate density, quality-improved, homogenised and of European relevance.
- To support data rescue activities to achieve an optimal European station density.

A proposal for the ongoing EUMETGRID / ECA&D / EURO4M projects is currently being fine-tuned. An appropriate proposal should be submitted to EUMETNET GA in 2010.

WMO-RA VI –XV, Brussels, 18-24 September 2009

The co-operation of ECSN with the WMO RA VI Working Group on Climate Related Matters (WG CRM) resulted in the RA VI RCC Network Implementation plan that was submitted and accepted at the RA VI-XV session (Brussels, 18-24 Sept. 2009). This plan describes the establishment of Regional Climate Centres (RCC) with the ECSN projects EuCLIS (DWD, RCC on climate monitoring) and ECA&D (KNMI, RCC on climate data) as nuclei. As a next step, ECSN will support the designation of a RCC on Long-Range Forecasting (Météo France and Roshydromet/Russian Federation).

ECSN's support of the Task Team Redesign RBSN/RBCN will be based on requirements originating from the ECSN data projects.

9th EMS Annual Meeting and 9th European Conference on Applications of Meteorology (ECAM), Toulouse, Météo France, 28 September – 2 October 2009

ECSN prepared the session's programme on climatology, the theme was as follows: "Climatology - new services responding to climate change", encompassing 4 topics:

- Climate observations and data management, climate monitoring, reconstruction and mapping, applications for decision support on adaptation and mitigation, climate change and society.
- Climate change assessments of trends and variability.
- Climate prediction and scenarios from seasons to century.
- Documentary and natural proxy data for the study of climate anomalies and hydro-meteorological extremes.

10th EMS Annual Meeting and 9th European Conference on Applied Climatology (ECAC), Zürich, ETH, 13-17 September 2010

In line with the EIG EUMETNET Framework for Climate Services on Climate (Change) Information, ECSN prepared the session programme for ECAC 2010 already in 2009. The theme of the session was: "High-resolution Climatology – towards climate change services".

The session programme deals with the following four major topics, which have been agreed with WMO GFCS:

- Monitoring: towards a reference climate and monitoring change.
- Understanding: processes and climate change.
- Services: translating science to users.
- Plenary discussions: topics include communication and adaptation strategies for climate change.

ECSN Data Management Workshop 2009, Copenhagen, DMI, 4-6 November 2009

At this workshop, European NMSs presented challenges, national experiences & practices in the field of climatological data. The workshop session programme focused on the following topics:

- Data management (behind the colourful maps), encompassing Databases, Dataflow, Quality Control, Data, Observational Practices & Strategy and Present Challenges.
- Products, tools & users.

A special session was devoted to major issues such as EUMETGRID, RCC etc.

Detailed proceedings can be obtained at: http://ecsn2009cph.dmi.dk/

The Ozone Layer over Central Europe in 2009

Wolfgang Steinbrecht, Hans Claude, and Ulf Köhler - Deutscher Wetterdienst

The 2009 total ozone annual mean fell within the expected range. At Hohenpeissenberg, it amounted to 326 DU, clearly higher than the 316 DU observed in 2008. Comparable behaviour was seen over much of the Northern hemisphere. In 2009, the slow recovery of the ozone layer from the large depletion caused by anthropogenic chlorine (from Chloro-Fluoro-Carbons or CFCs) continued. Fig.13.1 shows the long-term development of the annual means of the ozone column at Hohenpeissenberg. In the early to mid-1990s, ozone depletion was exacerbated by the large stratospheric aerosol loading from the Mt. Pinatubo volcanic eruption. Because chlorine loading is still very high, the risk of very low total ozone after a large volcanic eruption will continue for the next 10 to 20 years.

Apart from chlorine and aerosol loading, ozone variations are related to several other factors: The 11-year solar cycle, with an ongoing solar minimum in 2009, favoured low total ozone. The quasi-biennial oscillation (QBO) was easterly at 20 hPa through most of 2009, favouring high ozone. In 2008 the QBO was westerly at 20 hPa, which tends to result in low ozone. The polar winter vortex was disrupted by a record-breaking stratospheric warming in January 2009. This also contributed to high total ozone. In contrast, the vortex was fairly stable in 2008, favouring low ozone. Other meteorological factors, e.g. the North-Atlantic Oscillation, play a role as well.

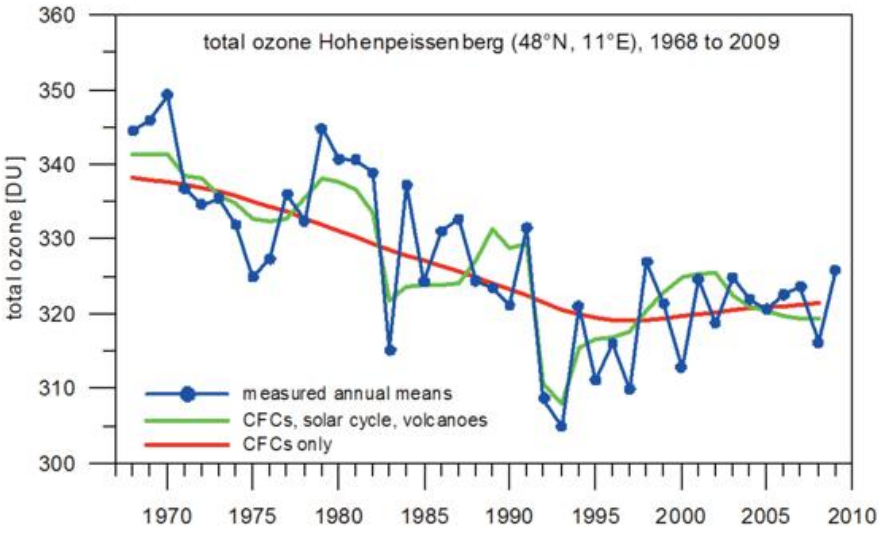

Fig. 13.1: *Blue curve: Total ozone annual means (DU) measured at Hohenpeissenberg. Red curve: Long-term variation attributed to anthropogenic chlorine (from CFCs). Green line: Long-term evolution attributed to chlorine, volcanoes, and 11-year solar cycle. Red and green curves are estimated by multiple linear regression.*

The records of daily column observations at Hohenpeissenberg (Fig. 13.2) reveal significant details between the relatively high annual mean of 2009 and the low annual mean of 2008. The largest differences between these two years occurred in January, February, and December – all winter months. Whereas the northern winter 2007/2008 was a “normal” winter with a fairly stable stratospheric winter vortex, the winter 2008/2009 was characterized by the earlier mentioned stratospheric warming in late January 2009. This major warming was accompanied by enhanced transport of ozone rich air from the tropics northwards, as well as by enhanced descent of ozone rich air over the polar region. In addition, the QBO favoured extratropical downwelling in 2009, but not in 2008. All this resulted in high ozone columns over much of the northern hemisphere in 2009. At Hohenpeissenberg, total ozone in 2009 (red line in Fig. 13.2)

was often above the 67% percentile from January to March (and also in December). On some days values were even near the overall maxima. In contrast, total ozone in 2008 was often below the 33% percentile from January to March, sometimes even near the overall minima. Other Central European stations obtain similar results. This shows that the substantially different ozone annual means in 2008 and 2009 were mainly caused by the different winter conditions in these two years.

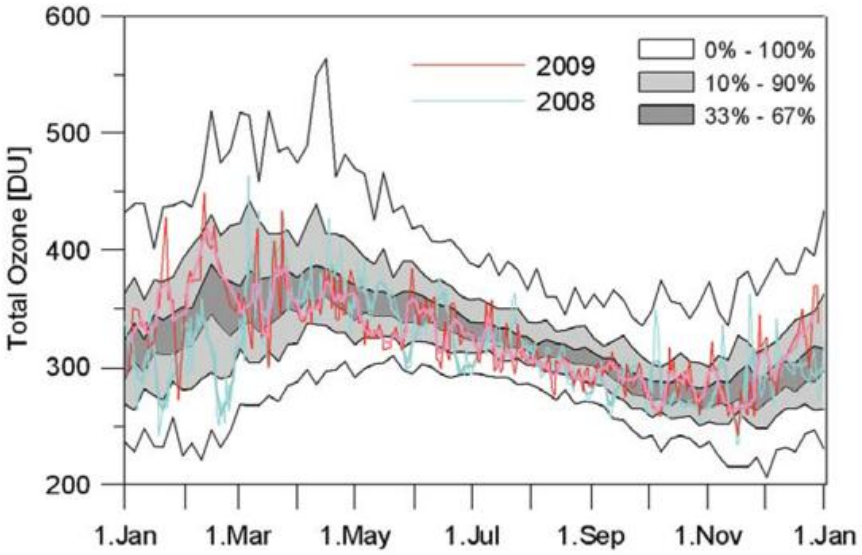

Fig. 13.2: *Red: Daily mean total ozone values observed at Hohenpeissenberg (47.8°N, 11.0°E) in 2009. Pink: 5-day running mean. Light blue/blue-grey: Same for 2008. Shaded ar-eas: Dark grey: 33% to 67% percentile range of all daily mean values observed from 1968 to 2009. Light grey: 10% to 90% percentile range. White range: Minimum to maximum observed daily means (=0% to 100% percentile range).*

The behaviour in the summers is quite different: From May to September, total ozone values in both 2008 and 2009 were usually below the 33% percentile, and sometimes even close to their overall minima. These low values through much of summer are due to the long-term ozone depletion caused by chlorine levels still being high and the ongoing solar minimum. They might also be connected to climate change, because a warmer troposphere and a higher tropopause favour lower total ozone. On sunny days, such low ozone values will result in enhanced UV-radiation at the earth's surface. At wavelengths shorter than 300 to 310 nm the UV-enhancement can be substantial (>30%).

The Bulletin is a summary of contributions provided by the National Meteorological and Hydrological Services. Foreword

Climate was again a hot topic in 2010, also in RA VI. This time, it was not only the global warming, but also the extreme winter cold spells which attracted much attention from the public. In fact, large parts of Europe experienced a cold and snowy winter 2009/10 and once more an outstandingly cold and snowy December 2010. On the other hand, an extremely long and intense heat wave affected particularly the European part of Russia and neighbouring countries in summer, and mild weather in the Arctic region caused again a very low sea ice extent.

It has become clear that the extremely negative values of the Arctic Oscillation were a main contributor to annual climate variability. In this context, the year 2010 showed very clearly that even in a time of global warming, extreme warm and cold periods can still occur repeatedly, which has to be considered when talking about adaptation strategies.

In terms of precipitation, some areas were equally affected by repeated extremes, such as flooding in eastern central Europe in May and in August and September. As for storms, we still have not forgotten the storm Xynthia crossing France and Germany in late February 2010.

All these examples show that a good co-operation of the national meteorological and hydrological services of our Region in climate issues is essential for monitoring and, as far as possible, forecasting regional climate variability. The development of a Regional Climate Centre (RCC) Network in RA VI is the right step in this direction. I was very pleased to attend the "WMO Workshop on Climate Monitoring including the implementation of climate watch systems in RA VI", which was jointly organised by the WMO and the Deutscher Wetterdienst (DWD) in Germany in 2010, and where representatives of the members of the RCC-Network and of the National Meteorological and Hydrological Services as well as other interested participants came together. The Network is now in its pilot phase, with the designation procedure in progress.

The Annual Bulletin on the Climate in RA VI, which is on its 17th issue this year, continues to be an important backbone within the RCC product suite. Considering the requests of some of our Members to extend our assessments beyond the area of our Region, a global overview of temperature and precipitation anomalies has been added. As in previous years, the Annual Bulletin also presents an extensive summary of all important climate events of 2010 in our Region, compiled from the excellent material provided by many of our Members.

Once again, it is a pleasure for me to thank all the Members for their contributions. My special thanks go to the editorial team of DWD, namely Dr Peter Bissolli, for compiling and writing all the texts and Volker Zins for his technical support as well as to all reviewers.

I wish you a pleasant reading and hope this Bulletin will be helpful for your work in climatology.

Ivan Cacic
President of WMO Regional Association VI

Outstanding Events and Anomalies in 2010

Temperature

- Long and intense heat wave in July and August in European Russia and adjacent areas
- Cold winter 2009/10 and cold December 2010 in large parts of Europe

Precipitation

- Several flooding events in eastern central Europe (May, August, September)
- Long summer drought periods in central European Russia and in the Middle East
- Extensive snow cover in large parts of Europe in winter 2009/10 and in December 2010

Storm

- Heavy storm (Xynthia) over south-western, western and central Europe at the end of February 2010

Annual Survey

1. Atmospheric circulation

The main features of the global atmospheric circulation in 2010 were a transition from El Niño to a very strong La Niña and a strongly negative Arctic Oscillation and North Atlantic Oscillation in particular during the cold season in RA VI, associated with the domination of meridional patterns over Europe.

1.1. El Niño / La Niña

2010 started with El Niño conditions stronger than those at the end of 2009. They were most distinct in February and then weakened rapidly in early spring (Fig. 0.1). A typical feature of El Niño is the stronger subtropical jet and a dislocation of the Icelandic low to a far more southerly position, which was very pronounced in February. As a consequence, wet conditions prevailed over Iberia and the Mediterranean in the winter 2009/10, whereas it was cold and dry particularly in northern Europe.

In April 2010, the Southern Oscillation index entered into a La Niña phase, which became gradually stronger during the course of the year. Full La Niña conditions had arrived in August 2010. The highest value was achieved in December with 2.9 (standardised), which is also the highest value ever reached in at least 60 years (according to data from NOAA) and was assessed as one of the five strongest La Niña events since the beginning of the 20th century. Nevertheless, the impact on the surface pressure field over the North Atlantic and Europe was masked by a strong negative North Atlantic Oscillation and Arctic Oscillation.

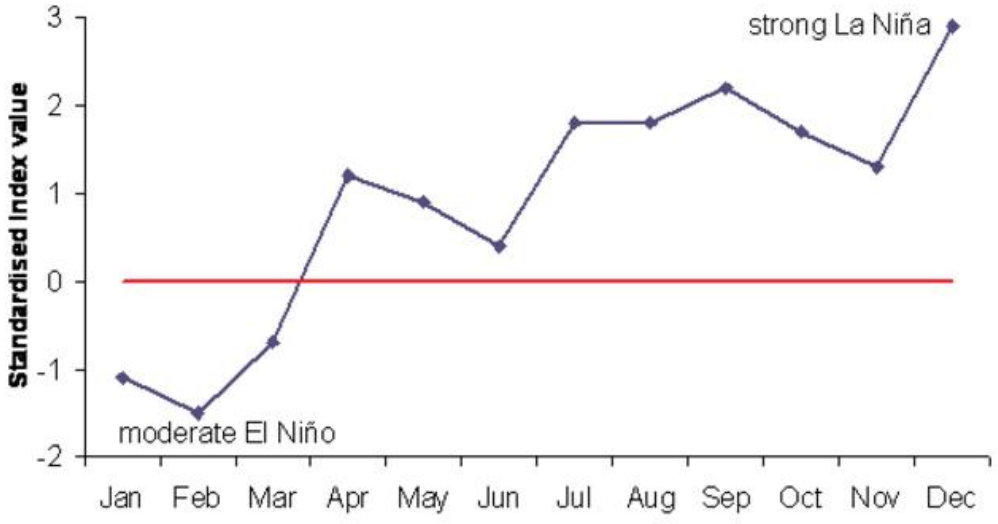

Fig. 0.1: *Standardised Southern Oscillation index for 2010, as expressed by the difference of standardised sea level pressure anomalies in Tahiti and Darwin (Australia)*
Source: NOAA, www.cpc.ncep.noaa.gov/data/indices/soi, 8 February 2012

1.2. Arctic Oscillation (AO) and North Atlantic Oscillation (NAO)

The Arctic Oscillation index (Fig. 0.2) was highly negative during the winter months January and February 2010 and once again at the beginning of the next winter in December 2010. This implies that a mainly meridional circulation pattern prevailed in the northern hemisphere during all winter months. As a consequence, there was a strong meridional exchange of Arctic air masses and milder air masses from more southern latitudes. Thus, most of Europe saw colder winter months than normal, whereas the Arctic was relatively mild. During the rest of the year, the AO index was close to zero, implying only weak impact. Averaged over the whole year 2010, however, the pressure gradient between middle and high latitudes of the northern hemisphere decreased compared to 2009.

The NAO index was negative during almost the whole year, except July when the index was close to zero. This implied the existence of a stronger-than-normal meridional circulation component over the North Atlantic; westerly airflows from the Atlantic to Europe were quite rare. Annual mean air pressure was up to 10 hPa higher in Greenland and the Icelandic low was dislocated towards Newfoundland while the Azores high was weaker than normal. Sea level pressure in Iceland reached its highest annual average on record since 1823 (1014 hPa). Like the AO, the NAO too had an extremely negative phase in the winter months, when the impact of the NAO on Europe is very strong. Iceland was often dominated by high pressure whereas low pressure prevailed over the Azores, which is the quite the reverse of normal conditions. This facilitated the arrival of cold continental air from the east in western Europe and prevalence of moist conditions over the Mediterranean countries.

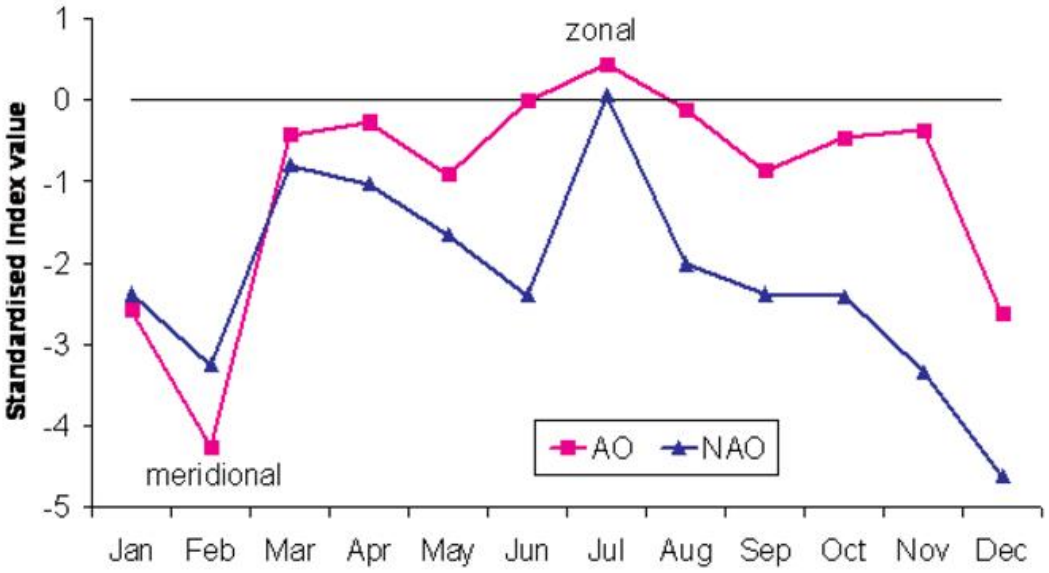

Fig. 0.2: *Standardised Arctic Oscillation (AO) index and North Atlantic Oscillation (NAO) index for 2010, as expressed by the difference of standardised sea level pressure anomalies between southern and northern latitudes over the whole northern hemisphere (AO) and the North Atlantic (NAO).*

http://www.cru.uea.ac.uk/~timo/datapages/naoi.htm

1.3. Zonality over the North Atlantic and Europe

Like AO and NAO, the zonal index over the North Atlantic and Europe (Fig. 0.3) also reflects the very extreme meridional situation in January, February and December 2010. In March, however, the zonality returned to normal conditions, and followed more or less the typical annual cycle until October, though with a systematic deviation towards a more meridional mean pattern, particularly in September. In November and even more in December, however, the annual cycle shifted again towards unusual meridional conditions. This shows that mainly the winter months had greatly contributed to a stronger meridionality and thus to a significant cooling in Europe, compared to normal conditions.

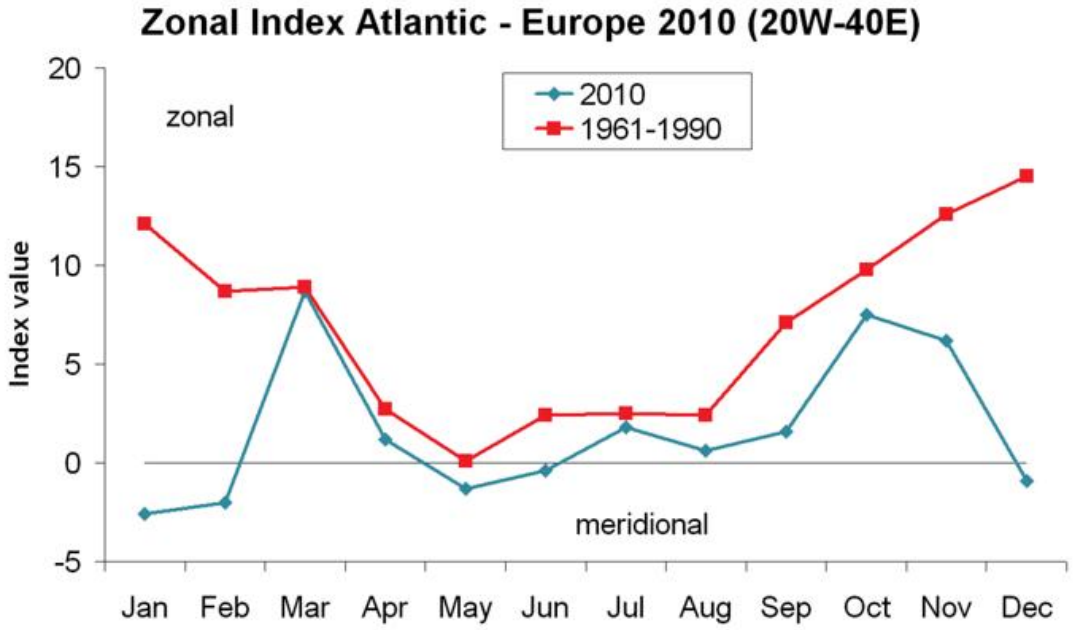

Fig. 0.3: *Zonal index over the North Atlantic and Europe (20°W–40°E) for 2010, as expressed by zonally averaged sea level pressure difference between southern and northern latitudes Source: Deutscher Wetterdienst, www.dwd.de/GWL*

1.4. Sub-regional Overview

1.4.1. Central and eastern North Atlantic

The weather over the North Atlantic was conditioned by a negative NAO almost throughout the year. This resulted either in a meridional warm airflow from south or south-west to the north (in most parts of the year) or in a cold easterly flow from the European continent particularly in the winter months February and December. Zonal airflows from west to the east only dominated in July and partly in autumn.

1.4.2. Arctic regions of Europe

The Arctic Oscillation was negative almost throughout the year, which implies an enhanced meridional exchange of arctic and warmer air masses. Especially the western European Arctic, particularly western Greenland, was influenced by a strong flow of warmer air from the south almost over the whole year.

The whole European Arctic saw considerably stronger-than-normal high pressure conditions and subsiding dry air. Only the eastern parts experienced some longer low pressure periods, especially in March and November.

1.4.3. Northern Europe (Baltic countries, northern European Russia, Scandinavia)

Northern Europe was particularly influenced by the negative Arctic Oscillation, especially in the three winter months (January, February and December 2010), but partly also in March and November when cold and dry air came either from the Arctic region or the cold continent in northern Russia. The summer half year, too, saw some periods when cold Arctic air moved to northern Europe, especially in May, June and October.

Several times over the year, large parts of northern Europe were under strong high pressure influence, with occasional low pressure systems occurring especially in spring and early summer or late summer in the southern parts.

1.4.4. Western and central Europe (Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxembourg, the Netherlands, Poland, Slovakia, Switzerland, United Kingdom)

Western and central Europe was also strongly influenced by the negative AO and NAO, though not as much as northern Europe. Prolonged periods with blocked weather patterns, and an associated absence of westerly airstreams, resulted in a year that was colder, drier and sunnier than average in most of the western areas. The most extreme months were again the winter months, when cold air masses reached all parts of western and central Europe and many low pressure systems with snow moved over central and western Europe, especially in December 2010.

The rest of the year showed quite a large variability, with high pressure situations (particularly in April) alternating with some intense low pressure systems.

1.4.5. Iberia

From January to March, Iberia was frequently affected by southerly frontal zones resulting from the stronger subtropical jet caused by El Niño.

The rest of the year was characterised by a large variability of cold and warm spells due to many meridional situations. Cold air from the north frequently reached Iberia, partly in spring and especially in autumn. In July and August, intense high pressure influence prevailed particularly in Portugal, partly as a result of a strong subtropical high associated with a developing La Niña.

1.4.6. Mediterranean (including Italy, Monaco and Malta)

In the winter 2009/10, the whole Mediterranean region was affected by a strong subtropical jet and more and stronger low pressure systems, triggered by El Niño. Throughout the year, frequently occurring meridional patterns brought cold air as far southwards as the western Mediterranean, especially in winter due to the highly negative Arctic Oscillation. Conversely, the Eastern Mediterranean was mainly affected by warmer air from the south and often under the influence of high pressure.

1.4.7. Balkan Peninsula (Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia)

The Balkan Peninsula was mostly influenced by warm air from the south. Cold air masses from more northerly parts of Europe reached these parts rarely, except in September and October and on some occasions also in the winter months. However, low pressure systems affected the peninsula frequently throughout the year.

1.4.8. Eastern Europe (Belarus, western Kazakhstan, Moldova, Romania, central and southern European Russia, Ukraine) and South Caucasus region (Armenia, Azerbaijan, Georgia)

In January, eastern Europe was strongly affected by cold continental air, particularly in the north. Meridional air mass exchange began to develop in February and the area was dominated by warmer air masses. However, especially in spring, temporarily colder air masses reached the South Caucasus. In summer, high pressure and warm and mostly dry air dominated the weather in eastern Europe, particularly in Russia where it caused an extremely long hot and dry period. High pressure conditions continued also in early autumn, but cold air masses came to central parts of eastern Europe particularly in October. In November, a southerly airflow advecting warm air from the south dominated, whereas polar air arrived from the north and extended southwards in December.

1.4.9. Middle East (Cyprus, Israel, Jordan, Lebanon, Syria, Turkey)

The Middle East was mainly affected by warm air from the south throughout the year. Intrusion of colder air from the north was very rare, mostly affecting only parts of Turkey. However, intense low pressure systems with abundant rain occurred at times, especially over Turkey in the cold months.

2. Temperature

2.1. Global Overview

According to WMO information, the year 2010 ranked as the warmest year on record, together with 2005 and 1998 since, at least, 1850. Data received by the WMO show no statistically significant difference between global temperatures in 2010, 2005 and 1998 (Fig. 0.4). The global mean temperature has increased by +0.7°C during the period 1881–2010 (linear trend).

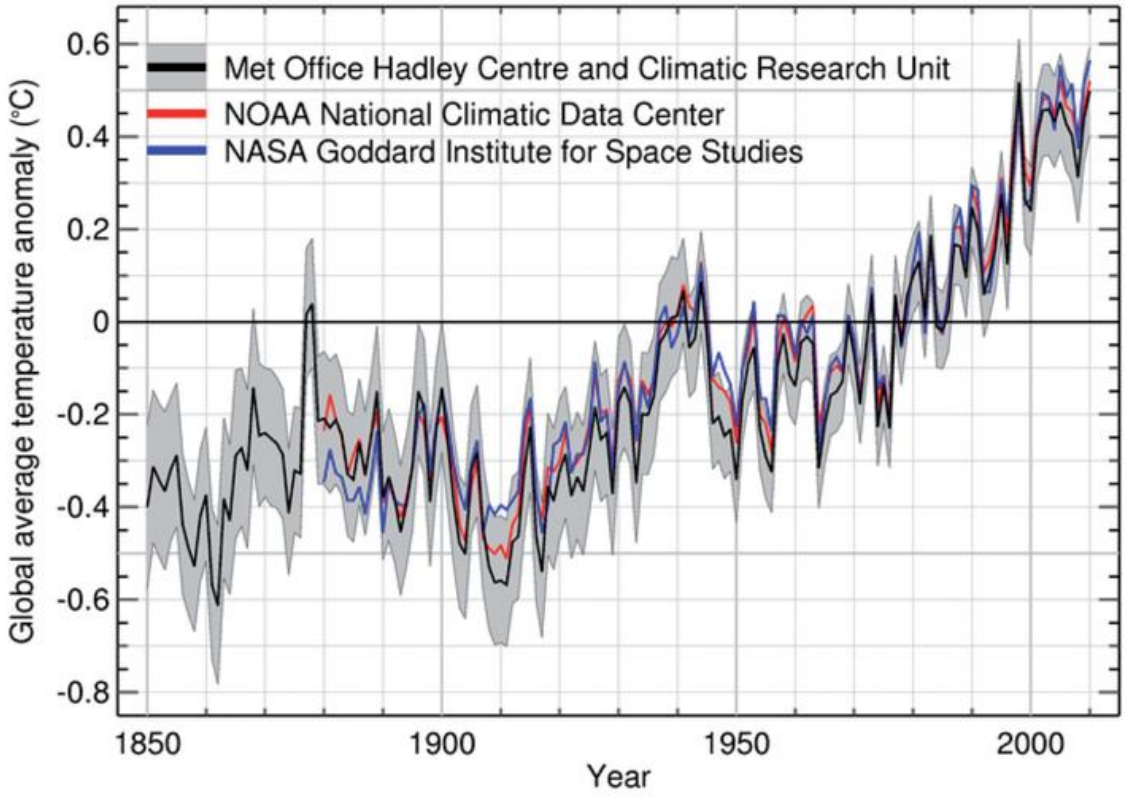

Fig. 0.4: *Mean global annual temperature anomalies 1850–2010 (reference period 1961–1990) Source: WMO, http://www.wmo.int/pages/mediacentre/press_releases/images/906_2010dataset.PNG*

The global annual mean temperature anomaly in 2010 was +0.53°C. This value is 0.01°C above the nominal temperature in 2005, and 0.02°C above 1998. The difference between the three years is less than the margin of uncertainty (± 0.09°C) in comparing the data. These statistics are based on data sets maintained by the UK Meteorological Office Hadley Centre/Climatic Research Unit (HadCRU), the U.S. National Climatic Data Center (NCDC), and the U.S. National Aeronautics and Space Administration (NASA). Highest anomalies were recorded in March (warmest March on record), lowest in December. The global mean temperature itself was 14.53°C in 2010.

In the northern hemisphere, the year 2010 was the warmest year on record; not so in the southern hemisphere, however, where the year nevertheless was still among the five warmest years.

For global land areas, a global anomaly of +0.92°C was computed according to NOAA data (Fig. 0.5). This was the second highest since 1880, behind 2007 (+0.96°C). In 2010, the earth's oceans were +0.37°C warmer than normal, making it the third warmest year since 1880 according to NOAA, following slightly behind 2003 (+0.39°C) and 1998 (+0.39°C).

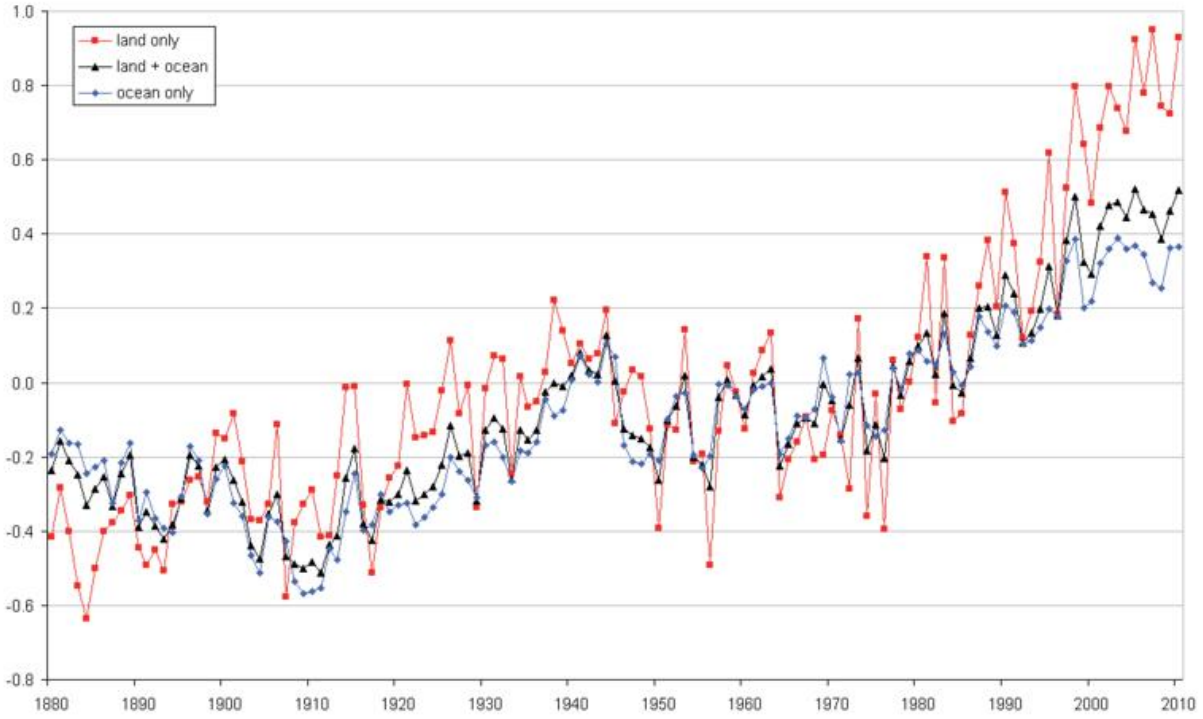

Fig. 0.5: *Mean global annual temperature anomalies 1880–2010 (recomputed to the reference period 1961–1990) over land, oceans, and land and oceans combined.*
Source: NOAA/NCDC, http://www.ncdc.noaa.gov/cmb-faq/anomalies.html#anomalies

2010 was warmer than normal over most of the global land areas (Fig. 0.6). The highest anomalies were reported for eastern Canada (more than +5°C on Baffin Island) and western Greenland. Other far warmer-than-normal areas (> +2°C) were northern Africa, the Middle East and north-eastern Russia. In some of these areas, this was the warmest year on record (western Africa, Sahara and Arabic Peninsula, Mediterranean, southern Asia, central and south-western Asia, Greenland and northern Canada). Exceptional heat waves in summer in several parts of Eurasia contributed largely to the high annual temperature level.

It was colder than normal particularly over northern and western Europe, central Russia, central and eastern Australia, parts of the Antarctic and a few smaller areas in north and south America, locally below -1°C.

Especially the spatial distribution of anomalies over the northern hemisphere reflects prevailing meridional circulation patterns associated with a highly negative Arctic Oscillation, particularly in winter. This circulation pattern modulated the general global warming by cooling parts of Europe and Asia due to meridional exchange of air masses whereas parts of North America were additionally warmer than expected from the global warming trend.

The sea surface temperatures were lower than normal in the eastern Pacific (due to La Niña), but above normal in most of the other regions (Fig. 0.6a). The tropical Atlantic was especially warm, with large parts recording their highest sea surface temperature ever, just like the ocean region around Australia.

Over the ten years from 2001 to 2010, global temperatures have averaged 0.46°C above the 1961–1990 average, and were the highest ever recorded for a 10-year period since the beginning of instrumental climate records. Recent warming was especially strong in Africa, parts of Asia, and parts of the Arctic, with many subregions registering decadal mean temperatures 1.2 to 1.4°C above the long-term average.

2.2. RA VI Overview

The anomalies observed in 2010 in the RA VI Region cannot be considered as representative for the whole globe. The areal mean for the European continent as well as the areal mean land surface temperature for the smaller area 35°–75°N, 10°W–30°E, both based on data from the Met Office Hadley Centre, were above normal in 2010 (+0.68°C, Fig. 0.7 and +0.24°C +/- 0.13°C, respectively), but clearly colder than all the other years of the decade 2001–2010. The last year in Europe that, as a whole, was colder than 2010 was 1998. Nevertheless, 2010 was still warmer than what is to be expected from a linear trend since 1900. After all, summer 2010 was the warmest summer on European average since 1900 (+2.1°C anomaly) and July and August 2010 were the warmest months for the same period (+2.9°C and +2.3°C, respectively). On the other hand, the cold months January, February, October and December 2010 were all colder than normal in contrast to the other months including the whole warm half year (April–September) which were warmer than normal.

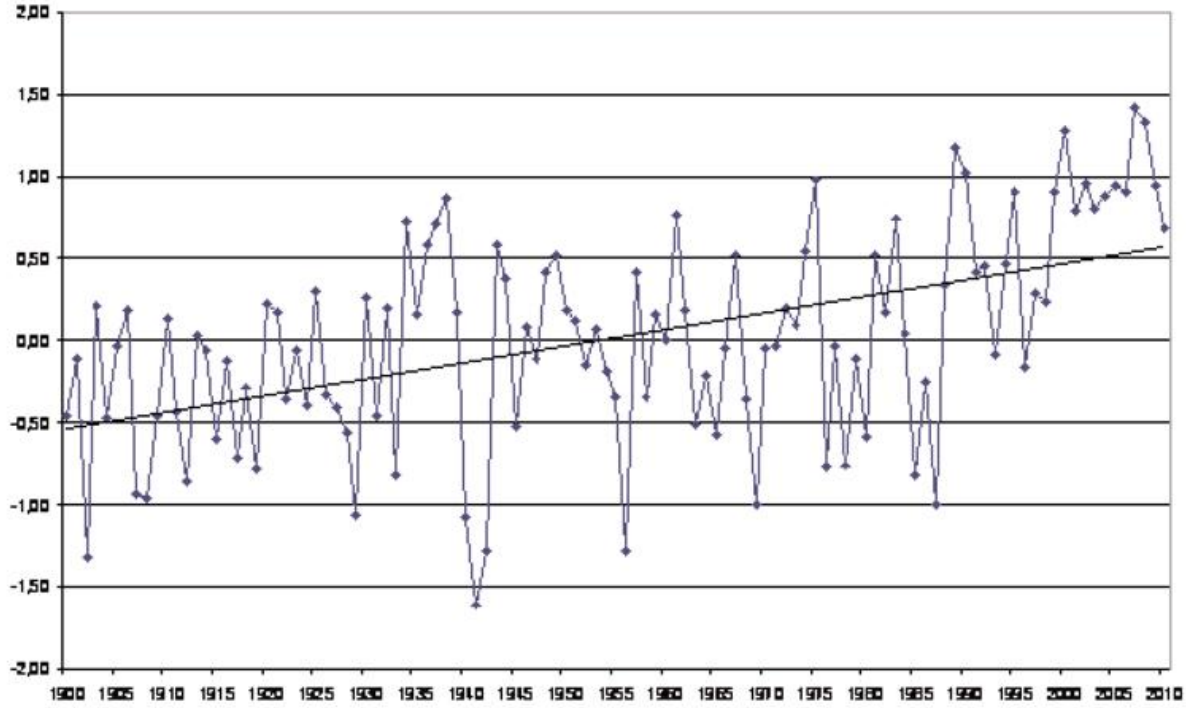

Fig. 0.7: *Mean annual temperature anomalies for the European continent (land areas of geographical continental Europe without islands) for 1900–2010 (reference period 1961–1990), based on data from Met Office Hadley Centre (United Kingdom)*
Source: Australian Bureau of Meteorology

On average, 2010 was colder than normal almost all over northern, north-western, western and central Europe, but only slightly colder in most areas (Fig. 0.8). Highest negative anomalies were recorded in Norway and Sweden, with values below -1°C. This was in contrast to most years of the recent decade during which nearly the whole Region was warmer than the 1961–1990 average. In most of northern, western and central Europe, 2010 was the coldest year since at least 1996 (Tab. 0.1). In some countries, in Germany for instance, the areal mean was below normal for the first time after 13 consecutive warmer-than-normal years.

During many months of the year, most of these parts of Europe were colder than normal, particularly January, February, May and September to December. March and June were cold in northern Europe.

Country	2010 was the coldest year since	2010 was the coldest year for ... years
Norway	1985	25
Sweden	1987	23
Finland	1987	23
Denmark	1996	14
Faroe Islands	1999	11
Latvia	1996	14
Lithuania	1996	14
Ireland	1986	24
United Kingdom	1986	24
Netherlands	1996	14
Belgium	1996	14
Luxembourg	1996	14
France	1996	14
Germany	1996	14
Switzerland	1996	14
Austria (summit regions)	1996	14
Poland	1996	14
Spain	1997	13

Source: Deutscher Wetterdienst, Germany

The rest of the Region was warmer than normal. Highest anomalies were recorded over western Greenland (> +4°C). Most of the other parts of the Arctic and also the south-eastern parts of the Region (southern European Russia, eastern parts of the Ukraine, western Kazakhstan, most of the southern Caucasus, Turkey, Cyprus and the Middle East) were more than +2°C warmer than normal. In most of these areas, the warming persisted more or less throughout almost the whole year, with only short interruptions.

2.3. European Arctic region

On average, the year 2010 was warmer than normal in the whole Arctic region. Annual anomalies ranged from near zero in the east up to +5°C in western Greenland.

While western Greenland was warmer than normal during the whole year, the other parts of the Arctic also saw some colder-than-normal periods, the more to the east, the more frequently. Svalbard, for instance, was colder than normal in March, August and November, though only slightly.

Greenland recorded its warmest decade (2001–2010, anomaly +1.4°C) since the beginning of modern measurements. Most stations in Greenland, except those in the east, recorded their warmest year ever in 2010 (Fig. 0.9).

The average temperature in Reykjavík (Iceland) was 5.9°C (anomaly +1.6°); it has only once been higher and that was in 2003. The temperature has now been above normal for 15 years in a row.

2.4. Northern Europe

Most of northern Europe was colder than normal (Norway, Denmark including the Faroe Islands, Sweden, Finland and western parts of the Baltic countries). Annual anomalies were below -1°C (locally below -2°C) in southern and central Norway and in central Sweden. Especially the cold months were far below normal (January, February, December; Fig. 0.12 for Norway). It was also cold nearly all over northern Europe in June, and partly in March, May and October.

On average, 2010 was warmer than normal in Iceland and in north-eastern Europe (northern European Russia and the Baltic countries). Highest positive anomalies in northern Europe were recorded in Iceland (> +1°C), which was colder than normal only in February, April and November. At +1.6°C, Iceland's capital Reykjavik saw its second warmest year on record. In Lithuania, only February, October and December were below normal.

2010 was the coldest year since at least 1996 in most of the countries in northern Europe, partly even since 1985 or 1987 (Tab. 0.1, Fig. 0.10 and 0.11). This means, it was also the coldest year in the decade 2001–2010. For most of northern Europe (except for the major parts of the Baltic countries), it was also the first year in the 21st century with a negative anomaly compared to the 1961–1990 reference. Even in the north-eastern countries, which were warmer than normal in 2010, it was far colder than in 2009, e.g. almost -1°C anomaly in Lithuania.

However, for whole decade 2001–2010 was the warmest decade on record in many places,for example in Finland since records began in the 1840's, and in Tórshavn on the Faroe Islands since 1890.

2.5. North Atlantic

The northern North Atlantic was +1 to +2°C warmer than normal, whereas the central North Atlantic and the Azores Islands were also warmer, but less than +1°C. Especially the warm half year (April to October) was clearly warmer than normal; the winter months were partly colder, particularly February.

While the minimum temperatures on the Azores were higher than normal, the maxima proved to be lower. In particular, there were more tropical nights than normal in the months July to September.

2.6. Central and Western Europe and the Alpine region

All over western and in most parts of central Europe (except for the east and the Alpine region), it was slightly colder than normal (between 0 and -1°C), mainly due to the cold months January, May and December.

In these areas, the cold year 2010 was characterised by a high number of extremely low mean daily temperatures, frost and ice days. In the United Kingdom, this was revealed, for example, by the daily Central England Temperature (CET) time series, which displayed several extremely low mean daily temperatures particularly at the end of the year (Fig. 0.13). Germany saw an extended frost period from 2009 until March 2010; peaks of minimum temperature were below -24°C locally in eastern and south-eastern Germany. The number of ice days was more than twice as high as usual. De Bilt in the Netherlands had 29 ice days (normal: 8) and 88 frost days (normal: 58), but also a number of warm days (maximum temperature 20°C or more) that was greater than normal (90 compared to 77). Belgium, too, had a very high number of frost days (74 in Uccle, 1981–2010 normal: 46) and ice days (27 compared to 7). In western Europe and most of central Europe, 2010 was also the coldest year since 1996 (Fig. 0.14 to 0.16).

Eastern central Europe and the Alpine region were slightly warmer than normal, with Slovenia having recorded a temperature of up to around +1.5°C above the normal. However, 2010 was nevertheless the coldest year of the decade 2001–2010 and the coldest year since 1996 in Poland, especially in the western half of the country.

Many months were colder than normal over the whole or almost the whole area, namely January, February, May, September, October and December (e.g. in Poland, Fig. 0.17). Late November was also very cold, marking an unusually early start of the winter weather with very low temperatures until just after Christmas. This was only partly compensated by the relatively warm months April, June and July. In the south-eastern parts of central Europe, on the other hand, November was also very mild on average.

2.7. Iberia

All over Iberia, 2010 was slightly warmer than normal on average (mostly 0 to +1°C). It was particularly warm in April, July and August. The other months were partly colder than the 1961-90 normal; October and November were colder over almost the whole peninsula.

Four heat waves occurred in Portugal in May, July and August. Nevertheless, 2010 was the coolest year since 1997 in Spain.

2.8. Mediterranean, Italian and Balkan Peninsulas

Almost the whole Mediterranean, Italy and the Balkan Peninsula were warmer than normal, but not as warm as the temperatures recorded for most of the previous years of the last decade. Annual anomalies were close to zero over the western Mediterranean and highest in the eastern Mediterranean (more than +2°C). Annual mean temperatures at several stations in Serbia and Bosnia and Herzegovina exceeded the 90th percentile. Athens in Greece had its warmest year since at least 1897, with an annual average of 20°C. Only the Balearic Islands were slightly colder than normal.

In the western Mediterranean region, nearly all months were slightly colder than normal, except April and July. Over the eastern Mediterranean, all months were warmer than normal. The Balkan Peninsula was colder than normal in September and October, in the northern parts also in December; the other months were mostly warmer or around normal; the summer months and November were extremely warm.

The whole decade 2001–2010 was the warmest since the middle of the 19th century in Ljubljana, Slovenia (Fig. 0.18), and Zagreb, Croatia (Fig. 0.19). In Bulgaria, it was the 13th consecutive year with higher temperatures than normal.

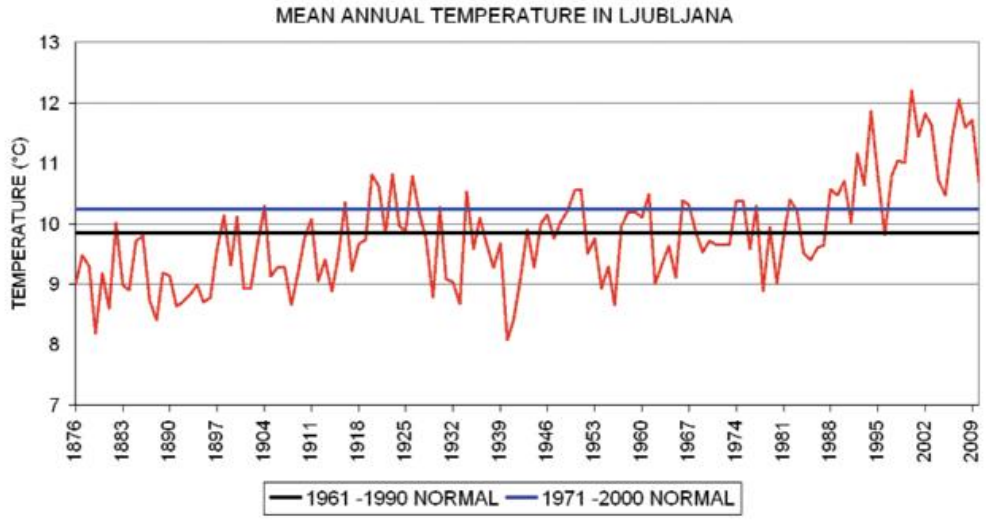

Fig. 0.18: *Mean annual temperature 1876–2010 in Ljubljana (Slovenia)*
Source: Environmental Agency of Slovenia

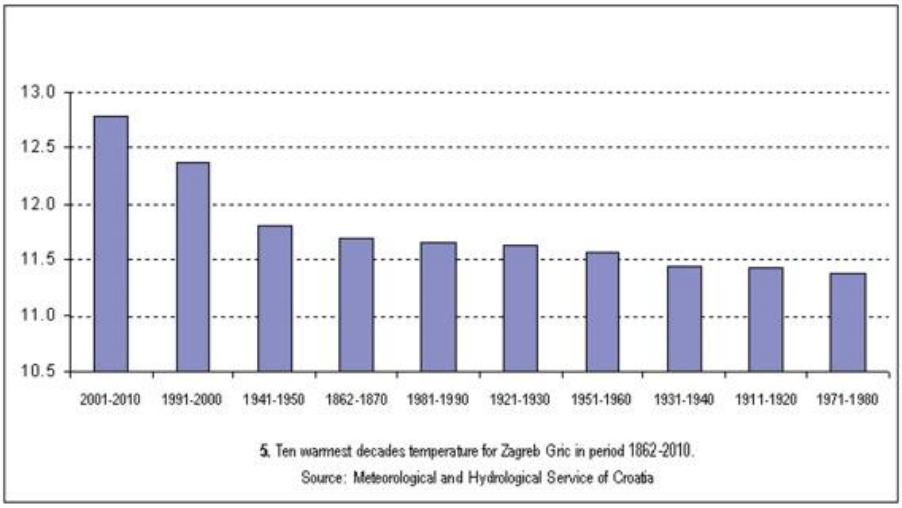

Fig. 0.19: *The ten warmest decades in Zagreb Gric (Croatia) in the period 1862–2010 and their mean temperatures in °C*
Source: Meteorological and Hydrological Service of Croatia

2.9. Eastern Europe and South Caucasus region

All over eastern Europe, the average temperature in 2010 was warmer than normal. The highest annual anomalies were to be found locally in the South Caucasus region and in Turkey (between +3 and +4°C). Anomalies were lower towards the north and the west of eastern Europe. The mean anomaly over European Russia was +1.4°C (mainly due to a heat wave in summer), which is slightly higher than 2009, but less than in other recent years. 2010 was one of the warmest years in the Ukraine, although the anomalies were smaller than further in the east (+1 to +2.7°C).

2010 was the warmest year in the South Caucasus since regular records began more than 80 years ago. It was the warmest year in Armenia since 1929 (Fig. 0.20) and west Georgia since 1951 (Fig. 0.21). 2010 also marked the 17th consecutive year with positive annual temperature anomalies in Armenia. The decade 2001–2010 ranks there as the warmest since 1900.

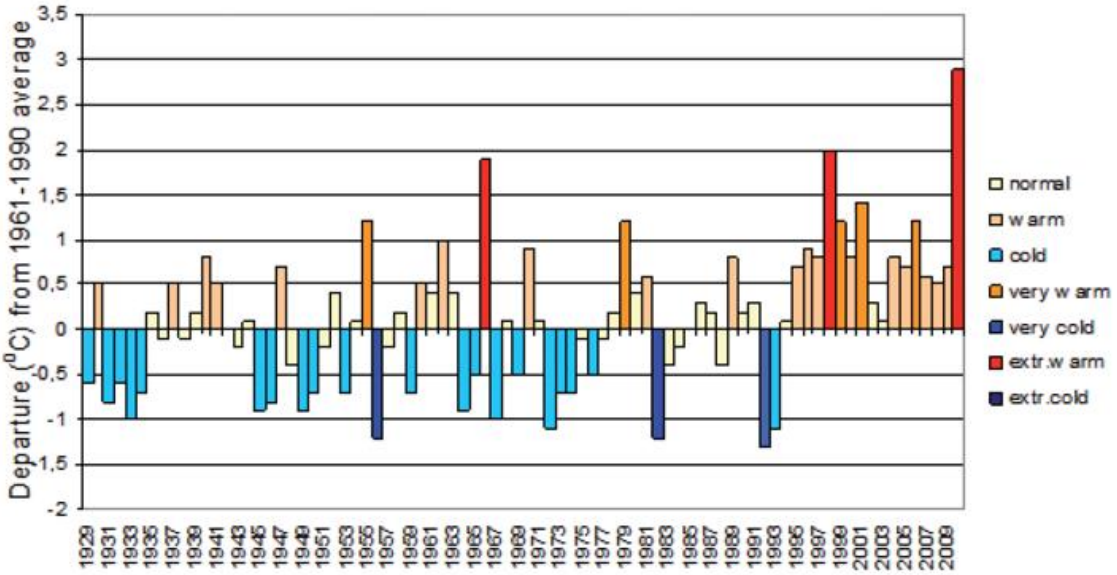

Fig. 0.20: *Mean annual temperature anomalies (1961–1990 reference) 1929–2010 in Armenia*
Source: Armstatehydromet

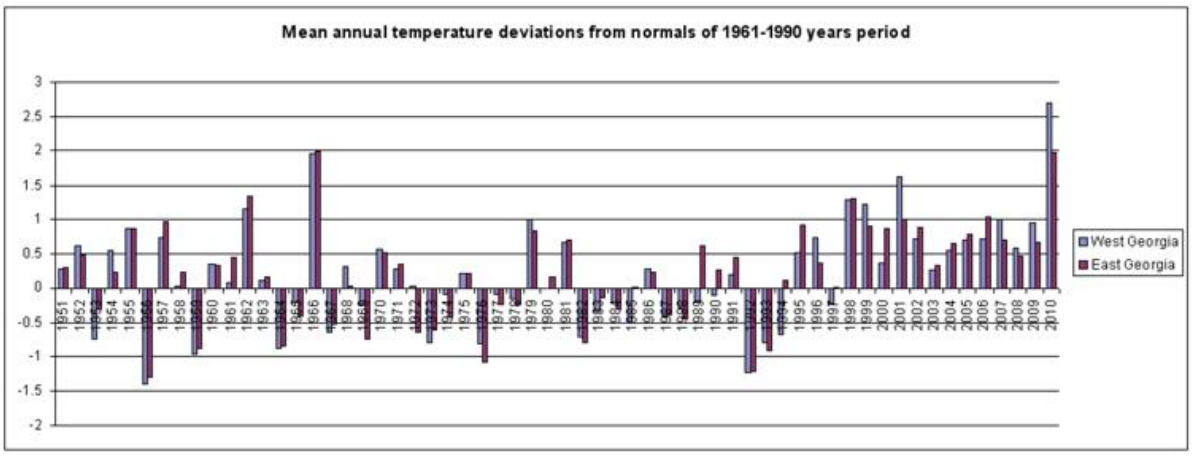

Fig. 0.21: *Mean annual temperature anomalies (1961–1990 reference) 1951–2010 in west and east Georgia*
Source: Department of Hydrometeorology of Georgia

Some months show extremely high positive anomalies (mostly above +4°C) almost all over eastern Europe: for example the summer months June–August as well as November in the Ukraine (Fig. 0.22). Other months were at least very warm in the South Caucasus and southern European Russia (January–March, September, October and December). The northern and western parts of eastern Europe (Belarus, Ukraine, Romania, Moldova, central European Russia and west Kazakhstan) had a few cold months compared to normal, particularly January, October and December.

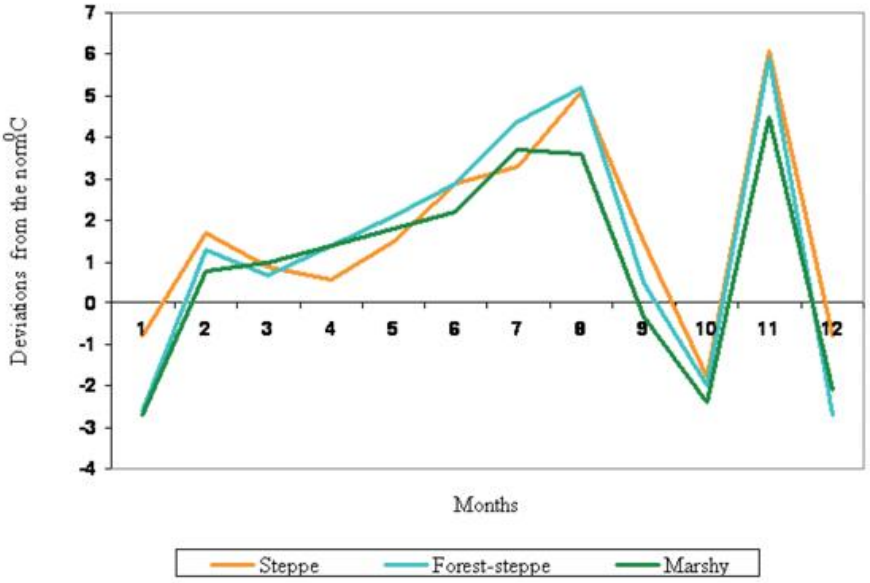

Fig. 0.22: *Mean monthly temperature anomalies 2010 (1961–1990 reference) in various vegetation zones in the Ukraine*
Source: Hydrometeorological Service, Ukraine

2.10. Middle East

The Middle East was much warmer than normal in 2010. Annual anomalies reached or exceeded +2°C almost everywhere, except in western Turkey, where they were slightly lower than that. Some places that normally are known to be the coldest areas in south-eastern Turkey show anomalies of up to +5°C. In Turkey, 2010 was the warmest year on record since 1940, much warmer than the previous years and exceeding an annual mean of 15°C (Fig. 0.23). 209 Turkish stations registered record-breaking monthly maximum temperatures at several occasions (particularly in December), and 14 stations in Turkey set new, absolute all-time daily maxima. The highest temperature in Turkey was 46.7°C in August. Heat wave conditions also prevailed in Cyprus several times, especially in August. Jordan reported seven heat waves in 2010, from May to October, and had its warmest year since 2001. Israel had its warmest January to March and August to November periods on record and recorded the highest annual mean temperature (20.3°C) since 1950 in Jerusalem (Fig. 0.24). These warm periods caused severe damage to agriculture, especially citrus and tomatoes.

The whole area was warmer than normal throughout the year. Only during the period April–June and once more in October, the anomalies were partly lower, or even negative in north-western Turkey.

3. Precipitation

3.1. Global Overview

According to an analysis by the United States National Climatic Data Center, globally averaged land precipitation in 2010 was the highest on record since 1900, 52 mm above the 1961–1990 average annual total of 1,033 mm. The previous wettest years, 1956 and 2000, also coincided with strong La Niña events like in 2010. An analysis by the Global Precipitation Climatology Centre (GPCC) ranked 2010 among the top ten in 110 years.

Across all continents, some land surfaces were wetter than normal in 2010 (Fig. 0.25). Several areas were outstandingly wet compared to the normal in terms of absolute and relative anomalies: especially the far north of South America, some eastern and south-eastern parts of Europe, most of India, Indonesia and eastern Australia. Some anomalies are clearly related to La Niña, which developed over the year and caused high precipitation totals over Australia, India / Pakistan and China / North Korea. Flood events in Pakistan (July/August) and eastern Australia (December) caused the death of thousands of people and made millions of people homeless.

Drier-than-normal areas were to be found, e.g. in southern Greenland, north-western Europe, parts of northern and southern America, southern Africa, the Middle East and western Australia.

3.2. RA VI Overview

Within the RA VI Region, much of the land area was also wetter than normal in 2010, especially on the European continent, although the deviations from normal were small in most parts (about two thirds) of that area (Fig. 0.26).

The relative totals for 2010 were particularly high (>125% of the normal, in some regions locally >150%) over large parts of eastern central Europe, the Balkan Peninsula, western Turkey, Italy, the western Mediterranean and southern Iberia. Some places in Turkey, Serbia and Moldova

reported their wettest year on record. Wet periods occurred throughout the whole year, with some extraordinarily wet spells in February in Italy and over the Balkan Peninsula and in May, August and September in eastern central Europe (flooding events).

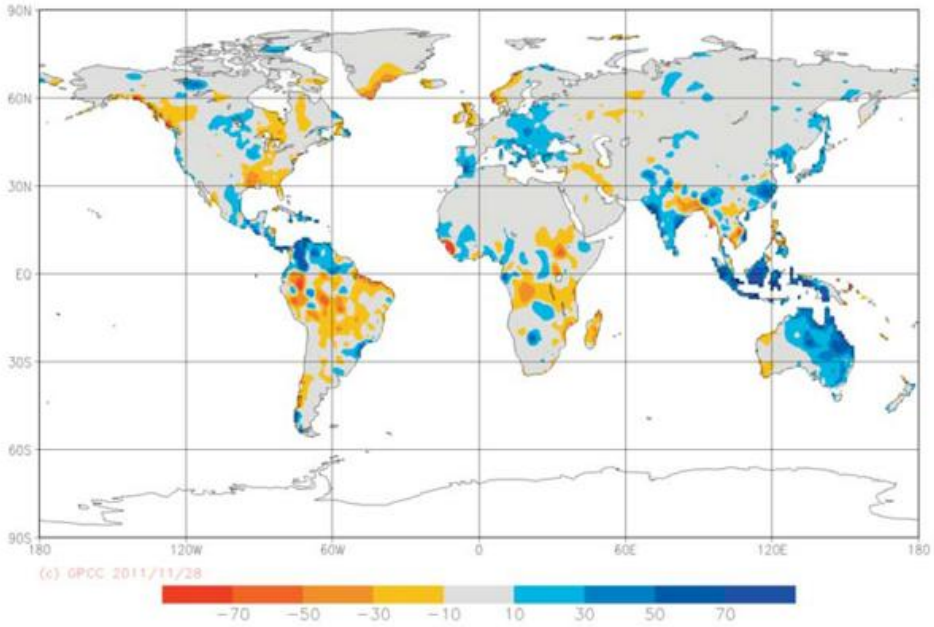

Fig. 0.25: *2010 annual global precipitation anomalies in mm (1951–2000 reference)*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

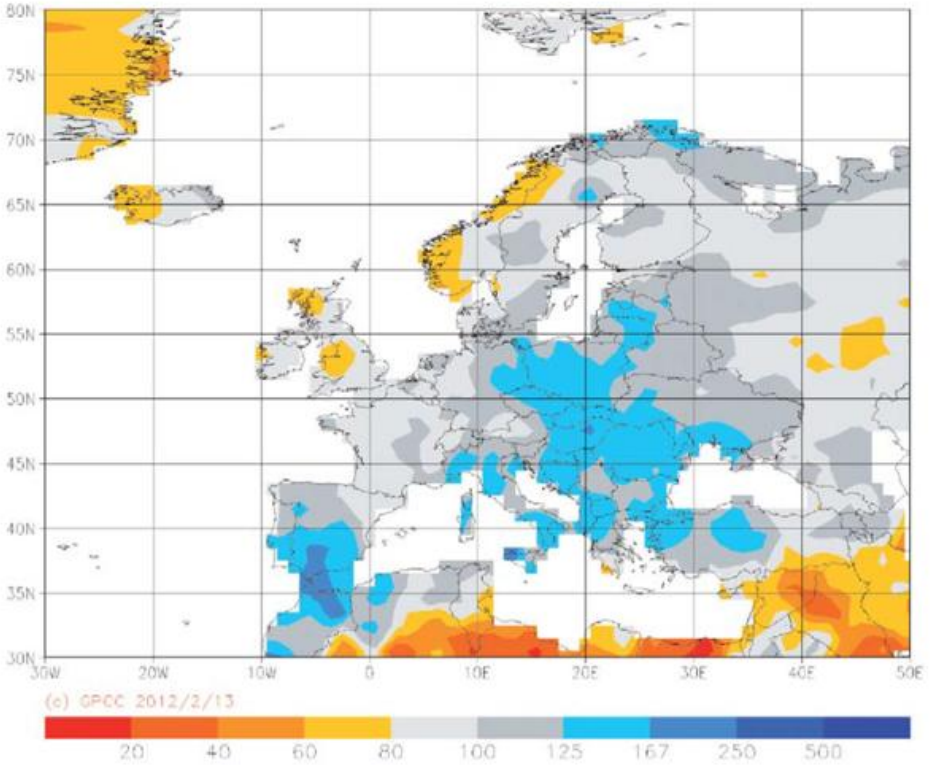

Fig. 0.26: *2010 annual precipitation amounts in WMO Region VI in per cent of the 1951–2000 normal*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Extraordinarily dry areas, however, were located in places particularly in the Arctic region (Greenland, Iceland, Svalbard), but also over the western parts of the United Kingdom and the Norwegian west coast, mostly with less than 80% of the annual total. This was mainly due to the frequent meridional circulation patterns or, expressed conversely, the absence of westerly patterns. It was also very dry in parts of European Russia, Georgia (especially due to a very dry summer) and near the eastern Mediterranean in Cyprus and in the Middle East, especially in the Lebanon, Israel and Syria.

3.3. Northern Europe and the Arctic

Most of the Arctic region was drier than normal. It was particularly dry at the coast of south-eastern Greenland, locally with less than 60% of the normal annual total. Western Iceland and parts of Svalbard also had quite low totals (<80% of the normal). The annual total in Reykjavík (592 mm) was the second lowest ever registered.

Most of northern Europe saw near-normal precipitation or was drier than normal. It was much drier than normal on the Norwegian west coast (locally <80% of the normal), particularly in the cold months.

Only a few places were much wetter than normal (>125%); these were located in northern Lapland, Sweden and the Baltic countries. Locally in parts of southern and south-eastern Sweden, it was the wettest year on record. 2010 was the 2nd rainiest year in Latvia in 87 years (behind 1928) and by far the wettest in the decade 2001–2010 (Fig. 0.27). Annual rainfall in Latvia exceeded 800 mm on average, which had last occurred 20 years ago. Lithuania was wetter than normal especially during the warm season from May to August, but also in December, whereas January, April and October were drier than normal.

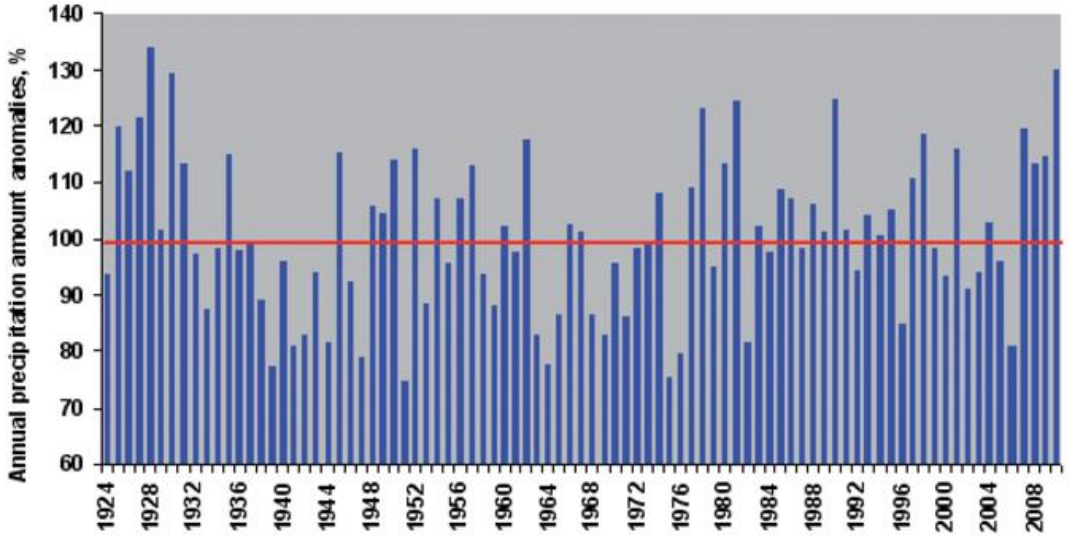

Fig. 0.27: *Annual precipitation amounts 1924–2010 in Latvia in per cent of the 1961–1990 normal*
Source: Latvian Environment, Geology and Meteorology Centre

3.4. Western and central Europe

Western Europe was drier than normal, especially across Ireland, the United Kingdom and most of France, but also western Switzerland. Less than 80% of the normal total was reached in the western parts of the UK. It was the driest year since 2003 in the UK. The first half of the

year was particularly dry, the driest such period since 1953 in the UK in general and since 1929 in north-west England and north Wales. In eastern England, the dry spell continued into July, causing considerable concern about water resources in these areas.

Most of central Europe was wetter than normal. The western parts of central Europe were close to normal (e.g. Belgium and the Netherlands) due to relatively few thunderstorms throughout the year, but abundant precipitation in August. Based on the annual totals, the eastern parts of central Europe were very wet. More than 125% of normal precipitation was recorded in large parts of eastern Germany, Poland and the Czech Republic, more than 160% in southern Poland, Slovakia and Hungary. Much of this was due to heavy precipitation events with flooding in May and early June and again in August and September. The damage caused by the two flooding events in August and September in Germany was estimated at several hundred million euro. The number of days with heavy precipitation (daily totals >30 mm) was considerably higher than normal; especially in eastern Germany which in places saw more than three times the normal precipitation, partly even the highest number on record. 2010 was by far the wettest year in Slovakia since 1881 (areal annual average of 1255 mm, locally far more, Fig. 0.28) and in Hungary since 1901. A station in the northern medium-high mountains in Hungary (Miskolc-Lilafüred Jávorkút) reached a new annual record with more than 1500 mm (Fig. 0.29).

3.5. Iberia

Most of Iberia was wetter than or near to normal. The south of the peninsula was particularly wet, with locally more than 200% in Andalusia (Spain, Fig. 0.30) and more than 180% of the 1971–2000 average in Lisbon (Portugal, Fig. 0.31), which with an annual total of 1598 mm suffered its wettest year since 1870. Portugal also had its wettest year of the whole decade 2001–2010 (1063 mm = 120% of the normal). It was especially wet over most of Iberia in

January–March (with around twice the normal for that period) and December, in Portugal also in October. To the contrary, dry conditions prevailed in the summer half year. It was the driest July and August and the second driest September in more than 20 years in Portugal.

Similarly, the annual precipitation totals were well above normal over the Azores Islands. The rainiest months were January–April and December.

Source: Agencia Estatal de Meteorología, Spain

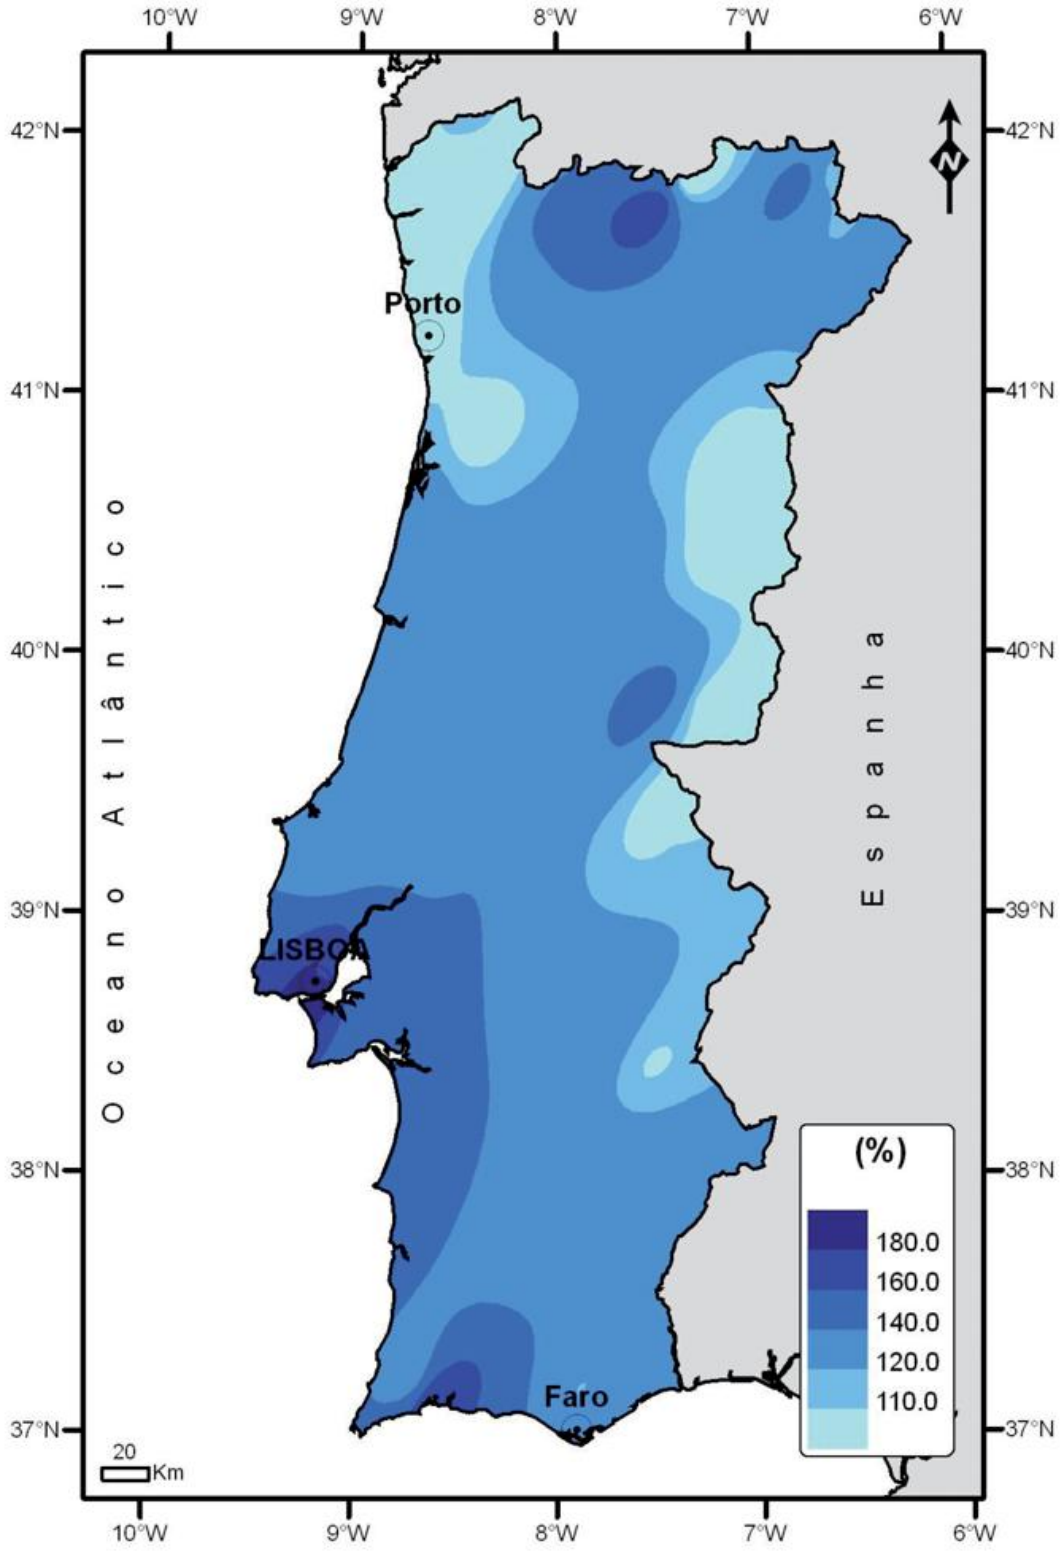

Fig. 0.31: *2010 annual precipitation totals in Portugal in per cent (1971–2000 reference)*
Source: Instituto de Meteorologia, Portugal

3.6. Italian and Balkan Peninsulas, Mediterranean region

Italy, the Balkan Peninsula and most of the other parts near to the Mediterranean were wetter than normal and some periods of heavy rain occurred. Large areas received more than 125% of the normal annual total, locally 175%. This was particularly due to occasional to frequent heavy precipitation (partly causing flooding and landslides) in January, February, and May–November.

Some places on the Balkan Peninsula saw their highest or second highest annual precipitation totals. With 1798 mm, Ljubljana in Slovenia recorded its second highest annual total since the beginning of measurements. Herzegovina had its wettest period in 2010 since the beginning of measurements, with Mostar station reporting an annual precipitation total of around 2500 mm. Extremely heavy precipitation events were frequent in the southern parts of Bosnia and Herzegovina, causing flooding of Neretva and Drina rivers at the end of November and the beginning of December. At least five main meteorological lowland stations in Serbia registered their highest annual total in the past 60 years, partly exceeding 1000 mm. At more than 170% of the 1961–1990 normal, some stations in Montenegro received the highest or second highest precipitation total on record (Fig. 0.32).

It was a dry year in Malta and in southern Greece. Malta had very low precipitation in the colder months (January, February, November, December) and in April, and had hardly any rain in summer.

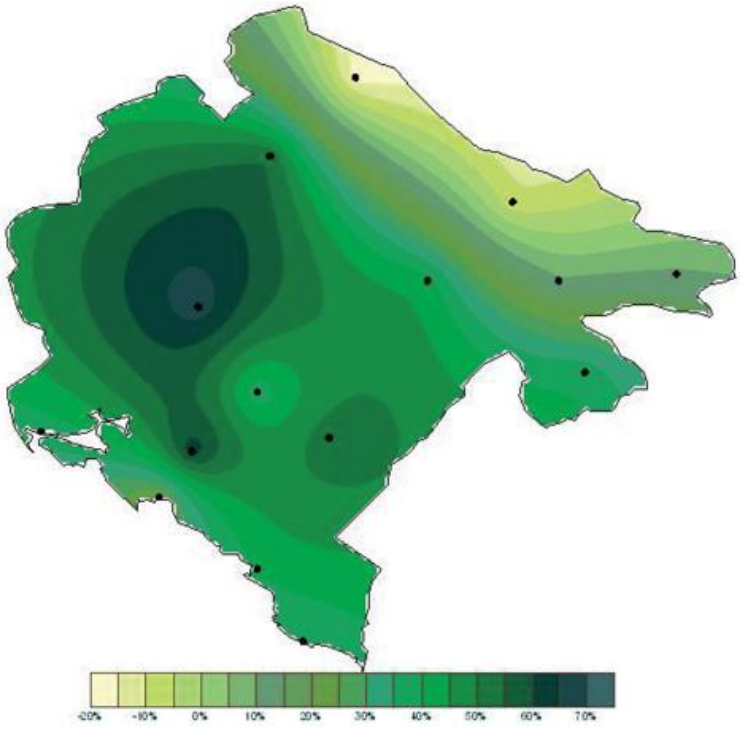

Fig. 0.32: *2010 annual precipitation totals in Montenegro in per cent (1961–1990 reference)*
Source: Hydrometeorological Institute of Montenegro

3.7. Eastern Europe and South Caucasus region

Eastern Europe was wetter than normal in its western parts and mostly dry or near normal in the east. It was particularly wet (>125% of the normal) in the western and southern Ukraine, Romania and Moldova. There were many very wet months in that area in all seasons, namely January, February, May, June, August, September, October (in the south only), November and December.

In Romania, the largest precipitation excesses of the year occurred in May and June, which climatologically are anyway among the wettest months in that country (Fig. 0.33). This excess precipitation fell over a soil which was already soaked due to the fact that previous months had also been wetter or around normal, which at times led to severe flooding.

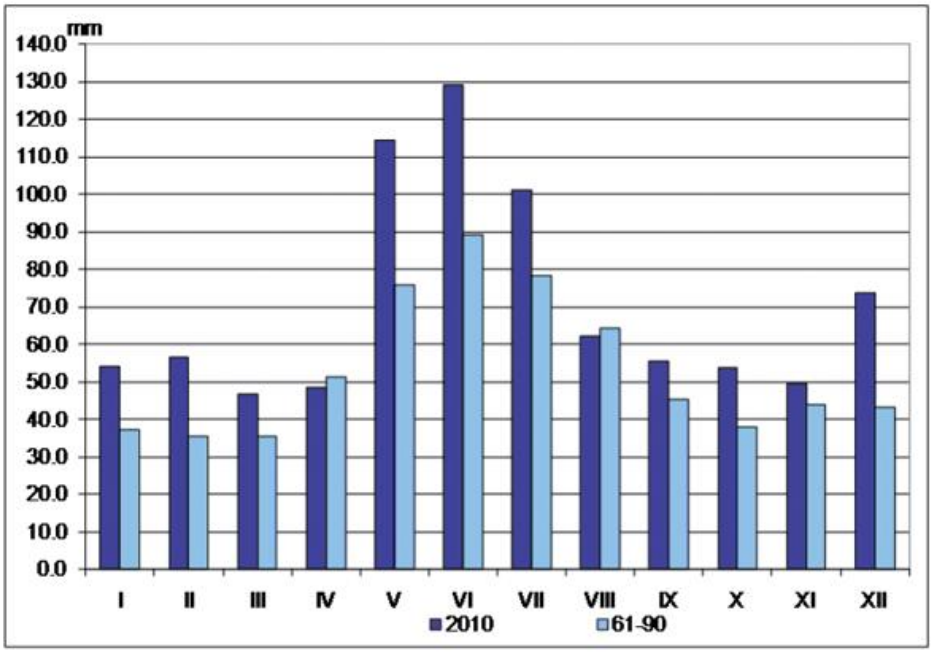

Fig. 0.33: *Monthly mean precipitation totals in Romania 2010 compared to the 1961–1990 normal*
Source: National Meteorological Administration of Romania

Moldova was also affected by high quantities of precipitation during the period May–July (300–510 mm, i.e. 60–80% of the annual normal fell during these three months), especially in the northern parts, but partly also in the south of the country. Such high amounts were registered for the first time since the beginning of observations in Moldova. The highest total in Moldova for May–July 2010 (510 mm) was recorded at the station Briceni, exceeding twice the normal for these three months (Fig. 0.34). The consequences of the high quantities were flooding of rivers and damage to houses and farmlands as well as power supply disruptions.

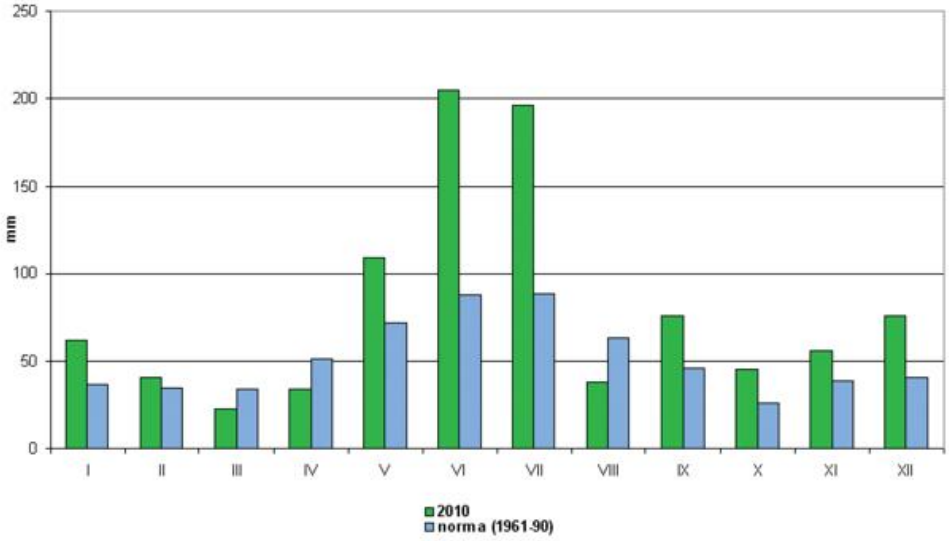

Fig. 0.34: *Monthly mean precipitation totals at the station Briceni in Moldova 2010 compared to the 1961–1990 normal*
Source: State Hydrometeorological Service of the Republic of Moldova

Some places in Southern European Russia received very much precipitation, 300–500% of the normal in some months.

Dry areas (locally less than 80% of the normal) were to be found in central European Russia, west Kazakhstan and the South Caucasus. Main contributors in Russia were the months April and June–August, in the South Caucasus June, August as well November and December in particular. It is noteworthy that during November and December most parts of the South Caucasus region did not receive any single drop of rain, although climatologically these two months are the second rainy period in that area after April–May. However, several heavy rainfalls and subsequent flooding occurred in Azerbaijan from April to June, the heaviest ones in May. The Kura river in Azerbaijan had high water levels from the end of April until the end of June; several villages were flooded. Thunderstorms with severe hail occurred very often in the South Caucasus from May to July. Overall, 19 days with hail were recorded at different locations in Armenia, with hailstones sometimes reaching 25 mm in diameter. Hail caused significant losses to agriculture due to the damaged crops. Wet conditions also prevailed in January and October in the South Caucasus.

In general, the weather conditions during the vegetation season in 2010 were very unfavourable for agriculture in Armenia. Extensive rainfalls in April damaged most of the blossoming fruit trees in the Ararat Valley; later, frequent hailstorms and heavy rainfall with dry periods in between caused significant losses to agriculture.

3.8. Middle East

Western Turkey saw a wet year (>125% of the annual total), whereas most of the other areas were drier than normal.

Turkey had some relatively very wet months, namely January, February, June, October and partly December, especially in the west. Some locations in Turkey saw hazardous flood events, e.g. Bursa, which had the wettest year on record (at 1328 mm nearly twice the normal). Cyprus also reported heavy rain and flooding, especially in January, February and April, as well as severe hail storms in April, May and December.

On the other hand, especially eastern Syria was very dry, recording local annual totals of less than 40% of the normal. More than a third of the stations in Jordan received less than 75% of the normal total.

It was extremely dry in the Middle East in spring and exceptionally dry in November. Israel had an extremely dry period around Haifa, the driest on record for August to November in at least 70 years. The long drought period caused a large forest fire in northern Israel in early December.

4. Snow

Unusually small amounts of snow fell in south-western Iceland. Reykjavík had its lowest annual number of days with snow cover (only 16 days) since observations started in 1921.

In contrast, 2010 was a year of abundant, widespread and long-lasting snow across large parts of northern, western and central Europe, particularly in the winter months January, February and December.

In the UK, snow depths accumulated to more than 50 cm across the high ground of eastern England and eastern Scotland in both January and December.

Uccle station in Belgium had an exceptionally high number of 53 snow days (compared to the 1981–2010 normal of 19), the highest number since the start of observations in 1901.

Locally record-breaking snow depths were measured in Germany in all three winter months; even in the lowlands such deep snow covers had not been seen for a long time. Since the 1960s, many places in Germany had not seen as many snow days.

In the plains of Switzerland, frequent snowfalls continued to occur even in the first half of March. In summer and autumn, it often snowed in the western Alps and by November it started to snow again in the plains of Switzerland.

Beside the Austrian alpine regions, the amount of fresh snow in Austria exceeded the 1971–2000 averages by around 30–60%.

Poland reported at least 70 days with snow from October 2009 to April 2010 in most of the country; in the west, this was more than twice the 1971–2000 normal. The mean snow depth in Poland was also high that season, 200–500% of the normal. On the other hand, in 2010 most of European Russia had fewer days with snow cover than normal.

5. Sunshine duration

Sunshine duration anomalies in 2010 showed much greater spatial variability than in the previous year (Fig. 0.35). Averaged over the Region, sunshine duration was around normal, but relatively sunny and relatively dull areas were still to be found in all its parts.

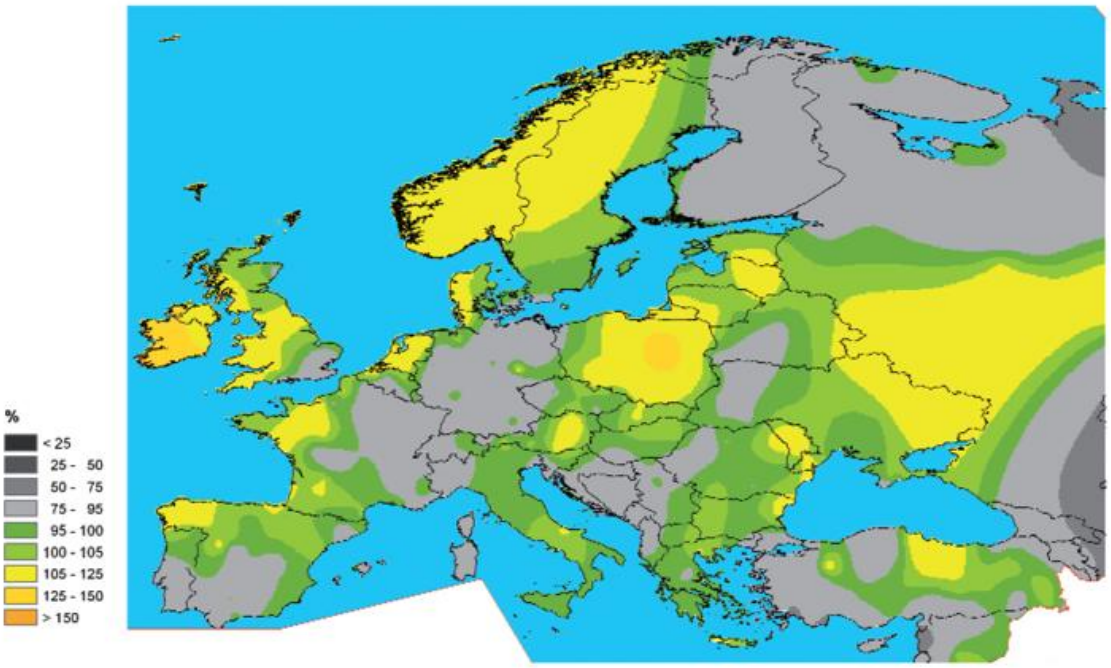

Fig. 0.35: *Annual sunshine duration in 2010 in per cent of the 1961–1990 normal in WMO Region VI (interpolation of CLIMAT data)*
Source: Deutscher Wetterdienst, Germany

The year was sunnier than normal in the Arctic region (Greenland, Iceland, Svalbard) and over almost the whole of north-western Europe (Ireland, United Kingdom, north-western France, the Netherlands) and the western parts of northern Europe (Norway, western Sweden, Denmark with the Faroe Islands). Although summer was quite dull in most of these areas (except Ireland and the Netherlands), the other seasons had a considerable surplus of sunshine.

The three winter months January, February and December 2010 were record-breaking sunny on the Faroe Islands. Southern Ireland received more than 1,500 hours of sunshine in 2010, which is more than 125% of the normal, and it was the sunniest winter on record in western and southern parts of Ireland. Several months were very sunny in parts of the United Kingdom, notably January, March, April, June and October to December. However, July and August were dull summer months in most areas of the United Kingdom. In Northern Ireland and western Scotland, 2010 was amongst the sunniest years on record.

The Netherlands had 1,772 hours of sunshine on average (normal 1550), locally up to 1,900 hours, but less than the average in 2009. 2010 had the sunniest December on record in Denmark, with a total of 81 hours of sunshine on average for the country.

In contrast, north-eastern Europe (Finland, northern European Russia) had a dull year, particularly towards the east, where less than 75% of the annual total was recorded. Sunshine was lacking especially in autumn.

Large parts of central Europe were also quite dull, namely eastern France, southern Belgium and large parts of Germany. Compared to the normal, there was a lack of sunshine already in all winter months, but also in May, August, September and November. Germany experienced its third dullest January and February since 1951, and winter 2009/10 was the second dullest behind 1969/70. Uccle in Belgium saw its dullest February (29 hours of sunshine duration) since the beginning of heliographic measurements in 1887. May was the dullest month on record (since 1951) in Germany (locally also in Austria), August the second dullest. The other months were mostly very sunny, particularly April (third sunniest April in Germany behind 2007 and 2009), which, however, did not compensate the deficit.

Large parts of eastern central and eastern Europe saw a sunny year, particularly Poland, eastern Austria, eastern Latvia, Moldova and central European Russia. Some locations in Poland received more than 1800 hours of sunshine in 2010, which is more than 250 hours above the 1971–2000 normal. Only February, May and December were dull in almost all these eastern parts. Over the whole year 2010, parts of eastern Austria had more than 125% sunshine than normal, but 2010 was also the year with the lowest sunshine duration in Austria since 1996 due to frequent rainfall in the summer months and an extremely low annual mean air pressure (Fig. 0.36).

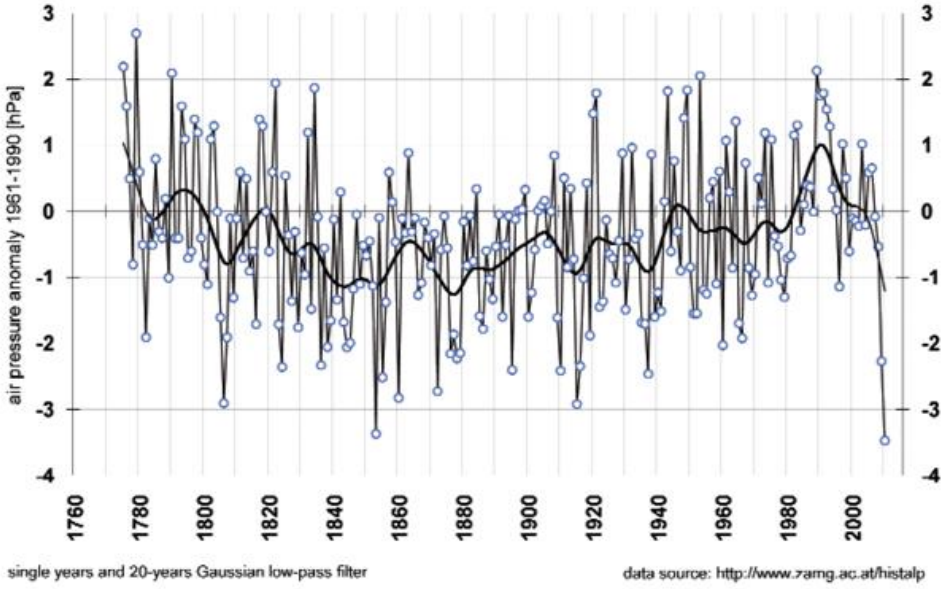

Fig. 0.36: *Anomalies (1961–1990 reference) of the Austrian air pressure stations 1775–2010 Source: Central Institute for Meteorology and Geodynamics (ZAMG), Austria*

Western Kazakhstan and the South Caucasus region had far below-normal sunshine, with less than 75% of the annual total in the east. Just the end of the year (November and December) brought above-normal sunshine to the South Caucasus.

The Mediterranean region and most of Iberia had around normal or below normal sunshine. Spring and summer were mostly sunny, but the winter and autumn months were mostly dull.

6. Wind

Globally, the tropical storm activity in 2010 was lowest since at least 1970, with a total of 67 storms, 38 of which developed to typhoons/hurricanes. Only the North Atlantic had an above-average activity (19 storms / 12 hurricanes vs. a long-term mean of 10 / 6) during the season from end of June to the beginning of November due to high sea surface temperatures in its tropical area. This was triggered by La Niña conditions due to weak vertical wind shear and by the continued warm mode of the Atlantic Multidecadal Oscillation (AMO). However, the strongest storm was typhoon Megi (central pressure 885 hPa) over the Philippines and China in October. Other tropical storms (Giri in Myanmar also in October and Agatha in central America in May) caused at least 150 deaths each. Only one tropical storm reached the RA VI Region as extratropical cyclone: storm Danielle moved from the central Atlantic towards the north-east and dissipated south of eastern Greenland on 03 September without causing any damage in RA VI.

In Europe, due to the frequent meridional circulation patterns, westerlies were rare, and with it also the number of intense cyclones.

Windstorms were markedly fewer than usual in Iceland. The average wind speed at all stations in Iceland was the lowest since 1965.

In winter 2009/10, many stations in Ireland registered record-low mean wind speeds.

Latvia measured the lowest wind speeds for almost 50 years for January, and also in February wind speeds were very low. Gusts up to 119 km/h were recorded in August.

Lithuania reported one strong squall line and one tornado in summer.

In Poland, geostrophical winds up to 81 km/h occurred in January and once more in November.

One extensive storm, Xynthia in February/March, affected large parts of France and Germany.

Several heavy thunderstorms and tornadoes occurred in Germany, particularly between late May and early July.

In Portugal, tornadoes and water spouts were seen in April (Lisbon, Tavira and Sintra), causing damage on buildings, and December (in central parts), when several people were injured and great damage caused at several locations.

Malta recorded its highest wind gusts since 1947 in July.

There were very few Etesian wind patterns in Greece (e.g. N–NW winds prevailing over the Aegean Sea). Cyprus saw some strong wind events in February, October and December, and also tornadoes in January–March, May and December.

Strong winds were recorded quite often in the South Caucasus in January and February, with mean winds up to 140 km/h and gusts up to 170 km/h in Armenia. Azerbaijan reported some severe storm events from January to March, with gusts up to 108 km/h, locally even more. Georgia reported wind gusts up to 115 km/h, highest in February, March and September.

7. Sea ice

7.1. Arctic sea ice

(Text kindly provided by the National Snow and Ice Data Center, University of Colorado, Boulder, USA, http://nsidc.org/arcticseaicenews/, 05 January 2011, added by text from NCDC: http://www.ncdc.noaa.gov/sotc/hazards/2010/9.)

Despite a late date of the maximum in winter 2009/10 sea ice extent, the minimum sea ice extent for September 2010 (4.6 million km²) was third lowest in the 1979 to 2010 satellite record, above only 2007 (the record low) and 2008 (Fig. 0.37). The average extent for September (4.9 million km²) was 30.4 percent less than the 1979–2000 average. Regarding the total amount of Arctic sea ice, according to the University of Washington's Polar Science Center (using a model that has compared well with observations), sea ice volume for September reached an all-time monthly low in 2010. The reported volume of 4,000 km³ was 70 percent below the 1979–2009 September average of 13,400 km³. Sea ice volume accounts for sea ice extent as well as the thickness of the ice.

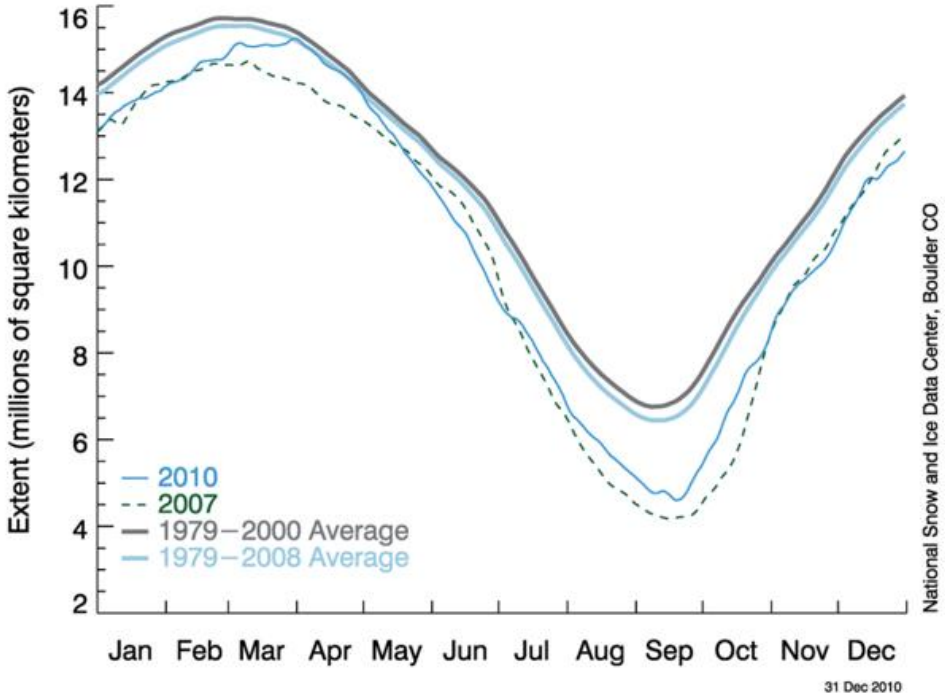

Fig. 0.37: *Arctic sea ice extent in 2010, compared to the 1979 to 2000 and 1979 to 2008 climatologies and the year 2007.*
Source: National Snow and Ice Data Center, University of Colorado, Boulder, USA

The late summer of 2010 saw an open Northwest Passage: this year, the deep water channel (the northern route) from M'Clure Strait to Lancaster Sound was navigable. The Northern Sea Route along the Siberian coast also became briefly navigable. It was the first time in modern history that both the Northern Sea Route and the Northwest Passage were navigable in a single season.

2010 started out with a highly negative phase of the Arctic Oscillation, an atmospheric pattern that in the past has favoured the survival of old ice through the winter, and more ice at the end of this summer. But this tendency seems to be changing. A recent study led by Julienne Strove of NSIDC showed that while wind patterns linked with the strongly negative Arctic Oscillation winter of 2009–2010 transported much old ice into the southern Beaufort and Chukchi Seas, most of this ice later melted. It may be that with a warmer Arctic, old rules regarding links between the atmospheric pressure patterns and sea ice extent no longer hold.

On 5 August, an ice mass of 251 km² broke down from the Petermann Glacier in north-west Greenland.

Freezing in autumn 2010 also was unusually slow due to far above-average temperatures. Arctic sea ice extent averaged over December 2010 was 12.00 million km². This was the lowest December ice extent recorded in satellite observations from 1979 to 2010, 270,000 km² below the previous record low of 12.27 million km² set in 2006 and 1.35 million km² below the 1979 to 2000 average. As in November, ice extent in December 2010 was unusually low in both the Atlantic and Pacific sides of the Arctic, but particularly in Hudson Bay, Hudson Strait (between southern Baffin Island and Labrador), and in Davis Strait (between Baffin Island and Greenland). Normally, these areas are completely frozen over by late November, but in 2010, Hudson Bay was not totally frozen till the end of the year. In the middle of December, the ice extent stopped increasing for about a week, an unusual but not unique event.

The low ice conditions in December occurred again in conjunction with above-average air temperatures in regions where ice would normally expand at this time of year. Air temperatures over eastern Siberia were +6 to +10°C above normal in December. Over the eastern Canadian Arctic Archipelago, Baffin Bay/Davis Strait and Hudson Bay, temperatures were at least +6°C higher than average. Southern Baffin Island had the largest anomalies, with temperatures over +10°C higher than normal. By sharp contrast, temperatures were lower than average (-4 to -7°C) over the Alaska-Yukon border, north-central Eurasia, and Scandinavia.

The warm temperatures in December came from two sources: unfrozen areas of the ocean continued to release heat to the atmosphere, and an unusual circulation pattern brought warm air into the Arctic from the south. Although the air temperatures were still below freezing on average, the additional ocean and atmospheric heat slowed ice growth.

As in winter 2009/10, a strongly negative phase of the Arctic Oscillation dominated the middle and high latitudes of the Northern Hemisphere in December 2010, bringing higher-than-normal pressures to the Arctic region, with lower-than-normal pressures in middle latitudes. However, unlike December 2009, when higher-than-normal pressures centered near the central Arctic, in December 2010 higher pressures centered near Iceland and the eastern tip of the Aleutians in the Pacific, and yielded a different pattern of winds. As a result, different areas experienced warm anomalies in 2010, and a different pattern of ice extent emerged.

7.2. Baltic Sea

(Text kindly provided by J. Vainio et al., taken from Bundesamt für Seeschifffahrt und Hydrographie (BSH, Federal Maritime and Hydrographic Agency of Germany), Baltic Sea Ice Services, http://www.helcom.fi/BSAP_assessment/ifs/ifs2010/en_GB/iceseason, 14 October 2010, shortened)

After a slow start in autumn 2009, very cold weather conditions over Scandinavia ensured a rapid development of the ice cover at the beginning of 2010. On January 8, the entire Bay of Bothnia was covered with ice; a week later the amount of ice also increased in the Gulf of Finland and the Gulf of Riga. During this period, ice also started to form along the coast in the Sea of Bothnia and in the Stockholm archipelago.

An intense low pressure system passing over Scandinavia on 27–28 January brought southerly gale force winds which pressed most of the ice in the Skagerrak towards the Norwegian coast. In the Bay of Bothnia, the ice drifted rapidly to the north/north-east, causing severe pressure in the ice field. Conditions were so severe that the area was temporarily closed for all traffic. After the storm, the cold weather came back and ice growth speeded up again, particularly in the Sea of Bothnia, the northern Baltic Sea and the Kattegat. Ice started to form outside the archipelagos in the northern Baltic Sea and along the east coast of Gotland.

In the southern Baltic Sea, ice formation resumed in the eastern waters in early January and spread quickly westward on the sheltered inner coastal waters. Ice formation continued until mid-February. By the end of January, new ice had also formed on the outer coasts, and the Pomeranian Bight was completely covered with ice.

On February 17, the area covered with ice expanded to 244,000km², marking the maximum area for the winter. This took place almost two weeks earlier than normal. At that time, the Gulf of Finland and the Gulf of Bothnia were covered with ice, with the exception of an approximately 6,500 km²-wide area in the eastern Sea of Bothnia off Rauma and Pori. The Gulf of Riga was also thoroughly covered with ice. In the northern Baltic Sea the ice edge ran from near Almagrundet to Glotovi and further on to the south/south-west. The central Baltic Sea off the coastline had a thin ice cover north of Öland and Klaipeda. The southern Baltic Sea off the coast of Germany was covered with thin fast ice in the insular areas. There was also thin ice and new ice in the Kattegat and Skagerrak.

In winter 2009/2010, the temperature remained below zero for an unusually long period of time without a break – a total of 60 days. The frosty winter ended on February 26 and, with the winds blowing from the south, the frozen area began to decrease.

In the Sea of Bothnia, the strong winds ripped large holes into the ice field in the northern part, and caused ridging and rafting in the south. During this time ice pressure in the southern Sea of Bothnia and the Sea of Åland was so severe that it caused substantial problems for traffic. On 3-4 March, conditions were particularly difficult in the Sea of Åland. A brash ice barrier outside of the Stockholm archipelago caught a number of passenger ferries and commercial ships, and icebreaking activities were intense.

The North Sea coast, its tributaries, and the Kiel Canal were completely free of ice by 7 March, the Baltic Sea waters of Schleswig-Holstein by 20 March, and the bodden waters along the coast of Mecklenburg-Vorpommern by 25 March. The numbers of days with ice varied considerably in the different areas: in the river Weser near Brake, ice occurred only on one day, compared to 96 days in the harbour of Neuendorf on the island of Hiddensee. Only a few stations, most of them located in the German Bight, remained free of ice throughout the winter of 2009/10.

In April, the sea ice continued to melt. The melting process proceeded rapidly also in the south and the Baltic Sea coast south of Stockholm was ice free around April 15. Lake Vänern was ice free around the 18th.

The remaining ice of the Sea of Bothnia disappeared at the end of April, while in the Gulf of Finland and the Bay of Vyborg it melted on May 2.

In mid-May, there was an unusually long and widespread heat wave, considering the time of year. The impact of the heat continued and, consequently, made the water warm and the ice to melt. Last ice in the Bay of Bothnia melted at the end of May and the Bay of Bothnia was ice free on May 31.

The time of the final melting, compared to normal, varied greatly. In the coastal waters of the northern Bay of Bothnia the final disappearance of ice took place two to four weeks earlier than average and in the Gulf of Finland about one week to more than a month later than average.

The duration of the ice winter in the northern Bay of Bothnia was over a month shorter than average. In the southern Bay of Bothnia and in the Vaasa archipelago the ice winter was one and a half to two weeks shorter than average, whereas it in the Quark was two weeks longer than average. In the other sea areas surrounding Finland the length of the ice winter was a week (the metropolitan area) to more than a month (western Gulf of Finland) longer than normal.

In the Finnish part of the Bay of Bothnia, the maximum thickness of the fast ice was between 40 and 85 cm, in the Sea of Bothnia between 30 and 60 cm, in the Archipelago Sea between 15 and 50 cm and in the Gulf of Finland between 20 and 60 cm. The thickness of the ice in the pelagic Bay of Bothnia was 30–60 cm, in the Sea of Bothnia 10–40 cm, in the Gulf of Finland 30–45 cm, in the Sea of Åland 10–35 cm and in the northern Baltic Sea 10–35 cm.

Seasonal Survey

Temperature

After a cold winter 2009/10 particularly in northern Europe, the other seasons in 2010 became warm, especially in the east of the Region with an outstanding hot summer particularly in Russia. Autumn was colder again in the western half of Europe. Greenland and the Middle East were much warmer than normal in all seasons.

Winter 2009/10 was cold in most of Europe, especially in the north, but mild in the Arctic, in south-eastern Europe and the Middle East (for figures see section “Seasonal Maps”, Fig. S1).

It was mild in the whole Arctic region. Anomalies amounted to +7°C in Svalbard; Greenland was more than +5°C warmer on average, locally exceeding the 90th percentile.

Northern, eastern, central, western and north-western Europe saw an exceptionally cold winter with hard frosts during all three winter months. The number of ice days (Tmax < 0°C) was higher than normal all over northern and central Europe. The negative temperature deviations from normal were highest in central Scandinavia and north-eastern European Russia (< -3°C, Fig. 0.38 e.g. for Sweden) and below the 10th percentile.

It was the coldest winter for at least 14 years in several countries of central Europe, in northern Europe and the Alps even for more than 20 years (Tab. 0.2). It could, however, not compete with the record cold winters of the 1940s or 1960s. Winter was particularly exceptional in north-western Europe (coldest for at least 30 years) and the Alps. High mountain stations in Switzerland registered the coldest winter in around 30 years. At the Jungfraujoch and Grosser St. Bernhard, it was even the coldest winter in 40 years. The long-term warming trend was one reason that winter 2009/10 was still milder than comparable spells in past decades, particularly in central Europe.

Country	Winter 2009/10 was the coldest since	Winter 2009/10 was the coldest for ... years
Sweden	1986/87	23
Finland	1986/87	23
Ireland and Scotland	1962/63	47
England and Wales	1978/79	31
Netherlands	1995/96	14
Belgium	1995/96	14
Germany	1995/96	14
Switzerland	1986/87	23

Tab. 0.2: *Last winter which was colder than that of 2009/10 in various countries/areas in northern, north-western and central Europe*
Source: Report of National Meteorological and Hydrological Services

Generally, the long duration of cold conditions during that winter was more unusual rather than any local extremes. There was a very long period with below-zero temperatures in central Sweden. Locally, it was the longest such period in more than 120 years of measurements. Helsinki in Finland had its longest cold spell since 1947. In Finland, the lowest temperature of that winter was -41.3°C in Kuhmo in the north. Some areas in Estonia also had the longest period without any above-zero temperatures ever registered, e.g. 76 days in Johvi. In Lithuania, the winter 2009/2010 was almost 4°C colder than the previous winter. Denmark recorded 74 frost days on average (normal is 53 days).

In north-western Europe, temperatures regularly fell well below -10°C in the Scottish glens and, at times, in some places in Ireland. The coldest spell was in early January, when night-time temperatures fell as low as -22.3°C in the Scottish Highlands, the lowest UK temperature since December 1995. Irish inland stations registered a total of 70–80 days with ground frosts; monthly mean temperatures were around 2°C below normal.

Winter in western and central Europe, too, was characterised by several notable cold waves. Belgium suffered three cold waves during all winter months. The winter in France was not exceptional (-1.2°C anomaly), but several cold waves occurred in January and February.

In Iberia, the winter season was slightly colder than normal on most of the peninsula (anomaly of -0.3°C in Spain), although not as cold as in the rest of most of western and northern Europe. It was characterised by frequent cold spells. February was the coldest month in Spain. Only the southern parts were warmer than normal.

Most of south-eastern Europe, the eastern Mediterranean, the Caucasus region and the Middle East had a mild winter. Anomalies ranged between +1 and +2°C in south-eastern Europe and exceeded +2°C across almost the entire Middle East, where the 90th percentile was exceeded; they were highest in eastern Turkey and the South Caucasus region (up to +5°C). It was the second warmest winter in the South Caucasus since 1935, behind 1965/66, and, in particular, also the second warmest winter on record in Armenia. Western Kazakhstan was only slightly warmer than normal.

All three winter months December 2009, January 2010 and February 2010 had a similar anomaly distribution; they differed only in terms of intensities (the strongest negative anomalies over the whole European continent were observed in January) and location of the lowest values.

This quite unusual temperature distribution resulted from extremely high negative values of both the North Atlantic Oscillation (NAO) and the Arctic Oscillation (AO) in all three winter months, and the subsequent frequent attenuation of westerly airflow. The mean surface air pressure distribution was characterised by an extended low pressure area centered over the North Atlantic east of Newfoundland and a large high pressure area over Asia. This facilitated the intrusion of cold Arctic air into Europe and caused flow of cold continental air from the east to prevail. A compensating flow led warm subtropical air to Turkey and the South Caucasus region. The NAO mean index for the three winter months (-3.1) was the lowest winter NAO since records began in 1821 (data from Climate Research Unit, UK) and ranges even below the values for the winters 1962/63 (very cold winter in western Europe) and 1968/69 (very cold in the east). The NAO index was strongly negative in all winter months, particularly in December 2009 and February 2010.

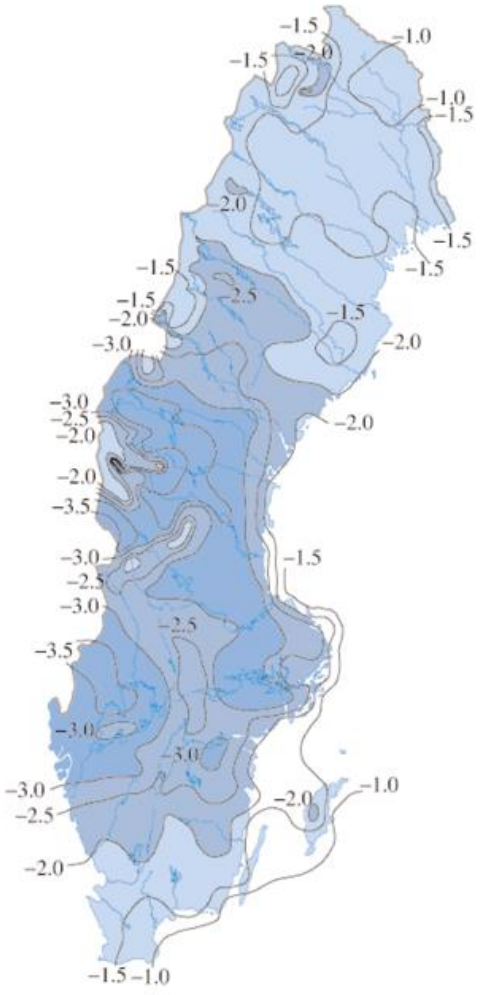

Fig. 0.38: *Temperature anomalies (1961–1990 reference) for winter 2009/10 in Sweden*
Source: Swedish Meteorological and Hydrological Institute (SMHI)

Spring 2010 was warmer than normal in almost the whole Region, except for a few small areas in various parts of Europe (Seasonal Maps, Fig. S2).

It was warmer than normal in the Arctic region. Western Greenland was still more than +5°C warmer than normal, whereas in other parts of the Arctic, the anomalies remained considerably smaller compared to the previous winter. The 98th percentile was exceeded in southern Greenland.

In most of Europe (except the Arctic and the south-east) and over the North Atlantic, the seasonal warming in spring was generally quite high after the cold winter and the temperature anomalies were positive almost everywhere; only locally they were slightly below zero. Especially April was warm in most of Europe, whereas March and May were cold in some parts.

Spring anomalies were only slightly above or around zero in most of northern, western and central Europe. In Sweden, weather varied between warm and cold spells during March and April, which prevented a rapid snow melt. No summer days (25°C or more) were recorded in Denmark. The Netherlands had a mild start of spring, but an extremely cool May.

The strongest warming occurred over eastern Europe, particularly in Russia in April and May (except the south, which was warm in March). Seasonal anomalies were higher than +2°C in parts of European Russia and exceeded the 90th percentile. In other parts of north-eastern and eastern Europe, seasonal anomalies were higher than +1°C. All spring months were warmer than normal in most of eastern Europe except the north-east, which had a cold March.

Almost all over Iberia and Italy, it was also warmer than normal, partly even more than +1°C and exceeding the 90th percentile. Especially April and partly May were warm, particularly in western and southern Iberia. Even so, spring 2010 was the second coldest spring in Spain since 1996 (behind 2004).

South-eastern Europe, the eastern Mediterranean and the Middle East, too, were warmer than normal, though not as much as in winter. Highest anomalies (>3°C) were to be found in eastern Turkey, where the 90th percentile was surpassed. March was exceptionally warm in the whole Middle East region. Spring in the Caucasus region was only slightly warmer than normal on average due to a warm March, but saw near-normal or slightly below normal temperatures in April and May.

Both the North Atlantic Oscillation and Arctic Oscillation continued to show negative values in all three spring months, which means that meridional circulation patterns were strongly prevailing, causing a stronger-than-normal seasonal warming in most of the Region. However, the spatial variability of surface air pressure was much lower than in the preceding winter. The Icelandic low was stronger than normal, but dislocated far to the south-west. Both the Azores high and the Asia high were weaker than normal.

Summer 2010 was also warmer than normal in almost the whole Region, except over the western Mediterranean, the Norwegian Sea and the Barents Sea, which showed negative anomalies between 0 and -1°C (Fig. S3). Averaged over the European continent, summer 2010 was the hottest on record. The most extreme conditions occurred in western Russia.

Greenland was mostly more than +2°C and large parts of the North Atlantic more than +1°C warmer than normal. The summer was the warmest ever registered in Reykjavík (Iceland). The 98th percentile was reached over all these areas.

Most of the western half of the continent was around +1°C warmer than normal, exceeding the 90th percentile. Several countries saw some longer warm periods, but not the whole summer was warm. June was colder than normal across Fennoscandia, but July and August were hot. In the United Kingdom, the monthly mean temperature deviation decreased from +1.5°C in

June to -0.1°C in August. Generally, western and central Europe recorded a warm first half of the summer, but August was around or slightly cooler than normal. Switzerland experienced a hot summer period from mid-June to mid July.

The highest anomalies occurred again in eastern Europe and the Middle East, but they were much higher than in spring and higher than the 98th percentile. New daily maximum temperature records were set in many locations in eastern Europe and Finland. Summer in Estonia started with cooler-than-normal temperatures, but became very warm in July and August, resulting in an anomaly of +2.6°C. The mean summer temperature in Tartu was 18.7°C, the highest value since 1866. Latvia saw its warmest summer for 87 years (+2.7°C anomaly), with 23 hot days (maximum >= 30°C) peaking in an absolute daily maximum of 34.8°C on 13 July. Lithuania, too, was especially warm in July and August (summer anomaly +2.8°C); highest maxima exceeded 35°C on 18 July and 15 August.

Highest deviations were above +4°C during all summer months in European Russia (Fig. 0.39) and adjacent areas in Belarus, the Ukraine and western Kazakhstan; highest seasonal anomalies in European Russia reached +5°C, daily anomalies even reached more than +10°C, temperature maxima exceeded 40°C at several stations south-east of Moscow. It was the warmest summer in European Russia for the whole 130-year period of instrumental observations; possibly it was even one of the hottest in eastern Europe for about 500 years. This was mainly due to an exceptionally long and strong heat wave in July and August centered in Russia, partly also already in June. New daily maximum temperature records were set in all summer months until 19 August. Over most of European Russia, daily maxima above 30°C lasted for more than one month during July/August and both months were the hottest since at least 1939 averaged over the whole area. The high temperatures triggered massive forest and peat fires in European Russia, with smoke and smog adversely affecting tens of millions of people. Thousands of people (an estimated number of around 50,000) lost their lives, half of them around Moscow alone. A land area of more than 1700 km² burned down. The Russian crop production decreased by about one third compared to 2009 and the world market price for wheat rose to twice as high as before. Economic losses amounted to 15 billion US dollars. The Ukraine, Belarus and Finland, too, had new record maximum temperatures. Maxima of air temperature reached 38-42°C in the Ukraine, soil temperatures in 10 cm depth 25-33°C, causing poor conditions both for late summer harvest and sowing winter crops.

Parts of the Balkan Peninsula were also extremely warm. The number of hot days was above normal throughout Slovenia. Several places in Bosnia and Herzegovina exceeded the 98th percentile. In all three summer months, several heat waves were recorded in the mainland of Greece with highest monthly anomalies in August. Extreme heat was also recorded in Turkey, with maxima of 46.7°C e.g. in Mut. Mean temperatures were above normal in all three summer months in the eastern Mediterranean and the Middle East (up to > +2°C), but particularly high in August. Israel also reported several heat waves, especially in August.

In the South Caucasus region, too, summer was much warmer than normal, with seasonal anomalies locally between around +4 and +6°C. It was the hottest summer in Georgia since at least 1957 and the second warmest on record in Armenia behind 2006. The South Caucasus was especially affected by a large number of hot days since it was influenced by very warm air masses coming from the south over a long time. Baku in the coastal area of Azerbaijan counted more than 40 days with more than 35°C, normally there are only a few.

Iberia also had a hot July and August, with this two-month period being the second warmest since 1960. Portugal had its second highest mean summer maximum temperature since 1931. July and August were exceptionally warm, particularly in Portugal and eastern Spain. Anomalies in the whole Mediterranean region were mostly positive, rising up to +2°C. Outbreaks of cold air occurred only occasionally.

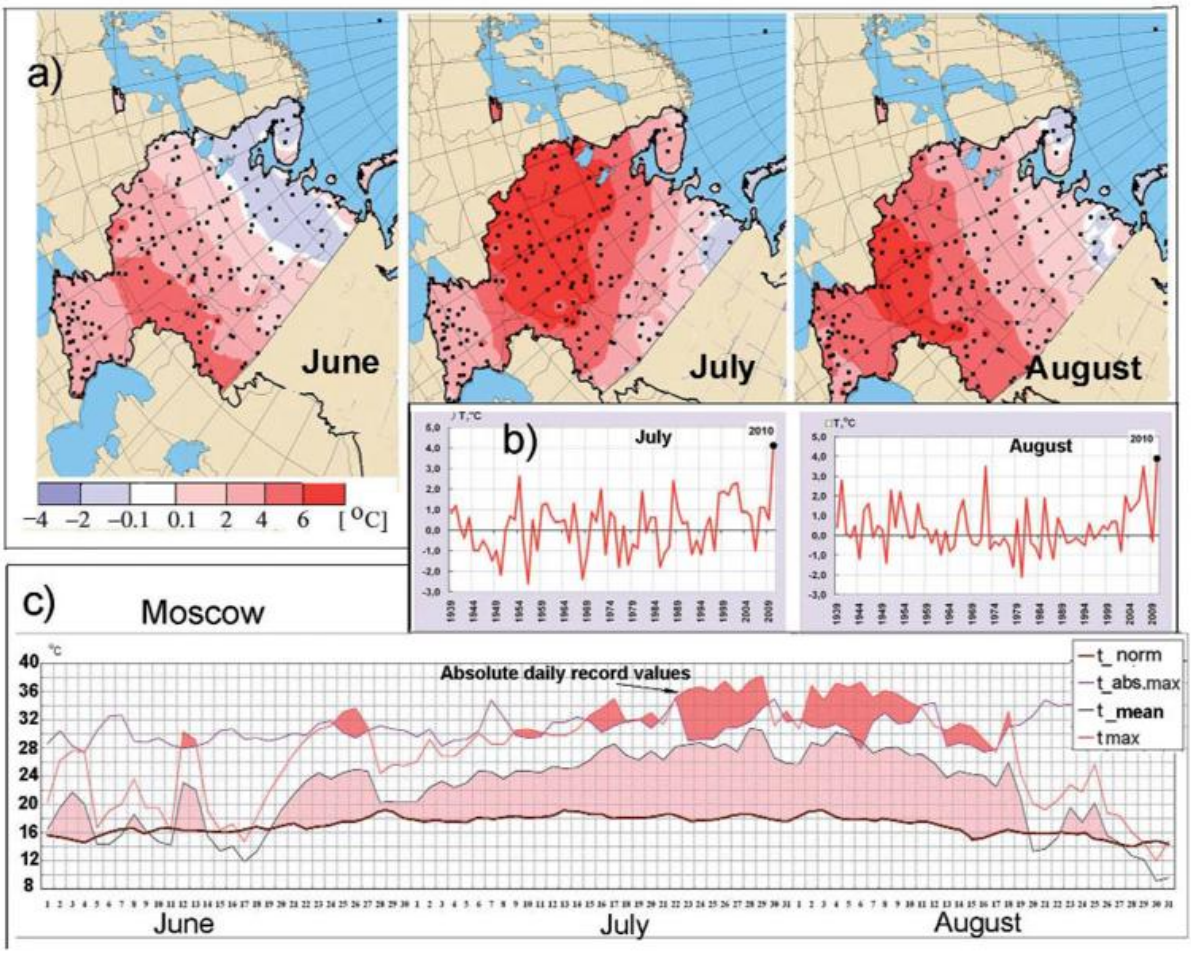

Fig. 0.39: *a) Monthly mean temperature anomalies (1961–1990 reference) in the summer months 2010 in European Russia*
b) Time series of monthly mean temperature anomalies averaged over European Russia in July and August 1939–2010
c) Daily mean (t_mean) and maximum (tmax) air temperature in Moscow June-August 2010, daily normal 1961–1990 (t_norm) and absolute daily maxima ever recorded (t_abs.max)
Source: Roshydromet, Russia

The mean minimum temperature was also much higher (> +3°C) than normal, especially over large parts of south-western, southern and eastern Europe. Some stations in Serbia saw new records for the number of nights warmer than 20°C.

The main reasons for the extraordinary hot summer were strong high pressure influence, particularly in eastern parts of the Region, but also dominating high pressure over the northern North Atlantic, especially in June and August (strongly negative North Atlantic Oscillation index in both months). During the summer, the Icelandic low was quite weak on average.

The high pressure area over Russia implied a blocking event in the northern hemisphere jet stream, which kept weather patterns almost stationary for more than one month. Russia is disposed toward blocking events during summer, and many of its prior heat waves also were associated with such blocking patterns. According to NOAA, the blocking pattern of summer 2010 was the most extreme and longest lasting one since 1920.

Autumn 2010 was cold in the western parts of Europe, but still warm in the east and in the Arctic ("Seasonal Maps", Fig. S4).

Once again, it was more than +1°C warmer than normal in the Arctic region and over most of the North Atlantic. Again, highest anomalies were to be found over western Greenland with more than +4°C, exceeding the 98th percentile.

Northern, western, central and south-western Europe were slightly colder than normal and locally below the 10th percentile. Anomalies were below -1°C over large parts of southern and eastern Norway and central Sweden, with the largest contribution from a very cold November. Denmark had its coldest autumn since 1998. Especially in the western parts of Europe (United Kingdom, Ireland, Spain), September was mild, but lower-than-normal temperatures occurred towards the end of autumn. In central Europe, it was the reverse: most of central Europe saw negative anomalies in September and October, whereas November was warmer than usual. The Baltic countries, too, were only slightly colder than normal and had a mild November. The whole season, however, was colder than autumn 2009 (difference at least about -1°C).

In the south-eastern parts of central Europe (especially Austria, Czech Republic, south-eastern Poland, Slovakia, Hungary), in Italy and on the northern Balkan Peninsula, November was extremely mild, whereas September and October were cold, resulting in a seasonal anomaly around zero.

Most of eastern and south-eastern Europe and especially the Middle East and the southern Caucasus saw a warm autumn, first in September (except for the Balkan Peninsula) and particularly in November. Only October was colder in most of eastern and south-eastern Europe. Large areas in the south-east of the Region were more than +2°C warmer than normal, surpassing the 90th percentile. Highest anomalies were to be found near the eastern Mediterranean with more than +3°C, e.g. in southern Turkey and partly in the Middle East. In these areas, all three autumn months were far warmer than normal, and likewise in the South Caucasus. It was the hottest autumn ever recorded in Armenia.

This season was again characterised by a highly negative North Atlantic Oscillation index and thus dominated by meridional circulation patterns, causing a cold airflow to prevail over western Europe and a warm airflow over the North Atlantic and eastern Europe. The Azores high was weak, the Icelandic low dislocated to the south.

Precipitation

Winter was especially wet in the south; the other seasons were particularly wet in eastern central Europe. Winter and autumn were dry in the north, spring in the west and summer in the east.

Winter 2009/10 was mostly drier than normal in northern, north-eastern, western and central Europe (except for parts of the Arctic and the Baltic countries), but wet in the southern parts of the Region. In most of western and central Europe, average winter precipitation was near normal, except for the south-eastern parts of central Europe (Fig. S5).

Especially Norway and Scotland, with their exposed locations for precipitation, saw a relatively dry winter, partly with less than 20% of the normal. Western Norway had its driest winter on record. Norway as a whole had around half of its normal seasonal precipitation totals and its second driest winter on record, surpassed only by winter 1899/1900. The Norwegian coast, large parts of Ireland and western parts of the United Kingdom were drier than normal in all three winter months. Dublin Airport had its driest winter since 1963/64. At most stations in Ireland, however, it was not as dry as in the winter of 2005/06.

Most of the southern half of the Region received a lot of precipitation, especially Iberia, the Mediterranean region, the Balkan Peninsula, Hungary and Slovakia as well as the areas around the Black Sea. Spain had seasonal totals exceeding 250% of the normal, particularly in the south, due to a persisting period of rainy weather originating from wet Atlantic air masses and many heavy rain events. It was the third wettest winter in Spain since 1947. At 1379 mm, Gibraltar set a new winter precipitation record. The station Lisbon in Portugal also hit a new record of winter precipitation (775 mm) for the time series since 1870 and a new all-time record for the period December 2009 to March 2010 (958 mm). As a consequence of the unusually rainy winter season, large areas of southern and south-western Iberia were affected by floods, particularly along the Guadalquivir river, with important socioeconomic impacts on agriculture, road/rail traffic, buildings and infrastructure. Floods were directly responsible for nine fatalities and for displacing about 1000 people.

On the Balkan Peninsula, Bosnia and Herzegovina reported seasonal totals locally exceeding 300% of the normal while places in Slovenia and northern Serbia reached more than 200% due to some heavy rainfall, particularly in February. Winter precipitation was also far above average throughout Romania and Moldova in all three winter months. The eastern Mediterranean, Turkey, most of the South Caucasus and western Kazakhstan were wetter than normal, with above 125% of the normal over large parts.

This distribution of precipitation resulted from a dominating high pressure influence in the north and low pressure influence in the south, reflecting the strongly negative Arctic Oscillation.

That winter was also characterised by a thick and persistent snow cover in large parts of northern, north-western and central Europe (Fig. 0.40). Over these areas, most of the winter precipitation, though mostly below normal in quantity, fell as snow, and there were new local snow depth records. The number of snow days was higher than normal, especially in south Scandinavia and central Europe, and it was one of the snowiest winters also in western Europe. Even Spain reported snowfall several times.

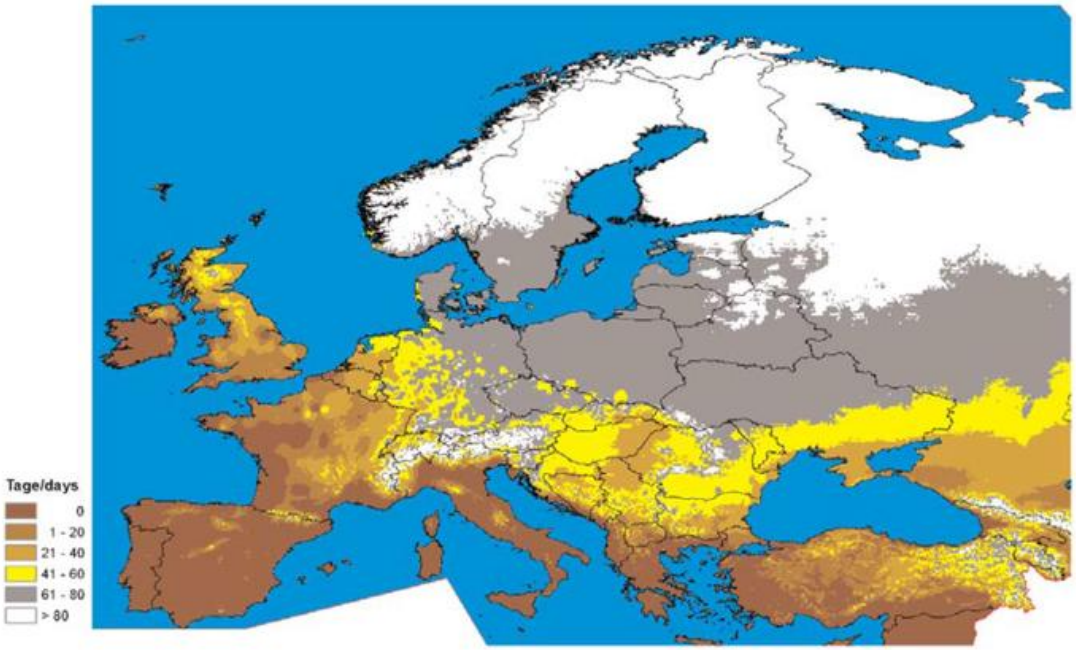

Fig. 0.40: *Number of snow days (number of days with a snow cover of at least 1 cm on the ground) in Europe in winter 2009/10*
Source: Deutscher Wetterdienst, Germany

In contrast, snow was relatively rare in Iceland. Reykjavík recorded 47 consecutive snow-free days from January to February, the longest snow-free period ever observed during this time of the year.

Significant snowfalls occurred in the United Kingdom from mid-December until the end of February and partly into spring. Snow depths in the UK reached up to 70 cm in Aberdeenshire. These were the most widespread snowfalls since the mid-1980s, affecting all forms of traffic as well as electricity and water supply. Ireland saw 20–30 days with snow in many places, mainly in form of showers, but snowfall accumulations were generally slight except on high ground.

In central Europe, very large numbers of snow days were to be noted. The Netherlands had 42 days with snow cover on average, more than three times the long-term average of 13. Such a large number of days with snow had not been seen for more than 30 years since the winter 1978/79. Uccle in Belgium had 31 snow days, the third highest number since 1901. It was one of the snowiest winters in the last 30 years in France, although the snow depths remained below historical records. Snow was also abundant in Germany; locally the highest depths on record and up to 73 snow days were recorded in the northern and eastern parts of the country, around twice as much as normal.

There was also more snow than usual in southern Finland because of the long lasting cold spell. Helsinki had not had so much snow since 1970, recording its maximum snow depth of that winter at 73 cm in late February, which, however, remained far below its highest record of 109 cm in 1941.

In Latvia and Lithuania, a steady snow cover began to form in the second decade of December and lasted almost the entire winter, except at the seaside. The snow cover in Latvia was two to three times deeper than normal most of that time. In the Ukraine, too, it was one of the snowiest winters in the past decade, with the highest maximum depth over the entire observation series.

In contrast, the snow cover duration was significantly lower than normal in most of European Russia. Even in the mountain regions of northern Caucasia, the snow cover persisted not as long as it usually does. The maximum snow depths, however, were higher than normal due to a rather large amount of precipitation as well as an absolute absence of thaws in central European Russia as had not been recorded for several decades.

Spring 2010 was dry in western Europe as well as over most of Russia and the eastern Mediterranean region, but wet in most of northern and eastern central Europe and over the western Mediterranean (Fig. S6).

It was a mostly dry spring in the Arctic region, namely in Svalbard and parts of Greenland.

Most of Scandinavia saw a wet spring (except for the southern parts), partly with more than 125% of the normal, with some heavy precipitation events causing locally severe mud slides, especially in late spring. Places in northern Norway received more than 200% of the normal, while stations in the southernmost parts of the country recorded only 50% of the normal. Southern Iceland and southern Sweden, too, were drier than normal, and Denmark also had a small precipitation deficit.

Likewise, many of the western countries of Europe (Ireland, the United Kingdom, the Low Countries, France, western Germany, Switzerland, northern Spain) were drier than normal, partly with totals of less than 80% of the normal, locally even less than 60%. It was the driest spring in the UK since 1984, due to the particularly dry April and May months with about 50% of the 1961–1990 normal in England and Wales. Uccle in Belgium had only 33 precipitation days in spring (normal: 49 days), the lowest number since 1990.

Most of Iberia and the western Mediterranean had a wetter-than-normal spring, except the north of Spain. Local areas in northern Iberia received less than 80% of the climatological average, whereas the southern parts received up to 125%. Lisbon in Portugal saw its rainiest spring of the last 51 years.

In most of eastern central Europe, spring was wet, too, although April was very dry. Especially Poland, the eastern Czech Republic, Slovakia and Hungary partly had around twice the normal amount. A large contribution to this anomaly came from a flooding event in May. In many areas, the number of days with a daily total > 20 mm was higher than normal. Large parts of the Balkan Peninsula were also wetter than normal due to some heavy thunderstorms in April and May, except for the south.

Precipitation was also above normal in the Baltic countries. In addition, melting of snow and ice blockages caused local floods in parts of Estonia and Latvia.

Central European Russia and parts of the eastern Ukraine were dry, locally with less than 60% of the normal, whereas the northern and southern parts of European Russia and the southern Caucasus region were wet.

The eastern Mediterranean region and the Middle East were extremely dry during the whole spring, mostly with less than 40% of the normal. March and April were unusually dry months in Greece. In contrast, the southern Caucasus region and west Kazakhstan were wetter than normal.

The reason for this large-scale precipitation distribution was a prevailing strong meridional circulation pattern, with frequent low pressure activity over eastern central Europe and high pressure influence west and east of it.

Summer 2010 was wetter than normal in most parts of Europe, but very dry in the east (Seasonal Maps, Fig. S7). The large number of days with daily totals >20 mm in many parts of Europe implies a large number of convective events.

The Arctic region was very dry, namely Greenland and Svalbard, but summer precipitation totals were between 125% and 150% of the normal in large parts of the Nordic and Baltic countries, except Iceland and southern Finland. Northern Norway experienced its second wettest summer on record, together with 1995 and behind 1921. Latvia experienced its third wettest summer for 87 years. Lithuania, too, had extraordinarily rainy weather that summer, which included 10 heavy rainfall and 3 large hail events.

Summer rainfall was close to average in western Europe, though with high spatial and temporal variability due to various wet and dry spells over the three summer months.

In most areas of Europe, the seasonal totals were only slightly higher than normal. However, over large parts of eastern central Europe (eastern Germany, Poland, the Czech Republic, Slovakia, Hungary), some parts of eastern Europe (western Ukraine, Romania), northern Europe and also west and south of the Black Sea, the totals exceeded 125% of the normal, in Latvia and Lithuania 150%, in parts of Slovakia even 200%.

There were a number of heavy rainfall events in various parts of Europe. Central Europe was particularly affected, especially the eastern areas. Two exceptional flooding events concerned especially eastern Germany, Poland and the Czech Republic. Germany recorded several periods of heavy rain with daily totals of more than 100 mm (such daily totals had not been measured in Germany in the previous years 2008 and 2009). Slovakia recorded its wettest summer in its history of precipitation measurements since 1881.

The Balkan Peninsula, too, received much heavy rain. In Slovenia, precipitation was abundant in the north-west. Many other parts had below-normal precipitation but also very intense thunderstorms during summer. Heavy precipitation in Romania between 20 June and 14 July caused severe flooding in many parts of the country. The rest of the eastern parts of the Balkan Peninsula were also wetter than normal as opposed to drier parts in the west.

Southern Spain, which already had received much precipitation in spring, also saw a lot of precipitation in summer, in places close to twice the normal, whereas other parts of Spain, Portugal, southern and western France were very dry. June was relatively wet in Spain, but July and partly also August were drier than normal. Average July precipitation over Spain (generally low in summer) was only around 50% of average. In southern Europe, it was generally very wet in June 2010, but became very dry in August.

In the Mediterranean, it was wet over Corsica and Sardinia, but dry over Sicily and Malta, in particular, which received only 1.4 mm during the whole summer and all of June (summer normal is 10.6 mm).

It was dry over most of European Russia and some adjacent areas (including southern Finland and most of the South Caucasus), particularly during the heat wave in this area in July and August. Some parts of eastern European Russia received less than 20% of the seasonal normal. Numerous forest and peat fires with subsequent air pollution occurred in many places; several settlements burnt down completely. It was the worst drought since 1972.

The main reason was the strong high pressure influence particularly over Russia, whereas low pressure systems were blocked over eastern central Europe.

The DWD drought index (Fig. 0.41) shows extreme drought conditions for the very dry areas in Russia and the Middle East and severe drought conditions over southern Portugal for that summer. Anomalies of this drought index imply that only the drought area in Russia showed an extreme deviation from normal.

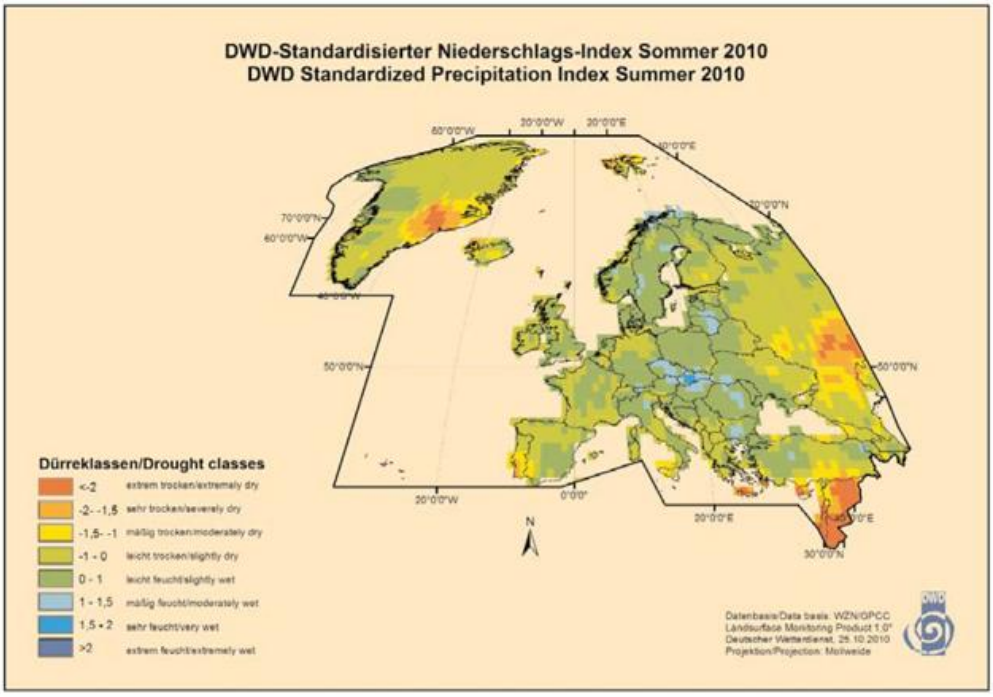

Fig. 0.41: *Standardized precipitation index (DWD version) for summer 2010*
Source: Deutscher Wetterdienst, Germany

Autumn 2010 was wet or around normal in most of Europe, but very dry in Scandinavia (except for the southern parts), the Arctic, the northern Alps and particularly the Middle East (Seasonal Maps, Fig. S8).

Especially Norway and most of Sweden were very dry, mostly with less than 80% of the normal precipitation, locally less than 40%.

Precipitation was close to normal in most of western Europe as a result of a dry October, but a wet November. However, several heavy rain events caused high above-normal anomalies in some places in France.

Some larger parts of central, eastern and southern Europe (eastern Germany, Poland, eastern Ukraine, most of Italy and the Balkan Peninsula) were particularly wet; partly they received around twice the normal seasonal precipitation. Especially September and November totals were mostly above normal across central Europe, but these wet spells were interrupted by a mostly dry October, with some local exceptions.

Autumn was wet in northern Spain, whereas the Spanish Mediterranean regions were drier than normal. However, the number of days with totals >20 mm was much larger than normal over the Mediterranean and northern Italy.

It was very dry in the Middle East and in Cyprus. That area received less than 40% of its normal precipitation, which means a prolongation of the dry summer period.

The distribution of precipitation reflects a centre of intense low pressure activity over eastern central Europe, the Balkan Peninsula and the central Mediterranean.

Monthly Surveys

January

- **Very cold in most of Europe, warm in the Arctic and in the south-east**
- **Dry in northern and western Europe, mostly wet in the south**
- **Heavy snowfalls in many parts of Europe**

Atmospheric circulation characteristics

As a continuation of the weather conditions in December 2009, the year 2010 started with a strong negative North Atlantic Oscillation (NAO) and Arctic Oscillation (AO) with only rare westerly flows over the North Atlantic and Europe. Instead, an extremely strong high pressure area extended from Siberia far into the west, reaching north-western Europe and even Greenland and causing a flow of cold and mostly dry continental air from the east to the west, which spread out more or less over the whole of Europe. The cold conditions were intensified by a persistent widespread snow cover. At the beginning of the month, a relatively stable, large cold trough extended from Scandinavia and north-western Russia to Iberia, causing low pressure conditions and frequent snowfall over large parts of Europe.

Over the North Atlantic, the Icelandic Low was shifted far to the south-west to a position south of Greenland and east of Newfoundland, causing a prevailing meridional airflow from the south which led mild air to the Arctic region.

The south-east of the Region was mostly affected by warm subtropical air masses from the south. Within these warm air masses, but also in a strong frontal zone between warm and cold air in more northern latitudes, cyclonic activity was increased, leading to frequent precipitation. At the end of the month, a polar low pressure pattern moved far to the south into the South Caucasus region, causing a cold and wet spell with snow and heavy rains.

Temperature

The Arctic region was very mild. Anomalies were highest over Spitsbergen, with more than +8°C. In southern Greenland, anomalies were between +4 and +6°C, and the 90th percentile[1] was exceeded. The minimum temperature in Reykjavík (Iceland) was above freezing for 21 consecutive days. This was the longest known such period at that location.

In contrast, large parts of the European continent were very cold (Fig. 1.1), as a continuation of December 2009. Deviations from normal were below -4°C over parts of eastern Europe (Baltic countries, eastern Germany, most of Poland, Belarus, European Russia) and southern Scandinavia and partly below the 10th percentile. Monthly anomalies were even below -6°C in southern Finland and large parts of the Baltic countries, particularly in Estonia (Fig. 1.2) and Latvia; they were below -8°C in central European Russia (central Chernozem region).

---

[1] Monthly percentiles for temperature and precipitation have been taken from surface observation data of the Climate Prediction Center (CPC) of the US National Centers for Environmental Prediction (NCEP): http://iridl.ldeo.columbia.edu/maproom/.Global/.Atm_Temp/Percentiles.html . Reference period is 1961-1990.

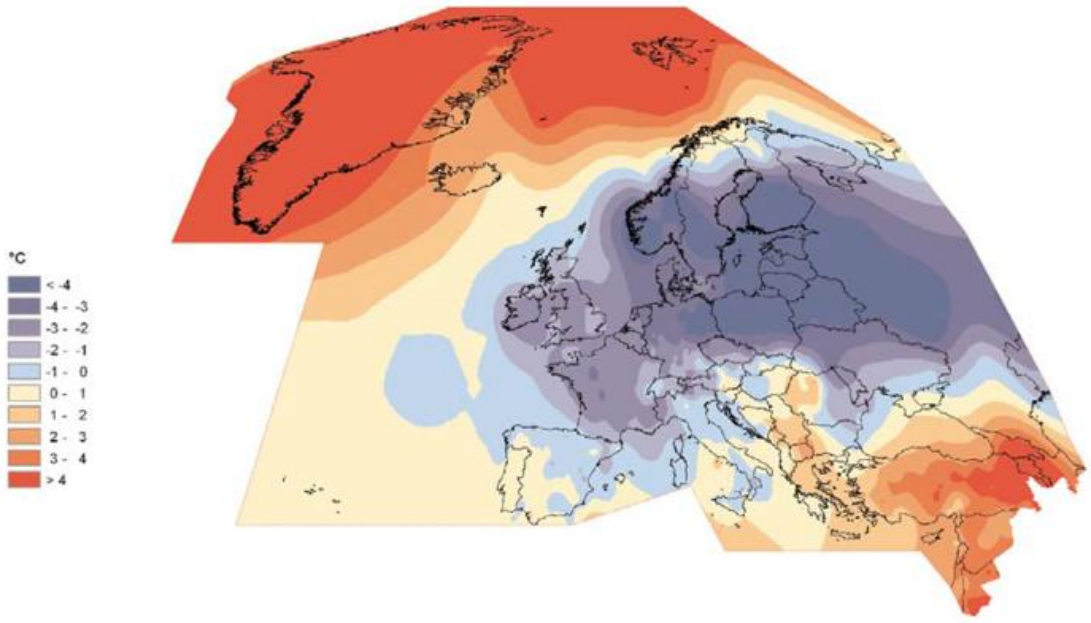

Fig. 1.1: *Monthly mean temperature anomalies in January 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

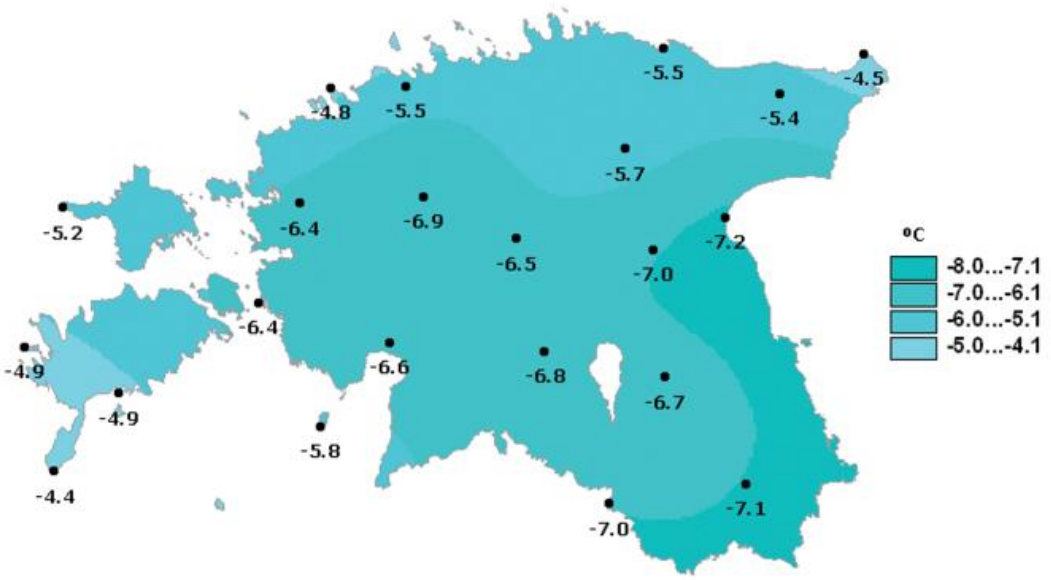

Fig. 1.2: *Monthly mean temperature anomalies in January 2010 (reference period 1961–1990) in Estonia*
Source: Estonian Meteorological and Hydrological Institute

Most of Scandinavia started the year with colder-than-normal temperatures; especially the southern parts were much colder than usual. The lowest minimum temperature in Norway was -42.4°C on 8 January. In Sweden, temperatures remained below 0°C during the whole January in Stockholm, which last happened in 1829. Minima in southern parts of Sweden were down at -30°C (e.g. in Gävle), the lowest since the 1960s.

Western parts of Europe also saw a frosty January. It was the coldest January over the United Kingdom since 1987, with anomalies around -2°C and sharp frosts; minima regularly fell well below -10°C in the Scottish Highlands and reached -22.3°C on 8th, the lowest UK temperature since 1995. Ireland also had a cold spell during the first 10 days of January (continued from December 2009); it was the most extreme cold spell over Ireland since early 1963. Taken as a whole, it was the coldest January since 1985 in Ireland and the coldest since 1963 in the Dublin area. Most places in Ireland recorded 22–27 days with ground frosts, compared to 12-18 days normally. For the first time since 1997, the monthly average temperature in De Bilt (Netherlands) was below 0°C. In France, too, it was the coldest January for the last 20 years and minima fell down to around -20°C south of Ile-de-France.

Central Europe also had an extremely cold month, especially in its eastern parts. It was the coldest January in Germany since 1987. Temperatures in Germany remained below zero most of the month; in eastern Germany, minima dropped below -20°C in late January. The lowest minimum was -24.3°C on 27 January. In Switzerland, it was the coldest January in 23 years; daily temperatures were not extremely low there, but they remained below average for almost the entire month. Poland had an anomaly of -5.4°C below the 1971–2000 normal, the daily minimum of that month (and year) was -30.3°C.

The cold weather in January was much more extreme in north-eastern parts of Europe, especially in the Baltic countries and central European Russia. It was the coldest January in Latvia since 1987. Starting on 6 January, temperatures in the whole of Latvia remained continuously below zero during the rest of the month; such a long frost period had last occurred 54 years ago. Likewise, there was almost a complete absence of thaws in Lithuania and central European Russia, as was last the case several decades ago; instead, severe frosts occurred in large areas, particularly in the second half of the month. The end of the month was especially cold in Estonia (with a minimum of -32.4°C at Jogeva) and Lithuania (with minimum temperatures between -25 and -30°C in many places and locally breaking all-time records for these days of the year). The Ukraine, further in the south, recorded less negative anomalies than the northern east European countries, but minimum temperatures were nevertheless quite low, down to -34°C in the Ivano-Frankovsk region.

The cold weather even reached some northern parts of the Balkan Peninsula, although only temporarily. In Slovenia, the monthly mean temperature was close to normal; anomalies were significantly negative only in the mountains, particularly during the last third of the month. Romania was only slightly colder than normal due to a very mild period from 6-12 January, but was very cold especially in eastern, central and southern parts from 24–28 January with new daily minimum temperature records (partly below -25°C). This cold spell also affected Bulgaria.

The western and central Mediterranean region and Iberia had monthly mean temperatures around normal, but also some temporary cold spells. A pronounced cold spell occurred in Spain from 7–11 January due to an invasion of continental cold air from the north-east. A minimum temperature of -16.0°C was recorded in Burgos on 10 January and other sites in the highland regions in the interior of Spain also saw minima below -10°C. Temperature anomalies in Italy were largely within the natural variability, slightly lower than normal in the north and a bit higher in southern parts. However, a cold outbreak of Arctic air occurred in Italy during the “giorni della merla” (“days of the blackbird”, 29–31 January), making these days the coldest of the year.

The Middle East including the South Caucasus region as well as large parts of the Balkan Peninsula and the southern and eastern Mediterranean were very mild. Monthly anomalies were around +2–3°C above normal in and near the Middle East and the 90th percentile was exceeded over large parts of the area. It was particularly mild at the beginning of the month. In Greece, the New Year's Day was the warmest ever recorded in January in 50 years, with a maximum temperature of 29.8°C at Heraklio on Crete island. Malta reached a daily maximum of 20.3°C on 7 January and Bar at the Adriatic coast in Montenegro set a new record (21.2°C) on 8 January. In the South Caucasus, up to 22°C were reached in Georgia, and 16–18°C in the lowlands of Armenia. Azerbaijan also had a very mild period at the beginning of January, with a new maximum temperature record of 26.6°C at the station Astara, but then saw a cold spell at the end of the month. In many parts of Israel, it was the warmest January since measurements began.

Precipitation

The Arctic region was partly wetter than normal, especially in Svalbard and parts of Greenland, locally with more than 200% of the normal. However, most of Greenland was dry.

Northern, western and large parts of central Europe saw a very dry January (Fig. 1.3). Monthly precipitation totals were below 40% of the normal over large parts of northern Europe; in northern Iceland and western Norway even below 20%. Several stations in Norway registered a new monthly low precipitation record for January. The totals were below the 10th percentile over most areas of northern Europe. Little precipitation was also recorded in the northern half of European Russia due to prevailing anticyclonic conditions, with 20–40% of the monthly normal in individual central regions. Most of western and central Europe received less than 80% of the normal, locally even much less.

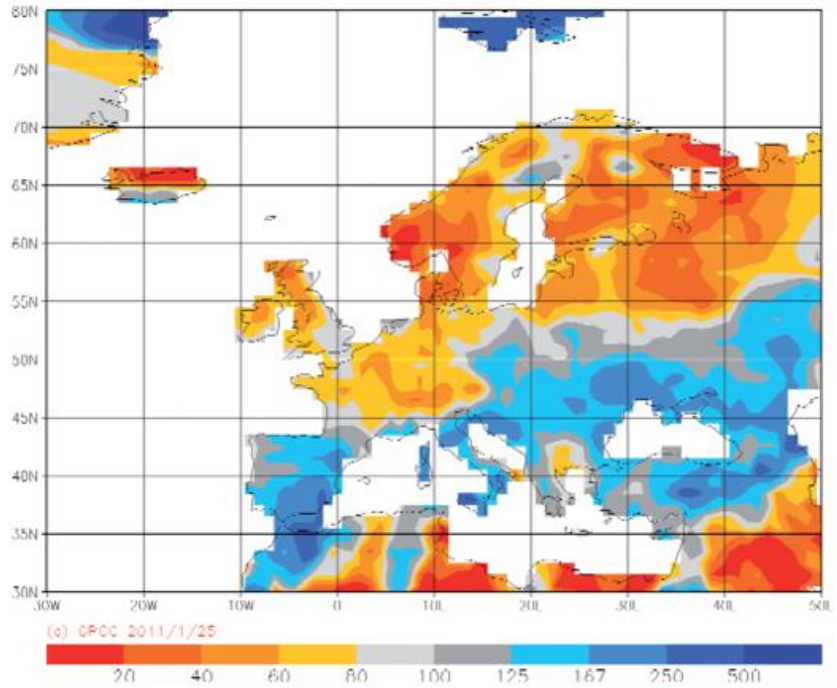

Fig. 1.3: *Monthly precipitation amounts for January 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Shannon Airport in Ireland received just 30 mm of precipitation over the whole month, which was the lowest January total since 1963. On the other hand, there were also some heavy rains in Ireland, e.g. a daily total of 58 mm was measured in Valentia on 12 January, the highest for January on record.

Most of southern Europe and southern parts of eastern central and eastern Europe were wet, including eastern and south-eastern Austria, the Czech Republic, Slovakia and Hungary. Especially the areas around the Mediterranean and the Black Sea received locally more than twice the monthly precipitation totals. The 80th percentile was exceeded over most of these areas, locally also the 90th percentile.

Some special extraordinary precipitation anomalies were recorded in Italy and on the Balkan Peninsula. Heavy precipitation at the beginning of the month caused flooding and mudslides in Italy. In Slovenia, too, most of the precipitation fell during the first third of the month; partly, it was abundant, with locally more than 200% of the normal. Places in Bosnia and Herzegovina received more than 300% of the normal. Serbia was partly extremely rainy in its northern parts, and especially the number of precipitation days was high, in some places even record-breaking. Flooding due to heavy rain took place in Montenegro at the Skadar Lake and in Bojana in early January. Bulgaria recorded 6 days with thunder activity, which was unusual for this time of year.

Highest precipitation totals (300–400 mm) were reached on Sicily, in southern Montenegro and northern Albania, where a severe flooding occurred. Generally, many places around the coasts of the central and eastern Mediterranean received high monthly precipitation totals of 100 mm or more. The same was observed for western and southern Iberia and for the southern and eastern coast of the Black Sea, parts of the mountain regions of the north Caucasus and eastern Turkey. Up to more than 500% (219 mm) of the normal monthly precipitation fell in east Georgia, more than 400% in the basin of Lake Sevan in Armenia and more than 200% in places of southern European Russia. Heavy rains hit Georgia at the beginning and Azerbaijan at the end of the month. Locally, more than 125–250% of the normal precipitation fell in places of the Middle East. Israel was rainy in the north and the south, mostly due to a heavy rain event from 17 to 21 January.

Snow

Due to the low temperatures, snow persisted for the whole month over large parts of northern, central and eastern Europe and some western and southern parts of Europe. Snow, freezing weather and ice caused widespread disruption to transportation and energy supply. More than 177 people died in Europe due to freezing conditions or accidents.

The monthly mean snow depth was higher than 20 cm over large parts of northern Europe, locally much higher. However, there was less snow than normal in the northern part of Norway and the western mountains in the southern part of the country opposed to more snow than normal in south-eastern Norway. The snow depths by the end of January were the lowest in 40 years in parts of the northern Norwegian counties Troms and Nordland. In contrast, some provinces in the Baltic countries received as much snow as they had not seen for approximately 25 years.

The UK Met Office reported January snowfalls as the most significant and widespread across the UK since the mid-1980s. Thousands of schools were closed; there was severe disruption to transport networks, the water and electricity supplies to thousands of homes and businesses were interrupted frequently, and a number of fatal accidents occurred that were related to the freezing weather conditions. In early January, daytime temperatures across the UK often failed to rise above freezing, significantly prolonging the period of lying snow. 57 cm of lying snow was reported from Westgate (County Durham) on 7 January. A spell of heavy snow affected western

areas of Ireland on 13 January (Fig. 1.4), but when temperatures rose slowly to near-normal values in the middle of the month, snow turned increasingly to sleet or rain, bringing flooding in some southern areas of Ireland.

Fig. 1.4: *Heavy snow at the observing station at Knock Airport, Ireland on 13 January 2010 Source: Irish Meteorological Service, from a series of pictures courtesy Mary Beston, Gerard Griffith, Liam Newman*

Frequent snowfall also occurred in France and Germany during the first half of the month (particularly after the snowstorm Daisy on 10 January), some snowfall also occurred later in the month, partly interrupted by freezing rain periods. At the end of the month, Germany was mainly snow-covered with more snow in the north-east of the country than in the south. 30 cm of snow fell in one night in Rostock (north-eastern Germany) from 29–30 January during a heavy snowfall event, which affected the whole of Germany. Some stations in north-eastern Germany had near 50 cm and new snow depth records were set.

In Switzerland, it often snowed in the plains north of the Alps, but the amounts were usually small. Zürich broke its record, with 16 days of measurable new snowfall. Geneva airport, which services the busy Alpine ski resorts, was forced to close over the weekend of 8 January due to heavy snow. Heavy snowfall covered western Switzerland again in mid-January; and towards the end of the month, even greater amounts fell in the eastern part of the country.

In north-east Poland, the snow cover was 48 cm deep, the same in Ljubljana in Slovenia. In an area around Leszno in Poland, snow even accumulated to a depth of 150 cm; about 200,000 houses were left without power. Snow depth reached 280 cm on the Slovenian mountain Kredarica only on the last day of the month. Romania had snow depths of up to 147 cm in the mountain area and 20–50 cm in the rest of the country; Bulgaria also had intense snowfalls of up to 4 m due to snowstorms. 30 cm fell in Varna near the Black Sea. In north-western Turkey, snowfall was 13 cm at Edirne and 5 cm at Tekirdag on 19 January after a wintry spell.

There was also snowfall in extended areas across the northern and interior parts of Spain and even in some places in Andalucia and coastal areas of Portugal at low altitudes, where such events are rare. For the first time in 50 years, snow was reported as far south as Seville in Spain. Widespread snowfall occurred over northern Italy at the end of the month from 29–31 January.

Due to high snow precipitation in the North Caucasus, avalanche hazards persisted there throughout the month. In the South Caucasus, it was snowy all over Georgia during the first two thirds of the month, but with interruptions. Snow depth was about 3 m in the mountains of Georgia. Azerbaijan received snow at the end of the month.

Significant weather events[2]

January 01:	Strong south-westerly winds of up to 130 km/h over southern and western Italy (Sardinia, Sicily and Tyrrhenian regions); sea storm along the exposed coasts.
January 03:	After heavy snowfall during several days in Switzerland, 4 people died due to avalanches.
January 03–04:	Heavy hail in eastern Georgia on 03 January; tornado in the coastal zone of Georgia on 04 January, causing serious material losses.
January 07:	UK almost entirely covered by lying snow, with depths exceeding 30 cm in many northern areas and more than 50 cm in some places.
January 08–11:	Strong winds in Bulgaria (up to 122 km/h in Kurdzhali).
January 09–13:	Snow and very cold temperatures particularly affected Switzerland, Germany and Poland and caused the closure of Geneva airport, cancellation of more than 90% of flights at Frankfurt airport and trains in Germany, as well as blocked roads, broken roofs and people frozen to death particularly in Poland, state of emergency on the coasts and islands of the Baltic Sea due to coincidence of snow masses, flooding and wind (gusts > 120 km/h). This event was caused by a Mediterranean low (Daisy) that led humid air from the Mediterranean to the Balkan Peninsula and to eastern and central Europe. Albania had a severe flooding in the districts of Shkodra and Lezha. Local flooding occurred on the Sava River in Serbia due to frequent precipitation.
January 17–18:	Heavy rain (up to 111 mm in 24 hours) and thunderstorms in Greece over the Aegean Sea; flash flood on Crete island.
January 17–21:	Israel and Jordan suffered from flash floods due to heavy rain. These were probably the worst floods in over a decade in Israel. 30–80 mm widely fell in the Negev Desert in Israel on 17 and 18 January, 2–4 times more than the monthly average. This rainfall was record-breaking with regard to daily totals for many stations in the Negev. The floods claimed the lives of 15 people and approximately 700 houses were engulfed.
January 21–29:	Glaze ice and hoarfrost accretion (35-80 mm) in the northern Caucasus (southern European Russia).
January 26–28:	Snow and very low temperatures severely affected many countries (Germany, Austria, Poland, Romania, Bulgaria and Turkey). In Romania and Poland, people froze to death; in Frankfurt, Germany, flights were cancelled and Bulgaria had a snow depth of more than 4 m due to snowdrift.
January 27:	125.6 mm of daily precipitation were measured in Norway (station Lurøy).
January 28:	Estonia reported very low water levels on the Baltic Sea coast. Germany reported that snowfall and low temperatures caused many accidents and affected the air traffic again. The Island of Rügen was isolated and the surrounding Baltic Sea was frozen.

[2] *Significant weather events of recent months are also presented in the Event Calendar of the WMO RA VI Regional Climate Centre on Climate Monitoring (RCC-CM) on the RCC-CM website of Deutscher Wetterdienst: http://www.dwd.de/rcc-cm - Products - Significant Weather Events – Monthly calendar*

End of January: Cold and wet spell with snow and heavy rains in Azerbaijan; gusts up to 118 km/h in some places. The wave height at the oil rocks station on the Caspian Sea was up to 7.3 m, which is very rare.

February

- **Cold over northern, western and central Europe, warmer than normal in the Arctic and in the south-east**
- **Dry in north-western and central Europe, wet in north-eastern, eastern and southern Europe**
- **Severe storm Xynthia over south-western, western and central Europe**

Atmospheric circulation characteristics

Like the other months of winter 2009/10, February 2010 was also characterised by very strong negative NAO and AO indices, even more extreme than in January. Cold continental air from the east continued to move into Europe, reaching even the south. This month, however, the main airflow affected more the northern areas of the continent. Westerly low pressure systems were quite rare, but at the end of the month, a severe storm (Xynthia) reached south-western Europe and crossed western and central Europe, while at the same time a south-westerly airflow brought some warmth to north-eastern Europe.

Over the North Atlantic, high pressure dominated over Iceland and low pressure over the subtropics, which is the very opposite of normal conditions. The result was that the prevailing easterly flow continued even over the North Atlantic and produced a cooling there.

Also in the south-east, there was no overall change of the circulation conditions compared to January. Especially the Middle East was still affected by an ongoing warm airflow from the south, particularly in the second half of the month. Cyclonic activity was still enhanced over southern Europe and the Mediterranean. The southern Mediterranean, however, profited from a ridge over its central regions in the middle of the month.

Over eastern Europe, a quasi stationary front formed west of the Russian blocking high, causing an area of higher-than-normal precipitation.

Temperature

It was still mild in the Arctic, with anomalies above +4°C (Fig. 2.1), as a continuation of the mild conditions in January, in Greenland even up to +8°C at the west coast. Again, the 90th percentile was exceeded over southern Greenland. Daily temperature maxima reached 3–7°C at the west coast of Greenland.

February was also another cold winter month over large parts of Europe. The highest negative anomalies between -5 and -7°C were recorded in northern parts of Scandinavia, largely with absolute monthly minimum temperatures below -30°C. The cooling was below the 20th percentile over whole Scandinavia. Large parts of southern Norway recorded their coldest February at least since 1994.

It was continuously cold in north-western Europe, though with weaker anomalies than in northern Europe (down to -2°C below normal in the north of the United Kingdom and in Ireland). Yet it was the coldest February over the UK since 1991.

It was the coldest February on record in northern and north-eastern European Russia, with extremely low daily minima. On 19 February, the air temperature dropped to -52°C (or 27°C below normal) in the north-eastern regions of European Russia, which was below the absolute February minimum for the entire period of record. Another location in north-eastern European

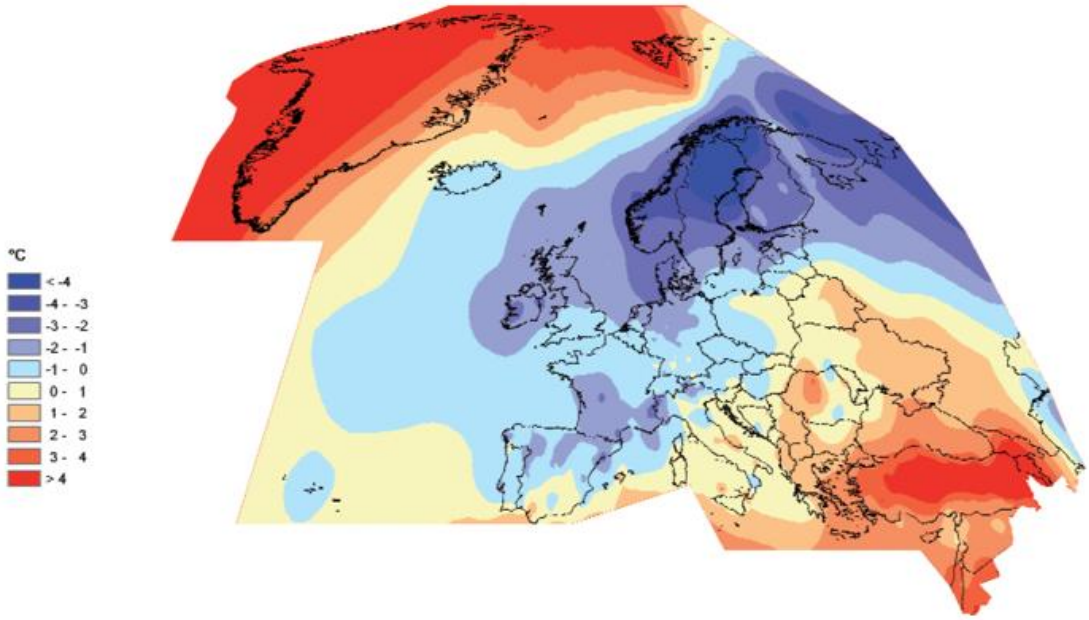

Fig. 2.1: *Monthly mean temperature anomalies in February 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Russia (station Hoseda-Hard, Nenets Autonomous District) registered the second lowest minimum ever recorded in Europe at -57.0°C (behind -58.1°C in December 1978 in the Komi Republic in north-eastern European Russia).

Different from January, monthly means in central Europe were close to normal (mean anomalies around -2°C to 0°C) due to a milder second half of the month and despite some low temperature events. Daily minima dropped below -20°C in Poland on 10 February.

The Alps saw cold weather especially in early periods of February. The first few days of February were extremely cold in Switzerland, with temperatures down to -35.6°C (La Brévine) and -25 to -30°C in Engadin. Except for one short foehn phase, the cold winter weather continued through the middle of February. In Austria, especially the first half was also very wintry before foehn brought mild temperatures.

Even parts of Iberia and the North Atlantic including Iceland and Azores were colder than normal, though not significantly (anomaly of -0.6°C in Spain). Italy, too, was slightly colder than normal, especially over northern and southern regions, and quite close to average elsewhere.

Similar to January, the Middle East and some adjacent areas were warmer than normal, with the warmer-than-normal conditions, however, extending further to south-east Europe. Deviations from normal exceeded +4°C, locally even +7°C particularly in Turkey and the South

Caucasus. The warming was higher than the 90th percentile in whole Turkey and further south. In the South Caucasus, up to 25°C were reached in Georgia, 20°C in Armenia. In Azerbaijan, the first half of February was cold, with temperatures below the freezing point, the second half, on the contrary, was very mild, with maximum temperatures up to 28°C in Astara (near to the Iran border). Israel had a prolonged heat wave of more than two weeks with highest daily maximum temperatures up to 33°C and record-high daily minima up to around 18°C. It was also more than +1°C warmer than normal over the southern Mediterranean. At 24.2°C, Luqa Airport in Malta recorded its 2nd highest February maximum temperature, the station Iraklion in Greece had 28.8°C on 20 February.

Precipitation

Due to the lack of westerly airflow and high pressure over the Arctic, it was far drier than normal especially at the west coast of Norway, in Ireland and the western parts of the United Kingdom, as well as in the Arctic region and southern Iceland (Fig. 2.2). Monthly totals were less than 40% of the normal over large parts and even less than 20% at the southern west coast of Norway, locally also in the Arctic. Precipitation was below the 10th percentile over Greenland, Iceland and Norway. Nuuk in west Greenland received just 1.3 mm during the whole month. Some Norwegian stations registered a new record for the lowest monthly precipitation total for February.

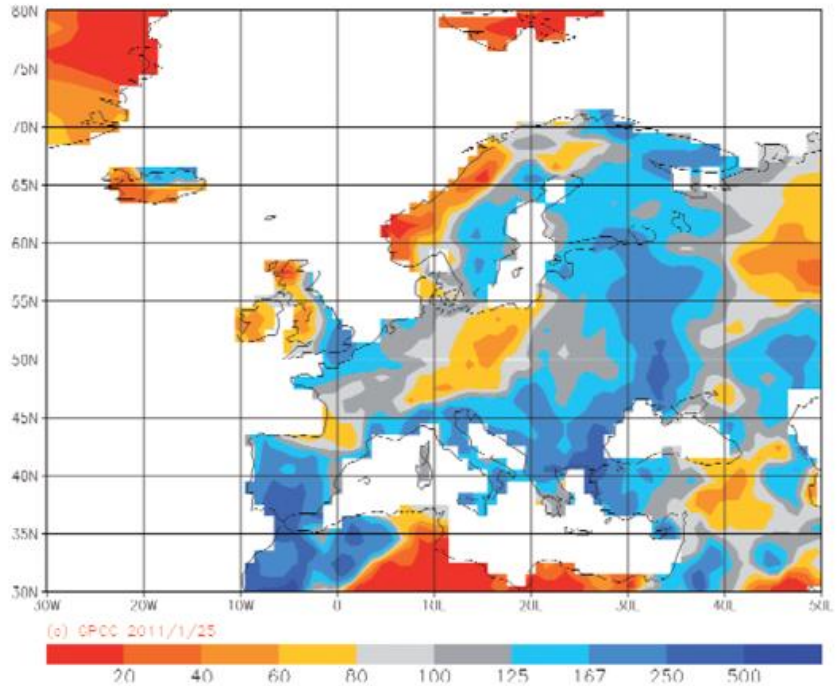

Fig. 2.2: *Monthly precipitation amounts for February 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

It was also dry in large parts of eastern central Europe and in the Alpine region, north-eastern European Russia, eastern Turkey, most of Armenia, northern Syria and Malta, locally with less than 60% of the normal.

The other parts of the Region, especially most of south-eastern central, southern and eastern Europe and most of the southern Middle East were mainly wetter than normal, mostly exceeding the 90th percentile, locally more than the double of the normal total (e.g. in most of Iberia, Hungary, north and west of the Black Sea and in Jordan).

It was the rainiest February for the last 24 years in Portugal. Monthly totals exceeded historic records at many stations in southern Spain. Italy had quite high precipitation in Calabria in the south, but also in the north in the Po Valley and northern Tuscany. New records of monthly precipitation were also set on the Balkan Peninsula after some heavy rainfall events, e.g. in Montenegro. A new local daily total record for February was achieved in Belgrade (Serbia) on 25 February at 39 mm. Bulgaria reported three days of hail, which is unusual for this time of year.

In the South Caucasus, western Georgia had up to more than 250% of the monthly normal (320 mm). Azerbaijan recorded heavy precipitation during the first half of the month, especially in mountain areas, causing landslides and floods.

Snow

Similar to January, February also saw a persistent snow cover during most of the month over large parts of northern, central and eastern Europe, but also in some places in the west and south. In the middle of the month, however, mild air masses caused widespread thaw in central Europe.

In the first two weeks of February, there was almost no snow in Iceland, but snow appeared later in the month even for a few days in the south-west of the island, causing disruption to land and air traffic.

There was less snow than normal in northern Norway and the mountains of western Norway, whereas snow depths were above normal in the lower parts and along the coast of southern Norway.

There were 100-year-record or near-record-breaking snow depths in southern parts of Sweden in late February, with depths over 40 cm. At times, train and road traffic was heavily disrupted due to heavy snowfall. In contrast, snow depths were relatively small in the northern mountains of Sweden due to low precipitation. Large portions of the Baltic Sea and the Swedish west coast were covered by ice. Around 17 February, the ice extent had reached its largest since 1987.

In the United Kingdom, there were heavy snowfalls in northern England, northern Ireland and Scotland in late February, with depths up to 70 cm at a lower lying station (283 m elevation) in Aberdeenshire on 26 February.

Exceptionally high snow depths were also recorded in the Baltic countries, with new records of 78 cm at two stations in north-eastern Estonia. Large amounts of snow caused much damage to roofs and frequent disruption to road and rail traffic. In Lithuania, the monthly mean snow depth reached 26–38 cm. In north-east Poland, the snow depth rose to 65 cm that month.

In Germany, snow depths accumulated to more than 25 cm in Hamburg, 38 cm in Berlin-Dahlem (highest value since winter 1969/70) and even more than 60 cm near the Baltic Sea. Road salt stocks became short. Most German inland harbours were closed due to thick ice layers. Many flights were cancelled in Frankfurt and Munich. The roofs of several buildings collapsed.

In the higher Alps, there have been quite some accidents due to avalanches.

Slovenia, too, had widespread snow, more than normal in the lowlands and the mountains. Ljubljana registered 27 days with snow cover and a maximum depth of 43 cm. The Kredarica Mountain had 390 cm.

Romania recorded some snowy periods in the southern half of the country and in the mountain area, where the snow depth reached 183 cm.

Italy saw the rather rare event of snow in the city of Rome (Fig. 2.3) and over the coasts of the central Tyrrhenian Sea on 12 February, which is extremely unusual in that region.

Due to heavy snowfall, the mountains of the north Caucasus reported avalanche-hazardous conditions. In Georgia in the South Caucasus, a stable snow cover only persisted in high mountains with a maximum depth of 175 cm.

Snow was also to be found in Jordan (up to 22 cm in Rass Munef from 03–05 February) and Israel in the mountains in the north at the same time.

Source: National Weather Service CNMCA, Italy

Significant weather events

February 01–03:	A low developed between Iceland and Denmark and moved to Germany, causing heavy precipitation and a snow storm in northern and north-eastern Germany. Snow depths at eastern German lowland stations reached new records on 03 February (Hiddensee 45 cm, Teterow 51 cm).
February 03–05:	30–50 mm of precipitation fell in the Negev Desert in Israel with flooding, but no serious damage.
February 09–17:	Abundant rain caused some of Bulgaria's major rivers to overflow (e.g. Tundzha in its lower part near the Turkish border and Ropotamo in the south-east of the country). On 16–17 February, Tundzha flooded agricultural land in the region of Straldzha and 42 towns and villages were without electricity.
February 10–11:	Strong southern winds with gusts of up to more than 100 km/h, heavy rain and thunderstorms over the Aegean Sea, Crete and Skiros islands in Greece; heavy rain with flooding in central and eastern Macedonia (Greece). Dust advection from Africa affected the whole of Greece.
February 12:	Unusual snowfalls over Rome and over the coasts of the central Tyrrhenian Sea (Fig. 2.3).
February 15:	Heavy rainfalls over southern Italy (Sicily and Calabria) with flooding and landslides. 2300 people had to leave their homes due to landslide risk.

February 20–21: In Moscow, a snowstorm produced a snow depth of 63 cm and thus broke the previous record of 62 cm set in 1966. Nearly 4,500 km of railway track had to be cleared of snow.

February 22: Flooding in Bosnia and Herzegovina (Sanski Most).

February 22–23: Wind gusts up to 108 km/h, coupled with extensive precipitation (up to 50 mm) on February 22 caused damage to houses and roads in Tbilisi, Georgia. Strong winds also in west Kazakhstan.

February 25–28: More than 100 mm of precipitation in 24 hours were recorded in places in Jordan (station Swaileh) and Israel (in the Judean Mountains).

February 27–28: Storm Xynthia affected several countries in south-western, western and central Europe at the end of the month, causing sea dikes at the French Atlantic coast to break and much damage by falling trees, etc. The mean sea level pressure was 969 hPa at its centre, when the storm arrived at the French Atlantic coast. Gusts reached up to 160 km/h along the coastline, 232 km/h on the Pic du Midi Mountain (2877 m altitude) in the Pyrenees, and exceeded 120 km/h in several places in France (Fig. 2.4), Germany, Switzerland and Spain, and 100 km/h in Portugal. Xynthia also led humid and very mild air masses to Germany (16°C near the upper Rhine valley) and 20 mm of rain in 12 hours fell around Saarbrücken (western Germany). Much damage was caused to buildings, trees and power lines; road, rail and air traffic was temporarily affected. In the French coastal town La Rochelle, streets were flooded by 1.5 m. It was one of the worst storms in coastal western Europe since 1999, although less intensive than storm Klaus in January 2009 in France. Xynthia was associated with a very high sea-level and large local tides. More than 60 people died Europe-wide, many of them during a storm surge at the Atlantic coast in western France resulting from the exceptional flooding. More than a million of people were temporarily without electricity. Further damage occurred across Spain, Belgium, the Netherlands, south-east England, Switzerland and Austria, whereas the storm reached Lithuania in a weakened state and without causing any extreme weather phenomena.

March

- **Mostly warm, colder in northern and parts of western Europe**
- **Mostly wet in the north and parts of the south, dry in parts of central Europe, the Alpine region, the Arctic and at the coasts of the eastern Mediterranean**

Atmospheric circulation characteristics

In March, both the NAO and the AO became much weaker compared to the extreme negative conditions of the preceding winter. This marked the beginning of the seasonal transition. However, both the Icelandic low and the Azores high were still weaker than normal.

Quite a strong Arctic low developed over north-eastern Europe, causing cold and wet weather conditions with snow in that area. Spring warmth arrived in Lithuania due to a south-westerly airflow only in the second half of the month.

In most of the other parts of the Region, cyclonic activity occurred from time to time. Especially in central Europe, the first half of the month was characterised by arctic air masses with widespread snowfall and frosts, the second half by a south-westerly flow of subtropical air masses. Apart from storm Xynthia, which developed at the end of February and lasted until the

beginning of March, only a few thunderstorms occurred in central Europe and the Alpine region at the end of the month. However, unstable weather dominated especially in southern parts of Europe.

In the easternmost parts of the Region, an upper-level ridge predominated at the beginning of the month, causing high temperatures; later, an upper-level trough caused a cyclone over the Black Sea and led to colder weather.

Temperature

It was very mild in western Greenland, with anomalies up to +8°C, and over the western North Atlantic. In contrast, eastern Greenland and the eastern European Arctic were colder than normal; the regions with sea ice extended south, reaching as far as about 65°N in the east of Greenland and 75°N around Spitsbergen.

Northern Scandinavia and northern European Russia were also colder than normal, with minima around -35°C, but the anomalies were far smaller than those for the winter months, mostly between -1 and -2°C, locally below -3°C in parts of northern Norway. Nevertheless, they were below the 20th percentile. The northern part of the Baltic Sea was still frozen, as were the Barents Sea and the White Sea. However, it was slightly warmer than normal on average in the Baltic countries, since the last decade of March was +2°C to +4°C warmer than normal in Latvia and record temperatures up to 20°C were reached in Lithuania.

The rest of the Region was mostly warmer or around normal, although partly with high daily maxima and low daily minima (e.g. -18.5°C and 24.1°C in Poland, -22.2°C and 24°C in Germany, -9.4°C and 25.4°C in Bulgaria). This was due to a first wintry and a warm second half of the month in these areas. The lowest minima were measured around 07 March following a cooling of snow covered surfaces; the highest maxima occurred around 25 March due to warm air advection. Northern Greece reported frost between -3 and -5°C in the first days of March.

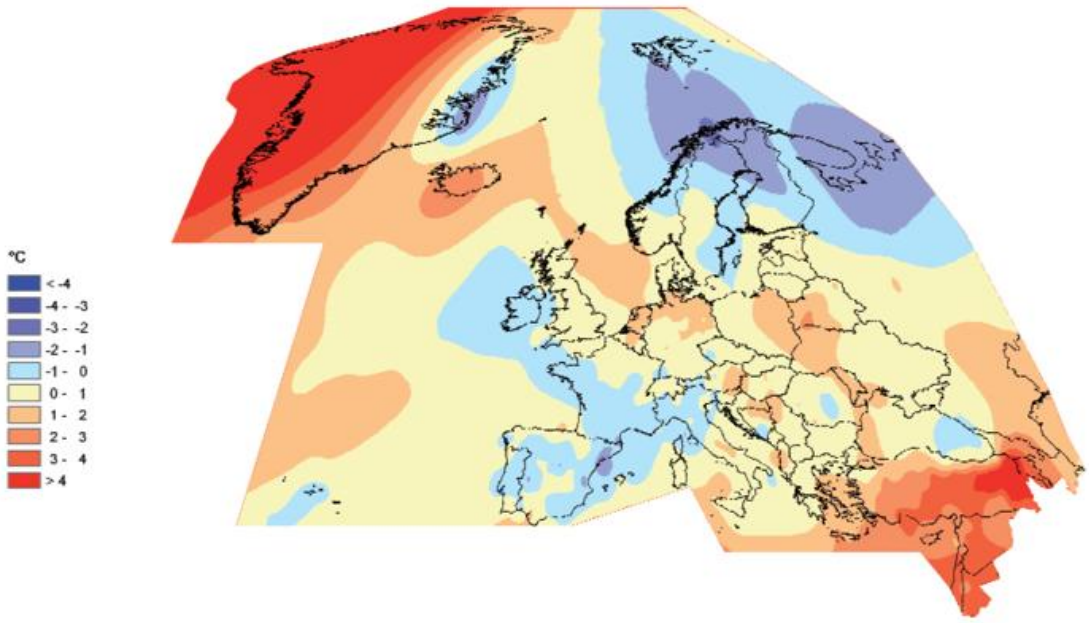

Fig. 3.1: *Monthly mean temperature anomalies in March 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

The sequence of cold and warm periods was very similar in many parts of Europe. It was rather cold in the United Kingdom, particularly during the first two weeks with some night frosts, but warmer from mid-month. In Germany, too, wintry conditions continued until the middle of March, when a warm period began, which was again followed by a strong temperature drop at the end of the month. Likewise, daily maxima in Switzerland stayed below freezing in the first half of the month, and the shores of Lake Geneva and Lake Neuchâtel were frozen solid from the spray of waves blown up by strong winds. However, temperatures reached 23°C in the central plains of Switzerland on 25 March due to the warm air masses coming in from the south-west and foehn. Such temperatures had last occurred there in March in 1990, and they dropped down after an advance of cold air one day later.

Some larger areas in western and south-western Europe saw monthly mean temperatures that were slightly below normal, especially Ireland, southern France, Iberia and northern Italy. Portugal had its coldest March of the last 24 years.

Only in the north was Italy colder than normal, whereas the other parts of the country were warmer than normal. The highest warming was recorded along the coastal areas of the southern Tyrrhenian Sea, especially in north-west Sicily and southern Calabria.

Once again, it was very warm for this time of year in the eastern Mediterranean, the Middle East and the South Caucasus. Monthly anomalies were highest over eastern Turkey and parts of the South Caucasus (e.g. in the basin of Lake Sevan in Armenia), exceeding +4°C or locally even +5°C and the 90th percentile. It was the third warmest March in the South Caucasus since 1966. West Georgia recorded maxima of up to 27°C in the lowlands. The southern Mediterranean also continued to be warmer than normal. Luqa Airport in Malta had its 3rd highest March temperature since 2000 (23.9°C). Temperatures reached up to 38°C in Israel, but were not record-breaking; however, there were some extraordinary long sequences of hot days (e.g. 8 consecutive days with maxima above 32°C in the Negev Desert) last recorded in March at least in the 1940s.

Precipitation

March was characterised by quite a high spatial variability of precipitation anomalies (Fig. 3.2). The Arctic region was mostly dry, except western Greenland which was very wet. It was likewise wetter than normal in most of northern and north-eastern Europe, locally exceeding twice the monthly precipitation total and the 90th percentile. The region of Varanger (Norway, county Finnmark) registered its highest March total since 1920.

In the United Kingdom, the first two weeks were dry, but the second half saw more changeable weather with rain at times.

In most of western, southern central and parts of eastern Europe, dry conditions were prevailing, mostly with less than 80% of the normal precipitation. Especially the Alpine region was dry and mostly below the 20th percentile, despite a few thunderstorms at the end of the month. In easternmost parts of Austria (Burgenland), March 2010 was the driest March since at least 1936 (station Neusiedl am See).

Most of the southern parts of the Region were wetter than normal, namely Iberia, the western Mediterranean region, most of the Balkan Peninsula including Romania, the low Volga and the Caucasus region and western Kazakhstan. Especially in Spain, the 90th percentile was exceeded. In Portugal, it was the third wettest March of the last 30 years. Southern Italy, too, was very wet, with heavy rain especially in Sicily. Malta received more than twice its normal precipitation, west Georgia in the South Caucasus up to more than 400% (313 mm). In southern European Russia, spring floods were recorded in rivers in the last third of the month. In Romania, March was the third consecutive month with above-normal precipitation, particularly in the south.

The eastern Mediterranean and the Middle East were mostly very dry for this time of year; partly they saw less than 20% of the normal precipitation, staying below the 10th percentile. In northern Israel, monthly totals were only 5–15 mm (10% of the normal), making March 2010 one of the three driest March months in the last 70 years besides 1962 and 2004.

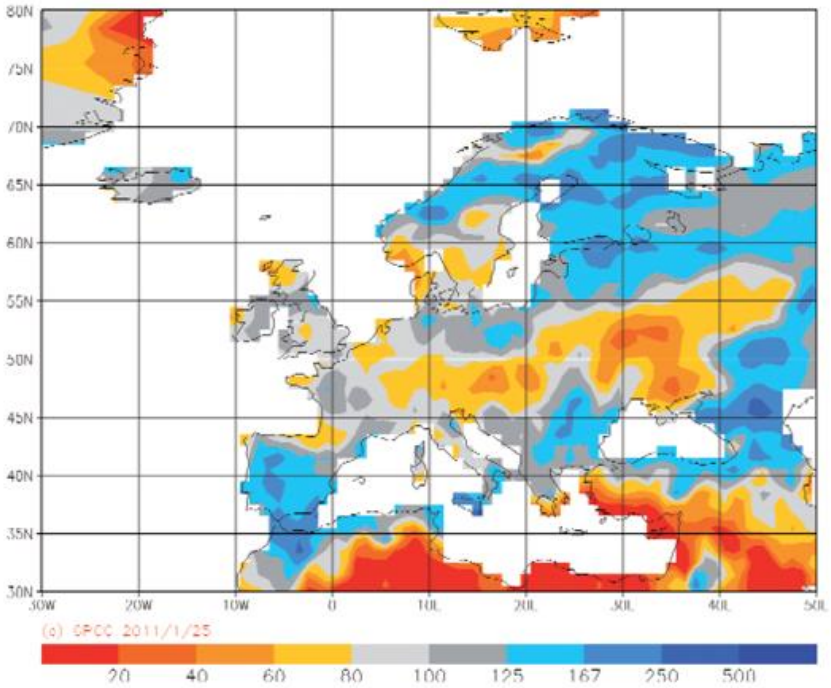

Fig. 3.2: *Monthly precipitation amounts for March 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Snow

March had a persistent snow cover in northern and eastern Europe. By the end of the month, however, there was considerably less snow than normal in most of the mountainous areas of Norway. Along the coast of southern Norway, there was more snow than normal, which melted at the end of the month in the lower parts of south-eastern Norway.

Late March was notable for prolonged snow across higher parts of Scotland and Northern Ireland. In contrast, a warm late March caused an intensive thaw in Latvia.

Some spells of snow also occurred in western, central and parts of southern Europe, especially in the first half of the month. Southern France (Provence) experienced a snowfall event from 7–9 March, which then moved towards the Pyrenees region. At the same time, heavy snowfalls also occurred in parts of Germany and Spain, producing in Germany (except in the north-east) another temporary closed snow cover, which disappeared shortly afterwards in the lowlands. Barcelona saw the heaviest snowfalls since 1962, whereas the southern Pyrenees had little snow left.

Intensive snowfalls likewise occurred in Switzerland in the first half of March. On 10 March, it also snowed down into the plains of southern Tessin. Another intense snowfall period started on 26 March; snow fell below 900 meter on the northern side of the Alps, and the high crests of the southern Alps received the considerable amount of 90 cm. In Austria, frequent avalanches were reported, especially during the first two thirds of the month.

In northern Italy, up to 30 cm of snow were measured near Bologna on 09 and 10 March, up to 50 cm on the surrounding hills and up to 75 cm in the Apennines.

In the mountain areas of Romania, snow fell during the whole month. The maximum depth was measured at 254 cm in Fagaras Massif. The remainder of the country temporarily had snow. Bulgaria reported snow on 08 and 09 March. Even Greece (including the Ionian coasts) had significant snow, particularly in northern and central parts.

In the South Caucasus, a steady snow cover persisted in high mountains during the whole month, with measured depths up to 171 cm.

Fig. 3.3: *Tree knocked down by snow in Ferrara (Italy) on 09 and 10 March. Source: ARPA-SIMC, Italy*

Significant weather events

March 01: Flash floods on the eastern Azores in the early morning.

March 03: 8 m high waves hit a cruise ship in the western Mediterranean Sea. 2 people died and 6 were injured.

March 04: Dozens of ships were stuck in the ice in the Baltic Sea.

March 06–11: An intense cyclogenesis over the Tyrrhenian Sea caused intrusion of cold air from the east, causing exceptional snowfall and high wind speed in several countries, namely France, Germany, Austria, Italy, Bulgaria, northern Greece, even Spain, as well many accidents and traffic disruptions (Fig. 3.3). High sea levels along the Adriatic coast with intense storms over the same area. A blizzard-like cold outbreak occurred in southern Romania. A daily total of 120 mm of precipitation was measured in Trikala (Greece) on 07 March. In north-eastern Europe, night temperatures locally dropped below -20°C in eastern Lithuania on 07–08 March.

March 08: Greece was affected by dust from the Sahara desert.

March 09: Storm of hurricane force (gusts up to 136 km/h) in Novorossisk (Krasnodar, southern European Russia).

March 09–11: Snowfalls over northern Italy and heavy rain over Ionian coasts and southern Sicily due to an Atlantic storm moving to Italy on a relatively low-latitude track. Slovenia was also affected by a snowstorm with gusts up to 200 km/h in the Primorska region.

March 22: Bulgaria reported Saharan dust and warned people suffering from asthma or similar diseases.

March 26–30: Germany reported a severe thunderstorm on 26 March passing from the west to the east, with heavy rain, hail and wind gusts > 80 km/h (locally >120 km/h), a second thunderstorm with heavy rain occurred in northern Germany on 30 March. Austria reported high wind gusts on both days, causing fallen trees and emergency for 3 boats on Lake Neusiedl. Switzerland reported high wind gusts on the 26th as well as some thunderstorms.

March 31: After Britain had seen its coldest winter for three decades, heavy rain, snow and gale-force winds pounded Scotland and Northern Ireland, killing one person and leaving tens of thousands without power.

April

- **Warmer in nearly the whole Region**
- **Mostly dry**

Atmospheric circulation characteristics

Similar to March, the NAO index was still negative in April. The Azores high was weak. High pressure conditions and sunny weather prevailed over nearly the whole of Europe, except in the north-east. The beginning of the month (around Easter) saw low pressure conditions, causing showers especially in central Europe.

A south Caspian cyclone, however, caused high precipitation around the Caspian Sea especially in the middle of the month.

Temperature

April was warmer than normal over nearly the whole Region (Fig. 4.1). The highest anomalies were recorded over the Arctic and in north-eastern European Russia (>+4°C, up to +8°C in north-western Greenland). Daily maximum temperatures at the coasts of Greenland and on the Arctic islands exceeded 0°C. Record-breaking maximum temperatures were registered in some north-western and eastern parts of European Russia in early April. However, the northern part of the Baltic Sea and the White Sea were still at least partly frozen. Slightly below-average temperatures in Iceland were related to the eruption of the volcano Eyjafjallajökull in the middle of the month.

Over most of Europe and the Middle East, the monthly temperature deviations were greater than +1°C, in both south-western and north-eastern Europe they were between +2 and +4°C. In parts of northern and western Europe and locally on the Balkan Peninsula, the 90th percentile was exceeded. Daily maxima exceeded 20°C in the United Kingdom (although minimum temperatures were around normal and there were some frosts), and it was the warmest April in 100 years. It was also the warmest April in central England since records began in 1659. Daily maxima exceeded 25°C in central Europe and 30°C in Greece.

In western and central Europe, however, April 2010 was not as warm as April 2007 and 2009. Cold weather with minima around the freezing point dominated in the first half of April in Germany and Switzerland, but temperatures often rose above 20°C in the second half, locally even above 25°C at the end of the month. The last third of April was also warm on the Balkan Peninsula, e.g. in Slovenia and Serbia.

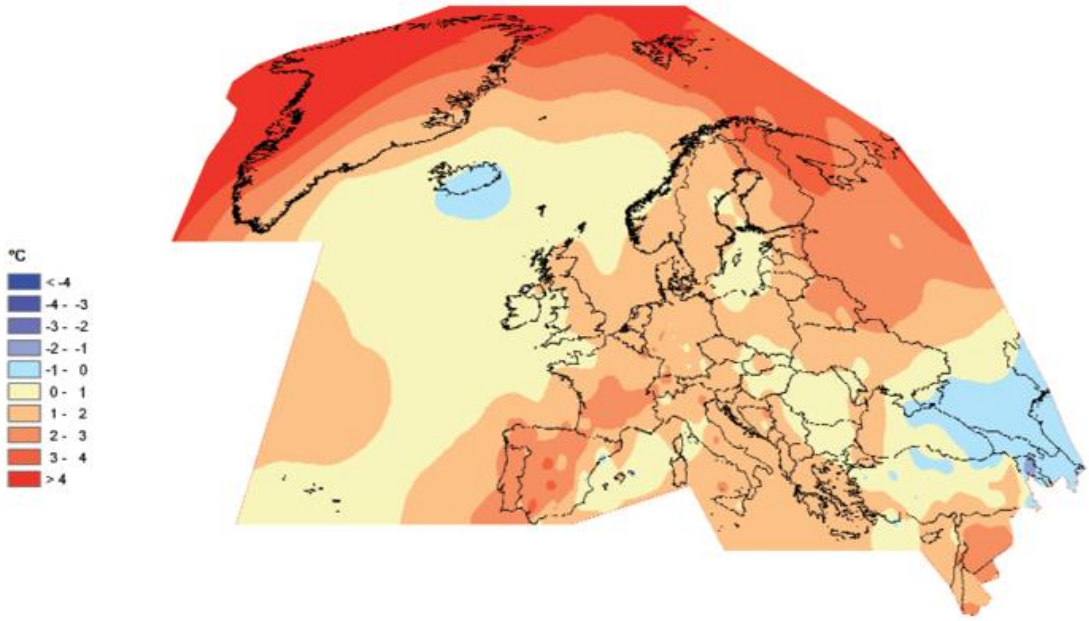

Fig. 4.1: *Monthly mean temperature anomalies in April 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

In Portugal, it was in fact the warmest April of the last 13 years regarding maximum temperature.

It was slightly colder than normal on Iceland and in the east in western Kazakhstan and the Caucasus region. In some regions of east Georgia, minimum temperatures dropped down to 1°C in the lowlands.

Precipitation

Most of the Region saw a dry April (Fig. 4.2). It was mostly dry in the Arctic, particularly in the southern areas of Greenland. Over large parts of western and central Europe and locally in the north and east, less than 40% of the monthly totals were recorded. Over France and Germany, in the eastern Ukraine and some places in Russia, the totals were below the 10th percentile and widespread below 40% of the normal; long dry periods were interrupted by only very short thunderstorms and rain, mainly at the beginning of the month.

In the United Kingdom, however, it was not as dry as in April 2007 due to an unsettled first week with some heavy rainfalls in places. Germany had its second driest April since 1893 behind 2007. There was no measurable rain for two weeks in parts of northern Germany.

Dust storms occurred in the steppe zone of the Ukraine; they resulted in damage to the rising crops.

It was particularly dry in the southern and eastern Mediterranean. Malta received only 1.2 mm the whole month (normal is 22.5 mm). Locally, Greece and the Middle East received less than 20% of the normal. At most stations in Israel, monthly totals were less than 5 mm.

It was wetter than normal (though mostly not significantly) in some places in the north and north-east (around twice the normal in north-east European Russia and some Norwegian areas), in the eastern Alpine region and most of Italy, in Hungary, over most of the Balkan Peninsula (except Slovenia), in the east over the lower reaches of the Volga as well as in west Kazakhstan and the South Caucasus region. Convective events with large hail, heavy rain, strong wind or even tornadoes occurred occasionally in the Mediterranean area and the Balkan countries.

Serbia was extremely wet especially in its central, southern and south-eastern parts and new local records for daily precipitation totals in April were set on 20 April (stations Kraljevo 50 mm, Kopaonik 44 mm).

In the South Caucasus, various areas in Georgia received around 300% of the monthly normal (up to 377 mm in western parts), in Armenia up to 250%. Heavy rainfall and flooding of rivers occurred especially in the highlands of Azerbaijan.

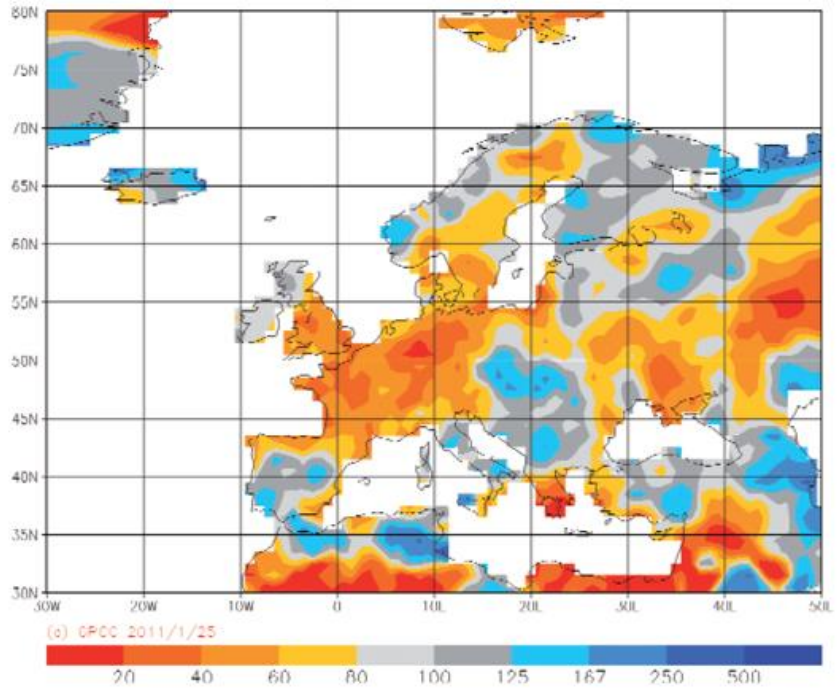

Fig. 4.2: *Monthly precipitation amounts for April 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Snow

In April, only most of Scandinavia, northern European Russia and the high mountains were covered with snow throughout the month. Snow disrupted traffic in north-eastern Iceland during the first days of the month. Scottish highlands reported up to 39 cm of lying snow on 1 April due to heavy snowfalls at the end of March. On the other hand, high temperatures caused rapid snowmelt even in parts of northern Europe, e.g. in Estonia, followed by severe flooding in the Tartumaa district.

There was some local snow even in Slovenia at the beginning of the month, but only for 3 days in the lowlands, whereas it persisted the whole month in the mountains (450 cm on Kredarica on 19 April and thus the annual maximum in this place). Romania had snow in mountain regions above 1700 m altitude. In the South Caucasus, snow persisted locally on high mountains in western Georgia. In the other regions, it melted in the middle of the month.

Significant weather events

April 07: Heavy storm around Sliven region in Bulgaria with gusts of 122 km/h.

April 14–20: Volcano ash from the eruption of Eyjafjallajökull on Iceland on 14 April was spread across Europe by upper-level winds. Although the eruption seldom rose above the tropopause, it stopped air traffic during several days, which was the largest disruption since World War II. Up to 23 European countries were affected; more than 100,000 flights were cancelled. As a consequence of the eruption, glacier surrounding of the volcanic crater partly melted, causing flash floods that destroyed the infrastructure of the region (flooding of local roads and risk of damage to bridges). Almost 800 people had to leave their homes in a small town situated beneath the glacier and some farmland was devastated, but no fatalities were reported.

April 24: Eleven events of avalanching in the Republic of north Ossetia (northern Caucasus, southern European Russia).

April 27–28: Late frost in Bulgaria caused some damage to fruit trees.

April 30: Southern Germany and Austria were hit by heavy rainfall with more than 30 mm in 24 hours at several stations. The highest 24-hour sum was reported for Waging am See: 51.6 mm.

May

- **Cold in north-western, western and central Europe, warm in the Arctic and in the east**
- **Mostly wet, dry in the west and the east**
- **Severe flooding in eastern central Europe**

Atmospheric circulation characteristics

In May, a meridional circulation pattern prevailed again particularly in the first half of the month. This time, most of Europe was under low pressure influence with partly intense convective phenomena, whereas high pressure dominated over the Arctic, the eastern North Atlantic in the west and over Russia in the east. The Icelandic low was dislocated far to the south-west. Cold and dry air masses from the north flowed continuously to western Europe, while warm air from the south brought warm Mediterranean air masses through eastern Europe to the polar cycle.

In western and central Europe, warmer air masses dominated in the second half due to a more pronounced zonal component.

Temperature

The Arctic region was around +2 to +3°C warmer than normal; even the northern North Atlantic was partly +2°C warmer than average. In Greenland, daily maximum temperatures exceeded 20°C at one station during the first decade of May 2010 (Kangerlussuaq in 67°N), and at three stations during the third decade. The arctic station Hopen on Svalbard set a new highest mean monthly temperature record for May and several stations in northern Norway (county Finnmark) registered the highest maximum temperature since the measurements started in the second half of the 19th century. All ice in the Gulf of Bothnia, most of the ice in the White Sea and much of the ice in the Arctic Sea had melted.

May was colder than normal over southern Scandinavia, north-western, western and large parts of central Europe including the North Sea and parts of the western Mediterranean (Fig. 5.1).

Especially the first half of the month was cold in western and central Europe, but the second half was warm. The United Kingdom, for instance, had cool weather with frosts in the first half of the month, but a warm spell from 20-24 May; Oxford had a maximum of 28.9°C and new May records were set in Scotland.

The beginning of the month (4–5 May) was also exceptionally cold in southern France, with maxima of 6–8°C in the lowlands. The second half of May, however, saw temperatures exceeding 24°C on several days over wide areas. France had its coldest May since 1996, the Netherlands and Germany since 1991. Particularly north-western Germany was cold on average, with anomalies below -2°C, which was below the 10th percentile; there were widespread frosts in the first third of the month in the northern and eastern parts of Germany as well as in northern and north-western Poland. Later in the month, temperatures in Germany reached up to 29°C on 24 and 25 May, in Slovenia up to 30°C on 25 May (station Bizeljsko). In Austria, it was the second coldest May since 1991, behind 2004.

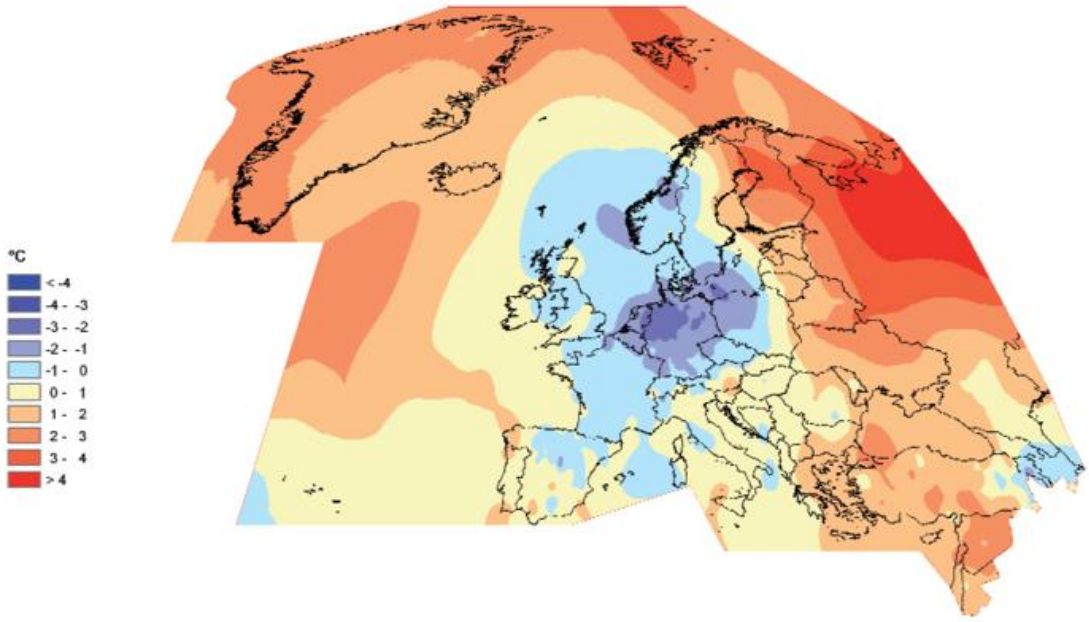

Fig. 5.1: *Monthly mean temperature anomalies in May 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Most of the other parts of the Region were warmer than normal, particularly the north-east. The highest maximum of that month in Finland was 29.6°C. Places in south-eastern Finland recorded their highest number of summer days ever seen in May. Around the middle of the month (14th, 15th), several summer days (maximum temperature of 25°C or more) were registered in Finland, Estonia and northern Russia. On 18 May, the maximum temperature rose as high as 26.4°C in Murmansk in north-western Russia, which was nearly +5°C higher than the previous record of 1984. In Lithuania, 22–27°C were measured in the second half of the month.

Anomalies were highest over northern European Russia (> +4°C), exceeding the 90th percentile. Record-breaking maximum temperatures were registered as early as at the beginning of May in several parts of northern and central European Russia, reaching 28–31°C in the central Chernozem region (near the Ukraine), i.e. +7 to +9°C above normal. The high temperatures were accompanied by hot winds and forest fires. Similar anomalies were recorded in the Volga region.

The eastern Mediterranean and almost the whole of the Middle East were at least +1°C warmer than normal. The warming was underlined by some warm spells with quite high daily maximum temperatures. Greece had a 5-day heat wave at the end of the month, with maxima exceeding 35°C. Israel and Jordan had a number of hot spells with temperatures up to 43°C in the Jordan Valley. The South Caucasus and some places in eastern Turkey were an exception in that area, recording just around normal monthly averages or even slightly colder temperatures.

Precipitation

It was very dry in most of Greenland and Iceland, western parts of Europe and southern Norway, particularly near the North Atlantic, locally with less than 40% of the normal precipitation, but also with locally heavy showers in Norway (Fig. 5.2). It was the driest May across the UK since 1991, despite some heavy showers at the beginning of the month, especially over Scotland and Northern Ireland.

Most of the other parts of Europe were wetter than normal. Large parts of northern Europe (except western parts) received more than 125% of the normal monthly average. Thunderstorms with heavy showers were recorded in many parts of Estonia, locally resulting in monthly totals of more than twice the normal.

Particularly over eastern Germany, Poland, eastern Czech Republic, Slovakia, Hungary, western parts of eastern Europe and some northern parts of the Balkan Peninsula, more than 250% of the normal was registered, exceeding the 90th percentile. In places across eastern Germany, southern Poland and Slovakia, even more than 400% were measured. This was mainly due to one heavy precipitation event in that area in the second half of the month. Large parts of eastern central Europe received monthly totals of more than 100 mm, near the border between Poland and Czech Republic even more than 300 mm, locally up to nearly 600 mm. Extreme flooding occurred especially in the catchments of the large rivers in eastern central Europe (Odra, Vistula, Danube and Tisza). However, the water levels stayed below those of the flooding event in 1997.

It was by far the wettest May on record in Slovakia and locally the wettest May in Poland. Intensive downpours over Poland and Slovakia caused serious devastation; many areas were flooded. The areas east of the Alpine region were also extreme in terms of heavy rain that month. Over large areas from Austria to Hungary, May 2010 was among the wettest ever registered, with both the precipitation totals and the number of rain days considerably higher than normal. Slovenia was particularly wet in its western parts, with locally more than 200% of the normal (Goriško), whereas some other parts of Slovenia were quite dry (50-60% of the normal).

The area with extreme precipitation extended even farther south. In Serbia, it was extremely rainy in the north (Vojvodina), with a monthly total of 195 mm measured at the station Sombor and a May record broken in Kikinda with 202 mm. In Italy, a station south of Parma recorded the wettest May since 1940 and extremely high historical values were also reached in several other places across the country.

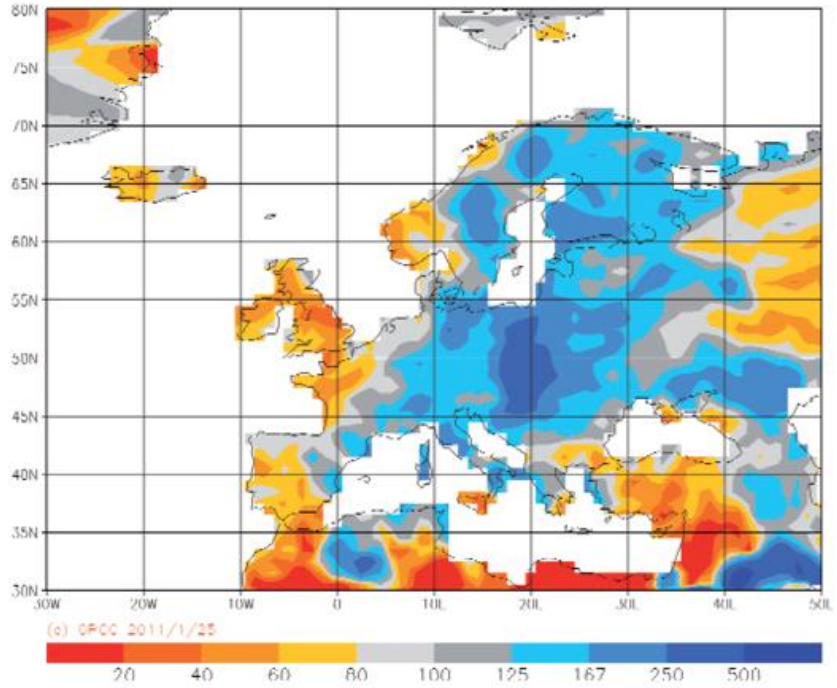

Fig. 5.2: *Monthly precipitation amounts for May 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Some eastern areas of the Region, e.g. eastern European Russia (except the south) and most of the Middle East were very dry. In all these dry areas, however, the monthly totals were below the 20th percentile only in some places. Heavy thunderstorms occurred occasionally on the central Aegean Sea.

Frequent convective precipitation with hail up to 20 mm in diameter occurred in parts of southern European Russia near the Caucasus, leading to monthly totals of twice the normal and more. The Ukraine was mostly very wet, too. May precipitation was close to normal in most of the South Caucasus, but heavy rainfall with hail occurred in places especially in Armenia (resulting in monthly totals locally up to 250% of the normal) and also in Azerbaijan, where several villages around the Kura River were flooded and many houses, bridges, roads, agricultural crops and power lines damaged (estimated worth: about 62.5 million US $). The river had risen at the fastest rate of the century.

Snow

There was still a snow cover at some stations in northern and central Scandinavia and on higher mountains in central Europe. At the beginning of the month, a cold spell produced snow even in the lowlands of southern France. In the middle and at the end of the month, snow fell in higher regions of the northern United Kingdom and Austria.

In other parts of the Region, snow had mostly melted. However, the first days of May brought some snowfall in the highlands of Azerbaijan, with depths of more than 20 cm. The high mountains in Georgia also had some snow until 8 May.

Significant weather events

May 03-04: A depression over the western Mediterranean Sea caused strong winds at the southern coast of France, with wind gusts of more than 110 km/h at several locations, partly even more than 130 km/h. The coastline of the Cote d'Azur was hit by waves up to 7 m high (mean wave height: 4 m). The cold air with maximum temperatures of only 6°–8°C was exceptional for the season and much snow fell in the Pyrenees and the Massif Central (30 cm above 1000 m altitude, 50–70 cm between 1500 and 1700 m and 50–100 cm between 1700 and 2000 m). Snow was even observed in Carcassonne and Narbonne.

Up to 200 mm of rainfall was recorded in the north of Mallorca Island in the western Mediterranean during this event.

May 07: A heavy thunderstorm caused the flooding of parts of the town of Shumen (north-east Bulgaria).

May 10-13: The Alpine region was affected by heavy rain and storm. South-western France, Switzerland, southern Germany and Austria were hit. Severe hail and high wind gusts occurred in Switzerland on the 11th. In Austria, the rain of the 13th caused the enormous damage due to landslides and flooding. 60 mm rain in one hour was recorded in the northern districts of Vienna, which were partly flooded.

May 12: Heavy rainfall in Yerevan (Armenia): 47 mm in 12 hours.

May 15-22: Outstanding flooding in Poland (Wisla), the north-eastern Czech Republic, Slovakia, northern Hungary, Croatia, Bosnia and Herzegovina, Serbia and Bulgaria, which was connected with very high and repeated rainfall especially in the catchment area of Wisla and Odra in Poland. Local precipitation totals for the period 15–18 May exceeded 375 mm. On 16 and 17 May, up to 200 mm of rain fell over southern Poland and the Czech Republic within 24 hours. The rains and subsequent overflowing rivers brought the worst flooding in more than a decade to Poland. Large areas of land were under water, river dams partly broke, several people died in the floods and thousands had to leave their homes. At the end of the month, the flooding also reached Germany (Oder). Some heavy rainfalls with thunderstorms and squalls, which caused trees to fall and ripped roofs from buildings, also occurred in southern Lithuania (up to 60 mm in 6 hours on 17 May). Wind speeds of 110 km/h were reported north of Budapest, Hungary.

May 17: Flooding of the Tiber River in Italy after a rapid cyclogenesis over the central Tyrrhenic Sea and intense, but not convective rainfall of about 120-240 mm within 36 hours. The peak water level in the river was 8.90 m on 15 May, but not record-breaking. However, new records of daily precipitation were set at two stations in Lazio (Italy).

May 18-21: Flooding of the Kura River in Azerbaijan, the biggest transboundary river in the Caucasus region as a result of heavy rainfalls in April and May. The water level reached its maximum from 18–21 May, but it continued to stay high until the end of June (Fig. 5.3).

May 22–23: Thunderstorms and heavy rainfall (21 mm per hour) with hailstone size up to 2.5 cm in diameter occurred in places of southern Finland, causing sudden flooding with several hundred thousand euro worth of damage to properties, agriculture and transport.

May 22–23: Heavy thunderstorm with hail and local floods in the Sporades region, Greece.

May 24: (Whit Monday tornado). A tornado in eastern Germany (Fujita scale F2–F3) caused severe damage to roofs, trees, power lines masts and cars. Flooding of cellars due to accompanying rain and hail were reported. A little girl died in a car that was hit by a tree.

May 25–26: Heavy rain fell in France (108 mm in Dinard, Ille-et-Vilaine, Brittany, with 67 mm within 1 hour). Hail hit Austria (e.g. Großmugl, Gänserndorf, east of Vienna), causing extended damage to wine yards and crop fields, and the south-east of Bavaria in Germany (reported hail size about 3 cm). Wind gusts also caused severe damage to roofs of buildings (Neusiedl am See).

June

- **Mostly warm, but cold in Scandinavia**
- **Dry in north-western and central Europe and in parts of Russia, wet in most of northern and southern Europe**

Atmospheric circulation characteristics

Cold arctic air moved southwards and affected particularly northern Europe where prevailing low pressure conditions caused much rain.

Over the North Atlantic, a stronger-than-normal subtropical high extended far to the north and frequently caused dry and warm conditions over much of north-western and central Europe, interrupted by occasional heavy thunderstorms. The Icelandic low was still dislocated south-westwards as in May.

High pressure influence also dominated over eastern European Russia, whereas other parts of eastern Europe and the Balkan Peninsula were much affected by intense convective events.

Most of southern Europe, in contrast, was affected by frequent and intense cyclonic activity. A cold air outbreak associated with a strong cut-off low occurred in Italy at the end of June.

Temperature

June was also warmer than normal in the Arctic region and over the North Atlantic. Anomalies exceeded +2°C and the 80th or 90th percentile over most of Greenland, western Iceland and large parts of the northern North Atlantic (Fig. 6.1). The June warmth in Iceland was particularly unusual. It was the warmest June on record both in Reykjavík (from 1871) and Stykkishólmur (1845).

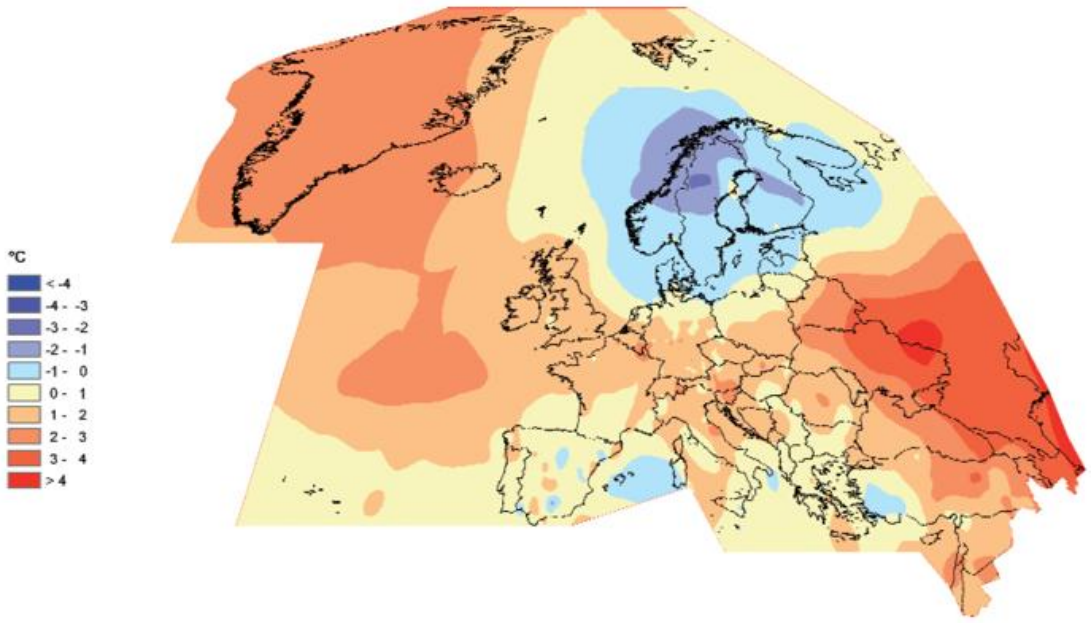

Fig. 6.1: *Monthly mean temperature anomalies in June 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

It was colder than normal across almost the whole of northern continental Europe (except small areas in northern Norway as well as southern and eastern parts of the Baltic countries) and over adjacent sea areas, with highest negative anomalies over central Sweden at around -2°C and thus below the 20th percentile. Northern parts of Scandinavia and European Russia still had frosts. However, a heat wave occurred at the end of the month in north-eastern Europe; in Estonia, it was by far the most remarkable heat wave in the 144-year time series of Tartu. Denmark also had its first summer day (25°C or more) just at the end of month on 28 June.

The other parts of the Region including the water surfaces were nearly all warmer than normal except a few areas in the south. Most of north-western, western and central Europe, the northern Balkan Peninsula and the Middle East had monthly anomalies of more than +1°C,

large parts of eastern Europe more than +3°C, in the Volga region more than +5°C, in the South Caucasus locally up to +6°C. All anomalies there were above the 80th percentile, partly even above the 90th percentile.

Some daily temperatures were relatively high in north-western and central Europe. Daily maxima exceeded 30°C locally in the United Kingdom. Central Europe saw a heat wave around 10 June, particularly near the Alps in southern Germany (Munich City 33.5°C) and in the northern plains of Switzerland due to an unusually strong foehn. Another warm spell occurred in central Europe at the end of the month, but was interrupted by a cold spell around the 20 June with local ground frosts e.g. in eastern Germany, which resulted in lower positive monthly mean anomalies compared to parts of western and eastern Europe.

South-eastern Europe generally had a hot June. Serbia had a heat wave from 7–14 June in most of its parts and a higher-than-normal number of tropical days and nights especially in the southern parts of the country; new daily maximum temperature records were set at some mountain stations. The period 10–15 June was also particularly warm in Romania, setting new highest local daily minimum and maximum temperature records, whereas the end of the month was cold in the south and east of the country. After a cool beginning of June, Bulgaria and Greece had a 3-day heat wave in the middle of the month, with maximum temperatures up to 37.6°C in Bulgaria and up to 41°C in Greece (long-term mean maximum for June at Ierapetra (Crete) is 29°C).

The third ten-day period was particularly hot in most of central and eastern parts of European Russia, with daily maxima up to 41°C in the Astrakhan region. This was the beginning of an extreme and extended heat wave in Russia, which continued during most of the summer. On 25 June, a maximum temperature record for June was established in Moscow with 32.8°C. The south of European Russia experienced the hottest June that had ever been recorded in 120 years of regular meteorological observations. Western Kazakhstan was also hot, especially in the middle of the month with maxima above 40°C.

The South Caucasus had some extreme positive temperature anomalies. Maxima in west Georgia reached up to 39°C. In Baku (Azerbaijan), daily anomalies were locally record-breaking, e.g. +8°C on 5 June.

In the Middle East, June was warmer than normal in Israel and was characterised by a large number (5–7) of Sharav days with a most extreme temperature of 46.6°C in the Jordan Valley. In the last 50–60 years, a similar number of Sharav days in June occurred only once in 1993. The Sharav reached even the coastal strip of Israel, which was rather unusual for the time of year.

In south-western Europe, June temperatures were near normal in Iberia and over the western Mediterranean. It was the coolest June since 1997 in Spain. A few places in the Mediterranean region were slightly colder than normal.

Precipitation

It was a dry June in the Arctic (except parts of western Greenland), and also in north-western and over large parts of central Europe, with widely less than 50% of the normal (Fig. 6.2) and thus less than the 10th percentile. The dry weather in Iceland affected the vegetation in some areas and local water shortages were reported.

Most of northern Scandinavia was mainly wet. At the northern coast of Lapland, the monthly totals were higher than 100 mm or more than 250% of the normal, which was more than the 90th percentile. For all northern Norway, it was the third wettest June on record. In contrast, southern and western Norway received very little precipitation, making it partly the driest June there since at least 1900. Southern Sweden, Denmark and Finland were likewise dry. Locally

heavy rainfall was reported from Estonia, with intensities of up to 52 mm in 24 hours. In Denmark, it rained mainly in the first half of the month, with high intensities especially on 7 and 8 June.

Parts of central Europe were extremely dry in June. Stations in Berlin (Germany) only received 2–3 mm during the whole month, which caused the driest June on record there (since 1908 in Berlin-Dahlem). Some stations in eastern Germany did not receive any rain for 2–3 weeks. Nevertheless, some intense thunderstorms were reported, particularly near the Alpine region and in eastern central Europe. Several rainfalls and thunderstorms with hail caused damage and flooding in northern Austria. In eastern parts of Austria, June 2010 brought up to 200% of the average precipitation, in Hungary about 150% of the country's average. Most of Slovakia was also very wet.

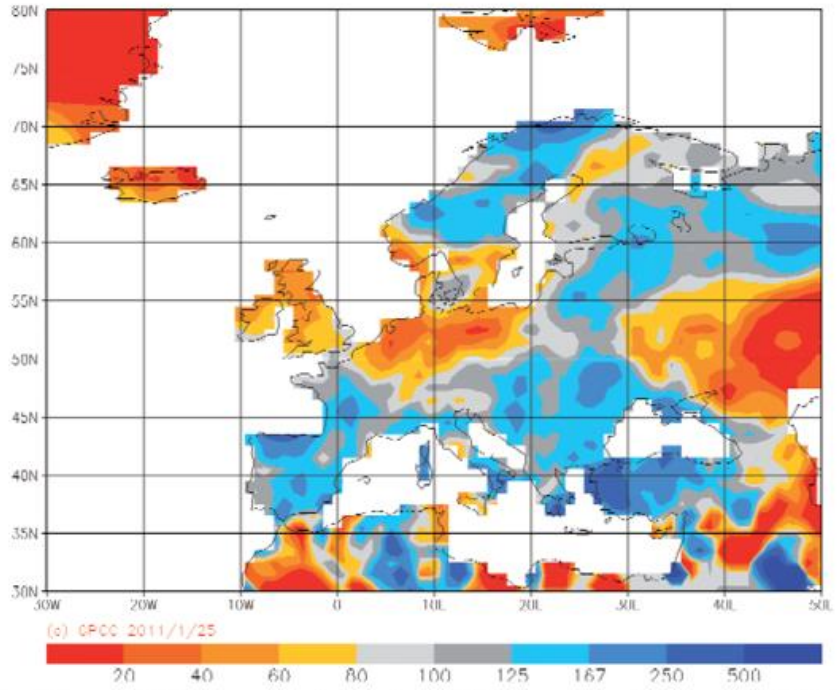

Fig. 6.2: *Monthly precipitation amounts for June 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

South-western and southern Europe, too, were mostly wet with frequent convective precipitation. The 90th percentile was exceeded in many places, especially in parts of Spain, Italy, most of the Balkan Peninsula and western Turkey, locally with more than twice the normal monthly totals, e.g. in Italy in some places near the Po river. The monthly total at Ferrara was the highest of the time series starting in 1924. In south-east France, monthly totals were up to 400 mm (more than 500% of the normal) due to a heavy storm on 15 June. Only a few areas in the Mediterranean region were dry (e.g. Sicily, Malta, Cyprus).

Another area with high precipitation extended from the Balkan Peninsula northwards to the Baltic countries and northern Russia, due to a slow moving depression at the beginning of the month. On the Balkan Peninsula, totals in Bosnia and Herzegovina as well as in Serbia locally rose to more than 300% of the normal and the number of precipitation days was correspondingly high in Serbia. During the third week of June, heavy rains in Bosnia led to more than 30 landslides and caused river floods. New monthly precipitation records were set, e.g. at the Serbian station Sombor with 240 mm, 113 mm of which fell just on one day (22 June,

setting a new record for June). Monthly totals in Romania were also high (over 100 mm) in most parts of the country, in the north-east even more than 300 mm, which was more than twice the June normal in some areas.

A larger, very dry area was to be found over central and southern European Russia, western Kazakhstan and the South Caucasus region. Parts of southern European Russia received less than 20% of the normal precipitation, which was less than the 10th percentile. A particularly critical situation existed in the last ten-day period of June, when central areas of European Russia and the Volga region received no rainfall at all or only a few mm. Some places in west Kazakhstan did not have any precipitation during the whole month. On the other hand, intensive convective activity in places with hail occurred in the North Caucasus region throughout the month, with monthly totals of 150–300% of the normal. The South Caucasus, particularly the eastern parts, and west Kazakhstan saw a dry June, partly with less than 40% of the normal. Places in east Georgia and Azerbaijan had around 30%, Armenia down to 14% of the normal. Other places, especially mountainous parts of western Georgia as well as places in the south-east of the country and in northern and central Armenia, had abundant rainfall, partly combined with hail in the second decade of the month. Azerbaijan saw intensive rainfall only in the first part of the month, causing severe countrywide flooding.

The Middle East, too, was partly very dry, but was not completely without rain. In Israel, there was some rainfall of a few mm on 24 and 25 June, which is rather unusual there for a summer month, but generally the country was in the midst of one of its longest and most severe droughts since the 1920s.

Snow

In June, there was hardly any snow in the Region except on some high mountains. On 20 June, however, snowfall in the Alps came down to 1000 m altitude within a cold spell due to a cut-off low which extended far to the south. On the Kredarica Mountain in Slovenia, the snow depth decreased considerably from its highest monthly value (235 cm) to only 35 cm at the end of the month.

Significant weather events

June 01–05: A quasi-stationary upper tropospheric depression over the northern Balkan Region (low Angela) caused heavy and long lasting rainfall, with flooding in southern Germany (Bavaria) due to 48-hour precipitation amounts between 80 and 208 mm and 24-hour amounts between 54 and 155 mm. 80 mm in 24 hours fell near Salzburg (Austria). In Hungary, the same depression caused between 50 and 120 mm in 72 hours in the southern and northern regions of the country and 30–47 mm in 48 hours in the northern region. High wind gusts occurred also (maximum 135 km/h). Bosnia and Herzegovina reported heavy rainfall on the 1st of June, with 79 mm at Gradacac. Croatia, Slovakia, the Czech Republic and Poland were also affected by high water levels in rivers and flooding. Further north, Lithuania reported heavy rain accompanied by thunderstorm and hail on the 3rd and 4th, with a maximum total of 84 mm in 8 hours at Elektrenai. Estonia reported precipitation amounts of 20–58 mm over the period 02–05 June.

June 07–08: Heavy rainfall in Mozdok (Republic of north Ossetia, southern European Russia). 140 mm of precipitation fell in one night, which is twice the monthly precipitation normal.

June 08: Heavy rains, which had affected Istanbul (Turkey) the days before, caused a river on the city's Asian side to burst its banks, inundating dozens of houses.

June 09–13: Thunderstorms with intense rain, hail, storm and tornadoes developed in a warm and moist air mass over central Europe and affected Germany, Switzerland and Austria seriously. Hailstones up to 3 cm were reported. Wind gusts up to 150 km/h (under foehn conditions) occurred in Switzerland. 30–50 mm of rain within short time intervals were reported for Germany and Austria.

June 11–19: Thunderstorms with heavy precipitation occurred in various parts of Europe. Heavy rainfalls in northern Spain (Galicia and Asturia) caused flooding at the beginning of the second decade of the month. In France, the region Provence - Alps - Côte d'Azur was hit by an exceptional event with precipitation amounts from more than 150 mm up to nearly 400 mm especially on 15 June. This is close to the amount that typically falls in a six-month period in this area. Flash flooding killed at least 25 people and left hundreds of others stranded in cars, houses or on rooftops. The rainfall event and subsequent flooding was the worst on record since 1827. The following days until the 17th brought further precipitation to Switzerland, southern Germany and Austria, and heavy hail to Slovenia. Hungary reported severe thunderstorms with heavy rain (60mm/2h in Kiskunmajsa), hail and high wind speeds (possibly a tornado north of Szeged). Bulgaria had large hail on 16 June. Even in northern Europe (Denmark) reported a heavy thunderstorm with hail on the 15th. Sweden saw heavy precipitation up to 126 mm in 48 hours on the 18th and 19th, causing flooding and landslides.

June 20–21: A remarkable change of the circulation with a cut-off low in the Mediterranean area brought a temperature fall of about 10 degrees to the northern and central Adriatic regions (even in Milano, the temperature fell from 25–27°C to 14–16°C from 19 to 20 June, which was followed by a sudden increase on 21 June). The Alps had snowfall above 1500 m and widespread thunderstorms occurred in northern and central Italy.

June 22–25: Heavy rain with flooding extended over the northern Balkan Peninsula to the east. Bosnia and Herzegovina reported heavy rain with close to 100 mm on 22 June, causing river flooding, landslides and broken roads; thousands of homes had to be evacuated. Many Bosnians feared that land mines planted during the Bosnian War in the 1990s could have been shifted by the floods. Also in Serbia, a great flood was recorded in the basin of the rivers Kolubara and Jadar, which lasted until 5 July and caused significant material damage. Heavy rainfalls unleashed floods in northern and eastern Romania (maximum 24-hour precipitation reported: 163 mm). Numerous people were killed and hundreds had to be evacuated from their homes. Several roads and hundreds of hectares of farmland were inundated, dozens of houses destroyed and several bridges damaged. Moldavia was also sincerely affected by floods due to some partly intense, partly enduring rainfall episodes. Rainfall led to sudden high water levels, especially on the River Prut. 4000 people had to be evacuated, more than 1000 houses were destroyed and agriculture and forestry were severely affected. The economic damage added to 0.15 % of the gross domestic product (BIP). Western Ukraine was affected as well.

June 23: Abundant rain in Georgia caused flash floods and damage to houses and roads, washing away bridges and farmlands. Two deaths were reported in the basin of Gldanula.

June 29: Heavy storm around Botev region in Bulgaria with gusts of 100 km/h.

July

- **Warm in nearly the whole Region**
- **Extreme heat wave in Russia and adjacent countries**
- **North-western, central and northern Europe mostly wet, south-western Europe and Russia very dry**

Atmospheric circulation characteristics

Low pressure systems, though with relatively warm air, crossed particularly north-western Europe within a strong frontal zone. Both the Icelandic low and the Azores high were stronger than normal this month, causing much rain over Ireland and the United Kingdom, but dry conditions over south-west Europe.

A very strong and extended Russian high caused an extreme heat wave over Russia and, to a lesser extent, in other countries, particularly in eastern Europe. A strong and persistent ridge also extended over Fennoscandia, leading to exceptionally warm and dry conditions there.

Some low pressure systems with convective activity also crossed central and parts of eastern and south-eastern Europe, but were blocked by the Russian high.

The Mediterranean region was first influenced by quite strong high pressure and advection of subtropical continental air masses over the central Mediterranean and Italy. Later in the month, a north-westerly flow prevailed, which brought cooler mid-latitude maritime air into the area.

Temperature

Nearly the whole Region had a warmer-than-normal July (Fig. 7.1). Averaged over the European continent, July 2010 was the warmest on record since 1900. The anomalies were higher than +1°C over nearly all land areas, in many cases they were even much higher, e.g. in large parts of eastern Europe more than +4°C (partly more than +5°C, e.g. in the Baltic countries and Belarus) or +6°C (locally even more) in European Russia. The 90th percentile was exceeded nearly throughout the Region, at least over land areas (with exception of Ireland and the United Kingdom and some areas near the coasts). Only parts of Svalbard and a small area over the eastern Arctic Sea were slightly colder than normal. The widespread warmth was due to a strong heat wave centred over Russia and was characterised by high daily and monthly means, maxima and minima as well as an exceptionally long duration. Tropical nights occurred more often than normal, particularly in southern Russia, but also in western and central Europe and in the southern parts of the Region (with minima even >25°C, e.g. in Portugal).

In northern Europe, July was one of the warmest ever in southern and western Iceland. Norway had positive anomalies of about +1 to +2°C, but no extremely high maxima; its highest daily temperature for the month and year was recorded on 10 July at 28.7°C. Anomalies were higher towards the east and south. Denmark measured a peak temperature of 34.1°C on 11 July on the island Bornholm, which was the highest value in Denmark since 1994. A couple of stations in southern Sweden reported new all-time high temperatures since measurements began in the mid-nineteenth century. The highest temperature in Sweden this month (and summer) was 35°C and thus the highest since 1994. In Finland, the highest monthly temperature was 37.2°C at Joensuu Airport on 29 July, the highest ever measured in Finland. Finland also set a new record in the number of summer days (>=25°C): 28 days in Lahti and Puumala in the south-east of the country. Monthly average temperatures, too, reached new all-time records in many places

of Finland (the highest was again in Puumala at 23.0°C). In the Baltic countries, Estonia had the highest mean in 60 years; daily maxima exceeded 30°C for up to 14 days and several stations set new maximum temperature records. Latvia had its warmest July for 87 years. In Lithuania, it was the warmest July over the last 50 years, with maximum temperatures up to 35.5°C. Belarus recorded its highest temperatures in 100 years.

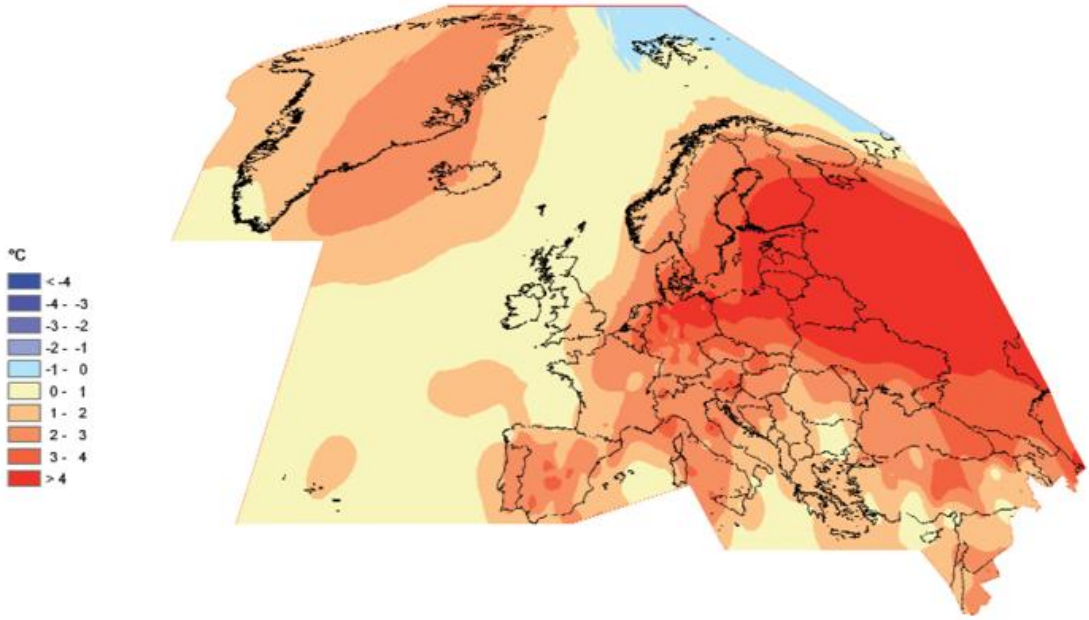

Fig. 7.1: *Monthly mean temperature anomalies in July 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

In western and central Europe, high temperatures were recorded during the first half of the month in particular. Daily maximum temperatures reached more than 30°C or even more than 35°C at many places. At 31.7°C, the United Kingdom had their highest daily maximum in 2010 on 9 July. The Netherlands were +1.5°C warmer than normal, and the highest daily maximum in the country was 36.2°C, here, too, on 9 July. Belgium had a one-week heat wave during 07–14 July. Luxembourg airport had 7 days with daily maxima of 30°C or more, which is far above the 1971-2000 normal of 2.3 days. France was +1.9°C warmer than normal averaged over the whole country, which means that July 2010 was by far not as warm as July 2006. Germany saw some new maximum records on 3 July in Bremerhaven (34.1°C) and Osnabruck (36.9°C), but the highest official value in Germany was 38.8°C in Bendorf (near Rhine River). Water temperatures in the German Baltic Sea exceeded 23°C at times. Switzerland recorded a long heat wave from 8–21 July, with daily temperatures of over 30°C, but no absolute records. It was the second warmest July at the station Lugano in Tessin since measurements began in 1864. Local new records were broken in Austria, e.g. the station Graz University registered the highest July average since the beginning of measurements in 1837 (+3.6°C local anomaly). During a 15-day heat wave, the loss of ice at the tongue of the largest glacier in Austria (Pasterze) was approximately 6 cm per day. The Czech Republic generally had a warm July, too, followed by a sudden drop of temperature at the end of the month due to a strong cold front.

In the second half of the month, the eastern countries of Europe were hot. Highest deviations from normal were to be found over Russia due to a long lasting and very intense heat wave. It was the hottest July ever recorded in European Russia, particularly in Moscow (+7.6°C anomaly). Many daily maximum temperature records were broken in European Russia (Moscow 38.2°C on 29 July) and many hot days were recorded, partly with temperature maxima of more

than 40°C, and also many tropical nights. Temperatures above 40°C were also recorded in west Kazakhstan. The hot weather had deadly consequences. More than 1,600 drowning deaths were reported in July as people tried to escape the heat across Russia.

The South Caucasus was also hot, with maxima up to 39°C in various parts of Georgia. A heat wave in Armenia set an all-time record of 10 consecutive days with temperatures above 38°C. Large parts of the South Caucasus were +2 to +3°C warmer than normal compared to the monthly average.

Extremely high maxima and anomalies were also recorded in the Middle East. Jordan had its highest daily maximum at 45.6°C on 31 July at Azraq (+8.2°C anomaly). Israel, too, had a heat wave at the end of the month, with daily maxima up to 44°C in the Jordan Rift and minima up to 33°C at the Dead Sea. In the coastal plain of Israel, minima reached 27–28°C, which was a new all-month record.

The Balkan Peninsula was affected by notable warm spells, too. Slovenia had two heat waves (10–17 and 21–23 July); in some parts of the country, the temperature rose up to 37°C. High maxima above 40°C were measured in Montenegro, e.g. 40.1°C at the station Podgorica on 16 July during a strong heat wave, which was abruptly terminated on 24 July when the local daily maximum dropped from one day to the next from 35°C to around 20°C. Serbia was very hot, too, and the majority of its stations reported record-numbers of tropical nights. High temperatures in Romania during the second half of the month were related with high humidity. The highest maximum in Bulgaria was 37.4°C. Greece had two heat waves on 14 and 15 July and from 24–26 July with maxima up to 38–40°C on the mainland (long-term mean maximum for July: 32–33°C).

In the central Mediterranean, Malta had its warming peak on 24 July (38.3°C), but became much cooler in the last week of the month.

Portugal, too, had two major heat waves that month (5–8 July and 26–31 July), with temperature maxima above 40°C, and recorded its highest mean daily maximum temperature for July since 1931.

Precipitation

Most of the Arctic region saw a dry July. Especially eastern Greenland received less than 25% of its monthly totals.

July was wetter than normal over Ireland and most of the United Kingdom (except the south-east of the country), most of Scandinavia, western and southern parts of the Baltic countries and large parts of eastern central Europe and the eastern and southern Balkan Peninsula (Fig. 7.2). Monthly totals were locally higher than twice the normal (e.g. in some areas of Norway, large parts of the United Kingdom except south-eastern parts, Lithuania and southern Poland) and exceeding the 90th percentile at least locally due to some heavy thunderstorm events.

Ireland and most of the United Kingdom were hit by large amounts of rain, whereas large parts of the French coasts were significantly dry. Germany was especially dry in its north-eastern parts, locally with less than 20% of the normal and extreme forest fire risk. In contrast, some thunderstorms with heavy rain caused a wetter-than-normal southern half of the country (locally twice the normal), especially in the last third of the month. Switzerland was dry in the west, whereas thunderstorms were concentrated over the country's east and the mountains as well as Austria and Slovenia. Golf ball-sized hail fell in southern Austria in the middle of the month; the hail zone had a length of 40 km. In Slovenia, most of the precipitation occurred during the last third of the month, and it was most abundant in western parts of the country; more than

twice the monthly normal fell on the coast. Heavy rain, hail and local flooding also occurred in Romania and Greece, resulting in twice the normal monthly total. The southern Ukraine saw an extreme flooding event in the catchment of the Danube River.

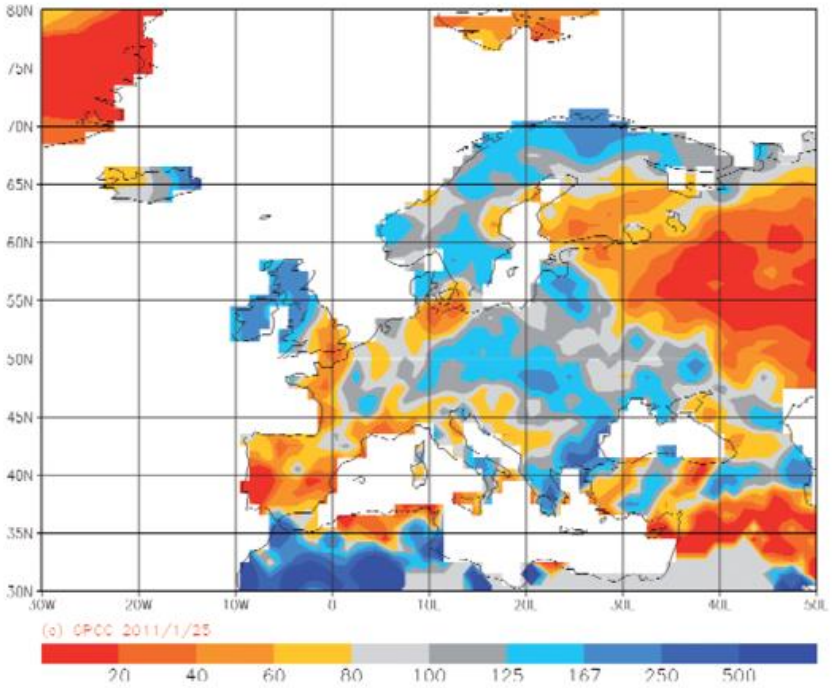

Fig. 7.2: *Monthly precipitation amounts for July 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

In contrast, it was extremely dry over southern Finland, eastern Estonia, most of European Russia, western Kazakhstan and western parts of the South Caucasus. Some areas of Russia, Georgia and western Kazakhstan received less than 10 mm precipitation; this was as little as 20% of the normal and clearly below the 10th percentile. These drought conditions, the worst since 1972, destroyed nine million hectares of crop in Russia and thus an estimated 20 percent of the nation's agricultural production, including grain, vegetables and fodder. Additionally, a state of emergency was declared in Russia when 948 forest and peat bog fires covering 26,000 hectares were burning in 18 provinces. Several villages were completely destroyed, leaving thousands of people homeless. Forty people were reported killed by the wildfires. Large areas including the capital Moscow were affected by smoke, which even reached Finland, largely affecting the air quality there due to high carbon monoxide levels.

In the South Caucasus region, Georgia was mainly dry (especially in the first and second ten days of the month), though with heavy rain in places, whereas Azerbaijan and Armenia were mostly wet or near normal due to unstable weather with frequent rainfalls and thunderstorms, partly with hail. Turkey also had some areas with high rainfall, especially near mountain sites. The Middle East was generally very dry.

It was also very dry in most of the Mediterranean region, on the western Balkan Peninsula, in Iberia (around 50% of its normal) and western and southern France. Southern Sicily (Italy) registered no precipitation at all. In contrast, precipitation was abundant in various other parts of Italy. In Iberia, it was the driest July in Portugal in the last 24 years.

Snow

Snow was recorded only in a few places in northern Scandinavia and in the higher Alps. Toward the end of July, the snowline in Switzerland fell below 2500 m.

Significant weather events

July 05: Austria was hit by heavy rain with thunderstorms. 145 mm in 24 hours (including 50 mm within 1 h) fell at a location in the Salzkammergut.

July 06: Heavy rain in Tallinn (Estonia) with 57 mm in 24 hours (70% of the monthly normal), causing damage to shopping centres.

July 06–07: Portugal reported a remarkable event at the southern Algarve coast in connection with a depression over the Atlantic between Madeira and Northern Africa. The sea surface pressure suddenly fell by 3-4 hPa and the sea surface level increased by 30 cm ('meteorological tsunami').

July 08: Finland reported a thunderstorm with heavy rain of 34 mm/h in the area of Helsinki. Hail of up to 2.5 cm in diameter caused traffic disruption in eastern Finland.

July 10: Switzerland reported a heavy thunderstorm with wind gusts up to 110 km/h, and heavy rain of around 60 mm in 1 hour (St. Bernhard, Zürich-Affoltern).

July 11: A violent thunderstorm occurred in western Austria (Vorarlberg) in the evening. Due to a debris flow which accumulated gravel and soil masses up to 8 meter high, some homes had to be evacuated.

July 12–13: Heavy thunderstorm over south-eastern Norway with locally very intense precipitation, e.g. 12 mm in 5 minutes in the Oslo area. Strong gusts in Norway and Sweden. Vinga station in Sweden reported a wind gust of 122 km/h, the highest gust ever reported in Sweden in July (mountain top stations excluded).

July 12: A downburst hit the island of Helgoland (Germany) in the North Sea. At least 8 people were injured on a campsite, two of them seriously. The campsite, where about 100 people were staying, was destroyed and a light aircraft on the nearby airfield knocked over. Wind gusts of more than 100 km/h were measured in several places in western Germany (e.g. in Aachen).

July 13: Lithuania reported heavy rain of 54 mm in 12 hours (Lazdijai) and 59 mm in 9 hours (Babtai).

July 14–15: A series of low pressure systems passed the UK on the 14th and 15th, bringing localised flooding and strong winds to parts of Cornwall, Devon and Wales. Severe gale force winds and gusts as high as 135 km/h brought down branches, trees and even roof tiles. Uprooted trees blocked roads and power lines came down - leaving around 1,500 people without electricity.

July 14: France reported heavy thunderstorms with many lightning strikes along a track from Paris to Eure et Loire. 40 mm of precipitation in 3 hours and wind gusts of more than 90 km/h were recorded at 6 stations, more than 125 km/h at 2 stations and more than 140 km/h at Saint-Hilaire-sur-Help. Similarly heavy thunderstorms hit Belgium at the end of a heat wave, producing 30 mm in 2 hours and wind gusts up to 135 km/h (Elsenborn). In the Netherlands, a campsite at Vethuizen was hit by severe wind gusts of a thunderstorm downburst. 2 people died and several were injured.

July 14–16: Heavy rainfall in the village Tsakhkavan in the north-east of Armenia: 58 mm in 4 hours on 14 July and 39 mm in 2 hours on 16 July.

July 15: Many fires in Estonia due to thunderstorms.

July 15–16: Another thunderstorm with heavy rain hit Austria and southern Germany. 88 mm in 12 hours were reported for Preitenegg (Kärnten), 52 mm in 1 hour for St. Michael/Leoben. Hailstones up to 9 cm diameter were seen near Starnberg (southern Germany).

July 16: Slovenia reported heavy rain: 48 mm within 45 min, a once-in-50-years event.

July 17: Heavy precipitation records were reported by Austria: 94 mm for Kalwang (Styria), 82 mm for Puchberg (Lower Austria) and more than 100 mm in the Kitzbühel Alps. In Tyrol, heavy rain and hail caused enormous damage around Innsbruck. Streets were flooded up to 50 cm high due to hailstones blocking the drains. Vegetable crops over an area of 400 hectares were destroyed in eastern Innsbruck. Similar daily totals also fell in southern Germany.

July 18–19: 101 mm of 24-hour rainfall had been recorded at Seathwaite (Cumbria) in the United Kingdom.

July 21: The centre of Perth (Scotland) had been seriously affected by flooding after 40 mm of rain fell during the morning.

July 22: Finland reported heavy rain with 60 mm/day in Sodankylä.

July 22–26: Several heavy rainfalls with thunderstorms hit Germany: Germany reported heavy rain for its regions Bavaria, Thuringia and Saxony, with totals around 50 mm in 1 hour at several stations. The region between the Allgäu and the Berchtesgadener Land in southern Germany received more than 100 mm within 3 days. Thunderstorms with heavy rain on 26 July brought locally even around 100 mm in 24 hours. A severe hailstorm was reported by Austria (south-eastern Styria) on 23 July, with an estimated damage to agriculture of 4 million euros. Golf ball-sized hailstones damaged roofs and vehicles heavily. In Italy, heavy thunderstorms with heavy rain and wind gusts also occurred in the eastern Po valley after a persistent period of hot weather and a following cut-off low.

July 23–24: Heavy rain in western Lithuania (85 mm in 11 hours) with hail (hailstones 3 cm in diameter) and a tornado.

July 26: Severe hailstorm damaged fields in central Estonia.

July 26–27: Twenty-six forest fires and 34 peat fires were burning in the Moscow region on 26 July, producing dangerous air pollution. Smog levels were five to eight times greater than normal. On 27 July, pollutant levels increased by about 50 per cent and were ten times higher than normal.

July 26: Heavy storm around Kaliapka region (Bulgaria) with gusts of 136 km/h, water spout near Sozopol (Black Sea, Bulgaria).

July 29–30: Finland reported heavy thunderstorms and downbursts in the south and middle of the country, with an extremely large number of lightning strikes and wind gusts up to 105 km/h during night time, which is very exceptional. Extensive damage due to falling and broken trees in central Finland.

August

- **Very warm in large parts of the Region, colder than normal in parts of the Arctic and western Europe**
- **Continuation of strong heat wave in eastern Europe and extension to the Middle East**
- **Very wet in central Europe, dry in most of the north, east and south**
- **Again severe flooding in eastern central Europe**

Atmospheric circulation characteristics

In August, a mainly meridional circulation pattern was dominating again. The North Atlantic as well as eastern Europe and the Middle East were mostly under high pressure influence and warm air advection, whereas low pressure systems crossed north-western and central Europe frequently from the north-west, bringing cold air which partly extended as far south as the Mediterranean. The airflow became more zonal in the second half of the month.

Cold and dry air from the eastern Arctic region only affected the northernmost parts of northern Europe.

Temperature

The North Atlantic, Greenland and Iceland as well as most of southern Scandinavia were mostly more than +1°C warmer than normal this August (Fig. 8.1). Southern Greenland was even more than +3°C warmer, exceeding the 90th percentile.

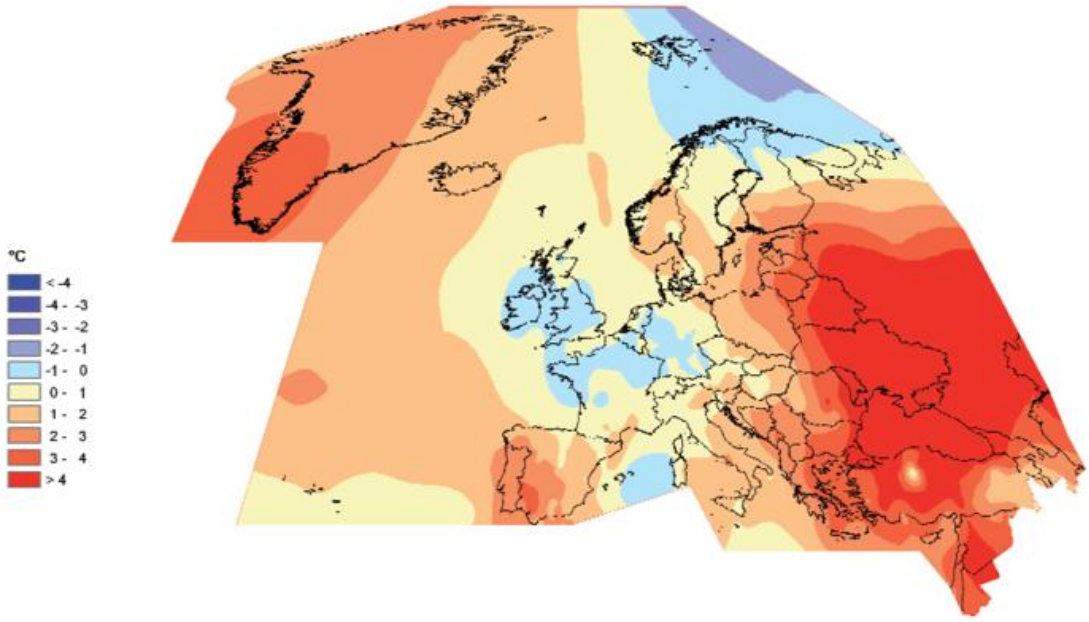

Fig. 8.1: *Monthly mean temperature anomalies in August 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Towards the east, the eastern Arctic Sea, the northernmost parts of northern Europe and Svalbard were colder than normal, with anomalies mostly between 0 and -1°C, in the east even below.

North-western, western and most of central Europe as well as the western Mediterranean had monthly mean temperatures near normal, partly slightly colder. It was the coolest August in the United Kingdom since 1993. Frost of -1.3°C was recorded in the highlands of the country on 26 August.

The Alpine region was warmer than normal. In the night 6–7 August, unusually high 25°C occurred over large parts of Switzerland due to warm air masses from the south-west. Up to 29°C had been measured in Basel at midnight.

Iberia profited much from subtropical high pressure influence and experienced a hot month. Portugal had its second highest mean maximum temperature for August since 1931. Especially in southern Spain, anomalies reached more than +3°C, which was more than the 90th percentile. Daily maximum temperatures exceeded historic records for August at several stations in the eastern half of Spain. Highest annual maxima for Spain were recorded from 25–27 August, reaching 44°C at several sites near the eastern coast in the provinces of Murcia, Alicante and Valencia. Italy was warmer than normal over most of the southern regions, Sardinia and the eastern Po Valley, whereas the rest of the country was within the natural variability of temperature.

It was extremely warm over most of north-eastern, eastern and south-eastern Europe, the South Caucasus, the eastern Mediterranean and the Middle East due to the ongoing strong heat wave, which had started at the end of June. In the whole of eastern Europe and the Middle East, the monthly mean was above the 90th percentile.

In eastern Europe, several stations measured new local daily maximum temperature records. The highest value in Estonia was 35.4°C, only 0.2°C less than the absolute country record. 35.8°C were reached in Lithuania on 15 August, and record-breaking daily maximum temperatures were reached on four days in a row (13–16 August). Belarus broke its all-time high-temperature record on 7 August with 38.9°C in Gomel in the south-west of the country. The Ukraine also saw a new absolute maximum temperature record of 42.0°C in Lugansk on 12 August. Highest anomalies (>+6°C) with daily maxima above 40°C and continued smog due to wildfires were to be found in the eastern Ukraine and south-western European Russia. West Kazakhstan, too, registered again maxima above 40°C. European Russia experienced its hottest August ever, with many new maximum temperature records, like the more than 38°C measured in July in Moscow. Maxima in Moscow were +15°C above average during the first half of August 2010. The two-month long heat wave finally broke on August 19th, when a cold front moved across western Russia, bringing rain and much cooler temperatures and clearing the thick smog that had hovered over Moscow for weeks. In the last decade of August, temperatures declined and the first frost occurred in north-western European Russia and in the upper Volga regions.

In the South Caucasus, maxima reached up to 42°C in west Georgia. There was also a large number of hot days, e.g. in Azerbaijan, with corresponding impacts on people's health. 160 cases of sunstroke were registered in Azerbaijan, nearly three times as many as in the previous year 2009. On 21 August, however, temperatures locally dropped to -4.5°C below normal.

Generally, this large heat spell with high monthly anomalies extended further south compared to July. Montenegro once again experienced a heat wave with maxima above 37°C later in the month and many fires were triggered in the hottest regions of the country. Bulgaria reported three heat waves with maxima up to 39°C, causing human discomfort and triggering forest and field fires especially in the south-east of the country. August was even warmer than July in Bulgaria.

In the central and eastern Mediterranean region, the heat wave went on for a longer time. Malta had its highest temperature on 21 August (36.0°C, Fig. 8.2) and its mean August maximum was almost +1°C higher than normal. Many Greek stations recorded both their highest ever monthly mean temperature and mean maximum temperature. High daily maxima were measured in Greece during heat waves from 13–17 August and 26–27 August at 38–41°C at many stations. The station Mut in Turkey reached a local record-breaking daily maximum of 46.7°C. On Cyprus, the station Athalassa recorded a maximum temperature of 45.6°C on 1 August, which was +8.4°C higher than normal, while the minimum temperature was at 29.0°C (+7°C above normal). This was the highest maximum temperature in Cyprus for 100 years. Monthly anomalies in Cyprus were also extremely high (around +3°C), which is considerably more than in June and July. In most parts of Israel, August was the warmest on record, mainly due to two major heat waves, partly with record-breaking temperatures up to 49°C. At times, the high temperatures were accompanied by high relative humidity. Minimum temperatures in Israel were also record-breaking and reached up to 30.0°C. Jordan also had two heat waves with the highest maximum at 48.8°C (+9.9°C anomaly from normal maximum temperature) in the Jordan Valley on 20 August.

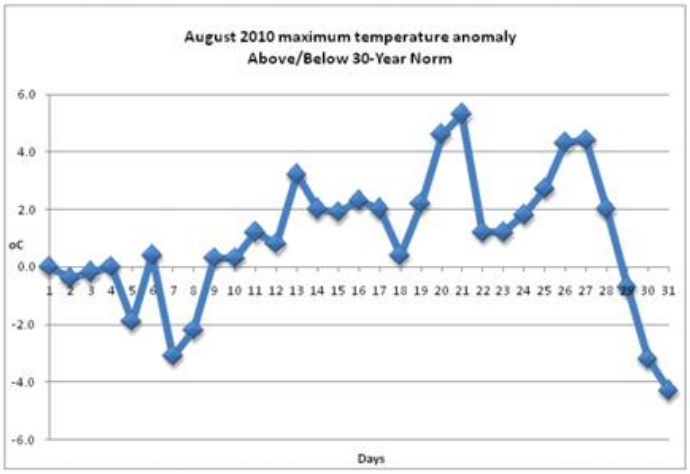

Fig. 8.2: *Daily anomalies of maximum temperature in August 2010 (reference period 1961–1990) at Luqa Airport, Malta*
Source: Malta Airport Met Office

Precipitation

The Arctic region (except western Greenland) and most of the northern parts of Scandinavia and Russia were dry, locally with less than 40% of the normal precipitation (Fig. 8.3), which was less than the 10th percentile. River levels in north-western Iceland were unusually low and there was water shortage in places.

Due to high pressure influence from the North Atlantic, it was also very dry in south-western France, northern Spain and particularly in Portugal. Less than 10 mm, which is less than 20% of the normal, was registered across the whole of Portugal, making it the driest August of the last 23 years. In most of these areas, especially those near to the coasts, the totals were below the 10th percentile.

South-eastern Spain, in contrast, was very wet that month with up to more than 400% of the monthly total at the south-eastern coast. This was mainly due to a heavy precipitation event on 16 August, which particularly affected some localised areas of central Andalucia just in the middle of the dry season.

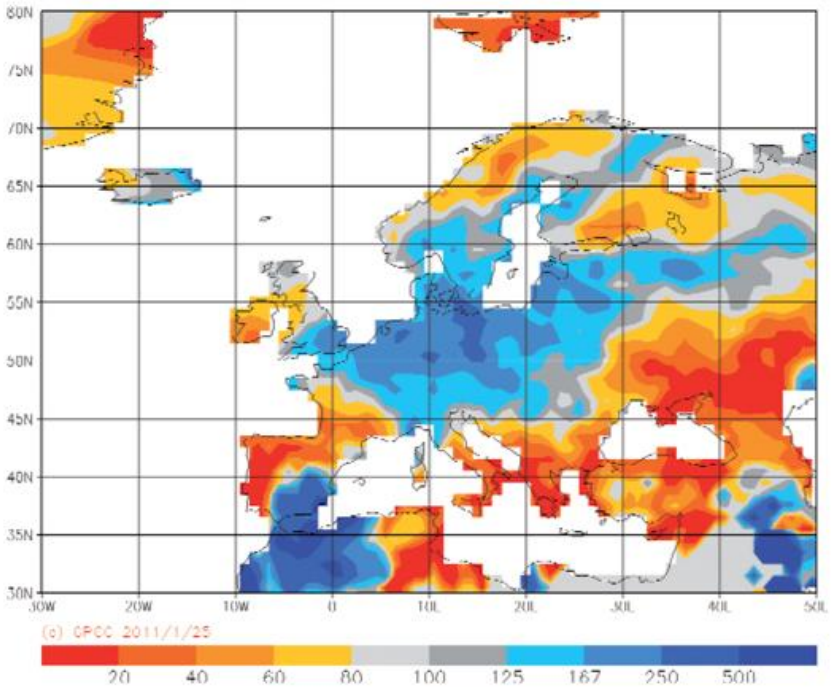

Fig. 8.3: *Monthly precipitation amounts for August 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Large parts of central Europe and much of the adjacent areas (as far as south-east England in the west, southern Scandinavia in the north, some parts of Russia in the east and northern Italy in the south) were also very wet, all with totals higher than the 90th percentile due to some heavy rain events, which were locally related to storms, heavy hail and flooding.

Several places in south-eastern Norway, parts of the south-eastern United Kingdom and northern France received more than twice the normal monthly precipitation total. Some Norwegian stations registered a new August record for monthly or daily precipitation. It was the second wettest August on record in East Anglia (United Kingdom).

August was extremely wet all over central Europe. It was the wettest or second wettest August in many parts of central Europe, with heavy thunderstorms. The Netherlands saw its second wettest August since 1901 (behind 2006), with 170 mm on average, i.e. nearly three times the normal. The wettest August since 1881 was recorded in Germany, with an areal mean of more than 200% of the 1961-1990 normal, locally more than 400% (Fig. 8.4). Poland received about twice the monthly normal on average. Particularly high totals of more than 200 mm (more than 250% of the normal, locally up to 500%) were measured in the border region of Germany, Poland and the Czech Republic, mostly due to a heavy precipitation event in early August. Precipitation totals were also very high in parts of eastern Austria and Slovakia.

The Baltic countries saw an outstanding wet August, too. Ruhnu Island in Estonia received 236 mm (more than 400% of the normal), which include one heavy rain event with 97 mm in 24 hours. Most parts of Estonia were very wet, especially during the second ten days of the month. It was the third wettest August in Latvia for 87 years. Heavy downpours, squalls, thunder- and hailstorms and even tornadoes also occurred in Lithuania.

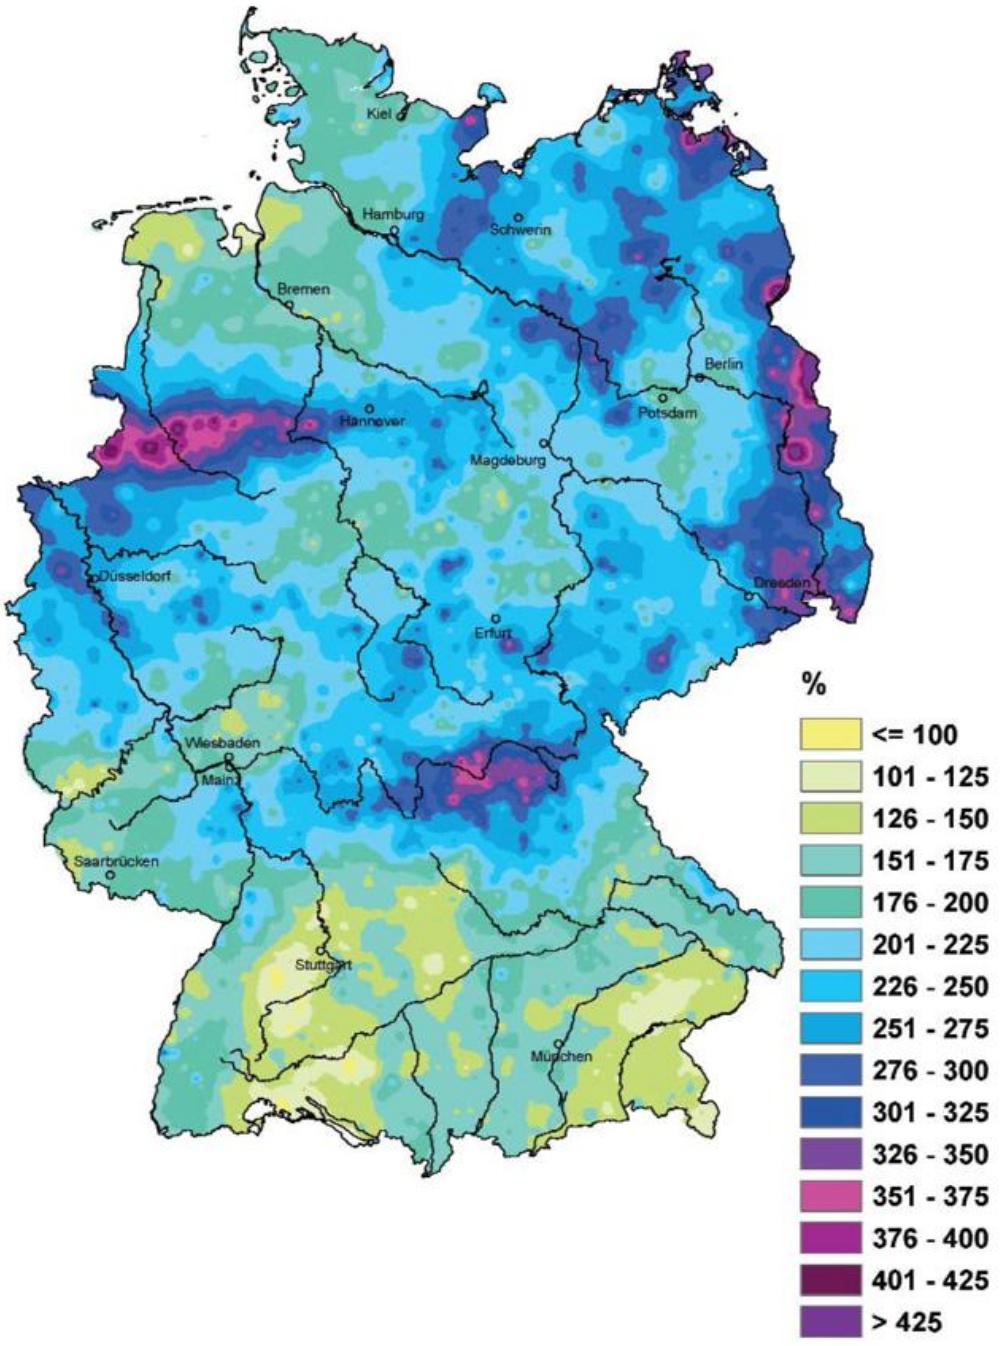

Fig. 8.4: *Monthly precipitation amounts for August 2010 in per cent of the normal 1961–1990 in Germany*
Source: Deutscher Wetterdienst, Germany

Towards the south, northern parts of Italy and the Balkan Peninsula were also affected by high precipitation that month. Rainfall totals in Italy were above normal over most of the northern regions and Tuscany. Locally, Serbia received up to three times the normal, with a new local record for the August monthly total set at Novi Sad (168.5 mm). Even in Romania, August precipitation was above normal in the mountainous and western regions.

Generally, it was also very dry over a large area around the Black Sea, namely in eastern Romania, Moldova, the eastern Ukraine, southern European Russia, northern parts of the South Caucasus, Turkey, the Middle East, Cyprus and even large parts of the southern Balkan Peninsula and central and southern Italy, locally with less than 20% of the normal monthly precipitation and mostly below the 10th percentile. Some of these areas were even without any rain at all or received only a few mm in the whole month, which was unusual except for the eastern Mediterranean area. The Ukraine received less than half of the normal precipitation throughout the country. There were more than 600 wildfires and 948 forest fires in 18 counties of western Russia at the beginning of August, with thousands of people made homeless. Forest fires also occurred in parts of Azerbaijan and agriculture suffered from drought there, but several days in the last third of the month were characterised by thunderstorms.

Snow

Snow was recorded in higher altitudes of the Alps only. On the first days of August, the snowline was as low as 2100 m in eastern Switzerland, covering the higher passes with a thin layer of wet snow. At the end of the month, the snowline went down to 1200 m altitude in the eastern Alps, and up to 40 cm of fresh snow was measured in the higher mountains.

Significant weather events

August 01: Nicosia in Cyprus reached a daily maximum of 45.6°C, which was the highest value recorded since the beginning of the 20th century.

August 04: The beginning of August 2010 was still characterised by the great heat in the east. Stations in Russia, Belarus and Ukraine reported very high temperatures. Moscow had 36.6°C, St. Petersburg 33.3°C, Luhansk nearly 40°C.

August 04: Thunderstorm with heavy gusts and large hails in central Finland, causing damage due to fallen trees; people were injured at the camping site of Uurainen.

August 04: Severe thunderstorms with very strong winds and hail up to tennis ball size in north-western Bosnia and Herzegovina (Bosansaka Krupa). Huge damage to infrastructure and losses in agricultural production.

August 05: In north-west Greenland, a huge chunk of ice broke off the Petermann Glacier into the Nares Strait. The ice floe was 251 km² in size, which equals a quarter of the floating ice shelf of the Petermann Glacier. It was the largest break-up in the Arctic since 1962.

August 06-09: Very high precipitation amounts fell in eastern Austria, eastern Germany, the Czech Republic and Poland, partly as long enduring rain and partly as very intense precipitation. This led to severe flooding of the Neisse and Elbe Rivers as well as smaller rivers like the Spree (Bautzen, east Germany). In the morning of 08 August, the water level in Görlitz (eastern Germany) of the Neisse River (707 cm, i.e. about 4.5 m above its normal level) exceeded the previous record of 21 July 1981; parts of the town were flooded. More than 1,400 residents had to leave their homes. In Poland, a water reservoir dam broke. Houses were flooded and streets and bridges damaged. Most of the rain fell in the Czech Republic, where the water level of the Elbe raised to 6 m, i.e. three times the normal value. Values of up to 200 mm in 24 hours were reported there. At least 11 people died in eastern central Europe. Damages were estimated to be over 215 million U.S. dollars in the Czech Republic alone. Southern Germany and Switzerland also had high precipitation amounts.

August 08: Wind gusts of up to 108 km/h, heavy rain (locally 69 mm in 8 hours) and hail (diameter 2 cm) in connection with intense convective activity was reported from western Lithuania in the afternoon. It was one of the stormiest and damaging meteorological phenomena of the decade 2001–2010. A squall line formed within a tropical air mass over southern and central Lithuania. Forests (about 4 million Euro), power lines and buildings were damaged and 4 people lost their lives. The thunderstorm also affected Estonia and Finland. In Estonia, gusts reached 144 km/h and weak tornadoes occurred, causing significant damage in towns, villages and on 1,100 hectares of forests. Electricity was disrupted in 60,000 households. Several people were wounded, one person killed. Hailstones of 6–8 cm size fell during a severe thunderstorm in Pirkanmaan (Finland) and gusts up to 115 km/h were measured in the western parts of the country. Never before had Finland reported hailstones bigger than these. This was the most severe thunderstorm in a series of days with highly convective activity. Beside fallen trees and flooding which affected air and road traffic, lightning strikes caused a power blackout to 21,000 households. Several people were injured at a music festival in Pori and one died.

August 08–09: Forest fires in Russia and prevailing south-easterly airflow brought dense smoke to the whole of southern Finland. The peak concentration of PM2.5 particles was measured as high as 241 μg/m³ in Imatra (south-eastern Finland), which was more than 20 times the average.

August 11–13: Fires broke out in northern Portugal, spreading to northern Spain near the borders of Spain and Portugal during hot and dry weather.

August 13–17: Large parts of central Europe reported intense precipitation. Daily totals were around 50 mm or more at many stations. Uccle in Belgium recorded a 48-hour total of 103.6 mm on 15 and 16 August, and precipitation was also intense in north-eastern France. Denmark was hit by heavy precipitation on the 17th, with 24-hour values of 138 mm for Billund and 157 mm for Blahoj Kirkeby. In Austria, thunderstorms on the 13th brought 64 mm in 1 hour in Eisenstadt (Burgenland), an event with a probability of once in 25-30 years. Public traffic in Vienna had to stop its service for one hour due to heavy rain, flooding of streets, and broken branches blocking railway tracks. Heavy precipitation also caused widespread damage in some regions of eastern Germany and central and eastern Slovakia, with destructive flash floods.

August 14–16: Thunderstorms with widespread and intense precipitation that produced daily totals up to more than 80 mm particularly over northern and central Italy due to a cut-off low.

August 16: Lithuania reported that the temperatures exceeded the highest August temperature maxima ever recorded at 12 stations. On this day, the maximum temperatures reached 28.3°C (Zoseni) to 33.1°C (Daugavpils).

August 16: At least 2 tornadoes were observed in Hungary.

August 16: Russia's two-month long record heat wave and drought was set to come to a dramatic end by a severe storm. In St. Petersburg, 100,000 were left without power, rail services were halted and trees fell in high winds. Temperatures around Moscow dropped to about 24°C, after nearing 40°C for weeks.

August 16: Heavy precipitation in central Andalucia (Spain). The episode, unusual for that season, locally brought over 200 mm of rain in just a few hours and caused three deaths and damage to infrastructure, mainly houses and transport networks (road and rail).

August 21–22: Strong N-NW wind over the Aegean Sea caused a fire at the palm-tree forest of Preveli (in the south of Crete Island). Forest fires also occurred in western Turkey.

August 23: Gusts of violent storm in south-western Denmark and northern parts of central Europe. Thunderstorms with heavy precipitation occurred in western Germany (up to more than 50 mm/day) and central parts of the country (more than 30 mm/day in the Rhön Mountains). Tornadoes occurred in various parts of Germany and in Belgium. During the early morning hours, a hailstorm affected the north-west of Poland, bringing down trees and power lines. Properties and homes were damaged and 3 people were injured. The hailstorm was followed by torrential rain.

August 25–26: In Turkey, the station Rize at the Black Sea coast reported 167 mm in 24 hours on the 25th. The same station had some additional 52 mm on the next day. 13 people died due to a mudslide, 168 houses were destroyed due to distorted urbanisation. 1729 hectares of field, roads and water pipes were damaged. Total economic loss was calculated to 20 million USD.

August 26: France reported daily maximum temperatures in the south-west between 39°C and up to 41.1°C. Switzerland reported very high night temperatures from the 26th to the 27th between 20°C and up to 23.8°C over most of the country. The mountainous stations also had night time values between 10°C and 18°C.

August 26–27: Up to more than 130 mm of precipitation fell in 24 hours in a wide band over the middle of the Netherlands. Many places experienced large-scale flooding. The eastern Netherlands and western Germany also received high precipitation totals of more than 100 mm up to 162 mm (about 200% of the monthly August normal) in 24 hours in a frontal band, which was relatively narrow in north-south direction. Swansea in the United Kingdom recorded a 24-hour total of 64 mm in the morning of 26 August.

August 29: Copious amounts of rain triggered floods and mudslides that killed at least 12 people in the northern Turkish town of Gundogdu. Dozens of homes were destroyed and several roads closed.

August 31: The last day of August 2010 brought snowfall in the Austrian Alps: 40 cm in 2000 m and 10 cm even down to altitudes of 1300 m.

August 31: Heavy storm in Botev and Kurdjali region (Bulgaria), gusts up to 144 km/h.

September

- **Cold in central Europe, warm over Greenland and in the east**
- **Wet with frequent heavy rain in eastern central Europe and over the central Mediterranean, still very dry in Portugal and in the east**

Atmospheric circulation characteristics

Both the Icelandic low and the Azores high were more intense and had a more westerly position than normal in September. Thus, warm air dominated over the North Atlantic and was also led to Iceland and Greenland.

A meridional circulation pattern, however, persisted over the European continent and cold and moist air from the north extended particularly to western and central Europe, temporarily also to the western and central Mediterranean.

High pressure influence dominated over the eastern parts of the Region, and warm and dry air particularly affected the Middle East and continued to move to areas in the north-east, especially in the second half of the month.

Temperature

September was still warm over the North Atlantic and particularly over Greenland and Iceland, with anomalies of more than +3°C (Fig. 9.1), which exceeded the 90th percentile. Towards the east, the anomalies were lower; over the eastern Arctic sea, they were even slightly negative.

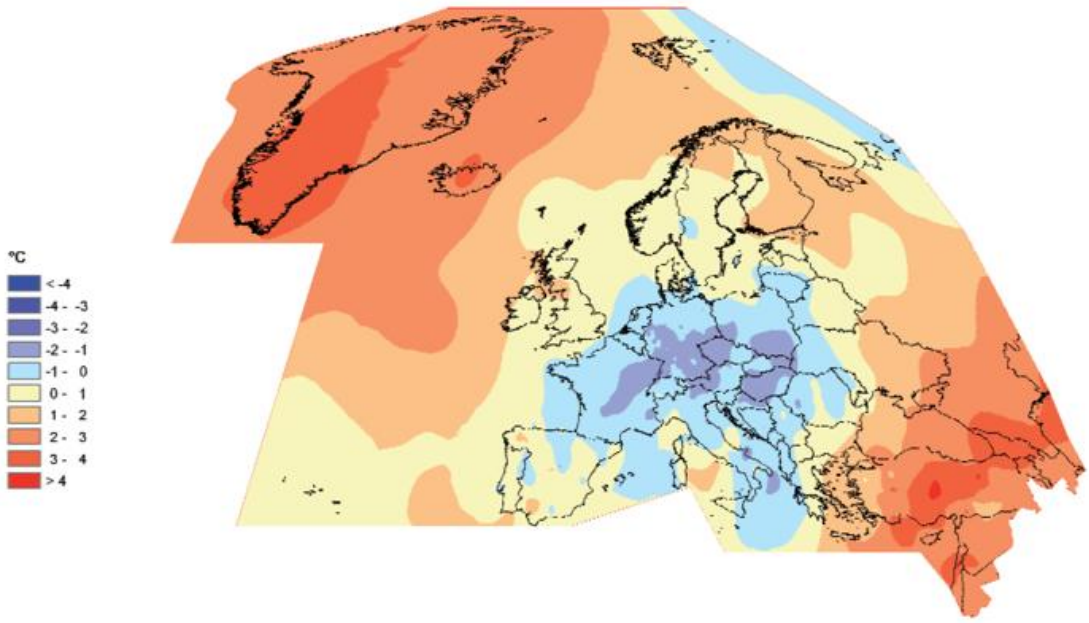

Fig. 9.1: *Monthly mean temperature anomalies in September 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

With 24.9°C, a new daily maximum temperature record for September was reached on 2 September in Greenland at the station Nuuk Airport. Iceland recorded the same peak maximum (24.9°C) on 4 September. It was the highest daily maximum of the whole year 2010 and most unusual to occur so late in the summer half year.

Northern Europe, Ireland and the United Kingdom were also warmer than normal, though with smaller deviations from the normal (less than +2°C), partly due to some cold nights. The United Kingdom saw some localised frost, but also daily maxima up to 24.6°C. Further to the south of the Region, most of Iberia also had slightly-above-normal temperatures, but the temperatures were also below the normal in some places.

Large parts of western and central Europe (including the southern North Sea) were colder than normal as well as parts of the western and central Mediterranean, Italy and the western Balkan Peninsula. Anomalies were partly below -1°C, particularly in southern central Europe, where even some local frosts occurred; but these were no extreme deviations. Temperatures reached 25°C only rarely in Germany.

It was still warmer than normal in eastern Europe, the eastern Mediterranean region and the Middle East, but the strong and extended heat area of the preceding summer in eastern Europe was retreating to the south-east. Anomalies still exceeded +2°C and thus the 90th percentile in southern European Russia, west Kazakhstan, the South Caucasus region, Turkey, the eastern Mediterranean and the Middle East. Locally in Turkey, the anomalies were higher than +4°C. Daily maxima reached up to 37°C in Greece south of the Aegean Sea and 40°C in west Georgia at the beginning of the month. Israel had once more record-breaking minimum temperatures up to more than 30°C at the Dead Sea.

Precipitation

It was wetter than normal over eastern Greenland, parts of Iceland, Ireland and parts of the United Kingdom (Fig. 9.2). The 90th percentile was only exceeded in eastern Greenland and parts of Ireland. In the United Kingdom, it was particularly wet in Northern Ireland, the wettest September there since 1999.

Because of missing westerly airflow conditions, the Norwegian coast and large parts of northern Scandinavia were very dry, as was most of the Arctic region, locally receiving less than 40% of the normal and below the 20th percentile. Places in northern Norway experienced the driest September in 25 years.

It also continued to be very dry in Portugal due to continuous high pressure influence, resulting in the second driest September of the last 22 years in this country. Monthly totals were below 10 mm in nearly the whole of Portugal, which was below the 10th percentile. The coasts of Spain, some southern parts of France and the western Mediterranean including its islands were also far drier than normal, whereas the interior of Spain was wet.

It was very wet in the whole eastern part of central Europe (except in some areas, e.g. in southern Germany and upper Austria), parts of the Baltic countries and north-eastern European Russia and, towards the south, in the north-western Balkan Peninsula and the central Mediterranean region, locally with more than 300% of the normal monthly precipitation (e.g. in eastern Germany and northern Croatia) due to some heavy convective precipitation events. In most of eastern central Europe and the north-western Balkan Peninsula, the 90th percentile was exceeded. River water levels were critically high in places and extensive flooding with significant damage occurred in Slovenia. At many Slovenian stations, precipitation was among the most abundant ever observed (up to 300% of the normal and up to more than 300 mm).

Most of European Russia, especially the eastern and southern parts, as well as west Kazakhstan, Turkey, Cyprus and the Lebanon were very dry, although this is not rare in these areas for this time of year. On the other hand, there was more than 250–500% of the normal rain locally in southern Syria and Jordan. Some places in the South Caucasus region also saw some higher-than-normal rainfalls, whereas especially Armenia received only 30–50% of the normal precipitation.

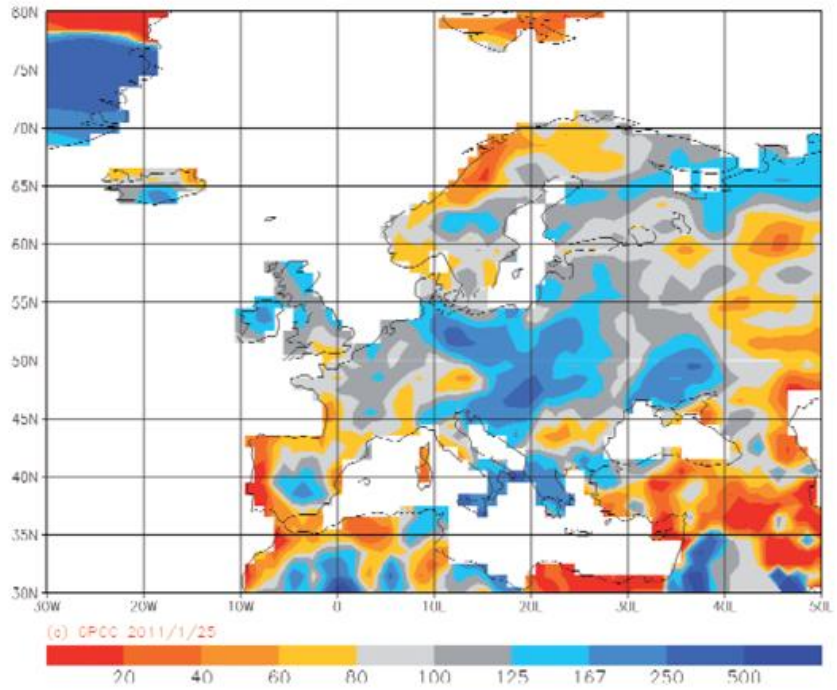

Fig.9.2: *Monthly precipitation amounts for September 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Snow

Snow was only to be found in the Alps and in higher elevations of the Carpathian Mountains. Wendelstein Mountain in southern Germany (1800 m altitude) had one snow day in September, with 2 cm of snow. The highest German mountain, Zugspitze (nearly 3000 m altitude), still had 4 days without any snow. Kredarica Mountain in Slovenia had 9 days of snow, with a maximum depth of 12 cm on 28 September. Romania had snow above 1700 m altitude at the end of the month.

Significant weather events

September 01–02:	Heavy precipitation hit Poland, the Ukraine and the Czech Republic. The Czech Republic reported heavy precipitation during the night from 31 August to 1 September with daily amounts of 100 mm or more at several stations.
September 02–04:	At least 3 tornadoes were observed over northern and eastern Germany.
September 03:	Heavy storm in Botev region (Bulgaria) with gusts of 90 km/h.
September 06–08:	Along with an Atlantic frontal system, intense rainfall occurred in southern France and brought about 90 mm and more at 7 stations (maximum 310 mm at Conquerac, Gard) on 6 September, and more than 100 mm

at 13 stations (maximum 254 mm) on 7 September. Overall, 20 stations had more than 100 mm within the 2 days; the highest 2-day sum was registered at Cardet, with 354 mm (half of the usual annual mean). Over 200 mm fell in 4 hours at Cavaillon (Vaucluse).

September 09: Heavy rain caused severe damage at the Italian Amalfi coast. Generally, the regions of Genoa, Liguria, Amalfi, Campania and Friaul received heavy rain.

September 11–12: Heavy rain (up to 117 mm in 24 hours) and flooding in Thessalia (central Greece).

September 14: Turkey and Georgia reported heavy precipitation, locally more than 100 mm in 24 hours.

September 15–16: Gusts up to 110 km/h in Denmark and northern Germany, causing disruptions of the ship traffic between Germany and the North Sea islands.

September 17–19: Severe precipitation hit Slovenia, resulting in catastrophic floods in many parts of the country. Former records were broken at many stations; it was the heaviest precipitation event for 60 years. On 18 and 19 September, 11 and 7, respectively, out of 18 stations reported more than 100 mm in 24 hours. One station near Idrija had more than 500 mm in 2 days; it was the most severe precipitation event in the last 60 years in Slovenia. During this precipitation episode, northern Italy also had heavy rain with flooding of the Seveso River. Metro stations in Milan had to be closed for a week due to 7–8 m high accumulation of debris. Several more countries were affected by heavy rain during this episode: Switzerland, Austria, Hungary, Bosnia and Herzegovina, Greece and Spain.

September 25–27: Heavy and long lasting precipitation of partly more than 50 mm per day and local flooding was reported by Germany, Poland, the Czech Republic, Switzerland, Liechtenstein, Austria, Slovenia, Croatia, Bosnia and Herzegovina, Romania, Bulgaria, Macedonia and Greece. The water levels of some rivers in eastern Germany rose and caused flooding of streets and agricultural areas in some places. Wind gusts in Bulgaria (regions Musala, Mouragash) of 100 km/h.

September 26: A daily precipitation total of 179 mm was measured in south-eastern Iceland.

October

- **Cold in nearly the whole of Europe, warm in the Arctic and in the Middle East**
- **Dry in most of northern, central and eastern Europe, wet in parts of the Arctic, southern Europe and around the Black Sea**
- **Heavy rain events in the Mediterranean region and in south-eastern Europe**

Atmospheric circulation characteristics

A large low pressure zone affected the Arctic and the northernmost parts of Scandinavia. The Icelandic low itself was not well developed, but mild air masses from the North Atlantic flowed to the Arctic region. The Azores high was centred south-west of the Azores and weaker than normal.

High pressure influence dominated over large parts of northern, western, central and eastern Europe; occasionally, cold air advection from the north reached these areas with localised snowfalls in the second half of the month, but also a few warm spells occurred due to southerly or Atlantic airflow, and foehn north of the Alps.

Further in the south, there was much cyclonic activity around the Black Sea and the Mediterranean. A Mediterranean mesocyclone, originating from a cut-off low, affected the western Mediterranean basin during the second week of October.

The Middle East was still affected by warm and dry air masses from the south.

Temperature

It was very mild over the North Atlantic and throughout the Arctic region (Fig. 10.1) due to continued high sea surface temperatures. Anomalies in the Arctic increased up to +4°C. The 90th percentile was exceeded in southern Greenland, Iceland and Svalbard. Especially the first half of October was unusually warm in Iceland. The northernmost parts of Scandinavia were more than +2°C warmer than normal, whereas southern parts were colder than average.

Temperatures were close to normal on average in the United Kingdom. However, for about 10 days from mid-month, it was colder there, with northerly winds and some very low overnight temperatures. This was compensated, however, by milder air due to frontal systems from the west and also because of some warm days with up to 23.1°C due to high pressure influence.

Most of the European continent, southern Scandinavia, Ireland and most of the western and central Mediterranean were colder than or near to normal. The highest negative anomalies were to be found over eastern central Europe and the northern Balkan Peninsula (around -3°C). In eastern central Europe, temperatures were lower than the 10th percentile. It was the coldest October in Vienna since 1974. The first third of the month was still warm in central Europe; maxima continued to exceed 25°C in south-western Germany and the Alpine region in early October due to foehn. However, first frosts occurred in the lowlands of Germany and in Denmark in the middle of October. Northern Italy was also particularly colder than normal in the second half of the month.

October temperatures were below normal in most of European Russia. In the first ten-day period of the month, slight frosts were recorded locally in its western and central parts, in some places with new minimum temperature records. On the other hand, northern and north-eastern European Russia was warm in October. In Murmansk, the air temperature attained 12.4°C on 6 October, which became a new absolute record-breaking value for this time of year.

The South Caucasus region, eastern Turkey, the Middle East and the eastern Mediterranean were at least +1°C warmer than normal. Most of these areas recorded temperatures higher than the 90th percentile. In some parts of the Middle East, the anomalies were higher than +3°C. Daily maxima still reached up to 32°C in west Georgia at the end of the month, when other parts of the South Caucasus were already affected by cold air masses. Jordan experienced three heat waves in October, with highest daily maxima at 42–44°C in the Jordan Valley (anomalies +8°C or more); the conditions were similar in Israel, with up to 42°C even in the coastal plain, where the highest October temperatures for the last 50-60 years were reached.

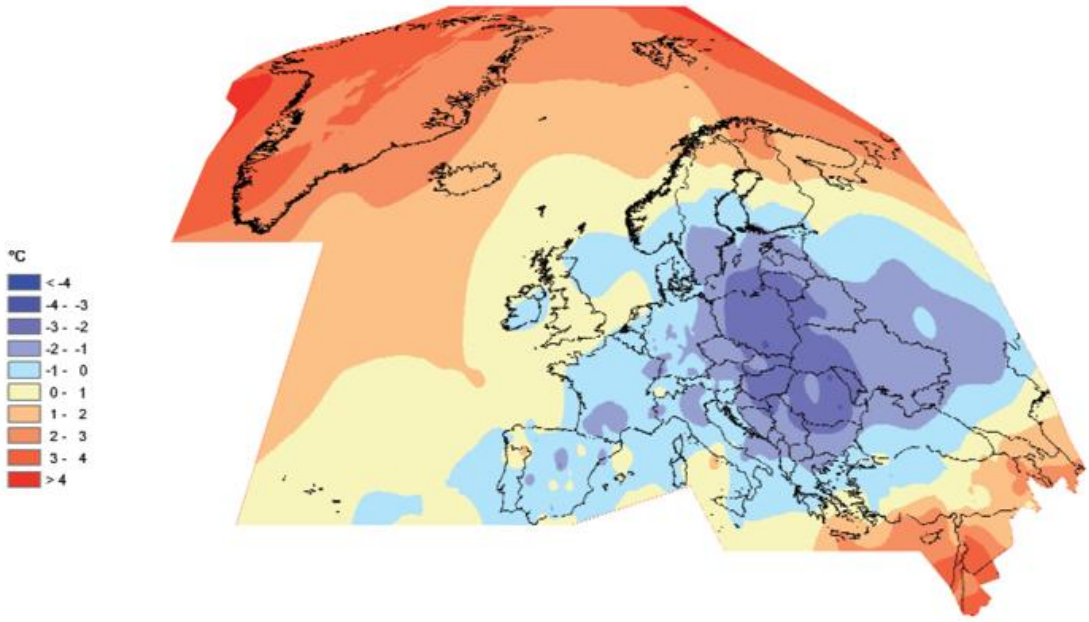

Fig. 10.1: *Monthly mean temperature anomalies in October 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Precipitation

It was wetter than normal in most of the Arctic region, especially in Svalbard (240% of the normal) and the northernmost parts of Scandinavia (Fig. 10.2).

In the United Kingdom, precipitation was close to normal in many areas, but it was drier than average in the west.

Nearly all other areas in northern, western, central and eastern Europe were drier than or close to normal. Fog was very frequent and long-lasting, especially near water surfaces in central Europe. The largest relative precipitation deficits were to be found in eastern Germany, Poland and central Sweden, with totals of 20% of the normal or less. In these two areas, the totals were lower than the 10th percentile.

Western parts of Iberia, France and the western Alps were wetter than normal, partly with more than 125% of the month's normal total, in southern France even 200–300% and in Lisbon in Portugal more than 300% of the normal precipitation.

The areas around the Black Sea and further east as far as west Kazakhstan as well as most of the Mediterranean region were also wetter than normal due to some heavy rain events. For the areas around the Black Sea, the 90th percentile was exceeded. Many of these areas

received more than 200% of the normal, e.g. some locations in Greece (Fig. 10.3). Locally, the totals were much higher, up to more than six times the normal in Turkey (e.g. Ankara). Malta had its 3rd wettest October since 1951.

The Middle East and Cyprus saw a very dry October (only 3 mm in Larnaca (Cyprus) compared to the normal of 19 mm; 4 mm in Damascus (Syria), normal: 12 mm). Israel and Jordan mostly received less than 60% of their normal total, locally less than 20% or even no precipitation at all.

Snow

Snow fell over most areas in Scandinavia and northern Russia as well as on the higher and lower mountains in central and parts of southern Europe. On 21 October, first snow fell in southern Germany down to 800 m altitude; on 25 October, first snowfall occurred in some alpine valleys down to 500-700 m altitude, with up to 20 cm of fresh snow in Carinthia (Austria). There were 18 days of snow on Kredarica Mountain in Slovenia (depth of 65 cm on 26 October). Azerbaijan in the South Caucasus region had some snow in the highlands, with depths up to 21 cm at the end of the month.

Significant weather events

October 05:	Italy reported heavy rain at the Ligurian coast. 3-hourly precipitation values in some places (Pero, Monte Gazzo and Pegli, all around 300–400 mm in 24 hours) exceeded the mean monthly values. On Monte Gazzo, one third of the mean annual precipitation amount fell within 6 hours.
October 09–12:	Rainy episodes in southern France led to several-day precipitation sums of more than 200 mm.
October 12–14:	Dust advection from Africa with wet deposition affected the whole country of Greece.
October 13–14:	123 mm rainfall in 24 hours was recorded in Bursa (Turkey). The return period of such an event is about 200 years. Lots of flooding and landslides occurred. Schools were closed for two days.
October 15–16:	Heavy rain (47–93 mm) and flooding of the rivers (water level 340–916 cm) in southern Krasnodar (southern European Russia) caused the death of 15 people. Mudflows in the mountains.
October 18–19:	Greek authorities declared a state of emergency on the Aegean Sea islands of Ikaria and Chios after flash floods left two people dead. Another ten people were trapped in their cars and had to be rescued. Authorities received 450 calls from owners of flooded homes and businesses. The daily precipitation sums of Naxos (55 mm) and Mytilini (82 mm) were well above the 50-year-return amounts for October based on the 1990-2009 time series. Islands of Xios and Ikaria received more than 200 mm in 24 hours.
October 25:	In Austria, the weight of the snow (up to 50 cm in mountainous regions) caused power lines in the Tyrol region to break.
October 26–28:	Heavy rain and thunderstorms in central and eastern Macedonia (Greece), with up to more than 200 mm in 24 hours. Heavy rainfalls also in Turkey, resulting in many flood and landslide events. Schools were closed for two days.
October 29–30:	Heavy rain hit Lisbon in Portugal with a daily total of 79 mm, 71 mm of which fell within 3 hours. Streets and places of the city were flooded.
October 30–31:	France reported an episode of extreme rain, with more than 100 mm of rain in 48 hours in the south-east of the country. The values partly were comparable or exceeded the mean monthly precipitation sums of October.

November

- **Cold in western and northern Europe, particularly in Scandinavia, very warm in central, eastern and south-eastern Europe and the Middle East**
- **Most of Europe wet, but very dry in the north and in the Middle East**
- **Early cold spell and widespread snow at the end of the month**

Atmospheric circulation characteristics

Cold Arctic air extended to most of Scandinavia, but came under prevailing high pressure influence. South of this high pressure zone, cold air from the north-east also moved temporarily to central, western, north-western and even south-western Europe, especially during the last week of November, leading to significant snowfalls and hard frosts at the end of the month. In addition, several deep Atlantic low pressure systems came from westerly directions and crossed north-western, western, central and eastern Europe, some of them were quite extended and intense. Numerous cyclonic disturbances also reached the Mediterranean area and Italy. During the first half of the month, mild subtropical air masses reached central and eastern Europe.

The Middle East and the South Caucasus region, temporarily also eastern and south-eastern Europe, continued to be mostly under the influence of high pressure and warm air.

Western Greenland was affected by a prevailing southerly flow of mild air from the North Atlantic and the Greenland high was stronger than usual.

Temperature

It was mild in western Greenland, with anomalies > +4°C; the central North Atlantic was also warmer than normal (Fig. 11.1). In southern Greenland, the 90th percentile was exceeded.

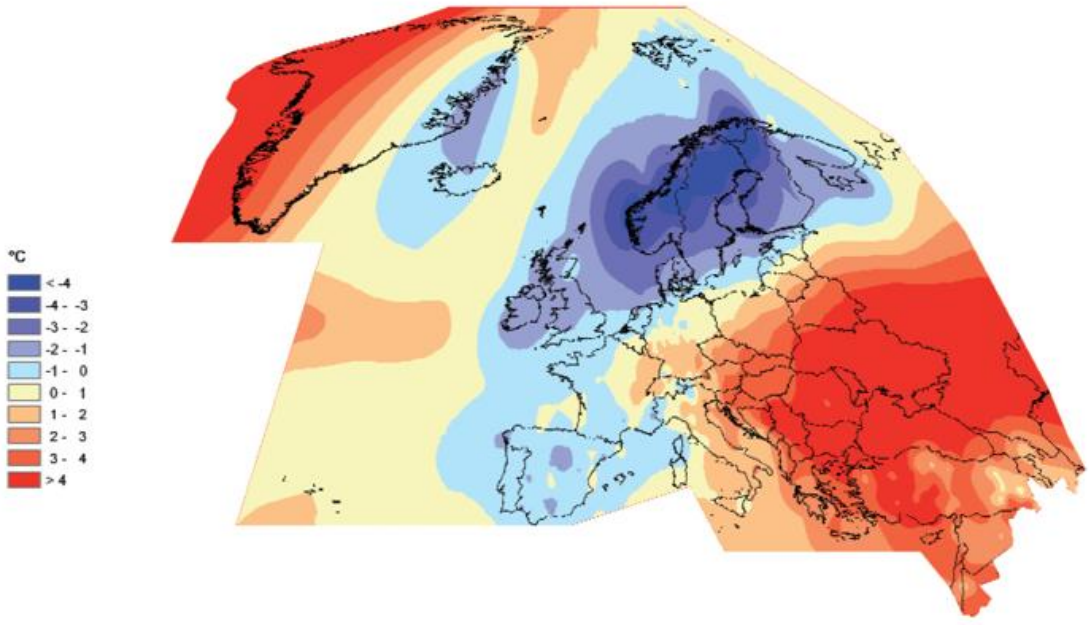

Fig. 11.1: *Monthly mean temperature anomalies in November 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Northern and large parts of western Europe were colder than normal, including the Arctic Sea. Especially the northern half of Scandinavia was very cold, with anomalies below -5°C, in Norway locally below -7°C. Temperatures were below the 10th percentile in nearly the whole of Norway (except the coasts) and most of Sweden (except the north-east). There was already ice on the Arctic Sea north of 78N. Norway had its coldest November since 1919, the United Kingdom since 1993.

Central Europe was mostly warmer than normal, in southern and eastern parts even between +1 and +4°C; only north-western Germany, the Netherlands and Luxembourg were slightly colder than normal.

The month started very mild in western and central Europe. During the first ten-day period of November 2010, it was unusually warm in several western and central European countries. On 4 November, high daily maximum temperatures of up to 19°C were recorded locally in the United Kingdom and widespread in Germany (except in the north of the country); later, on 14 November, 20°C were exceeded in Dresden in eastern Germany, which set a new local record for that time of year. Poland's maximum temperature reached up to more than 21°C, and Austria reported up to 23.7°C, both on 5 November; locally, these were new November records. The northern plains of Switzerland had up to 18°C, some valleys up to 21°C in the middle of the month due to foehn.

The cooling came particularly towards the end of the month in northern, western and central Europe. The Scandinavian countries reported very low temperatures that time, with a lowest minimum in Norway of -35°C at Karasjok-Markannjarga on 27 November. At many Norwegian stations, the records of the monthly mean temperatures and the absolute minimum temperatures were broken in the days 26–30 November. Similarly extreme low minimum temperatures were reported from Sweden with -36.6°C in Nikkaluokta in Lapland on 24 November or -34.4°C in Kvikkjokk-Arenjarka on 25 November (which was the lowest value since measurements started in 1888). Storlien-Visjövalen had -24°C on 28 November and thus its lowest temperature in November since 1962. Finland, too, experienced the coldest November days ever recorded. In Mariehamn on the Åland islands, the temperature was as low as -20°C.

The night of 27 to 28 November also brought extremely low temperatures to the UK; many November low temperature records were broken. In Wales, -18°C was recorded, in Scotland 15°C. Low temperatures were also measured in western France, with -10.1°C on 29 November at Mauron (Morbihan) or -15.3°C at Orleans (Loiret). Some stations in Germany, too, recorded very low temperatures at the end of November, locally less than -15°C on 30 November in south-east Germany. The Swiss station La Brévine registered -31.4°C on 30 November (a new record in 45 years); Poland recorded -14°C on 28 November.

Even Spain reported lowest minimum temperatures of -9.6°C on 29 November at Soria and -7.2°C at Leon-Virgen del Camino. These values were the lowest measured since 1942 and 1938, respectively. Portugal also reported lowest temperatures between -5 and -7°C on 29 November. The whole month was slightly colder than normal in almost whole Iberia and the western Mediterranean.

Most of eastern and south-eastern Europe, including south-eastern parts of central Europe (Slovakia, Hungary), Italy, the eastern Mediterranean as well as the Middle East and the South Caucasus region and the south-eastern Baltic countries were considerably warmer than normal. The 90th percentile was exceeded in almost all these areas. Lithuania had daily maxima up to 15°C in many places, breaking all previous records for November.

Anomalies were widespread above +4°C in south-eastern parts of the Region; they were highest in the eastern Ukraine, southern Russia and west Kazakhstan (Fig. 11.2) as well as in eastern Montenegro and parts of Israel, with more than +6°C; locally in Belarus, the Ukraine, Moldova, Serbia (Fig. 11.3), Bulgaria and at high elevations in Armenia, they were more than +5°C.

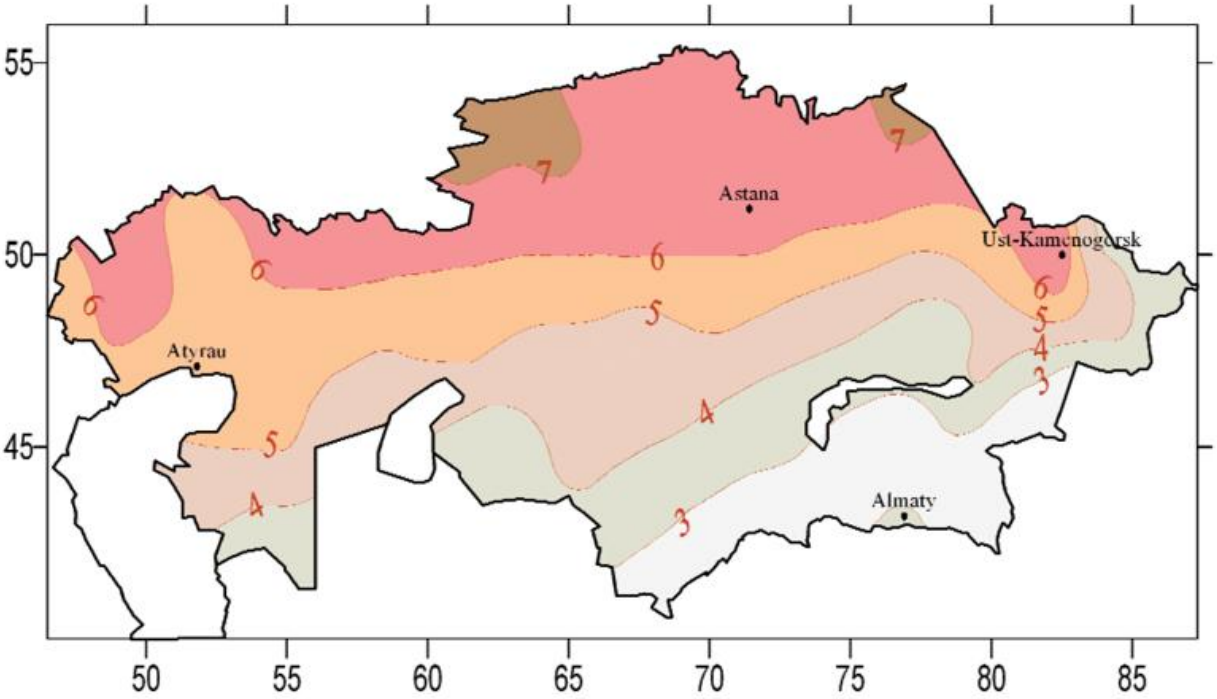

Fig. 11.2: *Monthly mean temperature anomalies in November 2010 (reference period 1971–2000) in Kazakhstan*
Source: Kazhydromet, Kazakhstan

The warm November in south-eastern Europe was characterised by several heat waves, which resulted in the high November averages. On 9 and 10 November already, warm air masses from Africa led to exceptionally high temperatures in that area. In Bosnia and Herzegovina, November was warmer than October, as had last been the case in 1963. It was the warmest November in 50 years in eastern, south-eastern and central Serbia, although no new records of maximum temperature were set. Instead, the duration of the heat was long; a 15-day heat wave took place in Serbia during the first two ten-day periods of the month. New maximum temperature records for November were set at 19 stations in southern and south-western Romania as well as at many stations in Bulgaria (highest maximum 28.9°C).

The first ten-day period was also particularly warm over most of European Russia and November temperature records were exceeded in many of its cities. In Moscow, 14.4°C was reached on 10 November, breaking an old record of 1927 (12.6°C) for that day of the year. Sochi, which is located at the Russian Black Sea coast, attained 22.1°C on 29 November, 1°C above the previous local record for that day of the year in 1990. During the first half of November, temperatures in European Russia were around +10°C above average. The extreme temperatures meant that badgers and hedgehogs could not go into hibernation and some species of hares and red squirrel did not receive their warmer winter coats. This can negatively affect the animals when regular temperatures return.

In the South Caucasus, daily maxima in west Georgia and Azerbaijan still reached up to 27°C. It was the warmest November since 1966 in Armenia.

In the Middle East, it was the warmest November on record in the mountain region of Israel, and up to 37°C were reached in the coastal plain and the Negev.

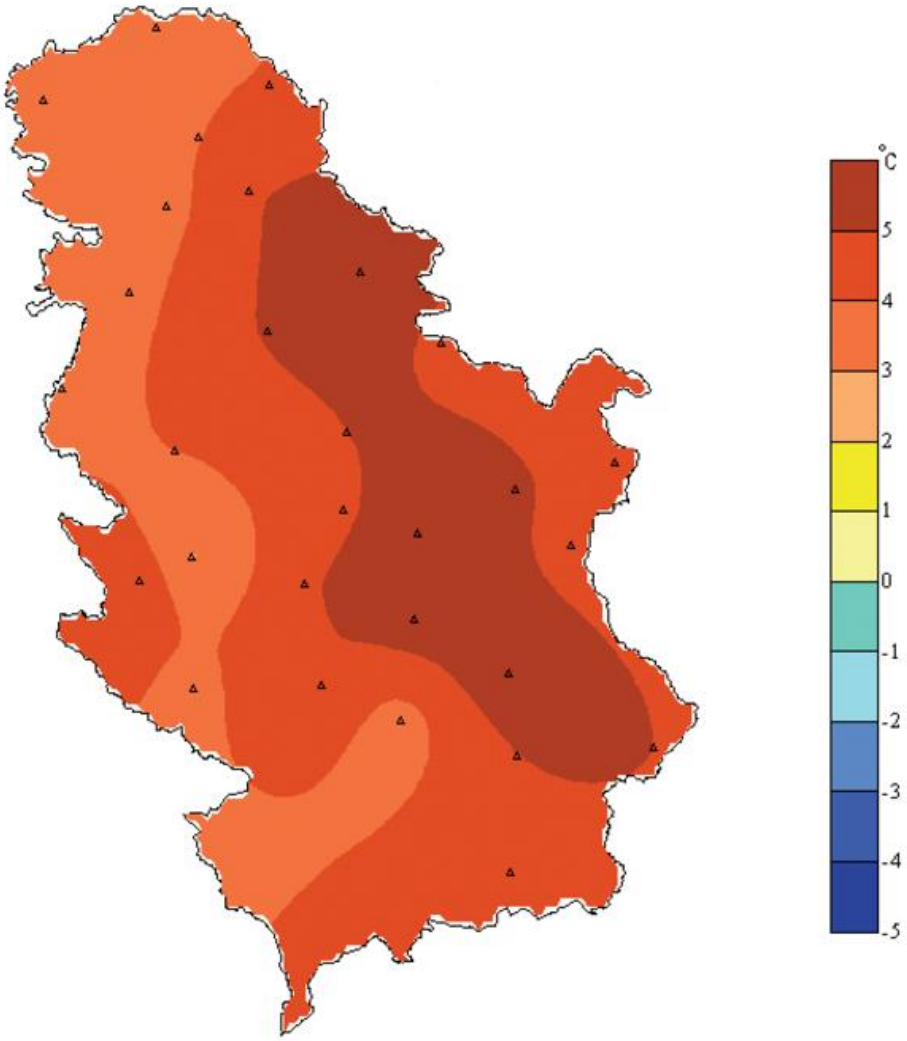

Fig. 11.3: *Monthly mean temperature anomalies in November 2010 (reference period 1961–1990) in Serbia*
Source: Republic Hydrometeorological Service of Serbia

Precipitation

It was mostly very dry in the Arctic region, in northern and central Scandinavia and on the Kola Peninsula (Fig. 11.4). Monthly precipitation totals were below the 10th percentile in nearly all these areas and locally less than 20% of the normal, in Greenland even below 10%. For south-eastern Norway, November 2010 was the second driest in the series going back to 1900.

In most of western, central and eastern Europe, including a large area around the southern Baltic Sea, precipitation was above normal. South-eastern Sweden was affected by heavy rain with some flooding. The United Kingdom was not so wet on average (close to normal in most areas), but heavy rain occurred in the first half of November. Several flooding events affected south-west England, northern France and Belgium. Locally, Germany and Poland, received more than 300% of the normal and high totals of 100–200 mm fell in many places in western parts of Europe. The 90th percentile was reached especially in eastern Germany, Poland, south-eastern Belarus and parts of western Russia.

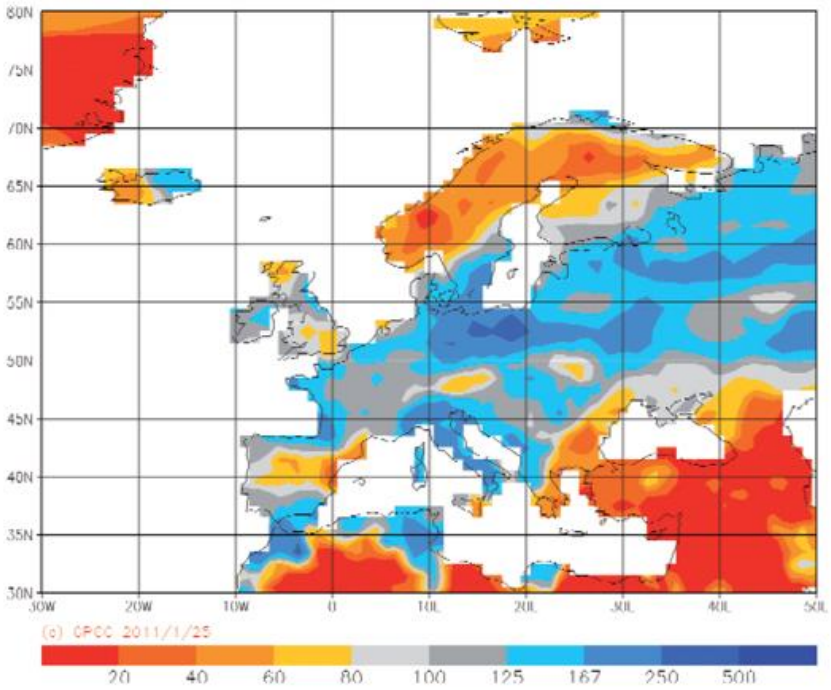

Fig.11.4: *Monthly precipitation amounts for November 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Southern Spain, the central Mediterranean, most of Italy and most of the Balkan Peninsula (except the east) were wet, with more than 125% of the normal totals. Three new monthly precipitation records were set in Italy, one of them at a station close to Piacenza, which had its highest monthly total of the time series starting in 1921, another one in Napoli with a monthly record total of 415 mm. More than 200% of the normal fell in places in Slovenia and Bosnia and Herzegovina, and almost as much in Montenegro. Especially in the second half of the month, heavy precipitation occurred in Montenegro and Bosnia and Herzegovina, in the former case within a series of 14 rainy days. 12 municipalities in Montenegro (out of 21) were continuously flooded, water levels in the lakes and rivers rose rapidly and more than 1,600 people had to leave their homes.

It was very dry near the Black Sea, over large parts of Greece (except the Epirus region in the north-west, which was very wet due to heavy rain especially at the end of the month), in the Caucasus region (north and south), Turkey, Cyprus, the Middle East, Malta and parts of north-eastern Spain, mostly with less than 20% of the normal precipitation. The totals were below the 10th percentile in the Caucasus region, Turkey and the Middle East. Many of these areas had only a few mm of precipitation or set new low precipitation records for November. Barcelona received only 6 mm of precipitation (8% of the 1961–90 normal). None of the stations in eastern Georgia received more than 5 mm; partly, there was no precipitation at all, like in places in Azerbaijan, Armenia, Turkey and Cyprus. It was the driest November in Cyprus since 1901 and the driest on record in Armenia, where not even a trace of rain was reported during the whole month, although November–December normally is the second rainy period there beside April–May. Several places in the Middle East (Syria, Lebanon, Israel, Jordan) were also completely rainless, which was not normal for that season. It was one of the three driest November months in Israel in the last 70 years; only 1946 and 1966 were also rainless at such a large scale.

Snow

In nearly all parts of Scandinavia and northern Russia, there was a snow cover during almost the whole month.

Snowfall was unusually heavy in northern Iceland during the middle of the month, whereas the south and west of the country only had light snowfall. A snow depth of 85 cm was reported at the station Kråkemåla in southern Sweden, setting a new November record for this area. Early heavy snowfall also affected large areas of northern and western Estonia due to the lake effect. Several Estonian stations measured new November snow depth records.

Since most of the month was very mild, snow came late in the month to most of the medium and lower regions of north-western, western, central and eastern Europe and was widespread in the last week of November. In central Europe, snow started to fall on low sites on 22 November. The United Kingdom saw its most significant and widespread late-November snowfalls (more than 40 cm) since 1965, particularly in eastern Scotland and north-east England, and its earliest widespread snowfall since 1993. At the end of the month, many countries were mostly snow-covered. In Germany, mountains of about 1,000 m altitude had 30–60 cm of snow, and even locations in the northern lowlands received up to 40 cm, the international airports Berlin, Munich and Leipzig between 1 cm and 16 cm. There were 200 flight cancellations at Frankfurt airport, Europe's third busiest international airport.

In the Alps, there was some snowfall already early in the month. Switzerland reported snowfall with up to 30 cm above 1,500 m altitude. Later, snowfall also occurred in lower areas and it snowed down to 600 m altitude locally on the southern side on the Alps. Austria, reported snowfall in lower places, too, e.g. in Bregenz (8 cm), Eisenstadt (10 cm) and Klagenfurt (20 cm). Kredarica Mountain in Slovenia had 275 cm on 30 November, setting new snow depth record for November since the beginning of measurements at that station. In the high mountains of Slovenia, snow persisted the whole month; at the end of the month, it also arrived in the lowlands, except the regions near to the coast.

Romania had a thin snow layer in some areas during the last ten days of the month; the depth exceeded 35 cm in some mountain areas.

In Montenegro, a long period of rain combined with higher-than-normal temperatures led to a rapid snowmelt in the mountainous regions.

In the south, there was some snow on higher and lower mountains, even in Iberia. Portugal reported snow at the stations Villa Real, Viseu, Braganca and Penha Duradas.

Significant weather events

November 01–02: Flooding in Veneto (Italy) after cyclogenesis over northern Italy and intense precipitation, locally exceeding 300–350 mm in three days. An area of about 140 km² was flooded; more than 6,500 people were isolated or displaced. The motorway between Verona and Vicenza was closed for a few days.

November 04: Heavy rain in the northern half of Germany, locally more than 70 mm in 48 hours, with flooding of streets in Hamburg. Strong wind gusts at the coasts and on mountains (141 km/h on the Brocken Mountain in Germany).

November 08–11: Heavy rain led to a flood situation in the Italian province of Salerno. 300 people had to be evacuated. Greece also had a heavy storm in Kerkira and north Peloponnese, with precipitation and flooding at daily totals up to 127 mm on 09 November. Heavy rain in Montenegro caused the water level in Morača (Podgorica) to rise by 10 m in just 48 hours.

November 08–12: Two deep areas of low pressure affected the United Kingdom and Ireland, the first bringing the lowest November mean sea level pressure to Heathrow Airport since its records began in 1949. Rain from the first system caused flooding in Emsworth in Hampshire. Homes were also flooded on the Isle of Wight, roads were closed and two schools were forced to shut. The second system brought a lot of damage and disruption due to the wind. Gale-force winds and torrential rain caused damage, with power lines brought down and bridges closed. The worst hit areas were northern England, north Wales and Northern Ireland, with gusts of around 130 km/h. Some 6,000 people in Northern Ireland were left without power. All ferry sailings across the Irish Sea were cancelled for a time. There was some localised flooding in Scotland.

November 11–14: A depression north of Ireland ("Carmen") brought intense rain and strong wind to large parts of northern France. In Granville (France), 48 mm of rain fell in 24 hours. The United Kingdom and Ireland also reported high wind speeds of > 100 km/h in gusts, with a maximum wind gust above 165 km/h at Capel Curig (Conwy, UK). The same low Carmen caused heavy rain in large parts of central Europe, due to a very stable zonal cold front. 2 people drowned in a flood in the Beaumont region (Belgium). In central and western Belgium, rivers and creeks flooded cellars and streets in many locations. Rail traffic was also affected. The station Uccle had 40 mm of precipitation on 13 November and accumulated 100 mm from 09 to 13 November, causing inundations especially in the centre of the country. In two days, Belgium received as much rainfall as it normally gets in a month. The Netherlands reported between 30 and 80 mm between 12 and 14 November, for Suid-Limburg 90–100 mm. The rain caused flooded streets and land-slides. Germany received heavy rain as well, with 48-hour values between 50 and more than 90 mm in a band between the Eifel and the Elbe east of the Harz Mountains. Highways near Dortmund and the fish market in Hamburg-Altona were flooded.

November 15–16: Ben Gurion International Airport in Israel had to be closed for several hours during the night due to visibility limitations. Seven consecutive nights with heavy mist and fog occurred in the coastal plain, which is uncommon for that area and time of year.

November 16–17: Heavy rainfall in the southern United Kingdom (Cornwall and parts of Wales) caused flooding and landslides. In Cornwall, streets and the mainline railway were closed and flash flooding affected over 100 houses. Heligan (Cornwall) received over 40 mm of rain in 2 hours. Ireland also reported localised flooding. Although damage was widespread, no fatalities or injuries were reported.

November 16: Germany received rain over a wide frontal band (depressions Ditte in the southern Baltic Sea and Emilya in the Mediterranean Sea), peaking to about 35 mm in 24 hours in Thuringia and northern Bavaria. The higher mountains had snow.

November 23: Thunderstorm with isolated hail at some locations in Romania (Calarasi, Medgidia, Videle).

November 27: Hail was registered in 19 out of 27 administrative regions of Bulgaria.

November 27–28: Southern Spain and the Baleares received heavy rain (e.g. Murcia 191 mm, Menorca 88 mm in 24 hours) due to a deep trough extending far south.

November 27–30: A lot of flights were cancelled due to snowfall in western and central Europe. 1,700 car accidents were counted in the German region of Northrhine-Westfalia. Many streets were closed throughout the country. Wind partly caused additional problems. The relatively warm southern Baltic Sea fed additional moisture into the air and caused even more snowfall in the eastern Holstein area (northern Germany), causing public traffic to break down and schools to be closed. In south-eastern Austria (Burgenland) and Hungary, the snowload was so heavy that trees and power lines broke and many thousands of households were without electricity.

November 29–30: Heavy storms in Bulgaria in the regions Morungash, Cherni and Botev, with gusts up to 122 km/h.

December

- **Very cold over most of Europe, warmer than normal in Greenland and the south-east of the Region**
- **Dry in northern and north-western Europe and in the South Caucasus region, wet in south-western, central and eastern Europe**
- **Long duration of snow cover in central Europe**

Atmospheric circulation characteristics

Similar to the previous winter 2009/10, December 2010 also saw extremely high negative North Atlantic Oscillation and Arctic Oscillation indices. High pressure was dominating over Greenland and Iceland, low pressure in the Azores region, which is the reverse of normal conditions. As a result, there was no westerly flow, but cold air from the Arctic spread out over nearly the whole European continent. A quasi-stationary front over central Europe persisted for several days, separating cold air from the north and milder air in the south. Especially in middle latitudes and in southern Europe, there was much low pressure activity, initiating frequent precipitation which came often as snow due to the low temperatures, temporarily in the southern half of central Europe also as rain.

Only some parts of south-eastern Europe, the Middle East and the South Caucasus region were mostly affected by warm and dry air from the south.

Temperature

It was warmer than normal in the Arctic, particularly in Greenland as well as in Svalbard, the very north of Norway, Iceland and large parts of the North Atlantic (Fig. 12.1). Anomalies in western Greenland exceeded +7°C and the 90th percentile.

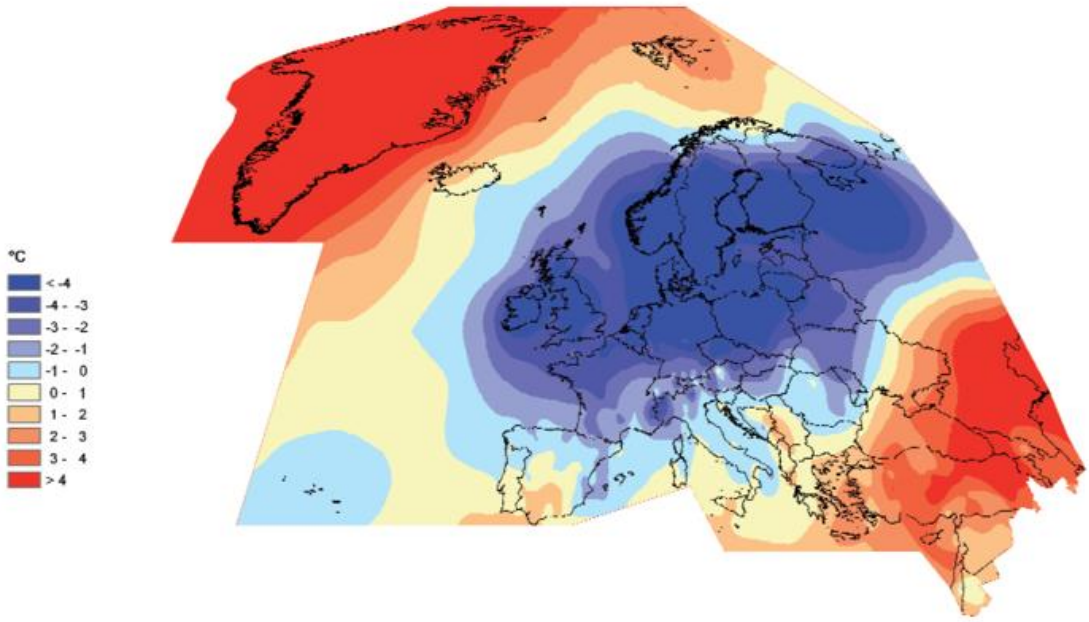

Fig. 12.1: *Monthly mean temperature anomalies in December 2010 (reference period 1961–1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Most of Europe, including adjacent ocean areas, experienced a very cold December, particularly during the first three weeks, except some parts of the south and south-east. Temperatures were below the 10th percentile over a large area covering the southern parts of northern Europe, the whole of north-western, western and central Europe and the northern parts of eastern Europe. In large parts of northern and central Europe, the anomalies were below -5°C, in many places even below -6°C. Highest negative monthly anomalies were as much as -10°C below normal at some locations in Norway and Sweden. High mountains in Switzerland (Jungfraujoch, Säntis) were around -3°C colder than normal.

Many places in Scandinavia had their coldest December on record. Some stations in southern Sweden also experienced the lowest minimum temperature, e.g. the station Linköping/Mamslätt reported -27.6°C on 23 December and a monthly mean of -8.2°C. The lowest temperature in Sweden in 2010 was -42.1°C at the station Nikkaluokta on 20 December. The harsh winter weather caused widespread problems for railway and road traffic, just like in January and February 2010. At -23.0°C on 22 December, the station Holbaek recorded the lowest temperature in Denmark since 1987. For Denmark as a whole, it was the second coldest December on record (only slightly behind 1981).

It was the coldest December in the United Kingdom in the last 100 years; the central England temperature record displayed its coldest December since 1890. In large parts of western and central Europe (Netherlands, Belgium, France, Germany), it was the coldest December in more than 40 years, in south-eastern parts of central Europe only since 1996 (e.g. in Vienna, Austria).

Minimum temperatures were also very low in western and central Europe and some local records were broken. Temperature minima in the United Kingdom dropped well below -15 °C in several locations between 18 and 25 December and remained below freezing during the day. On 23 December, Castlederg (County Tyrone) recorded -18.7°C, which was the lowest temperature ever recorded in Northern Ireland.

The lowest temperature in the whole of the Netherlands was -16.9°C on 20 December. Daily minima down to -18°C were recorded in north-eastern France. Daily minima below -20°C were measured in Germany and Poland, causing deaths due to freezing. The Czech Republic reported on 5 December that 68 of 151 stations recorded the lowest minimum temperatures for many years. In the higher Alps (altitude 3440m in Austria), minima were below -30°C; similarly low temperatures had last been measured there in 1981.

The number of frost days (minimum temperature <0°C) was also outstandingly high in western and central Europe. It was the highest number for December in the United Kingdom for over 50 years. Southern parts of northern Europe and northern parts of central Europe had frost almost the whole month (e.g. Luxembourg, Germany, Denmark, Poland, Lithuania), which was far above the normal of e.g. 17 days in Luxembourg or 15 days in Denmark.

In the south, even the Azores islands were colder than normal as a consequence of colder-than-normal sea surface temperatures due to an ongoing strong La Niña. Furthermore, northern Spain, the western Mediterranean, most of Italy and the northern Balkan Peninsula were colder due to several cold spells reaching the south throughout the month. Anomalies in northern Italy were below -2°C in places. A daily minimum of -48.3°C was recorded at Pale di San Martino on 27 December, the lowest temperature ever recorded in Italy. Like in Croatia, it was only slightly colder than normal on average in Slovenia because of two mild spells during the month.

In contrast, the south-east of the Region and the southern Mediterranean saw once more a mild month. It was warmer than normal in southern parts of the Balkan Peninsula, Turkey, the Black Sea, the eastern Ukraine, southern European Russia, west Kazakhstan, the South Caucasus region, Cyprus and the Middle East. The monthly mean temperatures were higher than the 90th percentile in nearly all of that area, partly even higher than the 98th percentile.

High temperature maxima were measured in southern Italy and on the Balkan Peninsula, locally with new records, e.g. in southern Italy and at Mostar in Bosnia and Herzegovina, the latter with 19.4°C on 9 December (previous record in 1971). Maxima up to 23°C were reached in Bulgaria. Especially the first half of the month was mild in Greece. In the second half, some extremely cold days were also recorded in south-eastern Europe. Zabljak in Montenegro had a daily maximum of -10.7°C on 14 December, the lowest daily maximum for that day of the year in 50 years. Similarly, Western Macedonia, too, had cold temperatures even below -12°C; even Greece experienced a considerable cooling later in the month.

In contrast, high monthly anomalies were observed in southern European Russia (> +7°C in individual regions) and in west Kazakhstan, Azerbaijan, Armenia and central Turkey, all up to +5°C or +6°C. Daily maximum temperatures near the Black Sea coast in European Russia and west Georgia reached up to 25°C (at the Russian station Wladikawkas in the North Caucasus even 27.1°C on 6 December, a new winter maximum temperature record for Russia), and roses bloomed in the north Ossetia valleys in the North Caucasus. On 26 December, Stavropol (also in the near area of the North Caucasus) still reached 17.1°C, exceeding the previous temperature record of 1954 by +6°C.

The eastern parts of the South Caucasus region also registered a new 100-year record of 22.7°C in Baku (Azerbaijan) on 12 December (previous record was in 1906). Similarly, Armenia recorded 20–24°C in the lowlands of its very southern and north-eastern parts.

Israel was especially warm on the first days of the month, with temperatures reaching up to 31°C in the coastal plain, the Negev and the Jordan Rift.

Precipitation

Nearly the whole of the Arctic region (except western Greenland), northern European Russia, Scandinavia, the United Kingdom and Ireland were far drier than normal (Fig. 12.2). The monthly totals were mostly smaller than the 10th percentile. Locally, they were less than 20% of the normal.

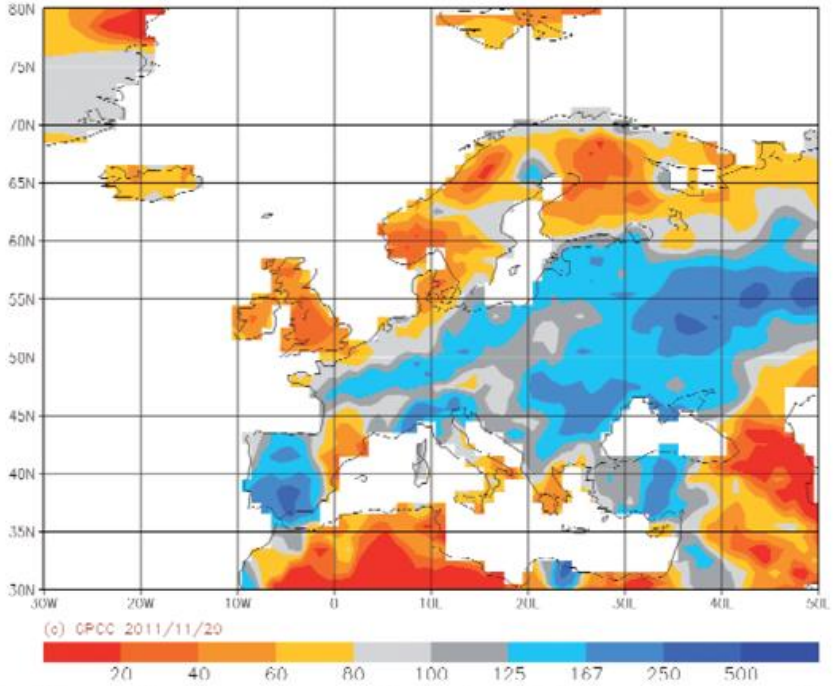

Fig.12.2: *Monthly precipitation amounts for December 2010 in per cent of the 1951–2000 normal in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Less than a third of the average rainfall was recorded over large parts of the United Kingdom. It was the driest December over the UK since 1963 and the third-driest in the 100-year series.

Large parts of western, central and eastern Europe were mostly wetter than normal. Strasbourg in eastern France had more than 300% of its normal precipitation due to a quasi-stationary cold front. The 90th percentile was exceeded only in some areas of central and eastern European Russia (around 400% of the normal in Kasan), the Ukraine and Romania. Latvia saw its wettest December for 87 years. Monthly precipitation totals in Lithuania amounted up to 95–120 mm in the western border regions, which was 150–200% of the normal. There was a huge flooding on the rivers of Transcarpathia, causing damage to settlements and infrastructure; historically high water levels were reached.

Some areas in the southern parts of the Region were wetter as normal, such as the Azores Islands, most of Iberia, northern Italy, most of the Balkan Peninsula except the south and most of the western half of Turkey due to some heavy rain events. Monthly precipitation in Iberia was among the highest in Europe and thus consistent with the tendency for above-normal precipitation in this region during negative NAO periods. On the Azores Islands as well as locally on the Balkan Peninsula (e.g. in Bosnia and Herzegovina), monthly totals were close to 400% of the normal or more; in southern Spain, they were higher than 300%, exceeding the 90th percentile. The wet weather also led to flooding of the north Hungarian rivers. In Serbia, the number of precipitation days was high, whereas the monthly totals remained within their normal range in most parts of the country.

On the other hand, many parts of the Mediterranean region (eastern Spain, central and southern Italy, Malta, Greece and Cyprus) were dry, partly with totals of less than 60% of the normal, although heavy downpour occurred and caused floods in the Greek regions Epirus and Crete.

A large area in the south-east of the Region (western Kazakhstan, southern European Russia, South Caucasus region, eastern Turkey and eastern Syria) was very dry, locally with less than 20% of the normal. The totals were below the 10th percentile particularly in western Kazakhstan and the South Caucasus region. It was the driest December on record (since 1966) in Armenia; only 2 mm of precipitation were registered in Yerevan, less than 10% of the normal. Other places of the Middle East (in the Lebanon, northern Israel, Jordan) were wetter than normal.

Snow

Heavy snowfalls disrupted traffic severely in many parts of Europe. Large areas of northern and central Europe, including the Alps, were covered by snow almost the whole month, partly reaching depths of more than 40 cm in the lowlands of central Europe, which is quite rare. Snow depths were even higher than at the beginning of the year. Roads, railways and air traffic were severely affected. Airports were forced to close in the Netherlands, Belgium, France, Germany and Switzerland. Many schools were closed, too.

Snowfalls occurred in almost all areas of the United Kingdom, especially in the first week, reaching depths of over 40 cm in parts of north-east England and eastern Scotland; 30 to 40 cm fell locally in parts of central Scotland in the morning of 6th. There was further widespread snow across the UK from mid-month to Christmas. The snowfalls were comparable to those experienced in January 2010, and were the most widespread and significant in December since 1981.

The Netherlands had just two days which were completely free of snow. Uccle in Belgium had 21 snow days that month, the highest number ever recorded since 1901. In France, particularly over Ile-de-France, such conditions of frequent snowfall and very low temperatures had not been observed for the last 30 years. It snowed for 14 days in Paris-Montsouris, leading to a total depth of 12 cm, the highest depth at this station since 1980; other French stations reached similar records.

Large areas of central Europe saw a white Christmas, which is unusual in the lowlands. Germany had its first white Christmas in most of the area since 1981. On 25 December, even the area near the Rhine River reached snow depths above 25 cm, which is quite extraordinary for that region. Around Berlin, the maximum snow depths of December 2010 were partly the highest December depths ever measured in more than 100 years. For the first time ever, Denmark saw a second nationwide white Christmas in a row (after 2009).

The Alpine region received a lot of snow, too. At 31 cm, a December snow depth record was broken in Geneva (Switzerland), forcing the airport to close for hours. Bern and Zürich also got new local snow depth records for December (57 and 58 cm, respectively). Before, such depths of fresh snow had been measured only in 1962 and 1979. Another snowstorm hit the plains of Switzerland on 17 December, bringing a widespread layer of 10 cm or more. On Christmas Day, the lowlands of northern Switzerland from Geneva to Lake Constance were covered in white and that remained until the end of the year. Snow also lay over the whole country of Austria already from the beginning of the month, reaching extraordinary depths also at lower stations. In Vienna, a maximum snow depth of 28 cm was measured, which happens approximately every 20 years and had not occurred for the last 29 years. Likewise, about 30 cm of snow fell in the Czech capital Prague on 2 December. On Kredarica Mountain in Slovenia, a maximum depth of 400 cm was recorded on 25 December, which was the highest depth ever measured there in December. Snow was also to be found in the lowlands of Slovenia for a period of 2–4 days; 35 cm were registered in Ljubljana.

In north-eastern parts of Europe, there were also unusually large amounts of snow in coastal areas in southern Finland. In the Helsinki area, the recorded snow depth of 67 cm was close to the deepest ever recorded. Estonia reported record-breaking snow depths from 20 out of 31 stations, with depths of 37–60 cm on 10 December. These values were the highest since December 1965 or earlier. The monthly average snow cover in Latvia was four times the normal, and it was the second snowiest December there for 87 years. At Christmas, however, a warmer spell with freezing rain occurred, causing an ice layer covering almost the whole country. Trees falling on power lines due to icing caused prolonged power failures. In Lithuania, a record-breaking mean depth of 39–56 cm was reached at the end of the month. Poland had a snow cover on all days of the month at most of the stations, with maximum snow heights of typically about 20–40 cm.

Even in the south of the Region, there was some snow, at least temporarily. Portugal had some snowfall in the highest areas of its northern and central parts. Italy saw depths of 10–30 cm. The Italian Isle of Capri experienced its first snow in 25 years on 3 December. On the Balkan Peninsula, a sudden heavy snowfall occurred across Bosnia-Herzegovina after a cold front passage in early December. From 17–19 December, it snowed in the whole of Montenegro. Further temporary snowfalls occurred in Macedonia and northern Greece; the station Larissa in eastern Greece received 30 cm of fresh snow on 16 December. Turkey had a widespread snow cover on two days. By the end of the month, a thin snow cover of 22 cm had formed on the slopes of the Aragats Mountain in Armenia at altitudes higher than 3000 m. In west Kazakhstan, heavy snowfall combined with temporary strong cooling occurred at the beginning of the month. Some non-accumulating snow was measured even locally in Jordan.

Significant weather events

December 02–05: In Israel, a large forest fire in the Carmel Mountains near Haifa broke out after a very dry 9-month period. It caused the death of at least 44 people. Continuous dry weather and strong winds prompted it to become one of the biggest wildfire in Israeli history and made it difficult to extinguish the fire. Over 41 people died in a bus caught in the flames. Around 17,000 people had to leave their homes and almost 5,000 hectares of land were burned.

December 02–05: A powerful Mediterranean cyclone first brought strong southern winds and then abundant rain to the west and the north of Bulgaria. The rivers coming downhill from the steep mountain of Vitosha into the capital city of Sofia flooded the freshly built ring highway. In the aftermath of the heavy rain, a part of the main road that links Sofia to Greece came to collapse, practically cutting the south-west of Bulgaria off from Sofia for as long as one week (Fig. 12.3).

Flooding and mudslides were also reported from northern Albania; more than 12,000 people had to leave their homes and 14,000 hectares of farmland were destroyed. Locally, the River Drina rose to its highest level in more than a century. Streets in the town of Shkodra were inundated by six and a half feet (two meters) of water. The only ways into or out of town were by boat or helicopter. Extremely heavy precipitation was also registered in eastern and southern parts of Bosnia and Herzegovina on 2 December; it was the wettest period on record there since beginning of measurements (Fig. 12.4). In northern Bosnia, the heavy rains triggered a landslide in the city of Tuzla, three people were killed. In southern Croatia, the River Neretva reached its highest level in 50 years, flooding 700 homes in the town of Metkovic.

Fig. 12.3: *Bridge over the river of Dzherman (south-west Bulgaria) destroyed during passage of a powerful cyclone on 02–05 December 2010*

Fig. 12.4: *Flooding in Gorazde (Bosnia and Herzegovina) after extremely heavy precipitation on 02 December 2010*
Source: Gorazde.tvsa.ba, provided by the Federal Hydrometeorological Institute, Bosnia and Herzegovina

December 03: High tides in Venice (Italy) reached 1.36 m above sea level, flooding more than half of the lagoon city, including the central St Mark's Square. The water level marked a record high for Venice. The tide was pushed up by a combination of heavy rains and strong winds that hit large parts of northern Italy.

December 04: Overflowing of the lake of Ioannina city (western Greece) due to successive rainfall events starting already in November.

December 05–08: Heavy precipitation affected extended areas in western Iberia, especially central and north Andalusia. 4-day totals ranged between 160 and 334 mm, and daily totals of 100 mm or more fell on 07–08 December in Andalucia (regions of Cordoba and Seville). The Guadalquivir River caused severe flooding near Seville, where dozens of homes had to be evacuated and at least 2 people died. A tornado developed in Portugal near Serta and devastated an industrial area (even a hall made of metal). The tornado was classified category EF3 on the extended Fujita scale.

December 06–13: 113 settlements in the Ulyanovsk region (central European Russia) were cut off from electricity because of glaze ice layers of 18–50 mm, causing state of emergency.

December 07–09: Snowstorm Monika and its very active slow moving front caused abundant precipitation in large parts of central Europe. The front separated cold air masses in the north with frequent snowfall and warmer air masses in the south with rain. On 09 December, freezing rain caused the temporary closure of Frankfurt Airport (Germany). Storm Monika also contributed to a considerable increase in snow depth in Estonia (e.g. 38 cm in 24 hours in Väike-Maarja). Road and rail transport was seriously affected. The snow load caused much damage to roofs, trees and power lines.

December 09: During a strong cold front at the station Kab-hegy in Hungary, a record wind gust of 170 km/h was measured.

December 10: Severe rain and flooding forced hundreds to leave their homes in the western Ukraine. The worst affected region was Zakarpattia.

December 11–13: Strong northern winds with gusts over 100 km/h over various islands in the Aegean Sea within an extratropical cyclone. Heavy rain and floods affected particularly Greece, western Turkey, later also the Lebanon and Israel, especially the coasts and harbours. On the Greek island of Samos, coastal roads were closed due to fallen rocks. Along the coast of Lebanon, waves up to 10 m high were observed. Stormy wind and high sea motion caused a transport ship to sink near the coast of Israel and heavy damage to areas close to the sea shore. Five people lost their lives. In Israel, the winds also knocked out power to hundreds of people and downed trees. In Jordan, highways were closed as winds reached speeds above 90 km/h and sand limited visibility severely. On a positive note, the storm ended a lengthy drought in Lebanon, Syria, and Israel.

December 15: Sorvaag (Faeroe Islands) had winds up to 135 km/h with 150 km/h gusts (on nearby hill) within snow squalls on passage of a powerful cold front. The temperature fell from 9°C to -5°C with a wind chill below -15°C. Conditions were less extreme on Shetland and Orkney, yet still harsh with freezing gales and bursts of snow.

December 15–18: Abundant snowfall in Italy after an intense cold spell (temperatures between -12 and -15°C in the region of Friul) and due to a frontal system with strong warm advection in the middle troposphere moving from north-western to south-eastern Italy. Florence had 10 cm of snow and even the coasts saw some snow which lasted just for one or two hours on 17 December. Greece and Macedonia also had very low temperatures (below -12°C in western Macedonia) and snowfall. A station on Crete (Greece) reported 41 mm of daily precipitation on 16 December.

December 18: Heathrow Airport in London was closed in the run-up to Christmas due to heavy snowfall.

December 23–24: Ship traffic in the harbour of Hamburg (Germany) was affected by ice. Parts of the islands Fehmarn and Rügen in the German Baltic Sea were cut off from the outside world. Just before Christmas, snow and freezing rain affected air and road traffic considerably in northern and eastern Germany.

December 25–26: Freezing rain in central European Russia. Operation of Moscow airports was brought to a standstill owing to ice. Hundreds of settlements were cut off from electricity.

December 30: Heavy storm in Botev region (Bulgaria) with gusts of 100 km/h.

ECSN Activities Report 2010

Support and co-operation in best climate practices

Responsible Member: KNMI; Programme Manager: Aryan van Engelen

The objective of ECSN, the European Climate Support Network, an optional Programme of EIG EUMETNET, is to support its members in their climate practices in order to provide better products and services to the European user community for the benefit of the environment, safety, economy and health.

In 2010, this objective was realised by a range of activities: running new programmes and projects (ECA&D, ECSM/RCC-CM, EUMETGRID, PEP725, Climate Change Services and HIST-EU), focusing on a better understanding of Europe's past, present and future climate and the provision of data and products, participating in or collaborating with major EU research projects: ENSEMBLES, MILLENNIUM and EURO4M, communicating and co-operating with other parties, such as WMO, WMO-RAVI, EEA, ESA, EUMETSAT, EUMETNET-EUCOS, EUMETNET-SRNWP, and co-ordinating activities: preparing and organizing the climatology programme of the EMS-ECAC 2010 and the ECSN Data Management Workshop 2011.

EIG EUMETNET

As of 1 January 2010, all (EUMETNET) activities (including ECSN) were transferred to the new EIG EUMETNET, which now has the legal status enabling it to sign contracts with third parties, bid for EU projects and employ staff. The three strategic goals over the next (10) years are: to improve efficiency by means of programme activities and changing to shared services, to invest collectively in science, technology and skills and to be an essential partner for EU/EC whenever capabilities and services from the meteorological community are required. It has been recognized that there is a need for more extensive European climate (change) services than are currently offered by EUMETNET. A new working group on Climate Change Services (co-ordinated by KNMI) was established to survey the European needs and the role to be played by EUMETNET and its Members, taking account of the Members' capabilities which include the Regional Climate Centres. The ECSN programme was extended by another year until 1 January 2012 and the PM ECSN was appointed as Interim Programme Manager Climate.

EUMETGRID (Met.no, http://eumetgrid.eu)

The main objective of EUMETGRID is to provide seamless access to the best available high-resolution gridded data sets in Europe and their related products and services. To achieve this goal, a main task is to develop and maintain a sustainable pan-European data infrastructure for accessing and distributing gridded climate information, based on the NMHS's sustainable observational networks, databases and meteorological infrastructures.

Highlights:

- EUMETGRID started with a kick-off meeting in Oslo on 25-26 January 2010.
- 24 European countries participate in EUMETGRID.
- EUMETGRID wiki has been established.

ECSM/RCC-CM (DWD, http://www.dwd.de/rcc-cm)

The aim of ECSM (European Climate System Monitoring) was to build a sustained operational Web platform for climate monitoring products in WMO RA VI. These efforts complement successful regional climate monitoring activities, such as the RA VI Bulletin, the European contribution to the annual BAMS Article on the State of the Climate, European contributions to the annual WMO Statement on the Status of the Global Climate, ECA&D, etc. All these activities are basic components of a systems approach for co-ordinated operational climate monitoring in WMO RA VI. Based on the analysis of a questionnaire on RA VI operational climate monitoring requirements (Gocheva, Hechler, Dec. 2007), the systems approach aims at implementing a RA VI RCC (Regional Climate Centre) node for climate monitoring.

Highlights

- 24 countries contribute to ECSM/RCC-CM.
- ECSM has been integrated into the technical platform of the RCC on Climate Monitoring (RCC-CM), which is currently in its official pilot phase.

ECA&D-ENSEMBLES/MILLENNIUM/EURO4M (KNMI, http://eca.knmi.nl)

The European Climate Assessment and Dataset (ECA&D) is aimed at creating and maintaining a pan-European set of high-quality daily observational data series and, on the basis of derived climate change indices, at producing assessments of climate change in Europe. ECA&D is based on a data set (E-OBS), which currently includes approx. 4,800 stations and over 26,000 time series. It was originally developed as part of the ENSEMBLES and MILLENNIUM projects (EU-FP6) and is now maintained and elaborated as part of the EURO4M project (EU-FP7). Like ECSM, it will serve as a platform for a RA VI Regional Climate Centre on Climate Data (RCC-CD).

Highlight

- ECA&D will be the technical platform of the RCC on Climate Data, currently in the official pilot phase.

PEP725 (ZAMG, www.zamg.ac.at/cost725)

Phenology is the study of the timing of recurring biological events in the animal and plant world, such as leaf unfolding and flowering of plants in spring, fruit ripening, colour changing and leaf fall in autumn, as well as the arrival and departure of migrating birds and the timing of animal mating. During the past decade, phenology has rapidly become an important tool for climate change impact studies.

Under Cost Action 725, a prototype database of European phenological records was set up. An ECSN project under the name PEP725 aims at the establishment and sustainable management of a full-scale phenological database.

Highlights

- Work plan and work packages have been defined.
- Kick-off in Dublin on 17 June 2010

Roadmap for embedding observation requirements from climatology in EUCOS

The roadmap aims to define a EUCOS Surface Climate Land Station Network (ESCLSN) as the climate counterpart of the EUCOS Synoptic Surface Land Station Network (ESSLSN). Key considerations of the roadmap are:

- The observational network should provide data sets that serve climate impact assessment and adaptation to climate variability and change.
- The network should become part of the EUCOS concept.
- The network should cover the whole of RA VI.
- The network should include terrestrial in-situ surface observations.
- The network sites should be available for electronic access (E-VCOMP).
- The design should be based on expert selection of stations from existing networks (WMO-SYNOP, EUCOS, RBSN, RBCN, GSN, ECA&D) and fulfil the demands of the major (European) climate services and projects, such as GMES, RCC, CCS, ECA&D, EUMETGRID, EuCLIS, SRNWP etc.
- Selection should be made according to the site and instrument criteria arising from the mentioned services, WMO and WMO-GCOS.
- Highest priority should be given to climatological reference stations.

HIST-EU (ZAMG)

The Responsible Member of the successfully completed HRT-GAR project (ZAMG) launched this initiative in order to extend the current HIST-ALP project (aiming at the creation of a database of long-term monthly homogenised series over the Greater Alpine Region) to the whole of Europe, with the following two main objectives:

- To extend HIST-ALP to HIST-EU with a climatological network described as long-term, of appropriate density, quality-improved, homogenised and of European relevance.
- To support data rescue activities to achieve an optimal European station density.

Highlights

- A questionnaire on potential user requirements was distributed and obtained a very positive response.
- Proposal elaborated.

10th EMS Annual Meeting and 8th European Conference on Applied Climatology (ECAC), Zürich, ETH, 13-17 September 2010

The theme of the conference was: “High-resolution climatology – towards climate change services”.

The session programme dealt with the following four major topics, which had been agreed with WMO GFCS:

- Monitoring for a reference climate and monitoring change
- Understanding processes and climate change
- Services translating science to users
- Plenary sessions on communication and adaptation strategies for climate change

The conference attracted a large number of experts (630) from 44 countries and high-quality contributions. Especially the Climate Services session and the Plenary sessions on Communication on Climate appeared to be very attractive.

ECSN Data Management Workshop (DMWS) 2011, Edinburgh, UKMO, October 2011

UK Met Office offered to host the DMWS 2011 in Edinburgh from 12-14 October 2011.

The Ozone Layer over Central Europe in 2010

Wolfgang Steinbrecht, Hans Claude, and Ulf Köhler - Deutscher Wetterdienst

2010: Highest ozone columns in 25 years

The annual mean ozone column for 2010 substantially exceeded the long-term mean since 1968 for the first time again after many years. At nearly 340 DU, the annual mean for 2010 reached the same high level as recorded in the 1980s, as shown by Dobson and Brewer measurement series at Hohenpeissenberg station in southern Germany (Fig. 13.1). The last time Hohenpeissenberg recorded similarly high annual means was in 1984, i.e. 26 years ago. Practically all monthly means of 2010 are above the long-term median (50th percentile), partly even above the 67th percentile.

Satellite data from Bremen University in Germany and from KNMI in the Netherlands showed that this distinctly positive development was not only observed at Hohenpeissenberg, but also for almost the whole northern hemisphere.

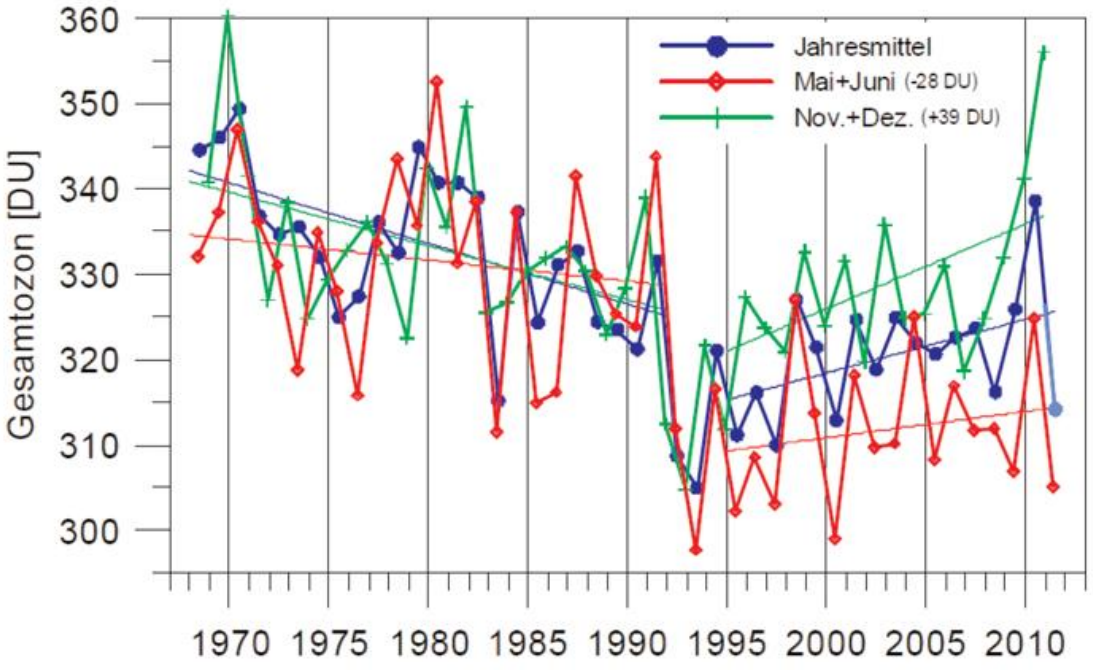

Fig. 13.1: *Ozone columns above Hohenpeissenberg. Blue: Annual mean ozone levels. Red: Mean ozone for May and June, shifted downwards by 28 DU. Green: Mean ozone for December and January, shifted downwards by 39 DU. The annual mean for 2011 is only an estimate (data for November and December of 2011 not yet available). Source: Deutscher Wetterdienst, Germany*

On average, the ozone columns in 2010 remained below normal only between 0°N to 20°N, from central America across the Atlantic to northern Africa, over wide areas of the tropics, and also in some parts of the southern hemisphere. In general, the spatial distribution of the 2010 ozone anomalies suggests increased transport of ozone from the tropics towards northern latitudes due to an increased Brewer Dobson circulation (in particular during the first half of the year). The importance of the quasi-biennial oscillation (QBO) of stratospheric winds over the equator should not be underestimated: easterly wind shear (between 50 and 20 hPa) in the tropics, if persisting from the end of the previous year into late spring, causes the Brewer-Dobson circulation to increase in strength.

As a result, more ozone than normal is transported northwards (e.g. in 2010, 1998, 1994). If there is a westerly wind shear, however, less ozone will be transported polewards (e.g. in 2008, 2002, 1997). The difference between the easterly and westerly phase of the QBO can reach up to 20 DU (see the years 2010 and 2008 in Fig. 13.1). In Europe, ozone columns also correlate highly with the North Atlantic oscillation (NAO) index, which roughly describes the distribution of high and low pressure areas over the North Atlantic. Positive index values are accompanied by low ozone levels above central Europe, and vice versa. In 2010, the values of the NAO index were as negative as in the 1960s. This coincided with frequent trough situations and low pressure activity over central Europe down to the Mediterranean and with high ozone columns. On the contrary, the local ozone minimum in western Russia probably resulted from the stationary, high-altitude anticyclone residing there in the summer (record summer with continuous heat-wave and forest fires).

What about the effects of chemistry? Ozone-depleting chlorine and bromine in the stratosphere have been decreasing for around 10 years now. Model computations show that from the chemical viewpoint no such large ozone increase can be expected from one year to the next. The chemical ozone increase induced by declining chlorine would only result in ozone columns that are about 4 DU higher than those of the mid-1990s, and almost equal to those of 2008 and 2010. Even though we do not yet know, or fully understand, all the factors that are responsible for the high ozone columns in 2010, it is a pleasure to finally be able to report again about 'good ozone columns', such as those during the 1980s – although the levels decreased again in 2011. The beginning chemical recovery of the ozone layer certainly has its share in this increase, despite the fact that globally – but not in Europe – the year 2010 was one of the warmest in terms of surface temperature.

Ash cloud from Eyjafjallajökull volcano affects ozone over Bavaria, Germany

The volcanic eruption of Iceland's Eyjafjallajökull ('island mountain') glacier in April 2010 is not the first volcanic event in the last two years to become clearly visible in the measurements taken at DWD's Hohenpeissenberg Meteorological Observatory. Already in August 2008, and again from the beginning of July 2009, the lidar at Hohenpeissenberg had recorded plumes of ash from the volcanic eruptions of Kasatochi (Aleutian Islands) and Sarychev (Kuril Islands). Unlike Eyjafjallajökull, these two volcanoes ejected their ash clouds high into the lower stratosphere (up to approx. 20 km). From there, stratospheric winds rapidly dispersed the aerosol clouds across the northern hemisphere, carrying them as far as central Europe despite the large distance. In comparison with the much more violent eruption of Mount Pinatubo on the Philippines, however, their impact on climate and ozone layer is negligible.

However, with a maximum height of only 10 km, the ash plume from Eyjafjallajökull did not reach the stratosphere. But due to Iceland's geographic location, it did enter the mid-latitude west wind drift and was rapidly carried to central Europe. During the first days of this extraordinary event, there were no means to directly and quantitatively measure the concentration of dust in the air. Instead, indirect methods were used to determine at least height and extent of the cloud.

Ozone being a highly reactive gas (which oxidises and decomposes very readily on almost all surfaces), it should be possible to detect volcanic ash by the effect it would have on the vertical distribution of ozone. This is why, extra ozone sondes were launched in addition to the DWD's regular ozone measurement programme. One of these supplementary sondes launched on 17 April 2010 must have flown through the ash cloud between about 3,000 m and 6,500 m. In fact, the ozone concentrations recorded showed a dramatic decrease, down to nearly 0 ppmV, before rapidly increasing again.

Conclusion: tropospheric ozone concentrations over Hohenpeissenberg were severely reduced due to increased surface reactions within the volcanic ash cloud. This means that it is possible to make qualitative statements about the presence of volcanic ash clouds and their dispersion. Other measurements have shown, however, that the impact of sulphur dioxide or other air pollutants on the ozone measurements should be small (see DWD Ozone Bulletin No. 126 (2010) for more details: www.dwd.de/ozonbulletin).

Outline

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI NMHSs as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network and WMO's World Climate Data and Monitoring Programme the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's ***Annual Statement on the Status of the Global Climate*** and the Special Supplement to the Bulletin of the American Meteorological Society (BAMS) ***State of the Climate***. The evolution of the RA VI Regional Climate Centre Network (RCC-Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ amongst the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC-Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

Notes:

- (1) This version of the Bulletin is an interim version, which will be further developed in the years to come. It has a new design and will be provided in .pdf format only. The aim is to optimise the content of the Annual Bulletin to achieve a high consistency of European climate monitoring information across publications, such as the recently introduced Monthly Bulletin on the Climate in WMO Region VI (cf. www.dwd.de/rcc-cm) and others. Furthermore, we are optimising the workflow to accelerate the Annual Bulletins production, saving time and money. The life blood of the Bulletin, however, will always be the national contributions from ideally all RA VI Members. Accordingly, we will continue inviting RA VI Members for national contributions.
- (2) Maps of the RA VI RCC-Network are based on the following data sources:
  - - Temperature: CLIMAT data and ship observations provided by the Global Collection Centre (GCC), run by Deutscher Wetterdienst
  - - Precipitation: Global Precipitation Climatology Centre (GPCC), run by Deutscher Wetterdienst
  - - Sunshine: CLIMAT data.

  Subregional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC) and the Southeast European Drought Management Centre (DMCSEE)

The following subregions are used in the Bulletin:

Central and western Europe: *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, Netherlands, Poland, Slovakia, Switzerland, United Kingdom*
Nordic and Baltic Countries: *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden*
Iberia: *Portugal, Spain*
Mediterranian, Italian and Balkan Peninsula: *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Serbia, Slovenia, Republic of Macedonia, Montenegro, Turkey* ***Eastern Europe:*** *Belarus, European Russia, Moldova, Romania, Ukraine*
Middle East: *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, western Kasakhstan*

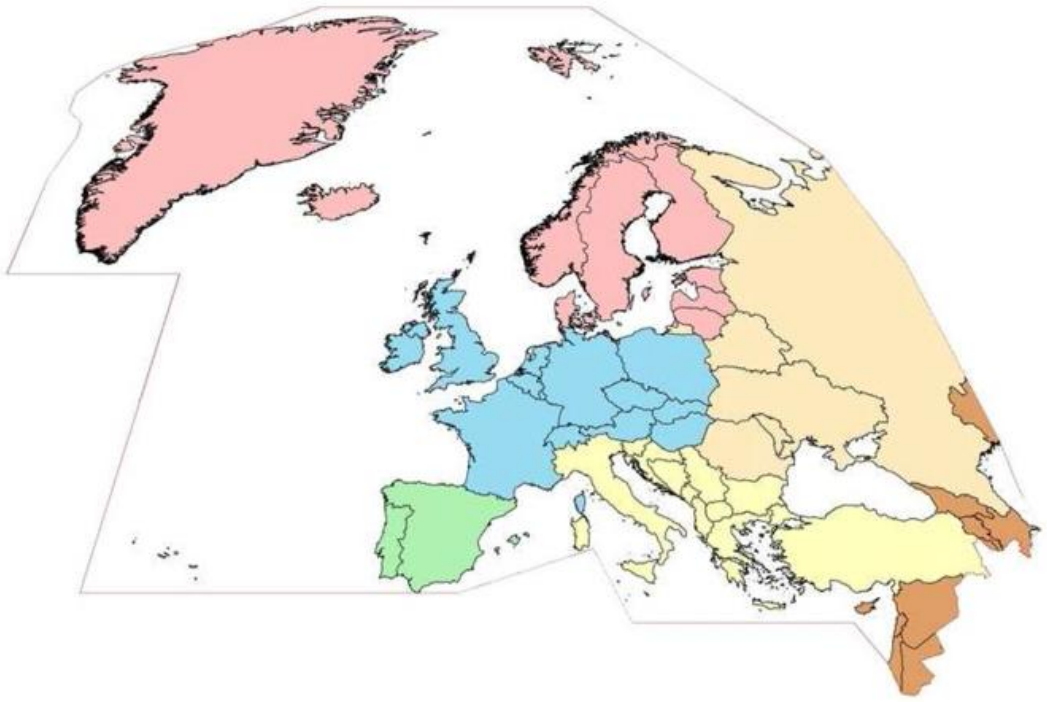

Fig. 1.1: *Definition of the 6 subregions within WMO RA VI*

References:

Note: *Primary information sources are the annual reports of RA VI Members, which are kindly provided by RA VI NMHSs. The names of Members, which contributed to the 2011 edition of the Bulletin are listed on page 3 above. Many contributions or also additional information may as well be found on the web, see below.*

Outstanding Events and Anomalies

Temperature

- The warmest year on record since more than 100 years in Norway(together with 1990 and 2006), Belgium, France, Switzerland and the higher mountains of Germany, Austria, Slovenia.
- Warmest winter on record at 5 stations on Greenland
- Warmest spring since 1659 in Central England (together with 1893), 2nd mildest since 1706 in The Netherlands, since 1910 in UK, since at least 1900 in France and since 1961 in Spain.
- Warmest summer since 1866 in Estonia (together with 2010) and since the early part of the 19th century in Helsinki, Finland. But coldest summer in places since 25 to 74 years in Ireland.
- Warmest autumn since 1900 in Norway and as well in places in Ireland (Dublin since 150 years) and the 2nd warmest at least since 1900 in France.

Precipitation

- The wettest year on record in Norway (since 1900, start of registrations) and locally in northern and southern Sweden. The wettest year since 1890 for Torshavn on the Faroer Islands.
- Highest number of snowdays in Uccle, Belgium.
- Driest spring in France since at least 1959. Driest spring in at least a century in The Netherlands and partly driest spring since 1910 in UK.
- Wettest summer since at least 1906 in The Netherlands

Sunshine Duration

- Sunniest spring in Uccle, Belgium since 1887 and for at least a century in The Netherlands.

Other Anomalies

- Largest ice extent in the Baltic Sea since 1987
- 2 major drought phases: in spring in western and central Europe and in autumn mainly on the Balkan

Events

- Unusually wide-ranging dust transport from Africa to Scandinavia in April
- Extraordinarily extreme precipitation on 2 July in Denmark (in Kopenhagen more than 100 mm/day at all stations) and southern Sweden
- Extremely heavy rainfall on 25/26 October with intensities resp. totals of 153 mm within 1 hour, 328 mm within 3 hours, 472 mm within 6 hours, 511 mm within 12 hours, 539 mm within 24 hours, 542 mm within 30 hours for Brugnato in the Ligurian province La Spezia, Italy.
- Storm ROLF on 3 to 8 November in western Mediterranian Sea area had tropical character and brought daily totals up to 200 mm, 2-day totals between 300 and 500 mm and locally 9-day totals up to 800 mm in southeastern France as well as extremely intense precipitation on 4 November in Geneva (Liguria) with intensities per 3 resp. per 6 hours with return periods between 200 and 500 years.
- 2 storms in December: JOACHIM on 15-16 December with gusts of 20 m/s or more on more than a quarter of the area of France and DAGMAR on 26 December with vast damage in southern Scandinavia.

Annual Survey

Atmospheric Circulation

1.1 El Niño/La Niña

The year 2011 started with a strong La Niña which ended in late spring (Fig. 2.1). During La Niña the tendency in late winter is for a positive North Atlantic Oscillation (NAO) pressure pattern, with mild and wet conditions in northern Europe and the UK and cold and dry conditions in southern Europe. Also very typical for La Niña is a strong extended Azores high. In fact, it was already in January 2011, when high pressure conditions developed over western and southern central Europe. This went on in February and in spring, when high pressure extended far to the north and east. As a result, much of Europe, especially western and central parts, saw an outstandingly warm and dry spring.

Another similarly strong La Niña developed at the end of the year. Again, the Azores high became strong in December 2011 and extended to the north and east. As a result, Iberia and the western Mediterranean saw a very dry December in contrast to many other parts of Europe.

Further information: UK MetOffice: La Nina 2011 NOAA NCEP CPC: ENSO regressions

1.2 Arctic Oscillation (AO) and North Atlantic Oscillation (NAO)

From January to May 2011, the NAO shows strong fluctuations between the positive and negative phase, and to a lesser extent also the AO. This was due to temporary relocations of the Icelandic low to the west or southwest, particularly in January, and to a lesser extent also in March. The positive phase was prevailing during that period, triggered by La Niña. On the other hand, high pressure conditions extended from the Azores high far into the European continent. The result was a strong warm airflow to the Arctic region, and also western and central Europe saw a mild late winter and a warm spring. NAO was strongest in February, but due to a blocking high over eastern Europe, it was mild in the west, but cold and dry in the east that month. Middle latitudes were mostly dry especially in spring, whereas most of the precipitation occurred in the north, but also in southern Europe due to some cyclonic activity in the Mediterranean.

In the summer months (June to August), both AO and NAO indices were negative. The Icelandic low was either missing or very weak or relocated eastwards, whereas high pressure over Greenland became stronger and extended, leading to further Arctic warming and dry weather there, whereas northern and temporarily also central Europe often had cyclonic conditions. Eastern Europe and the Mediterranean, in contrast, had prevailing high pressure and saw a warm and dry summer.

For the rest of the year (September to December), AO and NAO switched again to a positive mode. There was a zonal circulation over the North Atlantic, but similarly like in spring, high pressure conditions developed over the European continent and the frontal zone was over northern Europe. This development culminated to an extensive high over Europe, leading to an extremely dry November, and warm air flow in western Europe and cold air in the southeast. In December in contrast, this pattern was replaced by a zonal westerly flow with mild and wet weather over northern and middle latitudes, whereas the Mediterranean area became very dry.

Middle East	*-0.8*	*-0.1*	*1.5*	*-0.8*	*0.2*

Temperature:

According to BAMS Annual State of the Climate 2011 was together with the year 2007 on rank 1 of the warmest years in Europe. With respect to uncertainties it was at least one of the 6 warmest years since 1850. This result is based upon the CRUTEM3 dataset (Brohan et.al. 2006), see also BAMS July 2012, p. 186. 'Europe' is here defined as the land area within 35°N - 75°N and 10°W - 30°E. For 'Europe' defined as the land area within 35°N - 75°N and 25°W - 45°E and the E-OBS dataset 2011 came out on rank 4 since 1950 (van der Schrier, G., 2013; see also: Climate Indicator Bulletin: European Temperature) with an Europe-average mean temperature 10.9°C (=normal + 1.1°C, compared to CRUTEM3 with +1.23 +/- 0.14°C). This difference is essentially due to the area taken for 'Europe'. E-OBS includes more of the North Atlantic (Iceland) as well as more of Eastern Europe, the Black Sea area and Middle East where the temperature anomalies were smaller or partially even negative (Fig.2.2). Both definitions for Europe do not cover the complete RA VI region. But a dataset covering the complete RA VI area is not yet available.

Locally in northern parts of Sweden 2011 was the warmest year on record. 2011 was as a whole the warmest year on record (for more than 100 years) for Norway (equal to 2006 and 1990), the 2nd warmest year since 1900 in Finland, the warmest since 1900 in France and Switzerland. The Belgian station Uccle recorded the highest annual mean temperature since 1833. Also in southern Europe the year 2011 was a very warm year. At coastal, central and eastern parts of Montenegro 2011 was the warmest year since the beginning of the 20th century.Spain recorded the warmest year since 1961 and Portugal reported the highest mean of the daily maximum temperatures since 1931. In Austria, Germany and Slovenia it was the warmest year on record on the higher mountains.

Most remarkable is that the polar region of the whole northern hemisphere was much warmer than normal. For the Region VI it was warmer than normal through all seasons of the year. The Middle East on the other hand had the smallest positive anomaly of the annual mean temperature. See the table on page 22.

Note: *Small differences between the areal temperature anomalies in the tables on pages 21 and 22 and according values given by individual countries may occur due to the calculation method. The anomalies result from the temperature analysis (see RCC-CM: Products - Monitoring Europe - Temperature).*

Precipitation:

The annual precipitation totals in 2011 (reference 1961-1990) were above normal in Scandinavia, Iceland, eastern Greenland and northern UK and locally in southwestern Mediterranean as well as partially in southeastern Russia. They were below normal partially in southern and western Europe and in Middle East. Remarkable is a large area of drier than normal precipitation spreading from southwestern France and the northern Iberian Peninsula to southwestern Ukraine, including southern England, eastern France and western Germany, Switzerland, Austria, northern Italy, the western Balkan Peninsula and western Romania. The deficit is mostly between 10 and 30 mm, but 30 to 50 mm at the western Adriatic coast. In terms of percentages the largest almost coherent area covers the western Balkan, eastern Austria and northern Italy, where between 60 and 80 percent of the normal annual precipitation fell. Locally it was even less. In the wetter than normal regions especially in the north and east on the other hand the 90 percentile was exceeded (reference 1951-2000).

Sunshine:

It was sunnier than normal in most parts of Central Europe as well as parts of western and southwestern, southern and southeastern Europe and around the southern Baltic Sea. The surplus ranged mostly between 5 and 25 percent and was highest in Poland and southern parts of eastern Germany exceeding the normal by 25 to 50 percent. The other areas were mostly close to normal or slightly below normal. Only northeastern Russia and the region around the Caspian Sea received less than 50 percent of the normal. Spring and autumn largely contributed to the surplus while summer was rather dull.

Drought

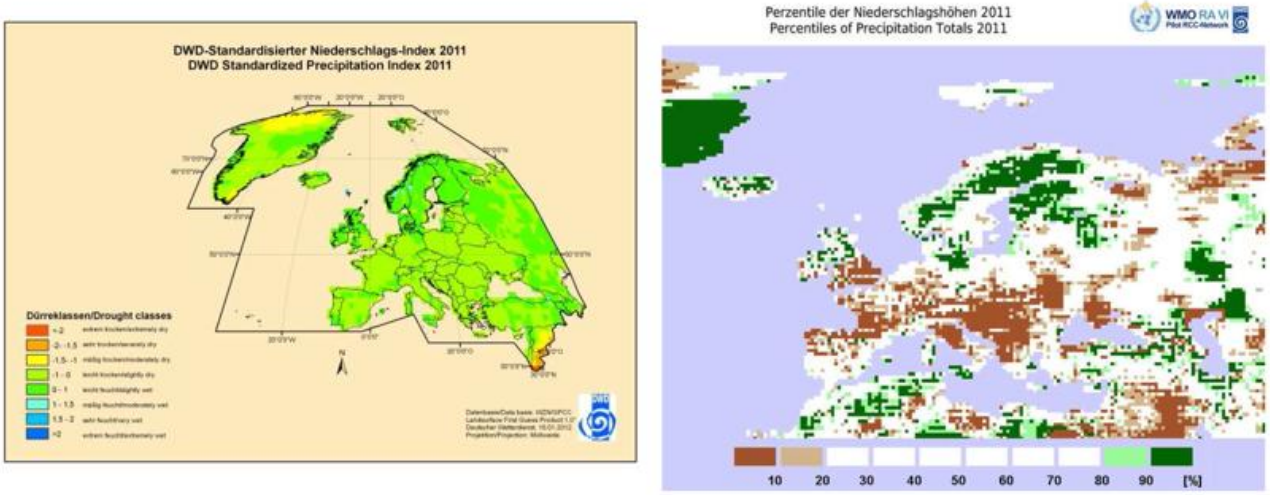

Fig. 2.3: *Annual means of the modified Standardized Precipitation Index (DWD-SPI) and precipitation totals in terms of percentiles 2011 based on GPCC data 1951 to 2000*

Drought Situation:

As the map of the modified Standardized Precipitation Index (SPI)(annual mean of 1-month DWD-SPI) shows, most of Europe was slightly dry over the year. The annual anomalies of the 3-months SPI and even a little more the 6-months SPI (see European Climate Assessment & Dataset - Indices of extremes) even show extremely dry conditions for many stations in western, southern and eastern Europe, including the southern British Isles. The map of the precipitation totals 2011 in terms of percentiles (on the basis 1951-2000) clearly show very dry as well as the very wet regions. The seasons spring and autumn 2011 mostly contributed to this result. Europe suffered from drought conditions during those seasons which were centered during spring in central and western Europe and on the Balkans during autumn. The spatial extent was large (see the maps) and affected regions which usually do not belong to the dry regions. Especially during November 2011 the drought situation spread over most of central, eastern and southeastern Europe and affected even northern Europe. Thus parts of Europe were affected by both drought events as for instance the United Kingdom. There is a Press Release of 8 June 2011 on the first drought episode under Drought conditions in Europe 2011 and a Special Report in Drought and precipitation extremes, in "State of the Climate 2011". Some additional information will be given in part 3 'Monthly Survey in the section for November.

Snow Cover

Fig.2.4 to 2.6 show the maps of first occurrence of snow, last occurrence of snow and duration in the snow period for Europe September 2010 to August 2011 on the basis of SYNOP reports.

Earlier (October/November 2010) than usual (December/January) snow occurred in the northwest and southwest (northern England and Scotland and higher elevated parts of the Iberian Penisula) of the European continent. Snow even occurred in western France and much of the Iberian Peninsula as well as southern Italy, the Ionean and the Aegean parts of Greece and western Turkey where no snow is expected according to the reference 1981/82 - 2010/11. In northern Russia and southern Finland snow fell already in October where it is usually to be expected in November. Snow fell later than usual in southern Russia, the Caucasus region and eastern Turkey.

On the other hand snow in the northwest melted earlier, already in January/February, where it ususally may be expected until February/March. Most of the early snow in the west (France, southern England) melted already in the same month. Snow remained longer than usual in Poland, partly in Ukraine and in western Turkey.

Overall the snow-season 2010/2011 was shorter than in average in eastern and northern Europe and in the Caucasus region while a short snow period occurred in the west where on average no snow occurs at all.

More information about snow conditions may be found on the RCC-CM-Webside (RCC-CM).

The snow cover extent for the entire Northern Hemisphere is operationally evaluated from satellite images by Rutger's Laboratory (see: 2011 Annual Report). The time series for annual snow extent covers 42 years, on a monthly basis up to 46 years. For the Northern Hemisphere the snow extent in 2011 was on rank 26 of 42, for Eurasia it was on rank 27. November 2011 was on rank 4 (of 46 years) of the most extensive snow cover in November on the Northern Hemisphere, in Eurasia it was on rank 5. January was on rank 6 (in Eurasia rank 11) of 45 years.

The Ozone Layer over Central Europe

(by Wolfgang Steinbrecht, Hans Claude, and Ulf Köhler - Deutscher Wetterdienst, Meteorological Observatory Hohenpeißenberg)

2011 was quite an unusual year for the ozone layer over the northern hemisphere, as was the very large decrease from 2010 to 2011. The major feature of 2011 was the extremely large chemical ozone depletion above the Arctic in spring of 2011. This record depletion, up to approximately 130 DU, exceeded what had previously been observed in the Arctic, e.g., in 1996, 2000, 2005. It was due to the still large levels of anthropogenic chlorine in the stratosphere in combination with an unusually stable and cold polar winter vortex. For the first time, the depletion in the Arctic was comparable in most aspects to the ozone hole occurring regularly above Antarctica. Figure 2.7 clearly shows the unusually low total ozone columns above the Arctic in early 2011 (top left panel). After the breakup of the Arctic vortex in April, ozone-depleted air-masses spread over the Northern hemisphere and contributed to the low total ozone columns observed throughout most of the year (other panels of Fig. 2.7). Additional factors favouring the generally low ozone columns at northern mid-latitudes in 2011 were:

- The phase of the quasi-biennial oscillation of the equatorial stratosphere (QBO) in early 2011. It resulted in high ozone in the tropics and low ozone at mid-latitudes, in the first half of 2011 (top panels of Fig. 2.7).
- The usually positive phase of the Arctic- or North-Atlantic Oscillation (AO or NAO) throughout most of 2011. It contributed to low ozone over the Atlantic sector from about 30°N to 50°N, and high ozone near Greenland / Iceland (right panels of Fig. 2.7). Note that this phase of the AO or NAO contrasted the largely opposite AO phase and high total ozone columns observed throughout 2010. The positive AO/NAO also contributed to the generally warm and sunny weather over much of Central Europe in 2011.

Figure 2.8 shows the time series of observed total ozone annual means (black dots, top) at Hohenpeissenberg in southern Germany (47.8°N, 11.0°E). Hohenpeissenberg results are representative for Central Europe, and are similar to much of the northern mid-latitudes The red line in the top panel of Fig. 2.8, and the lower panels, show ozone variations attributed to several influence factors. This attribution is done by multiple linear regression analysis and can explain about 80% of the variance. The regression result is shown by the grey line in the top panel. On decadal time-scales, total ozone shows a substantial decline from the 1960s until the late 1990s, and a beginning recovery since. This is due to the large increase of anthropogenic chlorine until the mid-1990s and the slow chlorine decline following the end of CFC production initiated by the 1987 Montreal Protocol. In Fig. 2.8 the chlorine related total ozone variation is represented by the red curve for EESC (=Equivalent Effective Stratospheric Chlorine). Another important factor is the 11-year solar cycle (orange line, bottom panel). On the inter-annual time-scale the QBO and the Arctic Oscillation (or North-Atlantic- Oscillation) play major roles (magenta and blue lines in Fig. 2.8). They act on ozone, but are also connected with the intensity of the polar winter vortex. In particular, QBO and AO played a major role in the large swing from high total ozone in 2010 to low values in 2011. Figure 2.8 also give an indication of the ozone columns to be expected over the next decade or so. The beginning slow recovery of the ozone layer should continue. However, large variations are to be expected. Because chlorine levels are still high, winters with a stable and cold polar vortex will result in substantial ozone loss, and even "ozone hole" conditions. Climate change and stratospheric cooling may actually favour such conditions in the future. Substantial ozone loss can result in very high levels of UV-B radiation, particularly on sunny days in spring, and in Central Europe. A major volcanic eruption with substantial aerosol loading in the stratosphere would also result in low ozone levels, comparable to the all-time lows observed in 1992 and 1993, and the low values seen in 2011.

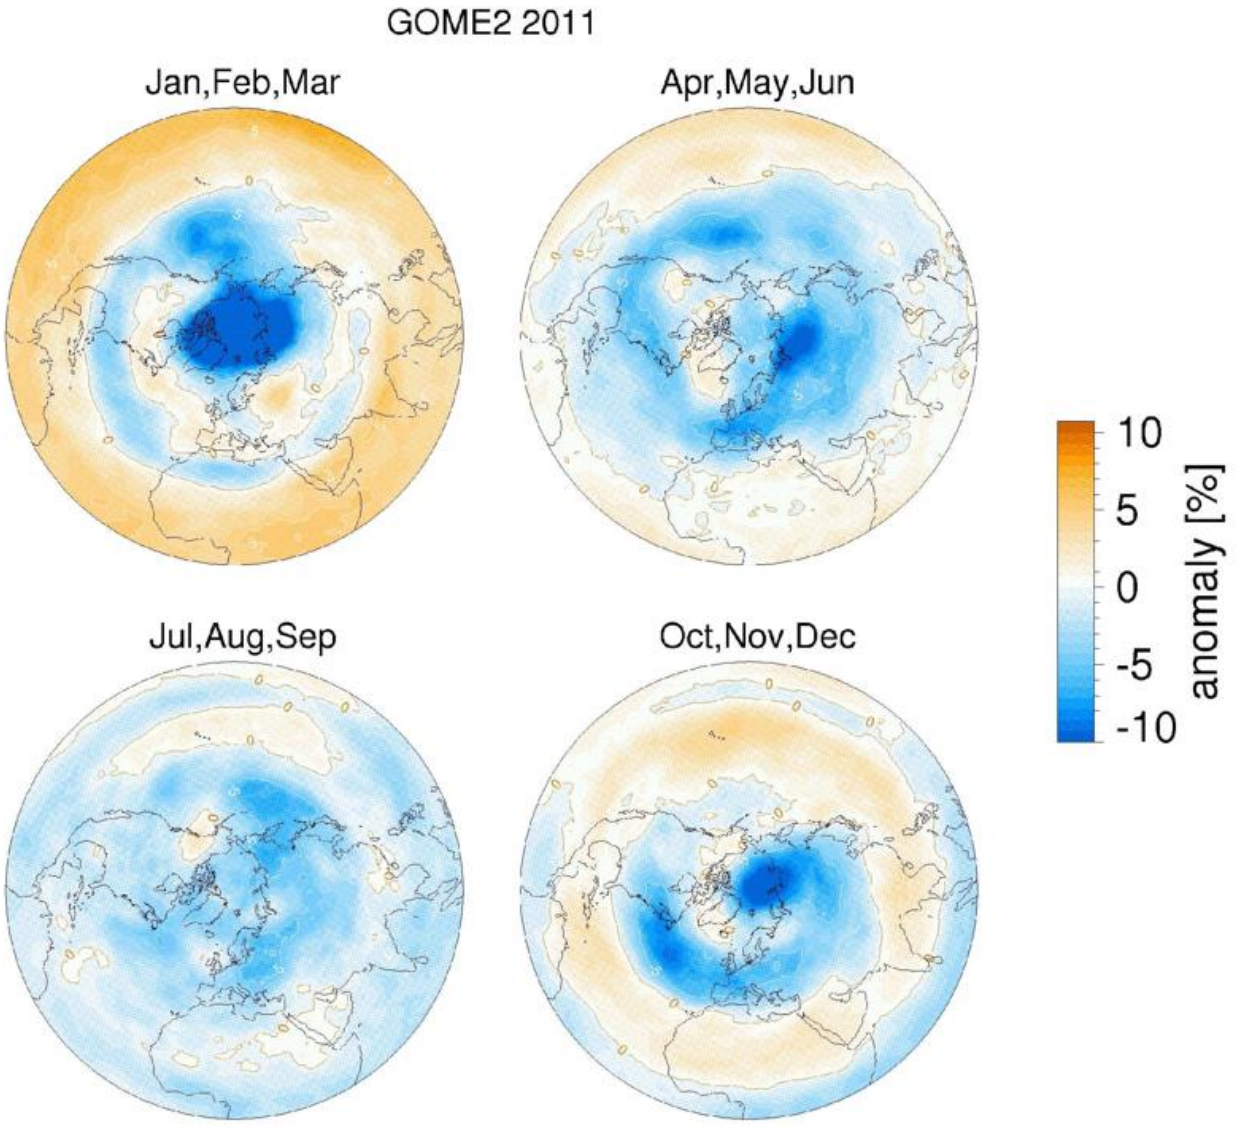

Fig. 2.7: *Relative deviation of the total ozone columns observed by the GOME2 satellite instrument in 2011 from the 1979 to 2010 climatological mean. Data source: www.temis.nl.*

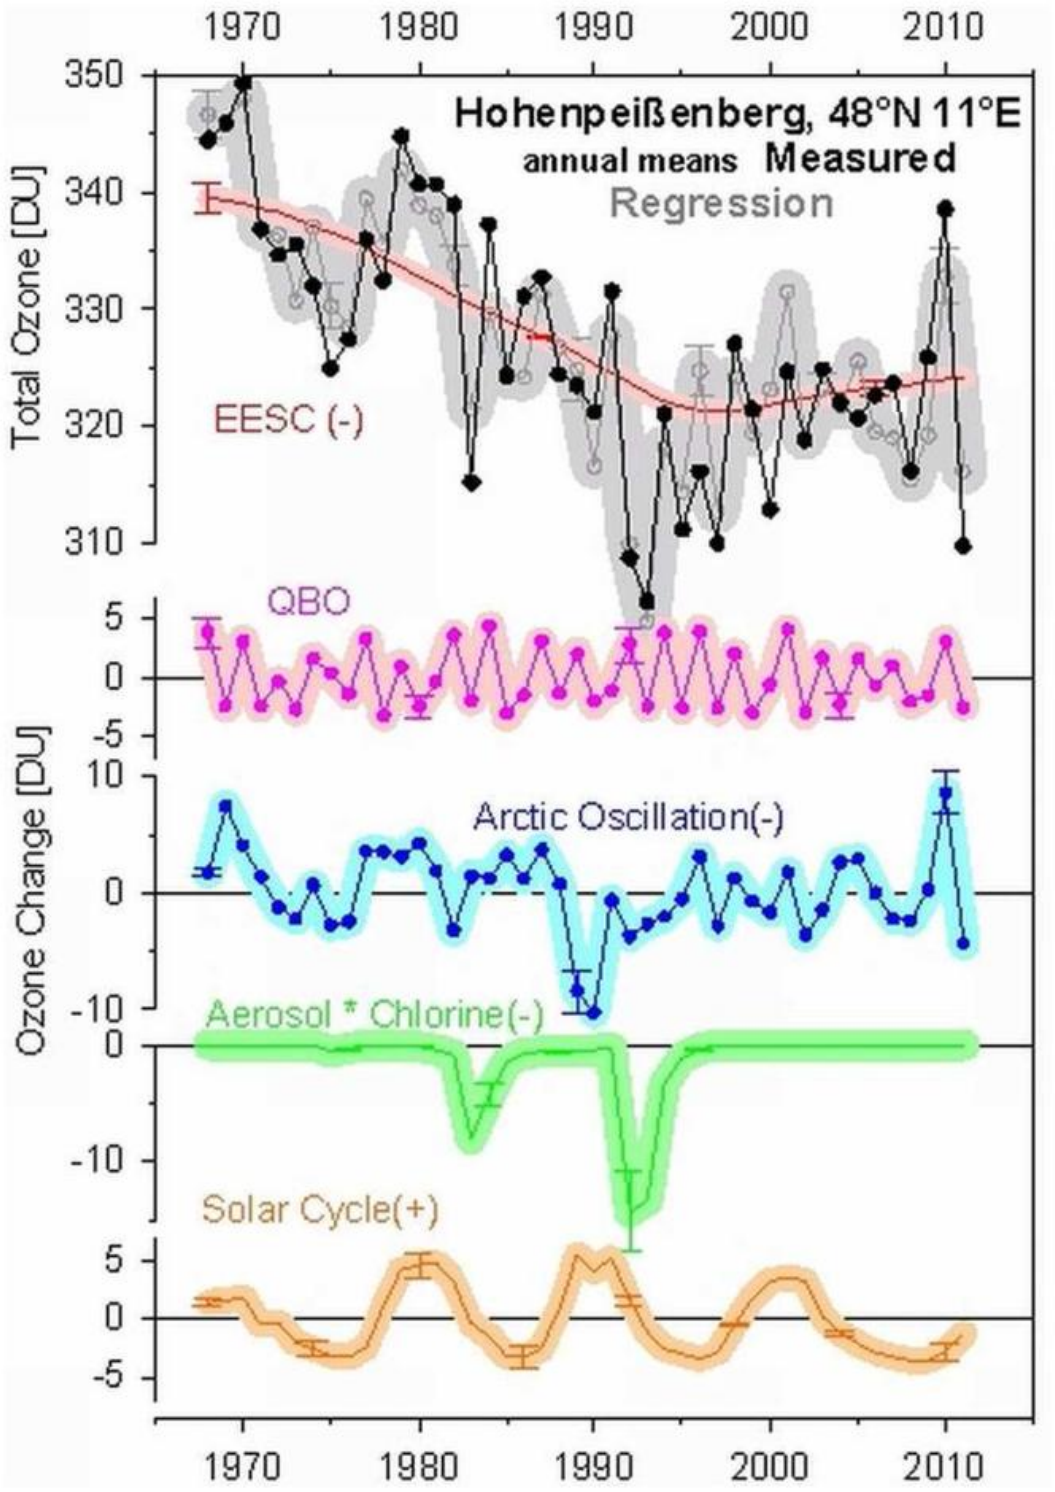

Fig. 2.8: *Annual mean total ozone observed at Hohenpeissenberg (47.8°N, 11.0°E) and variation attributed to influencing factors by multiple linear regression. Top panel, black: Observed annual means. Grey: Multiple linear regression result. Red: Ozone variation attributed to Effective Equivalent Stratospheric Chlorine. Lower panels: Variation attributed to the QBO (magenta), the Arctic-Oscillation (blue), enhanced stratospheric aerosol multiplied by EESC (green), and to the 11-year solar cycle (orange). Error bars (± 1σ) and thickness of the underlying lines give the approximate statistical uncertainty of the linear regression.*

Temporal Evolution of Climate Elements

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the NMHSs are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 subregiones defined above (Fig. 1.1). The table below informs about the lengths of the time series shown as well as whether they refer to spatial means of the country or single stations. Most time series are temperature time series. Each subregion is at least represented by one country. Time series of precipitation totals are fewer and there is no diagram for the subregion 'Eastern Europe'. Diagrams of long-term annual sums of sunshine duration are only provided by 3 countries and they belong to the subregions 'Central and western Europe' and 'Nordic and Baltic countries'.

Following this section, trend maps representative for the elements temperature and precipitation are shown. As reference period for these trend maps 1951-2011 was chosen. After this, we present examples of the temporal developent of other temperature related phenomena,such as the sea surface temperature in the North Sea and the mass balance of the Austrian Goldberg glacier.

Start of long-term time series of Temperature, Precipitation and Sunshine Duration

	Temperature		Precipitation		Sunshine Duration	
Country	Spatial Mean	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station
Armenia	1929					
Austria	1851[1]					
Belgium		1833				
Belarus	1881					
Bulgaria	1901					
Croatia		1862				
Denmark	1873		1873		1920	
Estonia		1866		1866		1953-1958, 1967
Finland	1900					
France	1900					
Faroe		1873				
Germany	1900		1900		1951

Sweden			1860			
Switzerland	1864					
Turkey	1941		1941			

1: Mountain Summits; 2: Mean of 58 homogenized stations

Temperature

Note: *Long time series of the mean annual temperature are available for each of the 6 subregions. The number of countries which provided information differs as well as the length of the series and the kind of presentation. The longest time series for areal means were proided by Austria (1851, for mountain summits), Switzerland (1864), Denmark (1873) and Belarus (1881). Most graphs are diagrams of the mean annual temperature over the years. Usually the mean annual temperature is given as a mean for the whole country. In a few cases the diagram refers to one station only. Some countries present the time series in form of anomalies from a reference (mostly the standard WMO reference period 1961-1990, except Belgium (1981-2010), and France, Hungary, Poland, Portugal, Spain, Turkey (all 1971-2000)). In this context this must be reflected when for instance the number of years with annual means above the reference is compared. Taking into account that the temperature is growing with time, the year from which onward the annual mean lies above the reference will be later when the reference is 1971-2000 than compared with the standard normal period 1961-1990. Some countries provide further statistics in their diagrams like a running mean or a trend line. Generally all time series document the rising temperatures with time and the increase of the rise during the last 15 years. Some special aspects will be discussed in the following.*

In **Central and western Europe** Fig 2.9 shows the time series of United Kingdom, Belgium (station Uccle), France and Germany. Fig 2.10 shows time series for the Alpine states Switzerland and Austria and of Hungary. In Austria the diagram refers only to the summits of high mountains. But both graphs, the one of Switzerland and the one of the Austrian summits resemble each other closely though the graph of Switzerland is given as anomalies from the standard WMO reference period 1961-1990. All years since 1986 were warmer than the normal and 2011 was the warmest. Concerning this aspect the graph of France may be considered as equal in result though the anomalies refer to 1971-2000. The temporal evolution at the station Uccle in Belgium, 1833 - 2011, shows 2 points of change of the temperature regime, in 1913 and in 1983. The reason for this effect is not clear as it is not observed similarly in other time series.

In the **Nordic and Baltic Countries** Fig 2.11 shows the time series of the mean annual temperatures of stations in Greenland and the Faroe Islands compared to Kopenhagen in Denmark. The longest time series start in 1873. The stations on Greenland show a higher temporal variability than Kopenhagen and Torshavn with low values around 1890 and 1985 and high values around 1930 and nowadays in the smoothed curves. The high values nowadays exceed the high values of the 1930er years. In Fig 2.12 we see similar but weaker variations for Norway, Finland and Denmark as country areal means. In any case the temperatures of at least the last decade are higher than formerly. This can as well be seen in Fig 2.13 for the Baltic states Estonia, Latvia and Lithuania were the series is given as anomalies from the standard normal period.

For **Iberia** Fig 2.14 shows the temporal development of the mean annual temperature of Portugal and Spain. In Portugal nearly all years from 1995 on had higher mean, maximum or minimum temperatures than the reference 1971-2000.

Similar results may be seen for **Mediterranean, Italian and Balkan Peninsulas**, see Fig 2.15, 2.16 and for **Eastern Europe** and **Middle East** as well, see Fig 2.17 and 2.18.

Overall 2011 was the warmest year within the shown time series for France, Belgium, Switzerland, Norway and Spain as well as for several stations of western Greenland and for the Austrian summit stations.

Precipitation

Note: *Most countries refer to the standard normal period or 1971-2000 as for the temperature except Israel, which refers to 1981-2010 resp. 1995-2009 for precipitation.*

For precipitation Fig 2.19 to 2.24 show the available time series for 5 subregions (except Eastern Europe).

For precipitation it is far less easy to draw conclusions from time series of areal means than for temperature. The spatial variability is larger and the spatial distribution of stations may have a decicive influence. So the following conclusions must certainly be taken with great care.

A slight growth of the annual precipitation totals with time can be seen for the United Kingdom and Germany in **Western and Central Europe** and a clear growth with time results for Norway and Denmark in the **Nordic and Baltic Countries**, but not for Latvia. In the other 4 subregions we cannot make a similar statement.

Central and Western Europe:

(Diagrams as provided by the NHMSs)

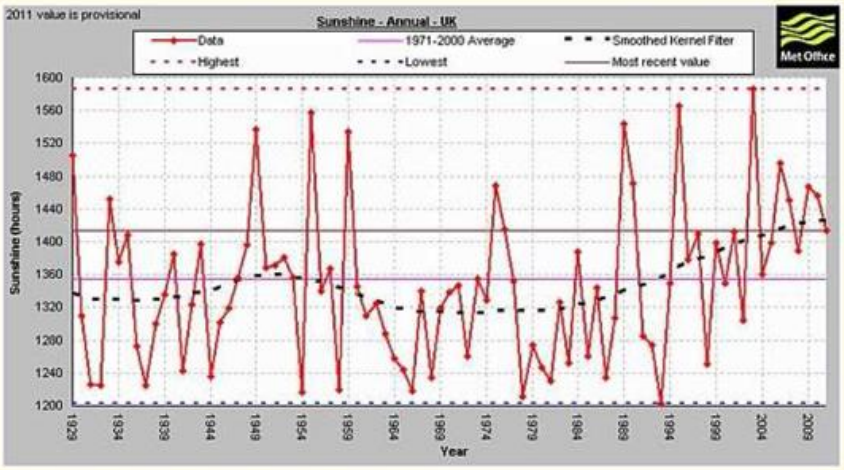
Sunshine

Note:*The sunshine duration time series are generally shorter than those for temperature or precipitation. For the reference periods Cyprus refers to 1981-2010 and France to the short period of 1991-2000.*

Only 4 time series are available for sunshine duration. In **Central and Western Europe** (Fig 2.25) the time series for United Kingdom starts in 1929 and the one for Germany starts in 1951. Both series show the year 2003 to have the highest annual sum of sunshine duration hours in the series. But a clear trend cannot be extracted from the graphs.

In Denmark in the **Nordic and Baltic Countries** (Fig. 2.26) also the year 2003 shows a very high annual sum of sunshine duration hours, the highest since a mimimum in the early eighties. Still a little higher was the value for the mid fourties and only a little less in the mid fifties. The value for 2011 was slightly below the running mean but still does not yet change the rising trend that existed since the mid of the nineteeneighties. The running mean value at the end of the series is more than 150 hours higher than the peak value around the year 1940. The series goes back to 1920. The highest value of the time series is recorded in 2003 in Estonia as well.

Central and Western Europe:



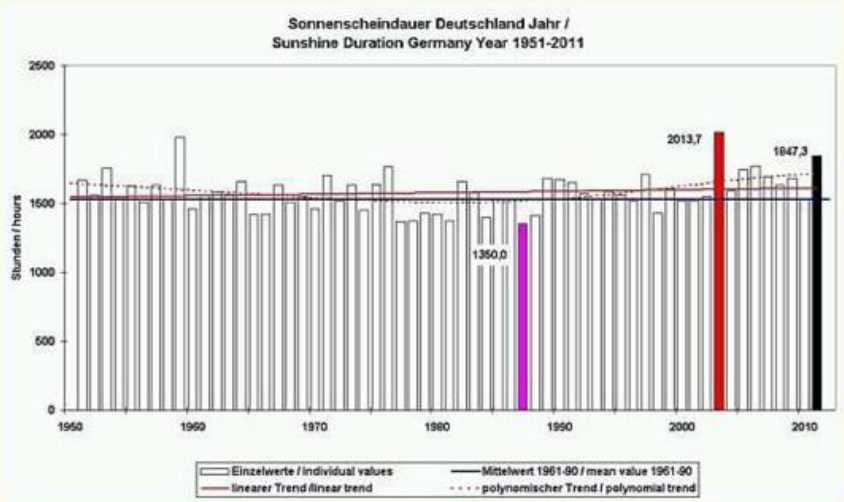


***Fig. 2.25** : Mean annual sunshine duration in western and central Europe*
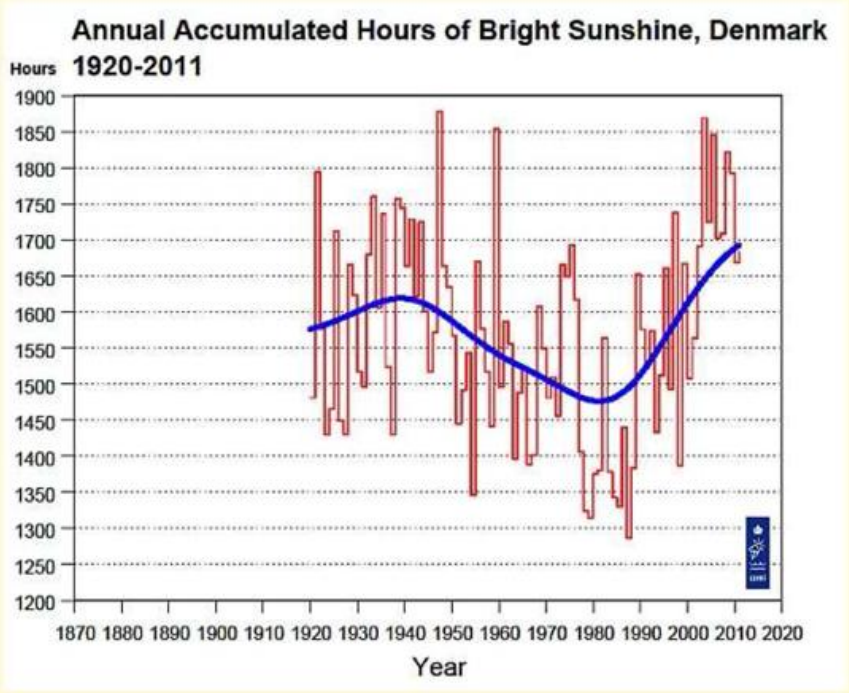
(Diagrams as provided by the NHMSs)

Nordic and Baltic Countries:



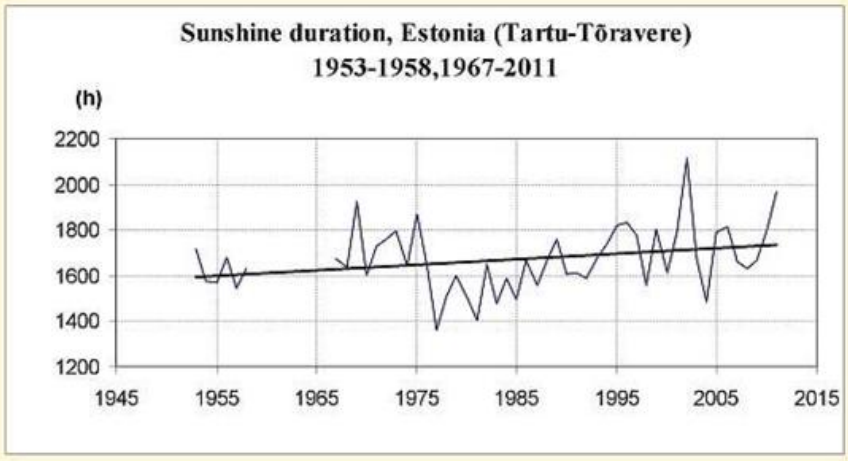


***Fig. 2.26** : Mean annual sunshine duration for Nordic and Baltic countries*
(Diagrams as provided by the NHMSs)

Trends of temperature and precipitation

Figure 2.27 shows the spatial distribution of trends for the mean annual temperature and the annual precipitation total as well as the cold spell duration index and very wet days for the time series 1951 - 2011 for stations in Europe contributing to the ECA&D data set. A warming trend for most of Europe can clearly be seen for the mean annual temperature. A corresponding decrease of the cold spell duration index is more visible for central Europe (perhaps due to the better coverage with stations) whereas elsewhere more stations are not significant.

For the annual totals of precipitation we can state roughly a different behavior between the south (mostly unsignificant) and the north (more slightly positive values) and the regions especially influenced by the North Atlantic seem to show clearer positive trends. This feature may eventually be explained by the influence of a warming North Atlantic. But many stations on the other hand are not sigificant. The distribution of trends for very wet days shows mostly unsignificant values.

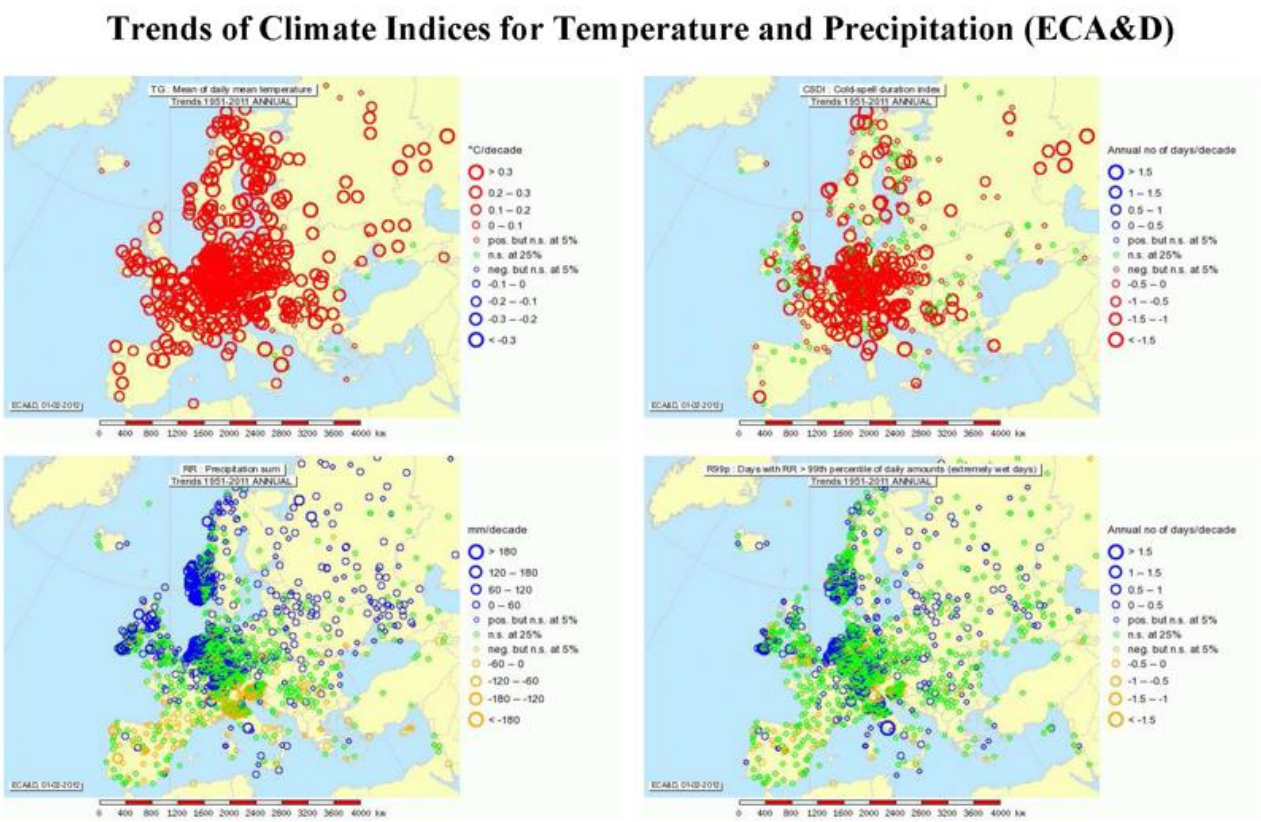

Fig. 2.27: *Trends of Selected Climate Indices 1951 to 2011 (Source: ECA&D, http://www.ecad.eu):*
Upper left: TG (Mean of daily temperature),
Upper right: CSDI (Cold spell duration index),
Lower left: RR (Precipitation sum),
Lower right: RR99p (Days with RR>99th percentile of daily amounts (extremely wet days)

Long-term temporal development of related phenomena

Fig. 2.28 and 2.29 illustrate 2 phenomena that are closely related to the temporal development of the air temperature.

In Fig 2.28 a ranking of the North Sea surface temperature since 1969 is shown. Note that the 'year' in this case refers to December to November. Presented are the ranks of the years 1969 to 2011. From 1988 until now most (all except 5 years) values are warmer than the median while before 1988 most values were colder. 2011 was on the warm side but close to the median.

In Fig. 2.29 the annual mass balance of the Goldberg glacier in Austria (as a representative of Alpine glaciers) is shown starting 1989. There are 6 years with a positive mass balance. All other years have a negative mass balance and the loss in the individual years is in most cases larger than the largest positive gain in individual years. This impressively illustrates the consequences of higher temperatures during the last years. 2011 had the greatest loss after 2003.

Long time series of more temperature related phenomena also on global scale can be found at NOAA/NCDC: Climate indicators

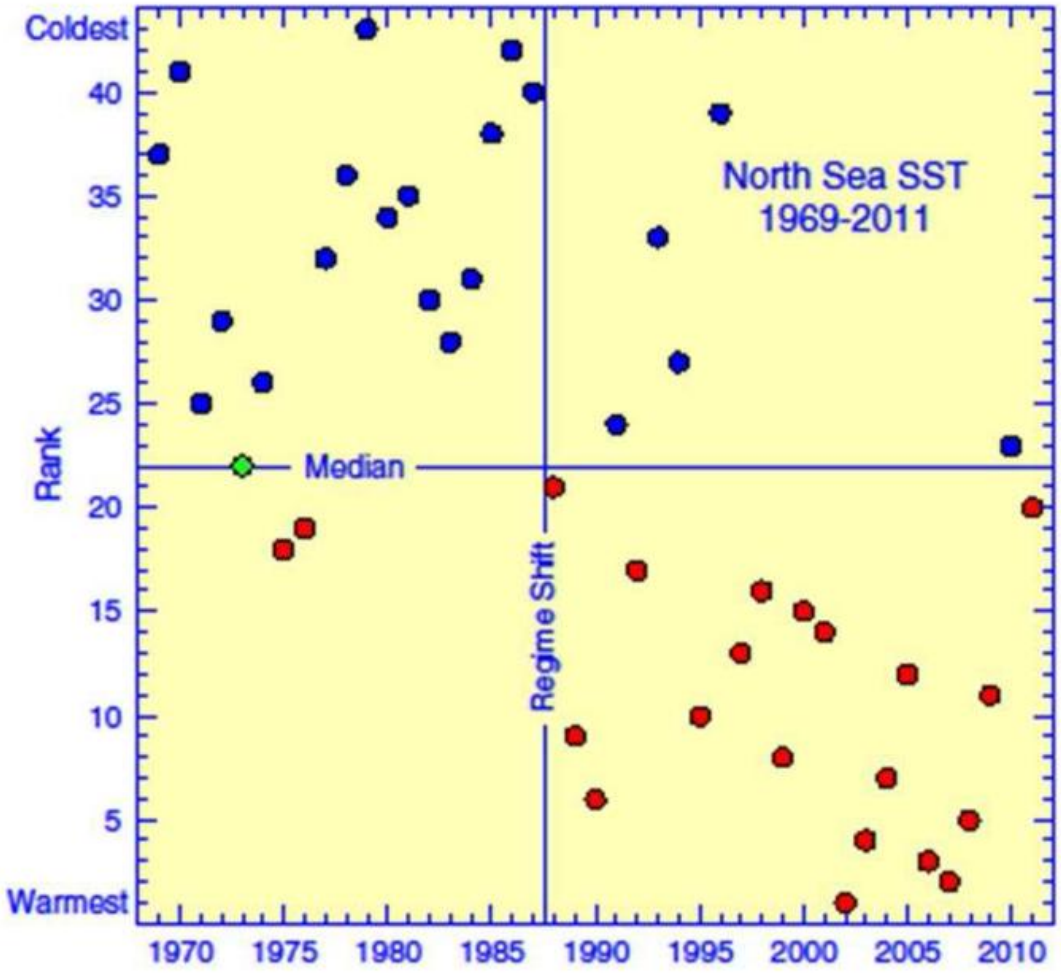

Fig. 2.28: *Rank statistics of the North Sea SST form 1969 to 2011 (Source: Bundesamt für Seeschiffahrt und Hydrographie BSH) (year2011means December 2010 to November2011)*

Seasonal Survey

Winter

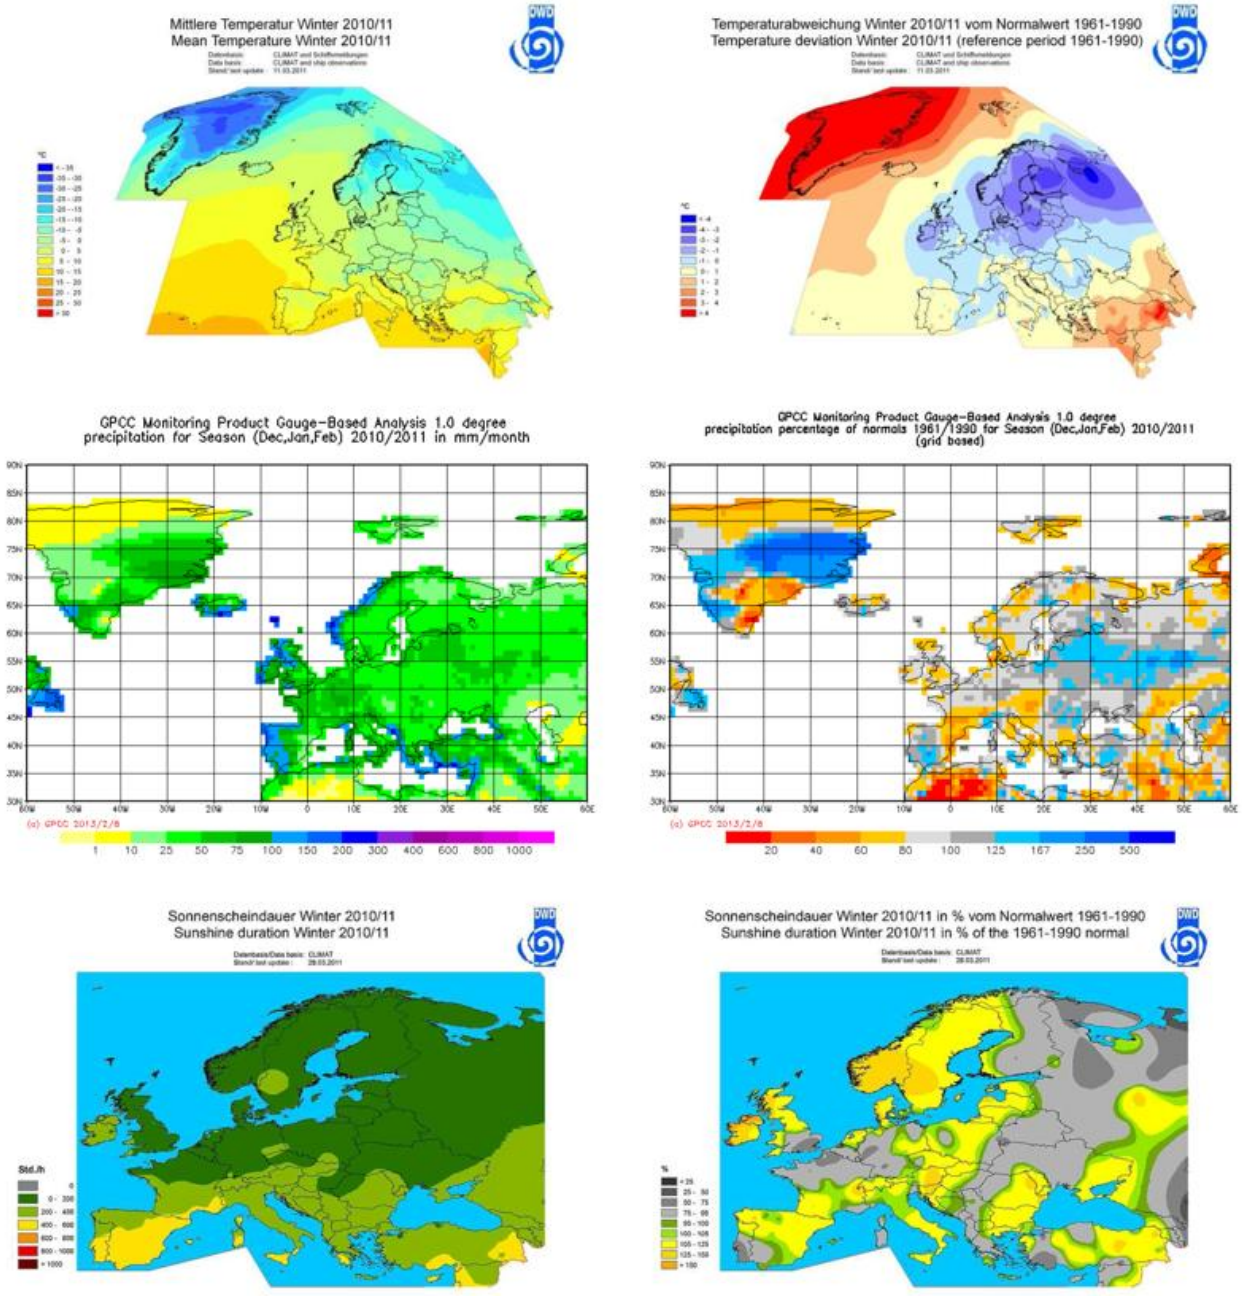

Fig. 2.30: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in winter 2011*
Source: http://www.dwd.de/rcc-cm

Winter

Winter 2010/2011 was in western, central, northern and eastern Europe as well as partly in the Mediterranean region colder than normal. The negative anomalies were largest over Scandinavia, the Baltic states and Russia. This is the western edge of a Siberian cold area where locally negative anomalies of more than 4 K were observed. Mean anomalies for Finland and Sweden resulted in -2.7 K resp. -2.2 K, in -1,8 K for the Baltic states Estonia, Latvia and Lithuania, for Denmark as well and in -1.4 K for Poland and -1.5 K for European Russia (see the table on page 21 and the remarks on the areal means from the spatial temperature analysis). Ireland and northern UK were similarly cold (-1.4 K for Ireland). This cold anomaly is mainly the result of the intense cold spell in December 2010. On the other hand it was warmer than normal in the north and northwest, especially in Greenland, where the areal mean of the anomalies resulted in +5.7 K and locally +6.4 K were reached (http://data.giss.nasa.gov/gistemp/maps). For 5 stations on Greenland it was the warmest winter on record. Also the Middle East and parts of southeastern Europe were clearly warmer than normal.

Precipitation was less than normal in Winter 2010/2011 over the British Isles and close to the North Sea and the Norwegian Sea on one hand and in southern France, around the Adriatic Sea and in Middle East on the other hand. The dry areas in the north may be related to the influence of high pressure in December 2010 and a low amount of water vapour (http://www.dwd.de/rcc-cm) in the atmosphere corresponding to the mentioned cold spell. Southwestern France had less than normal precipitation during each winter month (December 2010, January and February 2011). It was on the other hand wetter than normal on the western Iberian Peninsula as well as in the eastern Baltic Sea region and western Russia.

It was sunnier than normal over the northern North Atlantic, the North Sea and the Baltic Sea, Scandinavia and the eastern Central Europe as well as the western Mediterranean Sea and the Iberian Peninsula. Also the eastern Balkan Peninsula, parts of Turkey and of Russia and the Ukraine had more sunshine than normal.

Drought

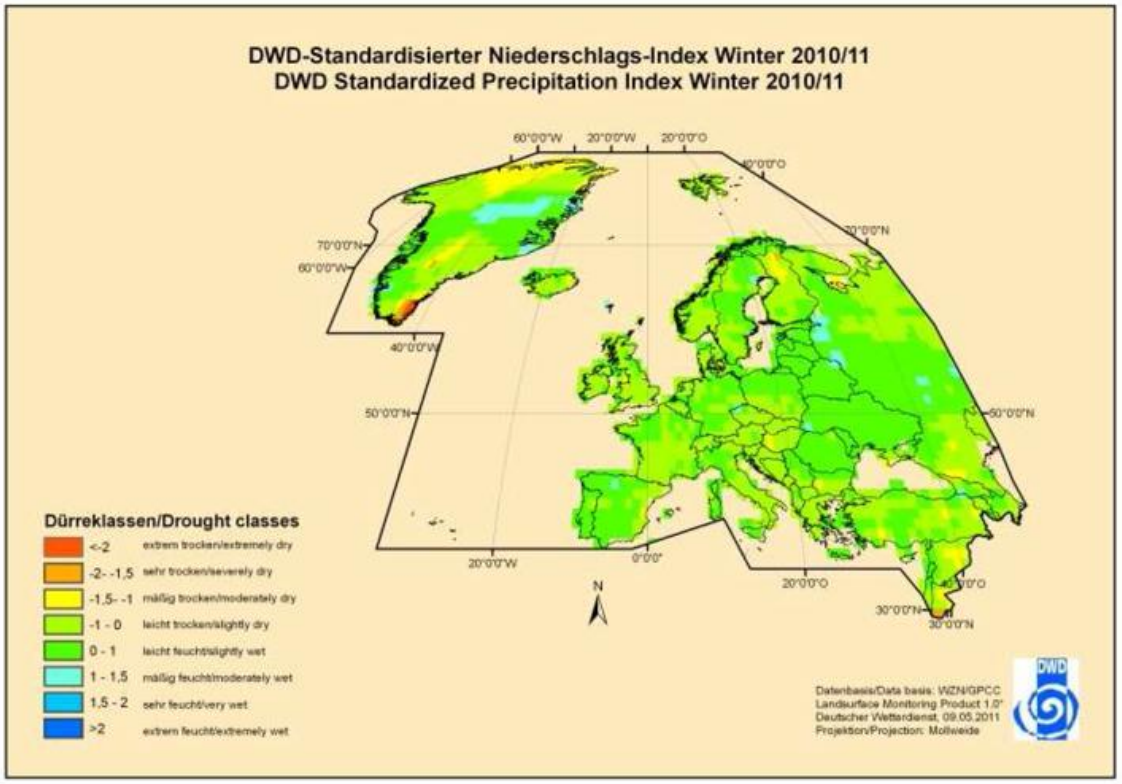

Fig. 2.31: *Means of the modified Standardized Precipitation Index (DWD-SPI), winter 2011*

Spring

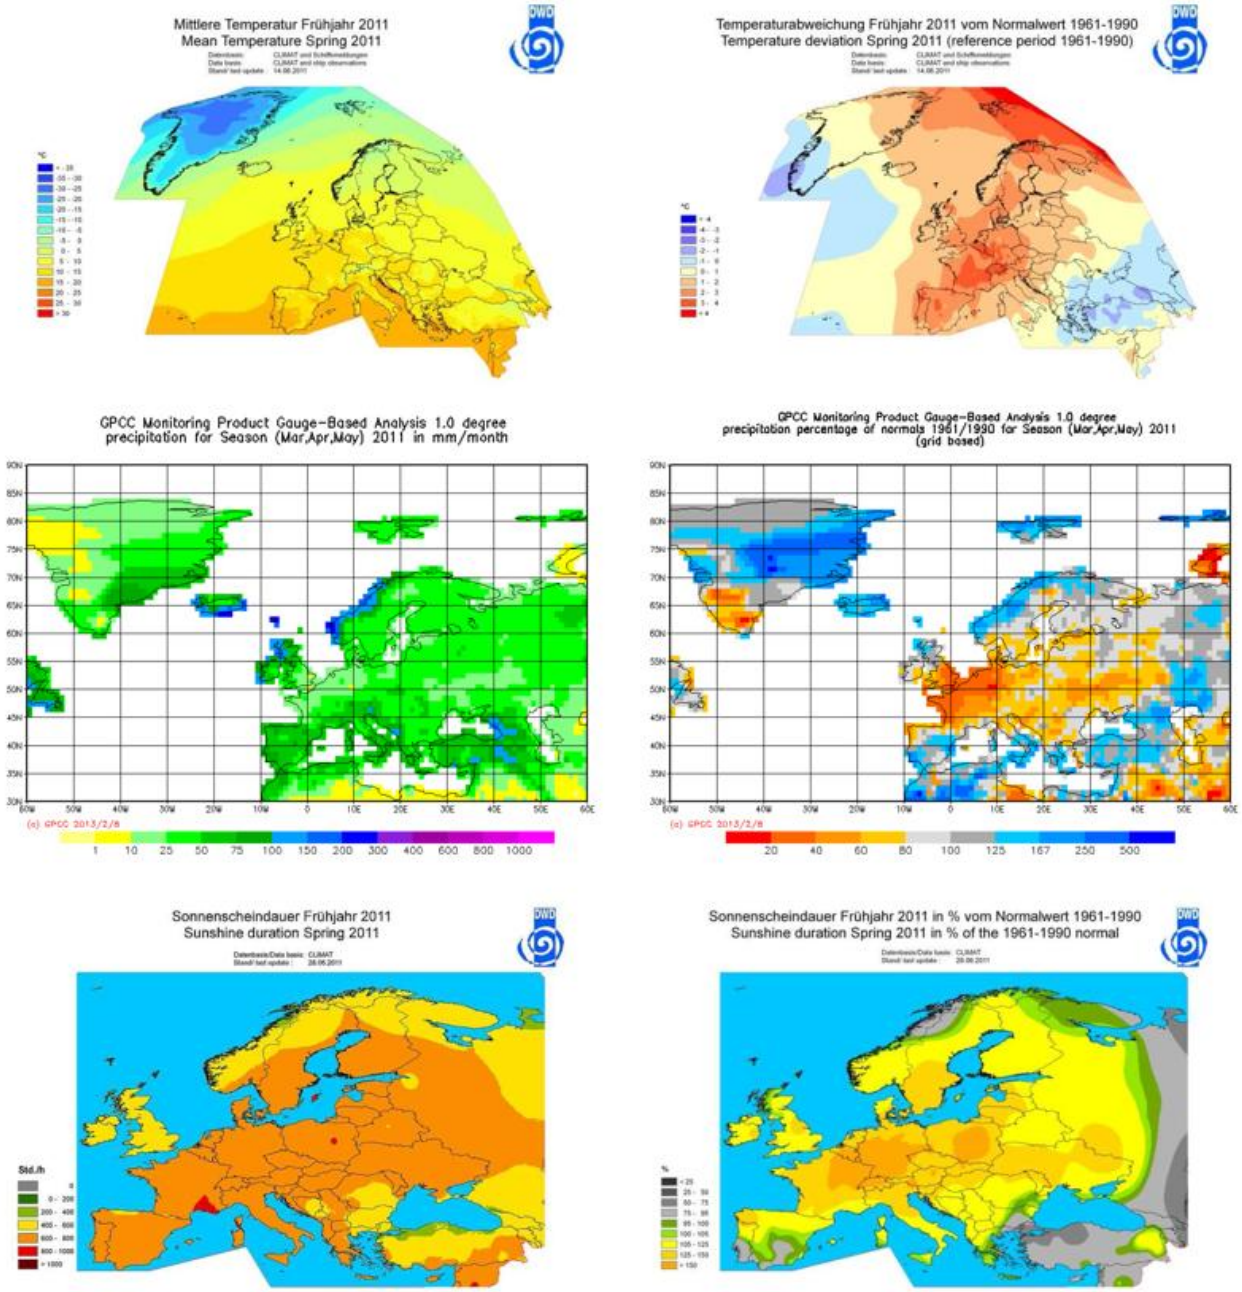

Fig. 2.32: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in spring 2011*
Source: http://www.dwd.de/rcc-cm

Spring

Spring 2011 had a nearly inverse distribution of temperature anomalies compared to the winter season. It was warmer than normal nearly in whole Europe. Only the Middle East and the western North Atlantic with southern Greenland were colder than normal. Overall the highest positive anomaly was located in the Arctic region again but in the northeast. Over northern Russia and the Arctic Ocean positive anomalies up to +6.6 K were analysed. The negative anomalies on the continent were restricted to the region of the Black Sea, Turkey and southern Russia and reached -2 K in Turkey. For central England spring 2011 was the warmest spring since 1659 (together with 1893) and it was the warmest spring since 1910 for whole UK. The Netherlands reported spring 2011 the 2nd warmest since 1706. In Spain it was the warmest spring since 1961.

While the northern parts of Europe (Iceland, Scotland, Norway) as well as partly the Mediterranean Sea and Middle East received more precipitation than normal in spring 2011, western and central Europe and southern England were remarkably drier than normal and drier were as well eastern and parts of southern Europe, the Balkan Peninsula and Belarus, Ukraine and parts of Russia. Mostly all 3 months had less precipitation than normal but the driest month in many countries was April. It was the driest spring in parts of southern England and East Anglia (UK) for 101 years, and the 2nd driest since 1910 in England and Wales, where only 45 % of the mean totals fell. In France spring 2011 was the driest since 1959 and in the Netherlands it was the driest spring for at least a century.

Spring 2011 was sunnier than normal nearly over whole Europe. In Germany, France, Belgium, Austria and Poland the sunshine duration exceeded partly more than 150 percent of the normal. It was the sunniest spring at Uccle (Belgium) since 1887 and the sunniest as well since at least a century in the Netherlands.

Overall spring 2011 was influenced by a slightly stronger than normal Azores high which extended far eastwards.

Drought

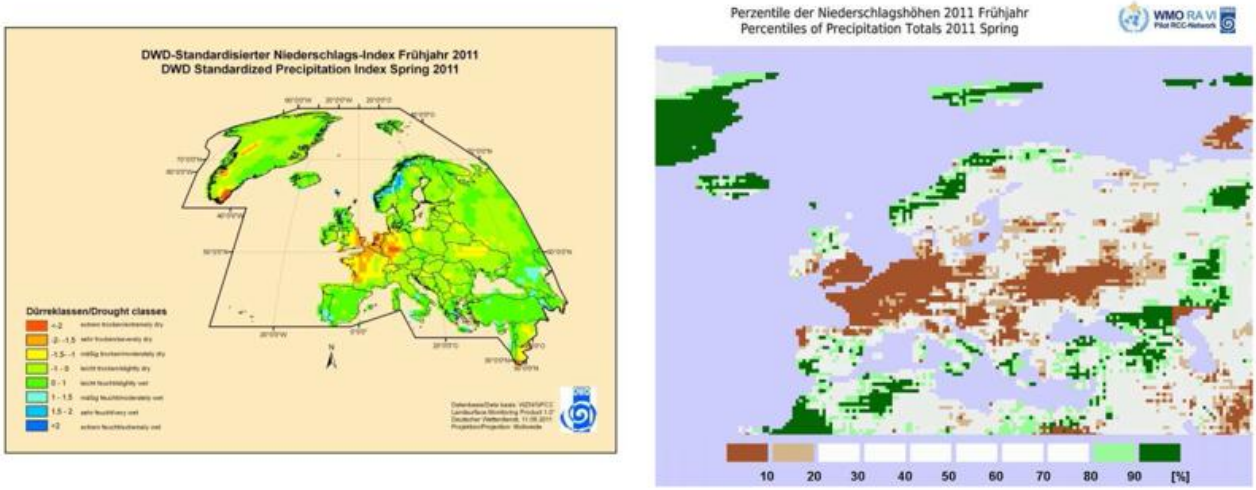

Fig. 2.33: *Means of the modified Standardized Precipitation Index (DWD-SPI) and precipitation totals in terms of percentiles based on GPCC data 1951 to 2000, spring 2011*

The two maps in Figure 2.33 show impressively the extent and spatial distribution of the standardized precipitation index (SPI) and the percentiles of precipitation in spring 2011. Generally the anomalies of the precipitation totals in percent, the SPI and precipitation percentiles tell the same but the precipitation percentiles make the weights of very small precipitation (below the 10th percentile) and the spatial extent of its area especially in eastern and southeastern Europe clearer.

Summer

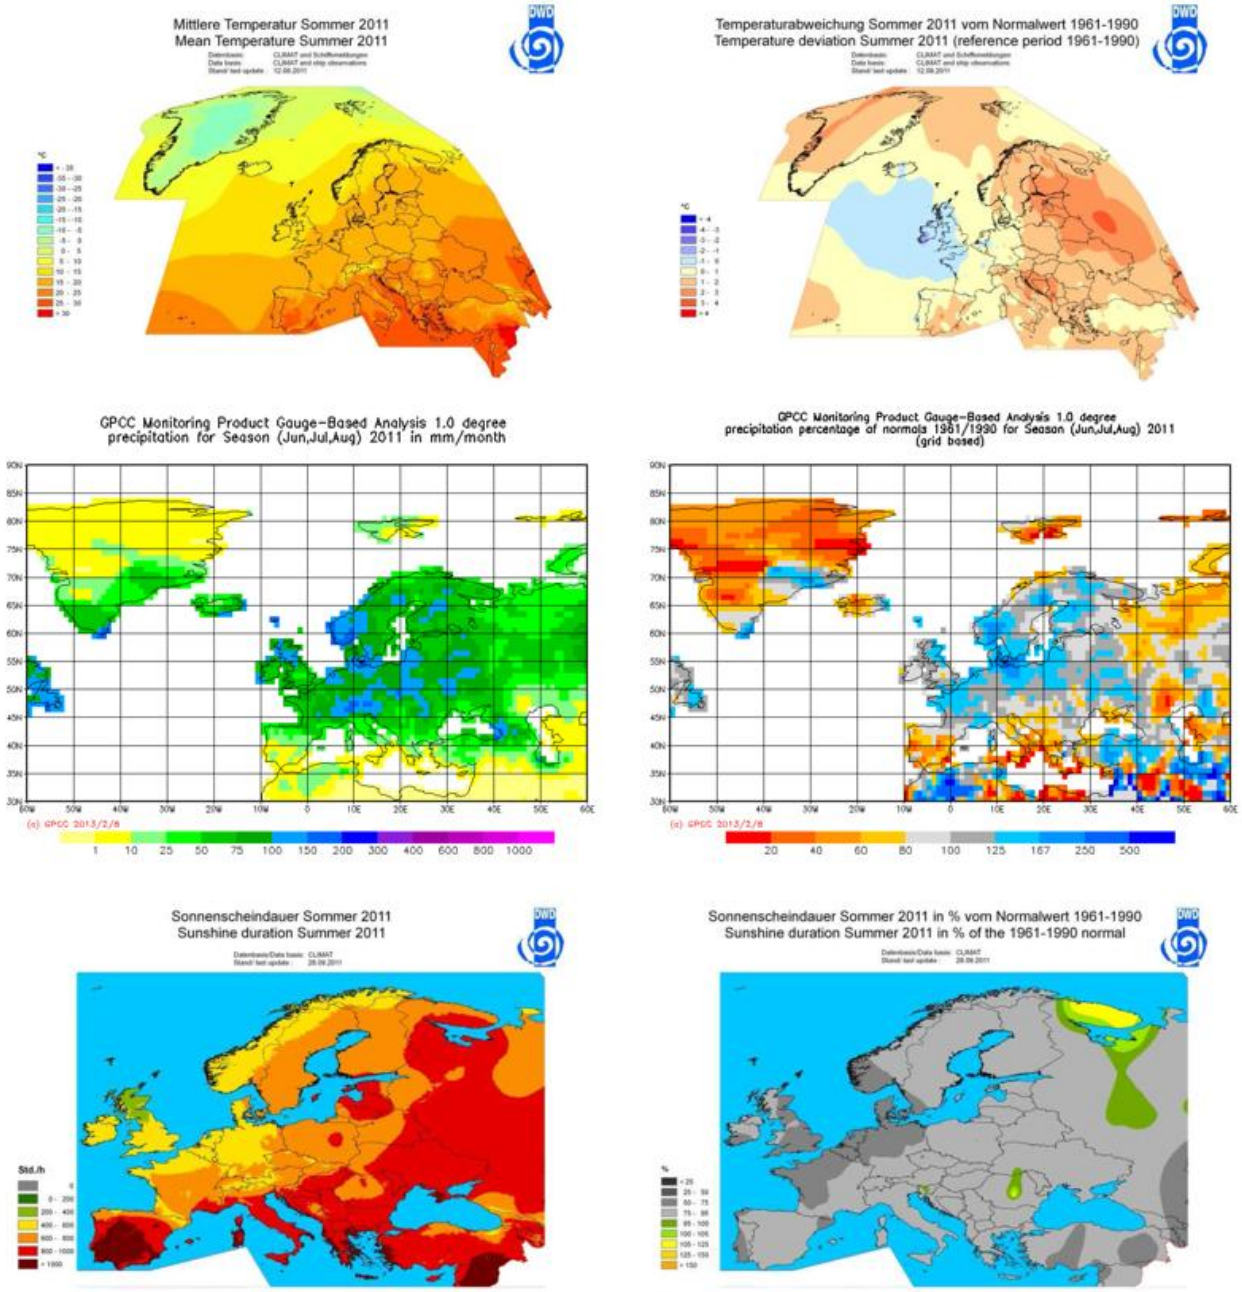

Fig. 2.34: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in summer 2011*
Source: http://www.dwd.de/rcc-cm

Summer

In western Europe the British Isles and France were influenced by a negative temperature anomaly over the Atlantic in Summer 2011. Everywhere else it was warmer than normal. The highest positive anomalies occurred in a small area around Moscow, Russia, where in July the anomalies came up to +5.3 K. Seasonal anomalies of +2 K or more as spatial means over the countries occurred in the Baltic states, Finland, European Russia, Belarus and on the Balkan Peninsula. In Estonia it was the warmest summer since 1866 (together with 2010). For Helsinki, Finland, it was the warmest summer since the early part of the 19th century as well. In contrast it was the coldest summer for 25 to 75 years in places in Ireland with -0.9 K as a spatial mean over the country. The evaluation of anomalies for climate indices (see European Climate Assessment & Dataset - Indices of extremes) shows the following features:

- The southwestern British Isles and Ireland had more cold days (days with a mean temperature below the 10th percentile of daily mean temperatures) than normal.
- the British Isles, southern Norway and the northwestern continent had less warm days (days with a mean temperature above the 90th percentile of daily mean temperature) than normal.
- The number of tropical nights was clearly above normal in the south around the Mediterranean Sea as well as around the Black Sea.
- The warm spell duration index had mostly slightly negative anomalies in western Europe and northern central Europe and slightly positive anomalies in southern and southeastern Europe.

Summer 2011 was wetter than normal mostly in western, central and northern Europe but drier than normal in southern and eastern Europe. It was the wettest summer since at least 1906 in The Netherlands. The evaluation of anomalies for climate indices (see European Climate Assessment & Dataset - Indices of extremes) shows the following features:

- Extremely wet days (days with a precipitation above 99th percentile of daily amounts) were more often in Norway, and close to the southern coasts of the North Sea and the Baltic Sea
- days with very heavy precipitation (equal or above 20 mm) were more often there as well as elsewhere in Central Europe, especially in the Alpine region.
- The highest daily amounts were clearly higher than normal in southern Norway, northeastern Germany and western Poland, the eastern Alps and locally in southern France, Italy and the Aegean Sea.
- In southern Norway, northeastern Germany and western Poland as well as locally the Baltic States, Ukraine and southeastern France also the highest 5-day amounts were remarkably higher than normal.

Summer 2011 had nearly everywhere less sunshine than normal. The dullest region with partly less than 50 percent of the normal was around the North Sea and at the western Atlantic coasts.

Drought

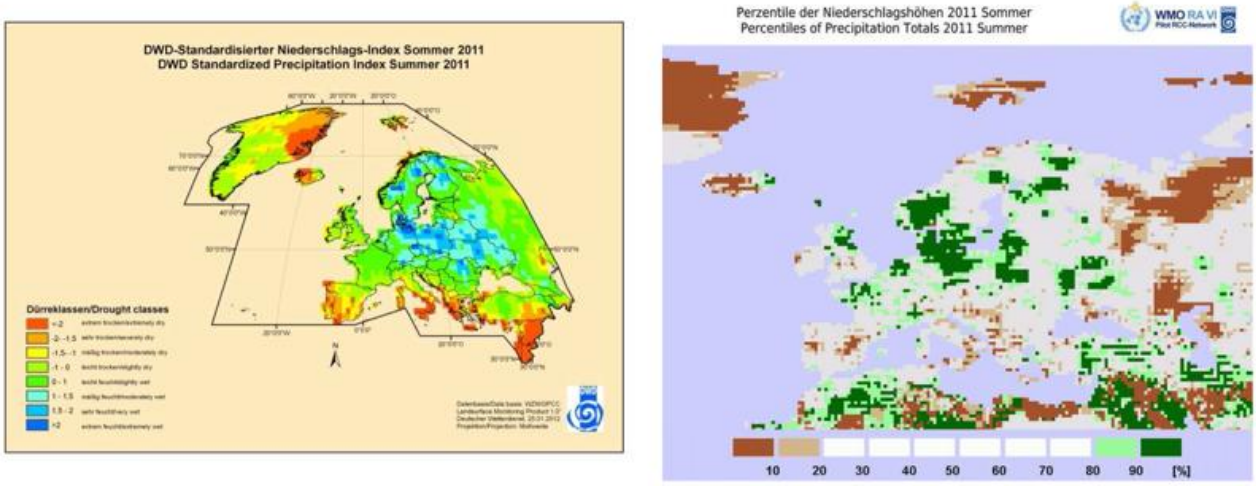

Fig. 2.35: *Means of the modified Standardized Precipitation Index (DWD-SPI) and precipitation totals in terms of percentiles based on GPCC data 1951 to 2000, summer 2011*

In summer 2011 more precipitation than normal fell in areas which were affected by the spring drought. The SPI shows a large area of 'very wet' or 'extremely wet' conditions in eastern central Europe and eastern Europe as well as northern Europe. The percentiles show that the areas of much more than normal precipitation are smaller, meaning that they are often still less than the 80th or 90th percentiles. Also within regions which received close to normal precipitation totals there were still some areas with precipitation below the 20th or even 10th percentiles. Thus water ressources may not have filled up enough during this time.

Autumn

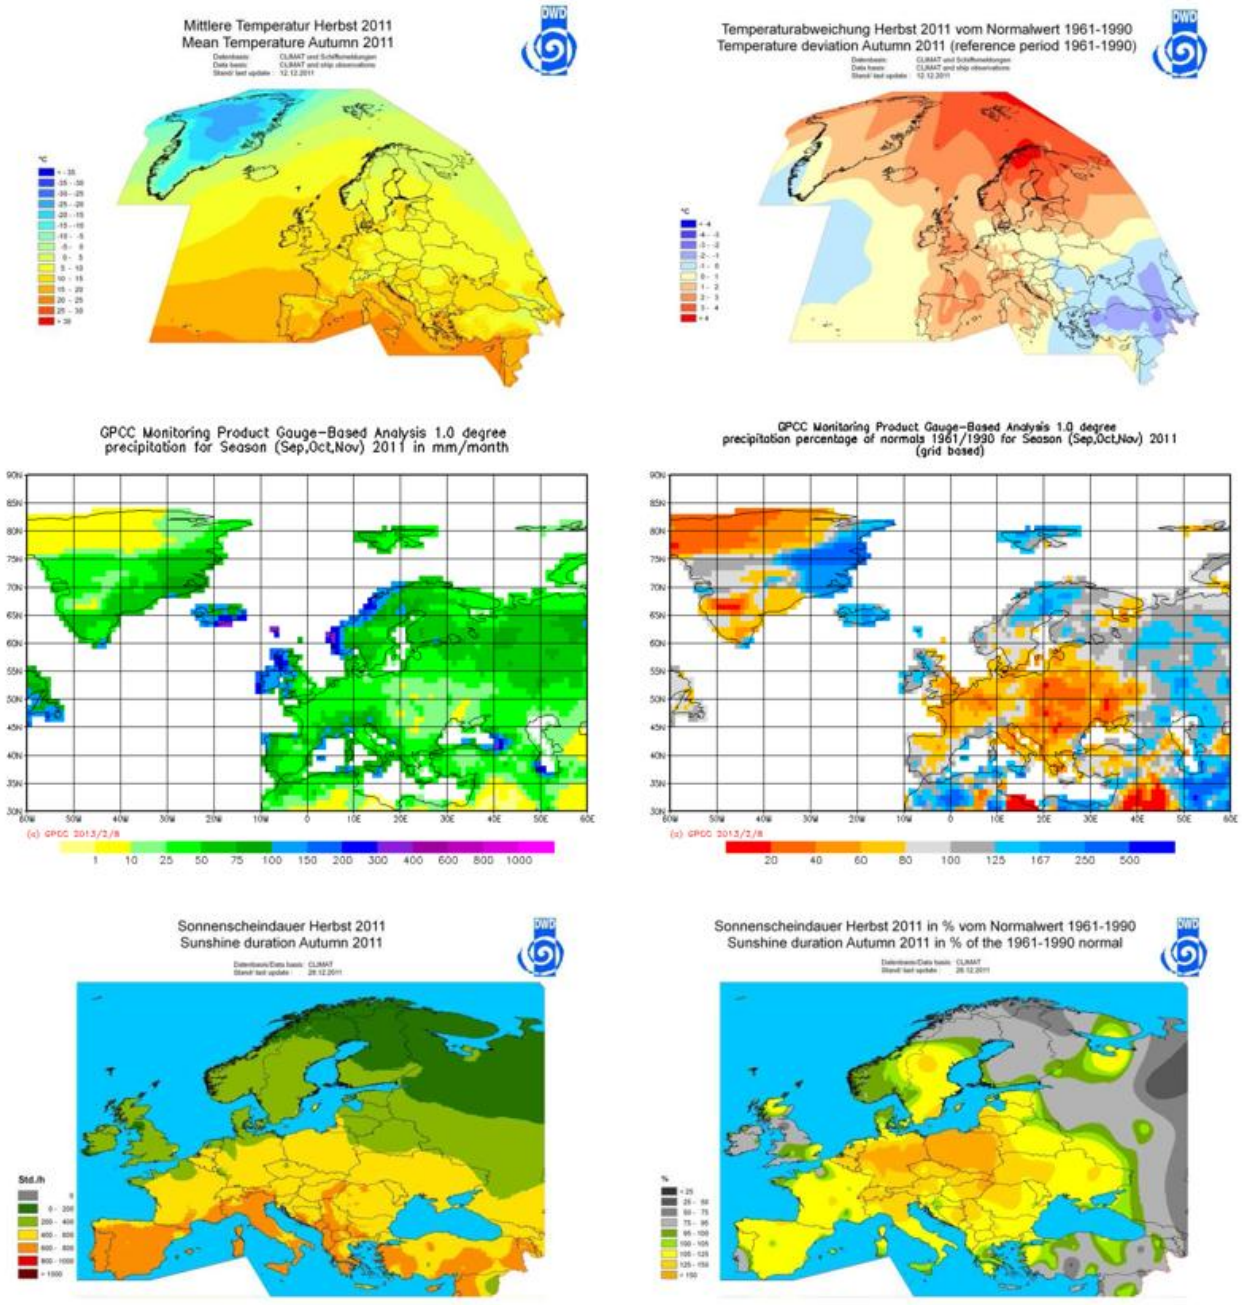

Fig. 2.36: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in autumn 2011*
Source: http://www.dwd.de/rcc-cm

Autumn

The distribution of positive and negative anomalies of autumn 2011 resembles the one of spring 2011. An area centered over the Caucasus with anomalies of -2 K and more over Turkey, the Caucasus countries and southern Russia, was colder than normal. Colder than normal was also the western North Atlantic and the southwesternmost part of Greenland. Everywhere else it was warmer than normal. The highest positive anomalies occurred in northern Scandinavia and the northeastern Arctic. It was the warmest autumn since 1900 in Norway, where the areal mean over the country came up to +3.1 K, and also the warmest autumn on record in places of Ireland (for 150 years in Dublin). Though the ranks are not reported it may be the same in Sweden (areal mean +2.9 K) and Finland (areal mean +3.3 K). Svalbard reached an areal mean of positive anomalies for autumn 2011 of +3.8 K). For the Baltic states the areal means of anomalies ranged from +1.4 K to +2.5 K, UK had +2.2 K, Iceland and the Faroer Islands +2.0 K. Autumn 2011 achieved rank 2 of warm autumn seasons since the beginning of the 20th century in France.

Summer days occurred remarkably more often than normal in southwestern, southern and southeastern Europe and tropical nights occurred locally unusually often in the central and eastern Mediterranean Sea area (see European Climate Assessment & Dataset - Indices of extremes).

Autumn 2011 was drier than normal on most of the continent, namely in central, western and southern Europe and parts of eastern Europe and of the Middle East. The precipitation totals for the season remained below 80 % overall, in eastern Europe and in western and partly central Europe below 60 percent and partly below 40 percent in eastern Europe and on the Balkan Peninsula. The greatest negative absolute anomalies in mm occurred around the Adriatic Sea. During the most outstanding month November 2011 a region extending from the North Sea to the Black Sea received less than 10 mm per month, partly less than 1 mm. This meant up to -70 mm in absolute anomalies (mm) and less than 20 % in relative anomalies. More information on November 2011 will be provided in the section 'Monthly Survey'. It was on the other hand wetter than normal in northern UK and Ireland, Scandinavia, Russia and most of the Middle East. But not only here but also in the dry areas heavy to extremely heavy precipitation fell in places like for instance in northern Italy in late October and in southern France in early November.

Autumn 2011 was sunnier than normal in Central Europe and in most of western, southern and eastern Europe and partly in the south of Scandinavia. See for comparison the maps of the number of days with cloud cover below 2 octa or above 6 octa (see RCC-CM: Products - Monitoring Europe - Cloud Cover.

Drought

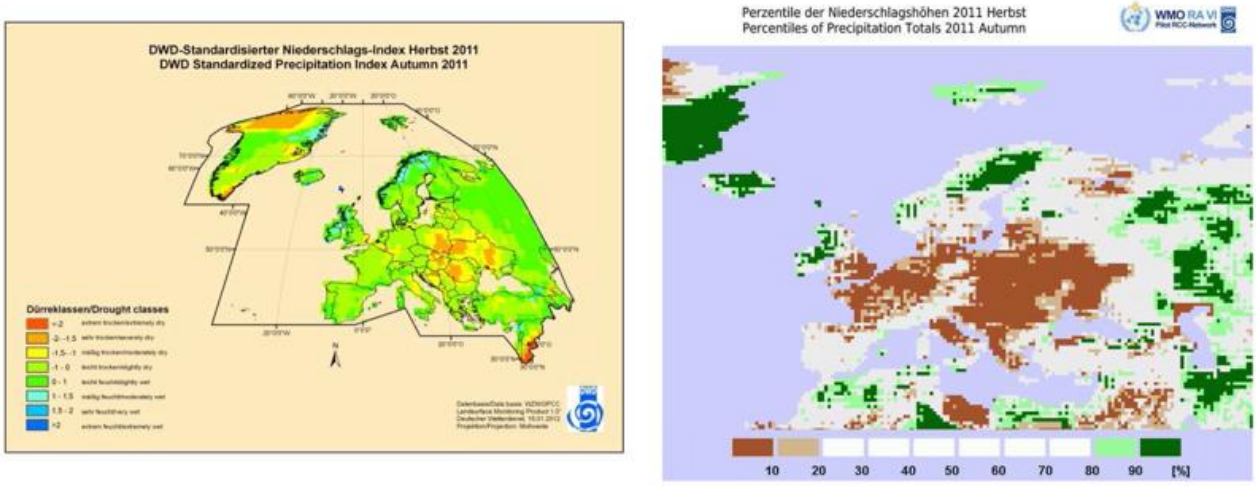

Fig. 2.37: *Means of the modified Standardized Precipitation Index (DWD-SPI) and precipitation totals in terms of percentiles based on GPCC data 1951 to 2000, autumn 2011*

In autumn 2011 the percentile map gives more weight of the dry area to the western and central European countries than the map of the SPI, though both clearly coincide that the largest coherent area with the driest conditions covers the northern Balkan Peninsula, eastern central Europe and western central Russia.

Monthly Survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2011 on the Climate in WMO Region VI - Europe and Middle East - which are available on Internet under http://www.dwd.de/rcc-cm.

January

Highlights:

- ***Temperatures were above normal in Europe with few exceptions of British Isles, southwestern France and western Mediterranean Sea.***
- ***Wet in northern Russia and Finland, mostly neutral or dry in western, central and southern Europe***
- ***Dull in northern and northeastern Europe, mostly sunny elsewhere***

Overview:

Temperature:

January 2011 had above normal temperatures in RA VI with few exceptions. It was cooler than normal for Ireland (with an anomaly of -1 to -2 K), parts of Britain, southwestern France and the western Mediterranean area as well as locally in the eastern Mediterranean, parts of the Black Sea, the Sea of Azov and the southeast of Ukraine. Temperatures of western Greenland were clearly above normal with an anomaly of more than +4 K. Most of Belarus and the northwest of Ukraine had positive anomalies of +3 to +4 K as well as eastern Turkey were even more than +4 K occurred.

Most striking is the positive anomaly of more than 4 K for Greenland. Some stations on Greenland had their warmest January on record. The Swiss mountain station Jungfrau Joch had its 3rd highest January maximum temperature of +0.7 °C.

Precipitation:

Much of the area of interest was dry or normal in January 2011 except northern Russia, Finland and central Russia as well as locations mainly in the central and Eastern Mediterranean sea (Sicily, Greece, western Turkey, Cyprus), west and south of the Black Sea and in the Middle East. It was especially fairly dry for southern France and northern Spain, the Alpes and the northern and western Balkan Peninsula as well as the Caucasus region and relatively dry for the British Isles and Ireland. Some remarkably high daily precipitation sums are reported especially from Norway 109 mm, United Kingdom 103 mm, Austria 110 mm, Portugal 133 mm, Turkey 116 mm and Greece 114 mm.

Lithuania and Latvia reported very high snow depths in January 2011. Lithuania had 60 to 68 cm of snow in the west at tbe beginning of the month. Latvia reported damages caused by the snowload. In Russia St Petersburg had the highest January precipitation total since obserbations began. 84.4 mm correspond to more than twice the normal value.

Sunshine:

The sunshine duration in January 2011 was remarkably below the normal in the north of European Russia, where a large area was nearly completely cloudy with 7 octa over the month (see Satellite-based Regional Climate Monitoring). Also in Germany a large portion of the country was as cloudy. Nearly as cloudy was the rest of central Europe, part of the Baltic Sea, parts of the northern Balkan Peninsula and the Ukraine where the sunshine duration was as well below the normal. Also rather dull was the northern North Atlantic with at least 16 dull days and further north in the Norwegian and the Arctic Sea at least 21 dull days. 6 - 10 fair days occurred for most of the Peninsula Iberica and in the western and the eastern Mediterranean Sea, as well as over the Alpes. Here as well as in a smaller region of northern Spain and the adjacant sea and for the eastern and southeastern Mediterranean even more than 10 fair days occurred but hardly more than 15. The British Isles and Ireland had a little more fair days with up to 10, the same for southern Norway and dull days were below 11 over the British Isles, the North Sea, much of Scandinavia and most of the central and eastern North Atlantic. This distribution of cloudiness corresponds to the positive sunshine duration

anomalies for Ireland and Scotland and southern Scandinavia and it explains also the patchy distribution in the Mediterranean and for the Balkan Peninsula. Only the positive anomaly in Central Europe does not match the cloud distribution well. But this is matter of small differences and possibly of spatial resolution of the satellite data in this case.

Monthly Means or Totals and Anomalies :

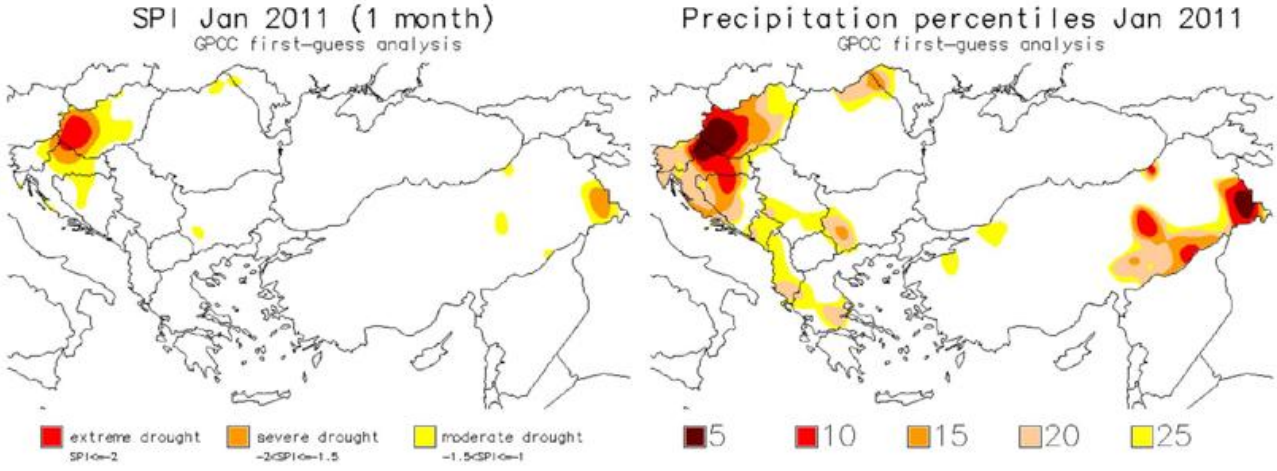

***Fig. 3.4** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
January 2011

February

Highlights:

- ***Very cold in eastern Europe, warm in the west.***
- ***Mostly dry with regional exceptions mainly for the British Isles, the Mediterranean Sea and the Caucasus region.***
- ***Sunny except the northwest of the continent and the British Isles, parts of the Balkan Peninsula and the Caucasus region***

Overview:

Temperature:

February 2011 was warmer than normal on the North Atlantic, in western and southern Europe and in the Middle East as well as over Greenland and the Arctic Sea. The anomalies in the north exceed +4 K, in England there is a secondary maximum of 3-4 K. On the other hand it was very cold in Russia, Finland and northern Sweden with anomalies below -4 K. Generally the negative anomalies also included all Scandinavia, Eastern Europe, the Balkan Peninsula, the Black Sea region and the Caucasus region as well as the central Mediterranean Sea. Rather impressive is the spatial distribution of the anomalies of the number of ice days (see the anomaly map of ECA&D).

It was the warmest February on record on the Faroe Islands and as well for at least on station on Greenland. The Austrian station Reichenau/Rax recorded its 3rd highest temperature maximum of February since start of the time series in 1865 with 20.6 °C. It was on the other hand one of the 10 coldest February months on record for European Russia, with anomalies well below -3 K for the whole region and up to -8 K in the center of the cold. Minimum temperatures of -46 °C were recorded.

Precipitation:

Most of Europe was dry in February 2011 with some exceptions which can partly be related to heavy precipitation like in Ireland, Scotland, Denmark, southern Sweden and northern Germany. Also the Mediterranean Sea received more precipitation than normal and remarkable highest daily totals were reported by Portugal (74 mm), Spain (57 mm), France (136 mm), Italy (151 mm), Greece (135 mm), Turkey (87 mm), Syria (92 mm), Israel (52 mm) and Lebanon (49 mm) (see table). Also the Caucsus area had more precipitation than usually. Georgia reported between 92 and 463 percent of the normal (corresponding 72-696 mm) in the west and 26 to 345 percent of the normal (corresponding ??) in the east.

In Estonia the snow depth was exceptionally high.

Sunshine:

Sunny conditions were prevailing in February 2011 in most of the area except Britain, most of France, Belgium, the Netherlands and western Germany, parts of the Balkan Peninsula, Middle East and the Caucasus region. The sunniest regions were the Baltic states, Finland, northern Russia and northern Sweden and Norway with more than 150 percent of the normal.

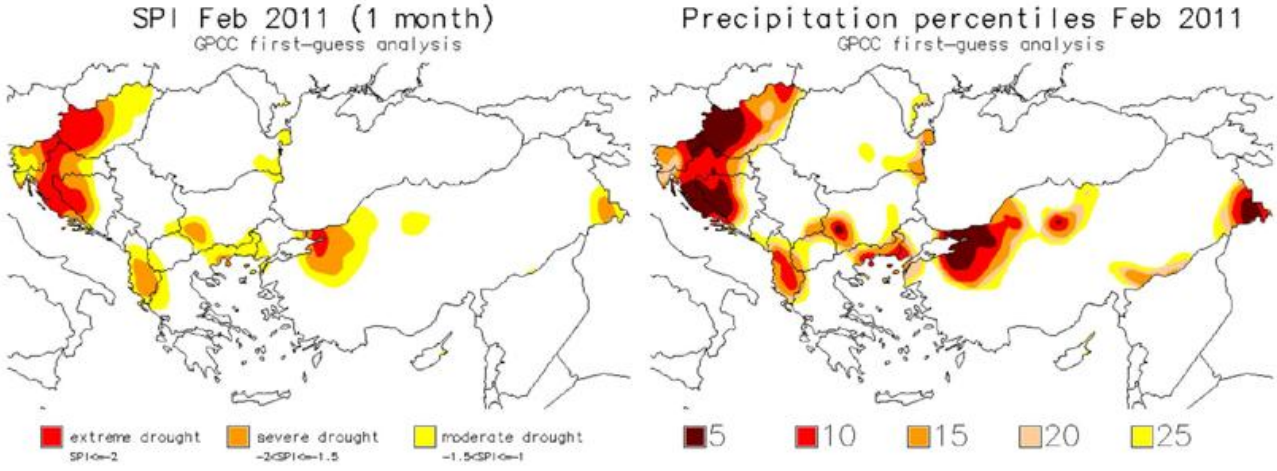

***Fig. 3.8** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
February 2011

March

Highlights:

- ***Mostly warm except parts of the eastern Mediterranean Sea, the Black Sea and the Caucasus and southern Russian region as well as south of Greenland.***
- ***Mostly dry, except the northern North Atlantic and Arctic Sea, the Mediterranean Sea and southern Russia.***
- ***Mostly sunny***

Overview:

Temperature:

March 2011 was relatively warm in most of the region except the southern Balkan Peninsula, the Black Sea region and southern Russia as well as the North Atlantic south of Greenland. The positive anomalies were highest for the Arctic regions but still were in the range of 2-3 K in the Alpine region and southwestern parts of Germany. Maximum temperatures close to 20 degrees C or even above were reached in many central and western European countries and even Denmark, Sweden and Norway achieved maximum values above 15 deg C.

On 10 March the Greek station Helliniko recorded its coldest March minimum temperature with -1.8 °C.

Precipitation:

March 2001 was remarkably dry for most of the region. Only southern Iceland, Scotland and western and northern Norway and parts of the Mediterranean Sea, especially southern Spain and Portugal, southern France, Italy and Lebanon received more precipitation than usual. The latter are related to some extreme events, see the event calendar. The lack of precipitation is on the other hand remarkable for large areas. The DWD standardized Precipitation Index shows areas of the class 'severely dry' or even 'extremely dry' in southern England, the low countries, Germany, Latvia, Belarus and Ukraine and parts of Russia, southwestern Turkey and Eastern Syria and Jordan.

In Germany March 2011 was the 7th driest since 1881.

Estonia and Russia (upper Volga region) reported exceptionally high snow depths. St Peterburg had record-breaking 73 cm of snow on 5 March and Estonia up to 82 cm in the northeastern parts.

Sunshine:

March 2011 was a sunny month almost everywhere except the Peninsula Iberica, western Turkey and eastern Bulgaria and Greece and eastern Russia. Most of Germany, Austria, the lowlands, the adjacent parts of France, Poland, and much of the Ukraine and a smaller part of Sweden had more than 150 percent of the normal. Correspondently the anomalies of the mean cloud cover are negative in March 2011 almost everywhere, except the Peninsula Iberica and the northern Mediterranean Sea area. Large areas in central and southern Europe had more than 6, partly more than 11 fair days and the number of dull days mostly below 10, in the Mediterranea Sea area, over the British Isles and in much of Scandinavia, the Baltic states, Belarus, Ukraine and Molova below 5 days.

In Germany it was the 2nd sunniest March since 1951.

Wind:

On 7-9 March strong gale winds with gusts up to 34.7 m/s occurred over the Aegean Sea.

Monthly Means or Totals and Anomalies :

March 2011

April

Highlights:

- *Very warm in most of Europe*
- *Very dry in most of Europe*
- *Sunny in most of Europe*

Overview:

Temperature:

April 2011 was warmer than normal in central, southern and northern Europe, but cooler in the eastern Mediterranean, around the Black Sea and in the Caucasus area and the western North Atlantik and western Greenland. The positive anomalies in most of the European countries were above 3 K or even above 4 K on much of the Peninsula Iberica, in France, the Benelux countries, Germany, Poland, Switzerland, the Czech Republic, Denmark, as well as parts of Sweden, Norway, Finland and southern England. Also for the eastern part of Iceland it was one of the warmest April months of record. Many records were broken. Ireland reported the 'warmest April on record' at most of the northern and some southwestern stations. UK registered the warmest April since 1910 and the warmest for over 350 years in central England. In the Netherlands it was the warmest April since 1706 together with April 2007 and 2009. In Denmark it was the warmest April on record. In Norway it was the warmest April since 1900, in Sweden ist was the warmest April on record at several southern as well as northern stations. Also the Faroe Islands had their warmest April.In Germany April 2011 was on rank 2 since 1881 after 2009. In France it was the second warmest April since 1900, after 2007. In Switzerland April 2011 was the second warmest after 2007 since the records started in 1864. In Austria it ranged on the third place since 1800. In Portugal it was the warmest April since 1931.

Slovakia recorded the first 'summer day' on 7 April at most stations in the west and north-east. This is at many stations the earliest recorded 'summer day'. Switzerland as well reported such high temperatures on 7 April. On 9 April even 31.8 °C were recorded in Locarno-Monti. Spain reported 37.4 °C on 9 April in Murcia which means as well a new record.

Precipitation:

April 2011 was dry in most of central, western and eastern Europe as well as in northern Europe except the Norwegian coast. It was on the other hand wet in most of the Mediterranean Sea area, the Black Sea area and the Middle East. The dry weather lasted already the third month and consequences of the drought occurred.

In France it was one of the driest April months in 50 years with below 30 percent of the normal precipitation totals. The years 1982 and 1984 were similarly dry in France. In Montenegro it was the driest April since measurements began for parts of the country. The coastal areas recieved onla 2 percent of the normal precipitation. In Israle on the other hand it was the 2nd or 3rd wettest April of the last 70 years in places and the number of rainfall days was the largest of the last 60 or 70 years.

Sunshine:

The sunshine duration was above normal in April 2011 nearly everywhere except Russia, the Caucasus, the eastern Mediterranean Sea and the Middle East. In most of France, Germany, Switzerland and in parts of the Netherlands, Austria and northern Italy as well as Poland and Lithuania and in central England it came above 150 percent of the normal.

April 2011

May

Highlights:

- ***Warm in western and southwestern Europe***
- ***Ongoing drought in western Europe but many heavy precipitation events on the other hand***
- ***Sunny for most of the European continent***

Overview:

Temperature:

Western and southwestern Europe including the east of the British Isles were warmer than normal in May 2011. The anomalies exceeded 3 K in Portugal, parts of Spain and France and Austria. The the eastern Mediterranean area and partly Balkan Peninsula as well as much of the North Atlantic were cooler than normal or close to normal. In central Turkey the negative anomalies range between -1 and -2K. In Poland in Torun with -7.2 °C the lowest May temperature since 1951 was measured.

France recorded its warmest May since 1900. Switzerland had the 3rd warmest May since 1864. Portugal had its warmest May since 1931.

Precipitation:

In western and southern Europe it was mostly extremely dry. The drought lasting from February 2011 on was ongoing (see http://www.wmo.int/pages/mediacentre/news/drought_en.html). Also it was dry in southern Ukraine and central European Russia as well as parts of the Middle East. It was on the other hand wet in Ireland, Scotland, most of Scandinavia and parts of northern Russia as well as the southwestern Mediterranean area and the southern Peninsula Iberica and the northern central and eastern Mediterranean Sea and parts of the Middle East as well as the eastern Black Sea region and southern Russia.

In France it was the driest May of the last 50 years with only 37 percent of the normal.

Sunshine:

Most of the European continent was sunnier than normal. Scandinavia - except in the south - , Ireland and western UK, the southern Iberian Penisula, the eastern Mediterranean Sea, most of the Black Sea reagion, the Caucasus and the southern and northeastern parts of European Russia were slightly dull. In Austria it was the sunniest May since the beginning of measurements in 1884.

Wind:

In Ireland the highest winds during the last 25 years were recorded in places. The station Belmullet in County Mayo registered the absolutely highest windgust ever recorded in May with 40 m/s.

May 2011

June

Highlights:

- ***warmer than normal***
- ***More precipitation than normal except in southwestern Europe, eastern and southeastern parts of central Europe and the east***
- ***Mostly fairly sunny in eastern central Europe, western Russia, the Balkan Peninsula and parts of the Mediterranean***

Overview:

Temperature:

The temperature anomalies were close to or above normal everywhere except over the northeastern North Atlantic with negative anomalies below -1 K for western Ireland and for Iceland and 0 to -1 K in most of Turkey. The highest positive anomalies occurred in the Arctic and westernmost Greenland with more than 3 K but on the continent in most of Finland, northern Sweden and Norway, the Baltic states, Poland, Belarus, Ukraine and western and northeastern European Russia as well as partly in the Adria region and on the southern and central Iberian Peninsula the anomalies also exceeded 2 K. Latvia had the 2nd warmest June (and July as well) within 88 years while Israel recorded the coldest June since 1980. It was as well abnormally hot in Murmansk where 29.4 °C were regisered on 8 June.

Precipitation:

Positive anomalies of the total precipitation amount in June 2011 were received by partly the British Isles, the northern and northwestern continent, northern Europe with a maximum in southern Norway and Denmark, western and southern Russia, the eastern Balkan Peninsula, the western Caucasus region and Turkey as well as the Alpes. Less precipitation than normal fell on most of the Iberian Peninsula, in southwestern France, on the western and central Balkan Peninsula, in the Baltic states, northern and partly central and southern Russia and also in parts of central Europe. Much of the precipitation fell as heavy precipitation connected to convective activity.

In Norway it was the 2nd wettest June since 1900 with 170 percent of the normal. On 10 June the Italian station La Stella in the region Emilia-Romagna received precipitation of extreme intensity with 67 mm within 1 hour. On 27-28 June Switzerland received very intense precipitation.

Sunshine:

It was especially sunny in June 2011 in Poland with positive anomalies up to 150 percent of the normal and also fairly sunny for Ireland, the Iberian Peninsula, Italy, the western Balkan states and the east of central Europe except Slovakia, the Baltic states, Belarus and western Russia, southern Sweden and Finland and northern Russia as well as the Netherlands. Elsewhere it was close to normal or slightly dull.

Wind:

On 4 June a downburst of thunderstorms uprooted 100000 m² of wood in Sweden.

Other Phenomena:

Switzerland had heavy thunderstorms and hail in the beginning of June. On 1st of June a remarkable snowfall occurred at the Swiss station Adelboden (1320 m a.s.l.) with 11cm of freshly fallen snow.

June 2011

July

Highlights:

- ***Colder than normal in western and central Europe, warmer in the north, east and southeast***
- ***Wet to very wet in most of continental Europe***
- ***Mostly dull except in the east and southeast.***

Overview:

Temperature:

In July 2011 central, western and southwestern Europe was colder than normal but northern, eastern and southeastern Europe was warmer. France, Belgium and southwestern Germany had negative anomalies in the range of -1 to -2 K. Russia on the other hand had positive anomalies of more than 4 K. It was the 2nd warmest July of European Russia since the beginning of observations there. In Portugal the station Corvo registered 29.7 °C on 26 July and Punta Delgada on the Acores had 28.8 °C on 24 July. A highest maximum temperature of 44.3° C was reported for Russia. Also in Georgia maximum temperatures of 42 °C were achieved and Armenia had the highest July temperature ever recorded in Armenia on 31 July in Meghry. Such high values also occurred in Israel, Jordan (46.5°C in Rwaished, eastern Jordan) and Syriah (45° C). Sweden reported a tropical night on 23 July for Stockholm. Finland reported July 2011 as one of the warmest July months of the last 50 years and more hot days than normal. In Latvia July 2011 was (like June) the 2nd warmest if the last 88 years.

Precipitation:

Most of the European continent had more precipitation than normal in July 2011. Most striking were the positive anomalies for eastern Germany with more than 500 percent of the normal, but also in Denmark, southeastern Poland, and southern Norway and also smaller areas in France, Switzerland, the Balkan States, the Baltic States and Ukraine. Only the Mediterranean Sea area, most of the British Isles, central Skandinavia, northern, eastern and southern Russian and the Caucasus were dry. Precipitation fell often as convective precipitation with partly extremely high intensities.

In Denmark extremely heavy precipitation occurred on 2 July which brought 135.4 mm in 24 hours in Copenhagen. On 20 July the station Nizhni Novgorod in European Russia received 91 mm precipitation within 2 hours and 47 minutes. In Romania the station Siria received the highest July precipitation total on its record with 235.2 mm. 5 Romanian stations had 24 h precipitation totals which exceeded their former records.

Sunshine:

Most of western, northern and central Europe was dull while the Iberian Peninsula, Scotland and eastern and southeastern Europe were sunnier than normal.

Wind:

In Northern Lithuania a F2 tornado occurred on 27 July.

July 2011

August

Highlights:

- ***Cooler than normal in the northwest under influence of the North Atlantic, warmer especially on the Balkan Peninsula***
- ***Mostly dry in the Mediterranean Sea and Balkan regions as well as the Middle East and Russia. Wet in the north and northwest.***
- ***Mostly sunny except in the north and northwest.***

Overview:

Temperature:

August 2011 was warmer than normal on most of the European continent with a maximum of the positive anomalies of up to 4 K over the Adriatic Sea and the adjacent Balkan countries and Italy. Montenegro reported for the station Podgorica 4 consecutive days (23 to 26 august with daily maximum temperatures above 40 °C, which happened for the first time since 60 years. But also Switzerland reported August 2011 to be one of the 10 warmest August months since 1864. Germany reported August 2011 to be on rank 23 since 1881. The British Isles and the central North Atlantic as well as northeastern Russia were on the other hand cooler than normal.

Precipitation:

The western Iberian Penisula, Scotland, the western and northern European continent and most of Scandinavia as well as locally regions around the Black Sea and the Caucasus area received more precipitation than normal, while the western Mediterranean and the Balkan area, most of the countries around the Black Sea as well as central European Russia were dry. So in France the Haute-Normandie had the wettest August of the last 40 years while the Island of corse hat the driest August in the last 40 years. Norther Caucasis, paticularly Dagestan, received 300 to 400 percent of its normal precipitation in August 2012. In spite of the positive precipitation anomalies the soil moisture anomalies are still negative in most of France and southern UK according to the global analysis of the NOAA Climate Precition Center (http://www.cpc.ncep.noaa.gov/cgi-bin/gl_Soil-Moisture-Monthly.sh). The long-term reference is based upon 1979-2007.

Sunshine:

The Alpine Region and the eastern European countries Poland, the Czech Republic and Hungary were mostly very sunny and overall most of Europe except the west and northwest and the Middle East were sunnier than normal.

August 2011

September

Highlights:

- ***Warmer than normal on the continent as well as in the Arctic Sea***
- ***Drier than normal in the west and southwest, the western Mediterranean, northern Balkan Peninsula and eastern central Europe, wetter than normal for Ireland, Scotland, most of Scandinavia except the north, Russia, the Caucasus, parts of the Eastern Mediterranean and Middle East***
- ***Sunnier than normal over the western and central European continent,the south and the southeast around the Black Sea, less sunny in the north and northeast and the Middle East.***

Overview:

Temperature:

September 2011 was warm except on the central North Atlantik and regionally in the southeast (northeastern Turkey). It was particularly warm on the Balkan Peninsula and the Adriatic Sea as well as in the Arctic Sea. Records were broken in several countries: In UK September 2011 was the warmest September since 2006 and the equal-sixth warmest in the last 100 years. September 2011 was also one of the warmest months ever recorded in northernmost Sweden.In Germany September 2011 was warm on rank 10 since 1091 resp. rank 11 since 1881. In Switzerland it was the 4th warmest and locally the warmest September since 1864. In the southern and southeastern parts of Austria it was the warmest September since the beginning of observations in 1813. Also in the Netherlands rank 10 since 1901 was achieved. Norway had the 5th warmest September since 1900. Record high temperatures were measured during the first days of September at some locations and 29 september the highest temperature ever recorded so late in September occurred at Hudiksvall in central Sweden with 25.6 °C. As well southern Finland was exceptionally warm on 30 September with temperaures over 20 °C. The highest maximum temperature here was recorded at Porvoo with 22.3 °C. Serbia had the hottest September since 1994. Montenegro reported the warmest September since mesurements started. The anomalies ranged between +3.5 K to 5.1 K. During all first 7 days of September the maximum temperature rose above 33 °C in Podgorica for the first time after 60 years. In Bulgaria september was one of the thee warmest months. Croatia was mostly extremely warm (above the 98th percentile, reference 1961-1990). In Slovakia the mean temperatures were mostly on rank 1 to 5 since 1961. In Slovenia daily maximum temperatures broke former records at some stations on 4 September and overall the country reported a record warm September. Sinaia in Romania recorded the highest Spetember maximum temperature in its time series in 14 September 2012 with 27.2 °C.

Precipitation:

September 2011 was drier than normal in western, southwestern, mostly southern, far northern and in eastern central Europe. In Slovakia the monthly precipitation totals only ranked between 41 and 49 out of 51 years since 1961 and in the southeast of the country it was locally the driest September since 1901. It was wetter than normal in northern and northeastern Europe, northern UK and Ireland, partly in Germany and in the Alps and regionally in the central and eastern Mediterranean region and Middle East. The surplus was often caused by heavy precipitation. In Sweden in the rgeion Norrland some stations registered new records of monthly precipitation totlas since 1860 resp. 1876.

Sunshine:

September 2011 was sunny for most of the continent except the northwest, north, east and southeast. It was most sunny in Poland and most dull in northern Russia. In Slovakia for instance the sunshine duration of September 2011 was on rank 1 to 3 since 1961.

Other Phenomena:

In 2011 the lowest September average sea level pressure (995 hPa) on Iceland since measurements started in 1822 was recorded.

September 2011

October

Highlights:

- ***Colder than normal in the southeast, mostly warmer elsewhere***
- ***Widely drier than normal except in the central and eastern Mediterranean Sea, the Black Sea and under northern North Atlantic influence***
- ***Mostly sunny, except in the east and the British Isles.***

Overview:

Temperature:

October 2011 was warmer than normal in northeastern, northern, western and southwestern Europe. The northeast was warmest with anomalies above 3 K. But also in the north for instance in Norway many stations broke their former records for the highest maximum temperatures for October. The British Isles as well as the Peninsula Iberica had anomalies above 2 K and southern England and in southwestern Spain and Portugal the positive anomalies exceeded 2 K. In Portugal October 2011 was the warmest October since 1931. Spain had a new temperature record with 36.5 °C on 12 October in Jerez de l Frontera. Also Russia had a very warm October. Both reported anomalies of more than +4 K. Poland reported an extreme maximum temperature in Opole of 25.7 °C. Slovakia had as well a new record for October with 28.2 °C on 1 October in Dolne Plachtince. Slovenia recorded the 2nd highest October temperatre in Ljubljana with 26.1 °C. In France a heat wave during 25 September to 4 October with more than 30 °C in western and southern parts of the country brought record-breaking temperatures for October at some sites. This was as well the case in UK where the heat wave lasted 28 September to 3 October with more than 28 °C widel in central and western England and the provisionally highest October temperature ever recorded in UK with 29.9 °C in Gravesend on 1 October. 1 October also brought the highest October temperature ever recorded in Denmark (26.9 °C). It was colder than normal in the southeast, mainly the eastern Mediterraenan Sea with Greece, the Aegean Sea, western Turkey, Bulgaria and Romania with anomalies of -1 to -2 K as well as the western North Atlantic. The greatest negative anomalies were registered in northwestern Turkey with anomalies of -2 to -3 K. In Central Europe it was slightly warmer or close to normal.

Precipitation:

October 2011 brought totals of more than 150 mm under Atlantic influence at the western coasts of Scandinavia, in the north and west of the British Isles, on Iceland and in the northwest of the Peninsula Iberica. In Norway more than 400 mm were regionally achieved and several stations broke their former maximum values for October totals and also some stations broke their former records of maximum daily totals for October as well. Totals of more than 150 mm occurred also in the east, the west and south of the Black Sea, in southwestern Turkey, western Greece, southern Italy and in Slovenia and Croatia. This was absolutely (in mm) much more than normal especially in southern Italy and Algeria, in western Turkey and in Bulgaria and Romania, and east and west of the Black Sea as well as for places in Scotland and Northern Ireland, on Iceland and partly in Norway. But also northern Scandinavia received much more precipitation than normal. In terms of relative anomalies (percentages) the surplus around the Black Sea and western Turkey is even more pronounced and moreover the southeast (Irak, Jordan) as well as northwestern Africa had much more precipitation than normal. Much of the precipitation fell as extremely heavy precipitation with daily totals of 50 mm and more. Daily totals of 100 mm were exceeded in Turkey, Slovenia, Croatia, Greece, Bulgaria, Spain, Italy and France. In Italy a desatrous precipitation event occurred in Liguria on 25 October, when rain intensities between 50 mm/h and 153 mm/h occurred in the areas Cinque Terre, Val di Vara and Lunigiana. Borghetto di Vara received more than 50 mm/h during 6 hours and overall a total 472 mm over 6 hours. Much damage occurred and 13 people came to death. It was on the other hand drier than normal in western, southwestern and mostly central Europe. In parts of Poland October 2011 was extremely dry.

Sunshine:

October 2011 was sunnier than normal in northern, central, western and southwestern Europe and most of the Balkan Peninsula, but dull over most of the British Isles, the east and the southeast. The sunshine duration was exceptionally high in some countries (Belgium, Netherlands and Germany ranking below 10 for the sunny October months since time series begun).

Wind:

During 16-18 October desastrous storms with a lot of damages occurred in Bulgaria.

October 2011

November

Highlights:

- ***Warmer than normal in the Arctic region and in northern, western and southwestern Europe. Colder in the Middle East.***
- ***Dry on the European continent but partly very wet in coastal regions of the Atlantic and the Mediteranean Sea.***
- ***Mostly sunny on the continent, very sunny in Central Europe.***

Overview:

Temperature:

There is a strong positive temperature anomaly of more than +4 K in the Arctic region and most of Scandinavia and a similarly strong negative anomaly in the Middle East with more than -4 K over Turkey and the eastern Black Sea region as well. Western and southwestern Europe was as well warmer than normal withup to 3-4 K in parts of United Kingdom and western France.

Most striking was the large positive anomaly in the Arctic region. The Faroe Islands for instance had an anomaly of + 8.9K. And Iceland reported 'one of the warmest Novembers on record'. In northern Sweden some locations had their warmest November. November 2011 brought some new records for daily temperature values. So Switzerland reported a maximum temperature of 23.1 °C on 4 November in Altdorf in a Foehn situation and nearly a 'tropical night' (19.7 °C) in Glarus on 3 to 4 November. In Switzerland Nobember 2011 was the mildest November since 1864 in the summit regions. The mountain station Säntis had an anomly of +6 K (reference 1961-1990). Also in Germany it was the warmest November at many summit stations at least since 1900 (at Hohenpeissenberg since 1781). In France it was the 2nd warmest November since 1900 with an anomaly of + 3 K. In Norway it was the warmest November at least since 1900 with an anomaly of +4.6 K. The Norvegian station Svinoy fyr had the highest monthly mean since its start of the time series in 1867. In Sweden it was also the warmest November on record for several stations.

The western North Atlantik was cooler than normal up to -2- -3 K. As well in the Middle East it was colder than normal. So Armenia had the coldest November on record with negative anomalies of -4.5 to -6 K. Similarly cold was November 2011 in the south of european Russia. And in Israel it was the coldest November since 1980.

Precipitation:

Very dry conditions with monthly totals below 10 mm prevailed from the North Sea to the northeastern Mediterranean Sea and Black Sea region in November 2011. This dry period is extraordinary in both aspects, the spatial extent and the amount. The map of precipitation anomalies shows the European continent and southeastern United Kingdom, most of Scandinavia (except the western and northwestern parts, southeastern Europe and the most of the eastern Mediterranean region below 80 percent of the normal (reference 1961-1990) and also the modified SPI (DWD) was in most of the area below -1.5, meaning at least 'severely dry' (figures 3.41 and 3.42). The maps of South Eastern Europe (fig. 3.45) show 'extreme drought' and precipitation percentiles below 5 for most of the Balkan Peninsula, Greece and western Turkey (possible slight differences in the SPI-definition do not result in differences in this case). In Germany the average amount of precipitation in November 2011 was 2.3 mm compared to a normal of 66.4 mm (reference 1961-1990). It was even the driest month over all seasons (ahead of April 1893 with 3.7 mm). In Uccle, Belgium it was the driest November since 1833. Also Denmark and the Netherlands broke their records. Poland as well reported an extremely dry November for the whole country with many stations without any precipitation.

The drought situation is also described in "State of the Climate 2011" (p.197-198). Fig. 3.43 provides some more details concerning the climatological assessments for Greece, Slovakia, Hungary and Bulgaria. Bulgaria had up to 28 (of 30) days without rain in some areas. Moldova reported for the biggest part of the country 0 mm, or 1-3 mm only,as November precipitation totals. This was a new record since the beginning of Moldovian precipitation observations. Romania received only 3 % of the normal precipitation (1.2 mm) in November 2011.Ranking information is provided in the following table:

Country	Rank of dry November months	since (* = beginning of records)
Austria	1	1858*
Belgium	1	1833 (Station Uccle)
Germany	1	1881
Hungary	1	1901
Luxembourg	1	1947*
Slovakia	1	1881
Sweden	1 (locally)	*
Switzerland	amongst driest	1864*

The high temperatures and low precipitation led to a new phenomenon in the Swiss Alps: for the first time since snow measurements began in 1931 the Säntis (2502 m a.s.l.) had no fresh snow in November 2011. In Arosa (1840 a.s.l.) this phenomenon occurred two times before 2011 in the series since 1890, namely 1899 and 1920.

The European Atlantic coasts, the western Mediterranean Sea, the Levante coast and the eastern Black Sea area received on the other hand partly extremely large precipitation totals . France received 300 to 400 percent of the normal in the Pyrenees and the Mediterranean areas and in Italy the area of Liguria received the second devasting rain within only 10 days. In the area of Geneva intensities of 180 mm/h resp. 400 mm/12h occurred and 6 people came to death. The rain intensities between 3 and 6 hours wre estimated to have return periods between 200 and 500 years. This was partly caused by the Mediterranean depression ROLF which had tropical character. The event is as well described in . Wetter than normal conditions in the north coincide with the warmer than normal conditions there. So it was the wettest November for Jan Mayen since the start of registrations there in 1908.

Sunshine:

November 2011 was mostly sunny in Europe except on the Iberian Peninsula, around the North Sea, northern Scandinavia, the easternmost region and the Middle East. In Central Europe it was very sunny with more than 150 % of the normal. For instance in Germany November 2011 became the second in the line of relatively sunny November months since 1951 (behind 1989 and ahead of 1983). In Austria it was the sunniest November since 1884 in large parts of the country. In Switzerland it was the 2nd sunniest November since 1961 at stations in the central and eastern Alps.

Wind:

Greece reported strong gale winds with gusts up to 30.8 m/s in the Aegean Sea on 13-14 November.

Monthly Means or Totals and Anomalies :

November 2011

December

Highlights:

- ***Mostly remarkably warmer than normal except in the Atlantic region and the southeast.***
- ***Wetter than normal in western, central, northern and eastern Europe, dryer than normal mostly in the Mediterranean region.***
- ***Dull in central, northern and eastern Europe, sunny in the Mediterranean Sea region, western Balkan Peninsula and Poland.***

Overview:

Temperature:

December 2011 was warmer than normal in Europe and the Arctic Sea region. Most remarkable is the surplus of more than + 4K for eastern and northern Europe. Lithuania for instance had a positive anomaly (reference 1961-1990) of 4.3 K and recorded record-breaking 8 to 12 °C in many places on 26 and 27 December. Russia reported as well an anomaly of 4.2 K and for the Arctic Franz-Joseph Islands an anomly of +14 K is reported. Fig. 3.48 shows the spatial extent of the warm anomaly in Russia as well as time series of daily temperatures in December and of mean December temperatures over the years for 3 stations. The daily maxium temperatures in Moscow and St. Petersburg in 27 and 28 December were record-breaking. Belarus reported an anomaly of +5 K for December 2011. Armenia reported as well a new record for a December daily maximum temperature in Baku of 22.7 °C. It was colder than normal on the North Atlantic and in the eastern Mediterranean and the Middle East.

December 2011 was the coldest December in over 100 years in United Kingdom and the 2nd coldest since 1659 for 'Central England'.

Precipitation:

December 2011 was wetter than normal in western, central, eastern and most of northern Europe. Heavy precipitation occurred widely spread (see the Map of Climate Extremes below).

In Luxembourg it was the 3rd wettest December since records started in 1947 bringing more than twice the normal total. On 4 December the highest 1 hour precipitation of 15 mm/1 h was observed.

It was on the other hand dry in the western Mediterranean Sea and on the Iberian Peninsula and in the Middle East as well as in the Caucasus region and partly on the Balkan Peninsula and the soil moisture was still below normal in these areas according to the analysis of the Climate prediction Center (http://www.cpc.ncep.noaa.gov/cgi-bin/gl_Soil-Moisture-Monthly.sh). Reykjavik on Iceland reported the longest lasting snow cover since observations started in 1921 with 29 days in Dember 2012.

Sunshine:

Sunshine duration was well below normal in Ireland, western UK, central Europe as well as eastern and northern Europe. It was very dull in central parts of Germany and in European Russia and northern Scandinavia. It was on the other hand rather sunny on the Iberian Peninsula, parts of Italy, mostly in Poland, in Turkey and the Caucasus area. This patchy pattern corresponds fairly well with the anomaly of the fractional cloud cover (http://www.dwd.de/rcc -> products -> clouds).

Wind:

Storm JOACHIM hit France on 15-16 December. Remarkable was the spatial extent of the area with high wind speeds. It covered about one quarter of France with gusts of 25 m/s or more. The highest gusts occurred on the Puy-de-Dôme (up to 59 m/s in 1465 m asl).

Storm DAGMAR was devastating in Sweden on 26 December. UK reported generally stormy weather across Scotland from late November to mid December.

Other Phenomena:

Belgium reported a record number of thunderstorms for December. Uccle had 11 days compared to normal 3 days. Sweden reported the highest thunder activity ever recorded in December.

Monthly Means or Totals and Anomalies :

Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI NMHSs as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network and WMO´s World Climate Data and Monitoring Programme the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMOs climate system monitoring, complementing and detailing well-known regular global assessments, such as WMOs Annual Statement on the Status of the Climate and the State of the Climate Article published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ amongst the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

Notes:

- Maps of the RA VI RCC Network are based on the following data sources:
  - Temperature: CLIMAT data and ship observations provided by the Global Collection Centre (GCC), run by Deutscher Wetterdienst
  - Precipitation: Global Precipitation Climatology Centre (GPCC), run by Deutscher Wetterdienst
  - Sunshine: CLIMAT data.
  - Anomaly maps of climate indices are provided by the RCC-CD (ECA&D)
- Subregional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC) and the Southeast Drought Management Centre (DMCSEE)

The following subregions are used in the Bulletin:

Central and western Europe: *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, Netherlands, Poland, Slovakia, Switzerland, United Kingdom*
Nordic and Baltic Countries: *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden*
Iberia: *Portugal, Spain*
Mediterranian, Italian and Balkan Peninsula: *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Serbia, Slovenia, Republic of Macedonia, Montenegro, Turkey* ***Eastern Europe:*** *Belarus, European Russia, Moldova, Romania, Ukraine*
Middle East: *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, western Kasakhstan*

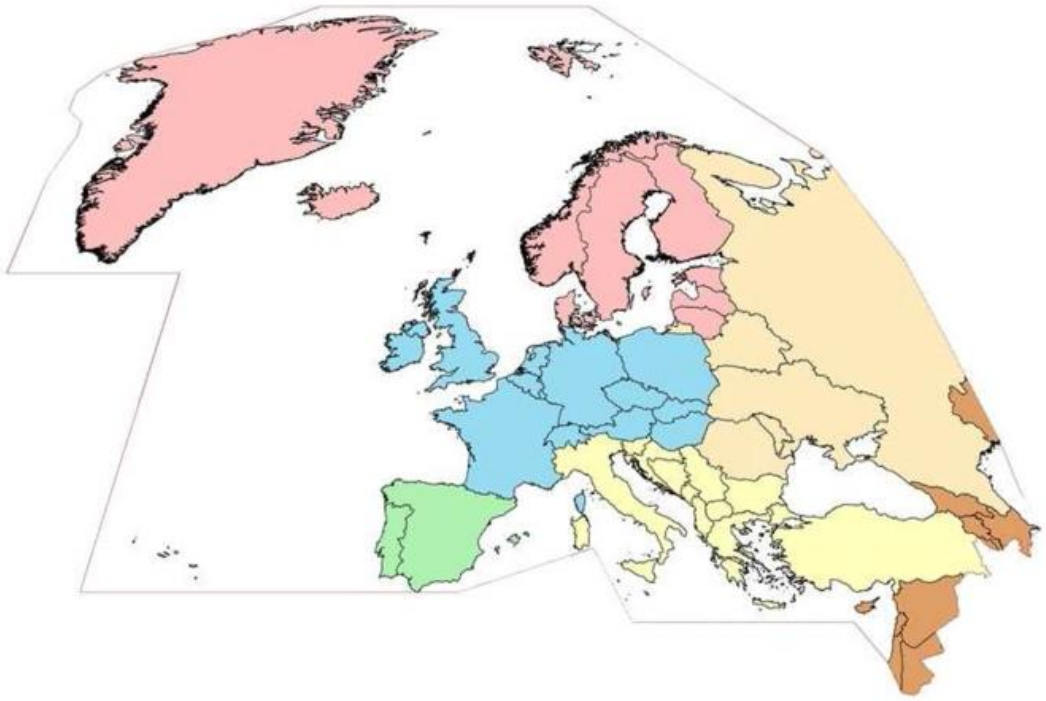

Fig. 1.1: *Definition of the 6 subregions within WMO RA VI*

Outstanding events and anomalies

Temperature

- 2012 the 2nd highest mean temperature at Svalbard Airport since 1912, after 2006.
- 2012 was the second coldest year in Sweden.
- The warmest summer on record in Israel together with the summer of 2010.
- Unusually warm March in northern, western and central Europe.
- Highest mean May temperatures since 1891 in southern European Russia.
- Warmest July on record in Hungary as well as in parts of Israel

Precipitation

- One of the wettest years of the last 50 to 150 years in the Nordic and Baltic countries.
- The 3rd rainiest year since 1768 in UK. The wettest in England since 1910.
- The driest winter since 1931 in Portugal
- One of the driest March months in several countries of *Western and Central Europe*.
- The wettest April in the England and Wales precipitation series from 1766 (Alexander and Jones, 2001)
- One of the driest Aprils in the last 70 years in northern Israel.
- The wettest June on record in Stockholm (with precipitation measurements since 1786)
- Exceptional widespread rain in northeastern Israel and unusually high rain totals in southern Israel in June.
- The driest August since 1901 in Hungary.
- The rainiest October for some stations in northeastern parts of Sweden for more than 100 years
- The wettest December on record in Belgium and one of the wettest in the last 100 years in northern and western Scotland

Sunshine Duration

- Highest annual sunshine duration on record in Hungary.
- The sunniest March in England since 1929

Other Anomalies

- A new record of high surface level pressure for Moscow (1025 hPa in late January; previous value 1024 hPa in 1946).
- A new record of high surface level pressure for the month of February in Haparanda, Sweden (1058.0 hPa on 1 February)
- A new record of low surface level pressure for Moscow (958.7 hPa on 6 November)

Events

- January air temperature above 0°C on Kheis Island (Russian Arctic islands),for the first time on record (since 1957).
- 2012 the highest daily precipitation total of the Norwegian Arctic stations on 30 January at Ny Alesund: 98 mm. This has an estimated return period of 200 years.
- Severe cold wave in the 1st half of February in eastern, western, central and southwestern Europe
- New record for the highest official surface air temperature (SAT) of May ever recorded in Greenland in May 24.8°C at Ivittuut/Narsarsuaq on 29 May 2013.
- Rain and several days of thaw have been registered at the ice cap of Greenland with high temperatures late June and several days in a row in July above 0°C.

Annual Survey

Atmospheric Circulation

The chapter on the atmospheric circulation gives information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based upon the Monthly Bulletins on the climate in WMO RA VI and the Global Climate Bulletin (MeteoFrance) and completed by reports of NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml.

STANDARDIZED NORTHERN HEMISPHERE TELECONNECTION INDICES (1981-2010 Clim)

North Atlantic Oscillation (NAO)
East Atlantic Pattern (EA)
East Atlantic/West Russia Pattern (EA/WR)
Scandinavia Pattern (SCA)
Polar/ Eurasia Pattern (POL)
Arctic Oscillation (AO)

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2012	1	0.86	-1.76	-0.46	0.57	-2.34	-0.220
2012	2	0.03	-1.73	-0.64	0.34	0.19	-0.036
2012	3	0.93	-0.64	1.35	-0.47	-1.42	1.037
2012	4	0.37	-0.28	-1.59	-0.93	-0.97	-0.035
2012	5	-0.79	0.52	-0.47	-0.58	-0.11	0.168
2012	6	-2.25	-0.11	0.01	-1.42	-1.75	-0.672
2012	7	-1.29	1.02	-1.43	-0.56	1.01	0.168
2012	8	-1.39	1.36	1.15	0.85	0.98	0.014
2012	9	-0.43	0.38	-0.49	-0.93	-0.70	0.772
2012	10	-1.73	-0.32	-1.01	-0.28	-0.17	-1.514
2012	11	-0.74	1.15	-0.59	0.68	-0.19	-0.111
2012	12	0.07	0.68	-0.88	2.00	0.35	-1.749

Table 2.1: *Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the AO, December 2011 to December 2012*

(Sources:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table Note that all values are standardized with the reference 1981 to 2010.

The influence of these teleconnection patterns differs with months or seasons. For Europe not only the best known NAO pattern is relevant but for individual months also one of the other teleconnection patterns may have an influence. The annual course of these selected teleconnection indices as well as the Southern Oscillation index (SOI) is as well illustrated in Fig 2.1. The Southern Oscillation (connected to ENSO) has usually little influence in Europe but may occasionally be of some importance. It is presented for completeness here. In Fig. 2.2 maps of the mean sea surface level air pressure are presented.

In **January 2012** high pressure centered close to the Azores as well as over Russia was well pronounced. Low pressure in the northwest was centered between Iceland and southern Greenland. Both pressure patterns - the Azores high and the Icelandic low were better developed than the mean and a distinct gradient zone

between both may be related to the storm events that occurred. The NAO index was positive with 0.86, EA and POL were strongly negative (-1.8 and -2.3). The western European negative precipitation anomaly was very consistent with the circulation pattern.

High pressure over western Europe as well as over Russia was the decisive feature in **February 2012**. The positive anomalies were highest west of the British Isles with more than 16 hPa. More than 12 hPa higher than normal was the sea level pressure on the North Atlantic between 40°N and 55°N, extending nearly to 30°W and including most of the British Isles and western and northern France. Similar anomalies occurred in northeastern Russia. The East Atlantic pattern (EA) was the strongest circulation mode (-1.7) while NAO was neutral.

Though the NAO was positive in **March 2012** (0.93) the distribution of the sea surface level pressure did not show the Icelandic low and the Azores high ideally. The center of the Icelandic low was situated between Iceland and southern Greenland. An extensive trough reached southward to nearly 40 N. A secondary but much weaker low laid over Russia. The latter had a negative anomaly of at least -12 hPa in its center. The anomalies of the Icelandic low were negative as well with at least 8 hPa it its center. The Azores high was shifted northeastward and was centered over northern France and the southerly British Isles. The positive anomalies of the Azores high exceeded 12 hPa. High pressure spread over western and central Europe, northern Africa, and westward on the North Atlantic between 20 N and 40 N. More influence than the NAO had the East Atlantic/West Russia pattern (EA/WR) and the Polar/Eurasia pattern (POL) with values of 1.35 and -1.42. The negative precipitation anomalies in western Europe were quite consistent with the pressure (and geopotential) fields and the induced blocked zonal circulation.

The surface level pressure was in **April 2012** characterized by positive anomalies on the Atlantic and negative anomalies on the European continent. The Azores High was weaker than normal and the Icelandic low was not developed. There was instead high pressure north of Iceland. The NAO index had a mean of 0.37. Also the AO was close to zero (-0.03) as the polar vortex was weak. The strongest circulation mode was EA/WR (-1.59) followed by POL (-0.97). There was no blocking over the region of interest. The positive temperature anomaly over most of the region is remarkable in this context. The negative or close to normal temperature anomalies over western Europe are related to the postive rainfall anomalies here.

In **May 2012** higher than normal sea surface level air pressure extended over the northern North Atlantic, western, central and southwestern Europe, while lower than normal sea level air pressure prevailed over the Azores and northeastern, eastern and southeastern Europe. The NAO index was negative with -0.91. Blocking was detected at the beginning and at the end of the month. The negative precipitation anomalies in Spain as well as the positive precipitation anomalies in southeastern Europe were consistently related to the pressure and geopotential anomalies.

In **June 2012** the Azores high was well developed and influenced the Iberian Peninsula, the western Mediterranean Sea and southern France. High pressure was also prevailant over Greenland while low pressure influenced most of the European continent with minima over the British Isles, Scandinavia and northern Russia as well as the Middle East. In terms of anomalies there were positive anomalies over Greenland and the northern North Atlantic, including Iceland. And there were negative anomalies mostly everywhere else with the minimum centered southwest of Ireland and spreading northeast to southern Sweden and southwest to the western North Atlantic. The NAO was negative and well below the normal (1961-1990) values minus 1 σ throughout the month. The monthly mean resulted to -2.25. The AO index was mostly negative during the first half of the month and close to normal during the second half. The monthly mean was -0.62. Strong were the Scandinavia pattern (SCAND) and the Polar/Eurasia pattern (POL) with -1.42 resp. -1.75. Like already in May the precipitation anomalies reflected the circulation patterns well whereas this is not so to the same extent for the temperature anomalies.

The surface level air pressure was generally close to normal in **July 2012**. There was a slight positive anomaly over the Azores, over Iceland and southern Greenland as well as in the east. The largest negative anomaly of -4 to -8 hPa occurred in a small area between Ireland and England as well as near Newfoundland. The NAO-index was negative with -1.29. Negative values had as well the relatively strong modes East Atlantic pattern (EA), the East Atlantic/West Russia pattern (EA/WR) and the Scandinavia pattern (SCAND) with -1.0 , -1.4 and -0.6. Positive was the Polar/Eurasia pattern (1.0). There was no blocking in July 2012. Again the precipitation anomalies reflected the circulation patterns well whereas the temperature anomalies did less.

The Icelandic low was centered further southward than normal in **August 2012** and the Azores high was weaker. The negative anomalies ranged between -4 and -8 hPa over Ireland and west and southwest of the British Isles. There was as well lower than normal sea level pressure in the eastern Mediterranean, southern Russia and Middle East with anomalies ranging up to -4 hPa. Northern, northeastern, central, southern and southwestern Europe had positive anomalies up to +4 hPa. The NAO index was negative with -1.4 and the East Atlantic mode (EA) was positive (1.4). Higher than normal 500 hPa Geopotential over northern Morocco and the central Mediterranean Sea to the Adriatic Sea were favourable conditions for heat waves over southeastern Europe. Positive anomalies of the heat content of the North Atlantic as well as in the Mediterranean Sea were as well noticeable.

The mean sea surface level air pressure of **September 2012** showsed a pronounced but tilted dipole of the Icelandic low and the Azores high. The Icelandic low was shifted eastward and stronger than normal while the Azores high is shifted westward and was only slightly stronger than normal in intensity or close to normal. The Azores high was extended far eastward but weak so that overall a negative anomaly prevailed. The gradient between both pressure systems was high in a zonal band from North America over the British Isles and the southern Baltic Sea to Russia, allowing low pressure systems to move eastward and bring first storms in the north and northwest. The most active circulation mode was the Scandinavia pattern (SCAND) with a value of -0.9. The strong gradient between the pressure patterns may explain the remarkable contrast in the precipitation anomalies between the highest northern latitudes (wet) and the southward latitudes (drier especially in central and southeastern Europe).

In **October 2012** the sea surface level pressure was lower than normal over most of the region with negative anomalies of -4 to -8 hPa from the central North Atlantic to eastern Europe, including southern Scandinavia and the Baltic Sea and the northwestern Black Sea as well as most of the Iberian Peninsula and the western Mediterranean Sea area. Iceland and Greenland had higher than normal pressure with anomalies of +8 to +12 hPa. The NAO and EA/WR were the most active modes in October with values of -1.7 resp. -1.0.

November 2012 was characterized by low pressure in the north, centered east of Iceland, and high pressure in the south with centers west of the Azores and east of the Caspian Sea. The negative anomalies were strongest with -8 to -12 hPa over the Faroer Islands and ranged between -4 and -8 hPa in a region from the Norwegian Sea and Iceland southward to the Iberian Peninsula. The northern, central, and southern European continent, the Mediterranean Sea and Middle East had negative anomalies between 0 and -4 hPa.EA was the most active mode (1.0) and NAO (-0.7) as well as SCAND (-0.7) show as well some influence.

December 2012 was characterized by low pressure centered on the Northern North Atlantic south of 60°N, high pressure centered southeast of the Azores as well as high pressure over Russia. The anomalies were negative on the North Atlantic with -8 to -12 hPa west of the British Isles and south of Iceland and positive over northern Russia and Scandinavia. The NAO index was close to zero but the AO index was negative with -1.7. The most active mode was SCAND (2.0). The next active modes for Europe were EA/WR (-0.9) and EA (0.7).

Annual Extreme Values

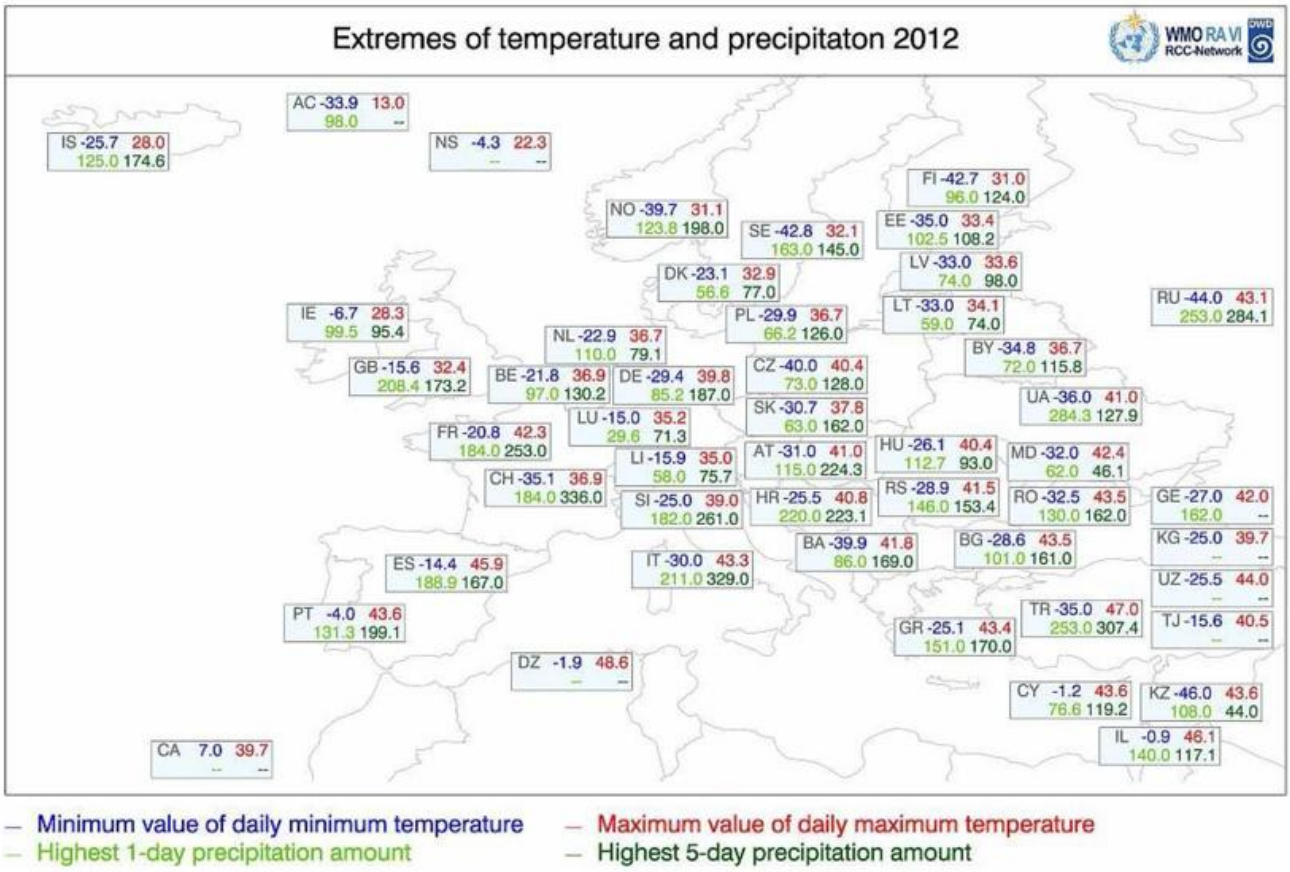

Fig. 2.4: *Annual extreme values for each country: highest daily precipitation total (mm), highest 5-daily precipitation total (mm), highest daily maximum temperature (°C) and lowest daily minimum temperature (°C) 2012*
Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP

In Fig. 2.4 the absolute annual extremes for 2012 of temperature (minimum and maximum), daily precipitation total and 5-day precipitation total for each country are given. Sources of this map are by order of priority:

- the reported values by NMHSs
- ECA&D data
- SYNOP data

.

The countries are represented by their Internet country codes.

In 2012 some new records were observed.

Temperature:

The year 2012 was in Europe overall warmer than the normal. Remarkable is the positive anomaly in the Arctic with anomalies of +3 K around Spitzbergen and north of it. But also the southern central Europe, the eastern Iberian Peninsula, the Balkan Peninsua, the central and the eastern Mediterranean Sea, Middle East, southern Russia and the Caucasus region had positive anomalies of 1 to 2 K. The European annual mean of the daily temperature 2012 was 10.6°C +/-0.91 compared to the mean over the normal period 1961-1990 of 9.8°C. Thus 2012 became the rank of 11 for the time series since 1950. The mean daily mmaximum temperature was on rank 12 with 15.5°C +/- 0.87 and the mean daily minimum was on rank 9 with 6.0°C +/-0.91. So for 2012 the night temperatures on the average were relatively warmer than the normal than the daytime temperatures and the daily means. These values are the result of the E-OBS dataset where 'Europe' is defined as the land area within 35°N - 75°N and 25°W - 45°E (van der Schrier, G., 2013; see also: Climate Indicator Bulletin: European Temperature). This area does not completely cover the WMO RA VI area. The highest mean annual anomaly is calculated for the subregion 'Eastern Europe' with + 1.5 K, closely followed by the subregion 'Mediterranean, Italian and Balkan Peninsula' with + 1.4 K. 'Iberia' and 'Central and western Europe' had a positive anomaly of 1.2 K and 'The Nordic and Baltic countries' as well as 'Middle East' had a positive anomaly of +0.8 K (see table of seasonal and annual means of anomalies of temperature).

Note: *Small differences between the areal temperature anomalies in the tables on pages 21 and 22 and according values given by individual countries may occur due to the calculation method. The anomalies result from the temperature analysis (see RCC-CM: Products - Monitoring Europe - Temperature).*

Details for individual countries or stations are as following:

- In the capital Nuuk on Greenland, the annual mean temperature was 0.1°C, which is 1.5°C warmer than normal (normal -1.4°C), but only 0.2°C warmer than the 2001-2010 average. The highest temperature 20.3°C occurred in July and the lowest temperature -22.3°C in March.
- 2012 the 2nd highest mean temperature at Svalbart Airport since 1912, after 2006.
- In Germany 2012 reached rank 16 of the warm years since 1881.
- In Switzerland 2012 was on rank 9 of warm years since 1864.
- In Austria the year 2012 was the seventh warmest since the start of low land temperature measuring in the year 1767.
- In Hungary on the base of the homogenized, interpolated data this year has been the 4th warmest since 1901 (behind years 2007, 2000 and 2008).
- For the first time excess of the mean annual temperature by 2 C° was recorded in southern Ukraine.
- According to the Meteorological Station of Chisinau (observation period 118 years), the average temperature for the year was +11,2°C (1,7°C to above normal) and took fourth place in the ranked list of high average annual temperatures.
- The year 2012 has been the 13th warmest year in Spain since 1961.
- Also in Slovenia 2012 ranked among the few warmest years ever.
- In Israel 2012 was one of the warmest in the last 60 years, yet it lagged far behind 2010.
- 2012 was the 10th warmest year over Armenia since 1929.
- In Sweden the national averaged mean temperature was slightly above the reference value for 1961-90, but still it was the second coldest year so far this century.
- In the 21st century year 2012 was the second coolest in Latvia.
- In Denmark out of the last 25 years in Denmark, 22 years including 2012 have been warmer than normal (1961-90).

Precipitation:

The annual precipitation totals of 2012 were overall close to normal. The existing positive or negative anomalies were small. They show generally a zonal pattern with positive anomalies north of 50°N on Greenland and the Arctic, in England and Wales, southern Sweden, Finland, the Baltic states, Belarus and partly Russia and negative anomalies on the Iberian Peninsula and southern France, Italy, Hungary and the northeastern Black Sea region and Middle East.. The southeastern Mediterranean region had partly positive anomalies. Absolute positive as well as negative anomalies did not ecxeed 30 mm generally, with a spatially limited exception in northern Portugal. But on shorter timescales of with respect to special aspects some noteworthy peculiarities occurred:

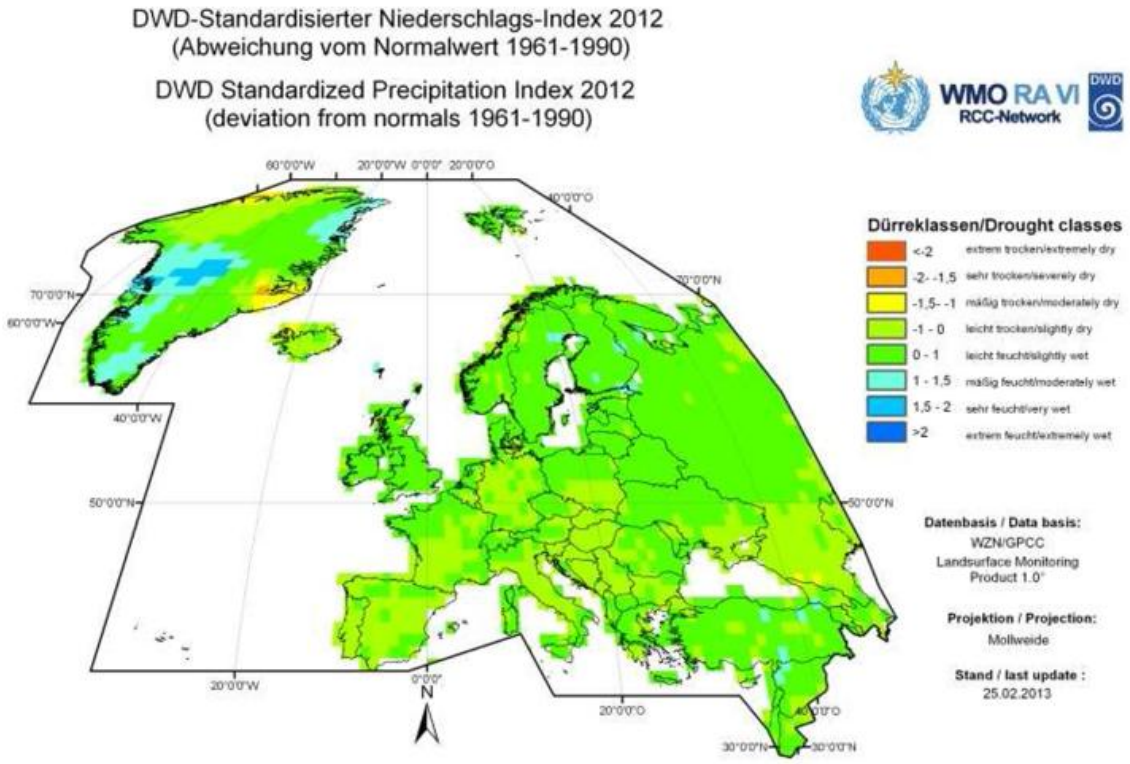
- It was the second wettest year since measurements started in 1890 in Nuuk on Greenland. Precipitation in Nuuk was 1.211 mm against the normal 752 mm, 459 mm or 61% above normal. The wettest year was 2005 with 1.221 mm.
- Year 2012 was the third rainiest in Sweden during the last 150 years. Some stations in central and northern Sweden with more than 150 years of measurements reported new all-time records for highest annual precipitation amount.
- The national average precipitation in 2012 is the highest in Finland since the start of the gridded precipitation data set in 1961, this means since at least 50 years.
- With a yearly precipitation amount of 832 mm (127% of normal) the year 2012 was the 4th wettest in the last 90 years and the second wettest in the 21st century in Latvia.In 2012, in ten months of twelve, the precipitation amount was above normal. The precipitation from December 2011 to July 2012 was continuously above normal (Fig.4). Such a long precipitation-rich period (8 months) was recorded for the first time in Latvia's precipitation measurement history .
- The year 2012 in Estonia was the wettest in 50 years.
- UK annual rainfall total of 2012 was 1331mm (121% of average), the second highest in the series, narrowly beaten by 2000 (1337mm).
- With an excess of 11 % to the average of 1961-1990 the year 2012 was one of the wettest since the last 35 years (stdev 9%) in Austria. In the alpine regions the deviation to the long term mean was 22%. So the year 2012 was here the wettest year since 1966.
- 2012 was again a very dry year in Hungary, the ninth-driest since records began in 1901.
- Moldova had a significant insufficient precipitation in June - September
- The rainfall amount was the highest ever recorded for a calendar year since 1902 in Cyprus.

Sunshine:

2012 was a sunny year in most of the European continent. The sunniest region was eastern Poland where locally a surplus of more than 150 % was achieved. Absolutely in the southeast the anomalies exceeded 400 hours. Dull were Finland and northern Russia, Belarus, southern Russia and Middle East as well as partly England, Ireland and Portugal. The following noteworthy peculiarities were reported:

- Hungary experienced its highest annual sunshine duration. Both the national average record (2404 hours) and the station record (2645 hours) were broken in 2012.
- The year 2012 was the sixth sunniest year in Austria since the beginning of the Austrian sunshine series in 1884.
- It was the 14th sunniest year in Germany since 1951.
- In Ljubljana, Slovenia, 2012 was the sunniest year ever.

Drought



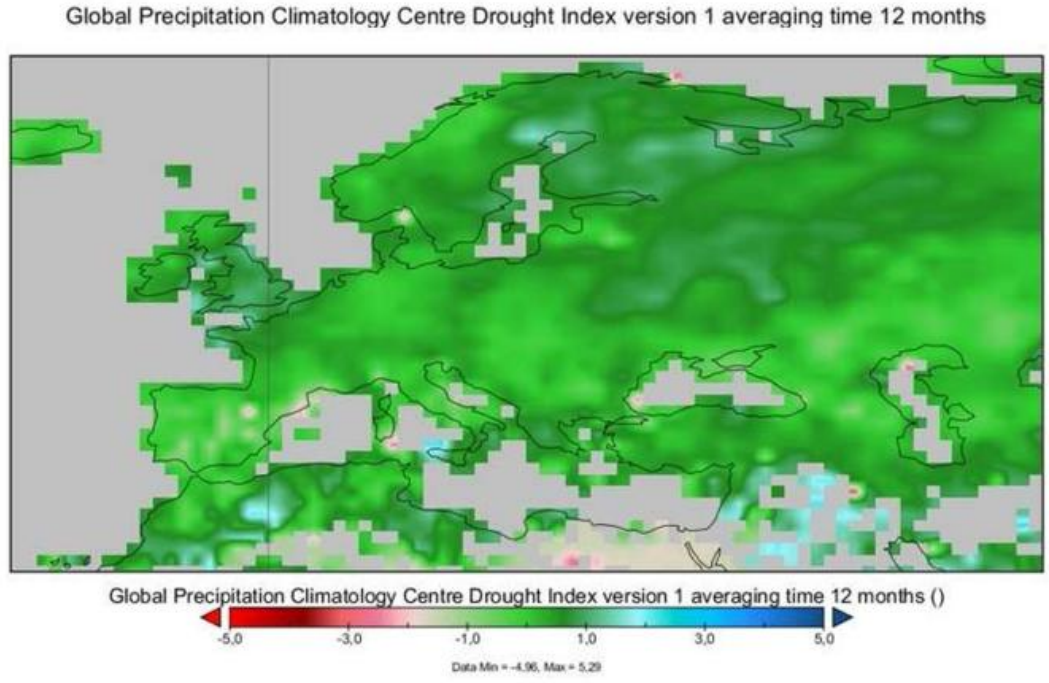


Fig. 2.5: *Annual anomalies of the modified Standardized Precipitation Index (DWD-SPI) and 12-month GPCC-Drought-Index 2012*

Drought Situation:

Over the year 2012 the anomalies of the mean 1-month DWD drought index shows slightly higher dryness than normal on the Iberian Peninsula and southwestern France, Germany, Italy, the northern Balkan Peninsula and southeastern central Europe as well as southern Russia and southeastern Ukraine. The 12-month GPCC drought index shows a very similar pattern with some higher dryness for the Iberian Peninsula.

Reports on longer lasting dry periods from the countries:

- Overall ist was the 8th driest year since 82 years in Portugal. In 2012 mainland Portugal was characterized by a drought situation, that started in the end of 2011 and remained for almost the entire year of 2012. The period with the highest drought intensity was in late winter and early spring (months of February and March), with almost the whole territory in the most intense classes of PDSI index, severe and extreme classification. For instance Portugal had precipitation totals for the period October 2011 to February 2012 mostly below 75 percent of the 1971-2000 reference (Boletim climatologico mensal - fevereiro 2012)
- Spain had well below 100 percent, mostly below 75 percent and partly below 50 percent of the normal precipitation for the period 01 September 2011 to 10 April 2012 (http://www.aemet.es/es/serviciosclimaticos/vigilancia_clima/balancehidrico).Spain reported the lowest precipitation total since 1947 for the 3-month period January to March and the driest summer season since 60 years.
- 2012 was also a very dry year in Hungary, the ninth-driest since records began in 1901. November 2011, March and August 2012 were the driest November, March and August on record. Furthermore the eleven-month period ended in September 2012 was the driest November-September period ever.
- Lack of precipitation was observed in the first 3 months of the year in Slovenia. On the coast drought persisted also during spring. Severe drought was observed in summer, it was the most pronounced on the coast.
- In the Ukraine in May, June and July the southeastern part of the country experienced long periods (up to 3 months) without rain against a background of high-temperature. Such conditions led to fierce drought.
- In Moldova precipitation deficits during June - September 2012 on the whole territory of the Republic of Moldova, contributed to the preservation during a long period of atmospheric and soil drought, attributing it to the category of very strong, as noted in an average of once in 20 years. Taking into account the affected area, the drought of 2012 is classified as a catastrophic one. This coincides well with the anomalies of the 6-month SPI and the anomalies of the maximum number of consecutive dry days (with RR < 1 mm) by ECA&D for 2012.
- In Armenia during a 4-month period (from August till November) the country experienced a severe shortage of rainfall which varied within the range of 30 to 60% of normal values.

Snow Cover

Fig.2.6 to 2.8 show the maps of first occurrence of snow, last occurrence of snow and duration in the snow period for Europe September 2011 to August 2012 on the basis of SYNOP reports and their anomaly referring to the last 30 years (1981/82-2011/12). Snow fell earlier than on average on most of the continent except the British Isles and northern France and parts of the Mediterranean region, southeastern Sweden and southeastern European Russia and Middle East. The snow season ended on the other hand earlier than on average in eastern central Europe, southeastern Sweden, parts of the Italian and Balkan Peninsula, Middle East and southern Russia. Over most of European Russia as well as in the higher mountains of Georgia the snow continues until the first decade of April. So overall the snowseason 2011/2012 was shorter than on average in most of Europe.

The snow cover extent for the entire Northern Hemisphere is operationally evaluated from satellite images by Rutger's Laboratory (see: 2012 Annual Report). The time series for annual snow extent covers 43 years, on a monthly basis up to 47 years. The annual snow cover extent over the Northern Hemisphere ranked 2012 as having the 12th least extensive cover on record (for 43 years). For Eurasia it was on rank 15 of the largest snow covered area resp. rank 29 of the least extensive cover. February 2012 on rank 3 of the most extensive snow covered area of 46 February months and December 2012 on rank 2 of the most extensive snow covered area of 47 December months were the most remarkable months of the year 2012.

More information about snow conditions may be found on the RCC-CM-Webside (RCC-CM).

Peculiarities as reported by the countries:

- In Russia Yekaterinburg received as little as 14mm of precipitation in February for the entire winter. This is the second time, when such low-snow winter is recorded for 120-year observations.
- In Latvia on 27th October snow height in some parts of Eastern Latvia was up to 35 cm. Such thick snow in October in Latvia is rare - on average once every 20 years.
- In Georgia the unprecedented maximum snow depth (354sm) was recorded in Khulo (Ajara) in March.
- In Slovenia it was snowing in most of the lowland already in the last third of October, but in December it was snowing also on the coast, where the snow cover depth reached 11 cm, which is a quite rare phenomenon on the coast.

Temporal Evolution of Climate Elements

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the NMHSs are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 subregions defined above (Fig. 1.1). The table below informs about the lengths of the time series shown as well as whether they refer to spatial means of the country or single stations. Most time series are temperature time series. Each subregion is at least represented by one country. Time series of precipitation totals are fewer but including a time series of the maximum daily precipitation total for the Upper Galilee in Israel there is as well each subregion represented with at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries and they belong to the 4 subregions 'Central and western Europe' and 'Nordic and Baltic countries' Mediterranean, Italian and Balkan Peninsula and Eastern Europe. Some countries contributed time series which were not available in 2011. Other time series that were available in 2011 are not available in 2012 on the other hand. So for Iceland a series of annual mean temperature since 1798 is now available for the station Stykkisholmur.

Following this section, trend maps representative for the elements temperature and precipitation are shown. As reference period for these trend maps 1951-2012 was chosen. After this, we present examples of the temporal developent of other temperature related phenomena,such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Wladyslawowo.

Start of long-term time series of Temperature, Precipitation and Sunshine Duration

	Temperature		Precipitation		Sunshine Duration	
Country	Spatial Mean[1]	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station

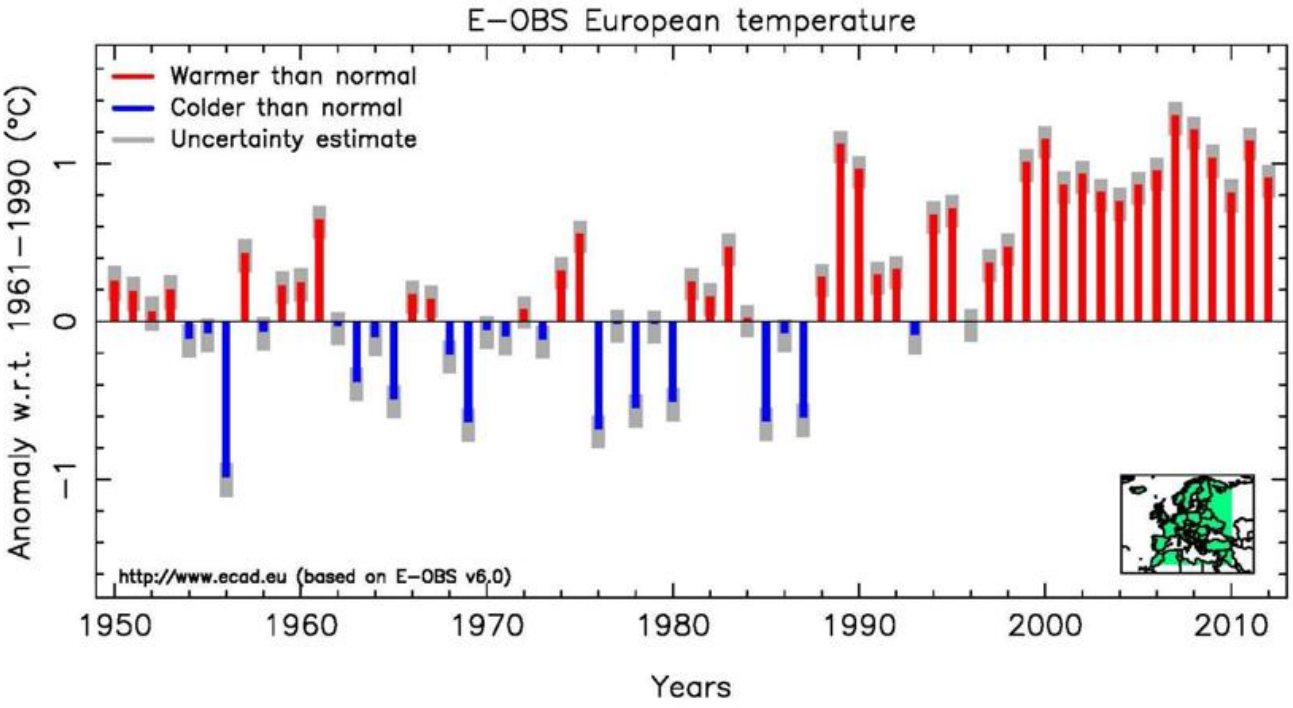

Fig. 2.9: *Time series of mean annual temperature anomalies for Europe (land area; 30 °W - 30 ° E; 30 ° N - 80 ° N) after Verver et. al. 2013*

Temperature

Note:

Long time series of the mean annual temperature are available for each of the 6 subregions. The number of countries which provided information differs as well as the length of the series and the kind of presentation. The longest time series for areal means were provided by Switzerland (1864) and Denmark (1873). Most graphs are diagrams of the mean annual temperature over the years. Usually the mean annual temperature is given as a mean for the whole country. In a few cases the diagram refers to one station only. The longest station series presented here has Stykkisholmur on Iceland, starting 1798.(Similarly long or even longer time series for stations exist as wll for more countries but the main focus here lies upon areal means.) Some countries present the time series in form of anomalies from a reference (mostly the standard WMO reference period 1961-1990, except Poland, Portugal, Spain and Turkey (all 1971-2000)). In this context this must be reflected when for instance the number of years with annual means above the reference is compared. Taking into account that the temperature is growing with time, the year from which onward the annual mean lies above the reference will be later when the reference is 1971-2000 than compared with the standard normal period 1961-1990. Some countries provide further statistics in their diagrams like a running mean or a trend line. Generally all time series document the rising temperatures with time and the increase of the rise during the last 15 years. Some special aspects will be discussed in the following.

In most series of all subregions 2012 was warmer than normal though the positive anomalies were smaller than in 2011. Exceptions were Italy and southern Slovakia. Extremes indices (number of hot days, number of tropical nights) may differ in behavior from the mean annual temperature (Turkey, Slovenia).

Precipitation

Note: *Denmark, Germany and Slovakia present annual precipitation totals while the other countries present anomalies from a reference period. Most countries refer to the period 1971-2000 for precipitation anomalies or the line of normal precipitation except Germany (1961-1990).*

For precipitation Fig 2.35 to 2.48 show the available time series for the 6 subregions.

With some caution the graphs give the information that precipitation has a rising trend in northern, western, central and eastern Europe but not in the Baltic states and not in the Mediterranean region and Middle East. The graphs for Iberia and the Italian Peninsula show a falling trend. The annual rainfall for Denmark has risen about 100 mm since 1870s. The lowest annual precipitation for the country as a whole was 464 mm in 1947, and the highest was 905 mm in 1999 For Switzerland 2 graphs are presented to show the differences between the north and the south. For northern Switzerland the annual precipitation is rising at least since 1940 while the graph of southern Switzerland undulates around the reference line. Israel contributed a time series of the annual maximum daily total in the Upper Galilee region which shows the highest value of 140 mm in 2012 in a series since 1949. This is related to the rain event in June .

Sunshine

Note:*The sunshine duration time series (Fig 2.49 to 2.53) are generally shorter than those for temperature or precipitation. Germany, Denmark and Slovakia provide annual totals of the sunshine duration while Russia provided anomalies from the normal period 1961-1990.*

All graphs show a rising trend of the sunshine duration at least since 1980, partly longer. Denmark has the longest time series starting 1920 which shows the strong possible variability. The sunniest year was 1947, with 1.878 hours, and the least sunny was 1987, with 1.287 hours. Since 1980, the trend has been towards more hours of sunshine and on the other hand less cloud cover. Considering time series of sunshine duration changes in observing techniques may cause some problems in comparing older and newer observations as is stated by Denmark with the following remark: "DMI has since 2002 observed the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. It should also be noted that all values before 2002 are adjusted as best as possible ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990.

Trends of temperature and precipitation

Figure 2.54 shows the spatial distribution of trends for the mean annual temperature and the annual precipitation total as well as the cold spell duration index and very wet days for the time series 1951 - 2012 for stations in Europe contributing to the ECA&D data set. Less stations than in 2011 are presented but the result ist not different. A warming trend for most of Europe can clearly be seen for the mean annual temperature. Corresponding to this warming trend the trend of the cold spell duration index (CSDI) is negative for many stations on the continent.

For the annual totals of precipitation we can state roughly a different behavior between the south (often unsignificant but partly cearly negative) and the north (more positive values) and the regions especially influenced by the North Atlantic seem to show clearer positive trends. This feature may eventually be explained by the influence of a warming North Atlantic. The distribution of trends for extremely wet days shows a generally similar pattern with differences at single stations.

Trends of Climate Indices for Temperature and Precipitation (ECA&D)

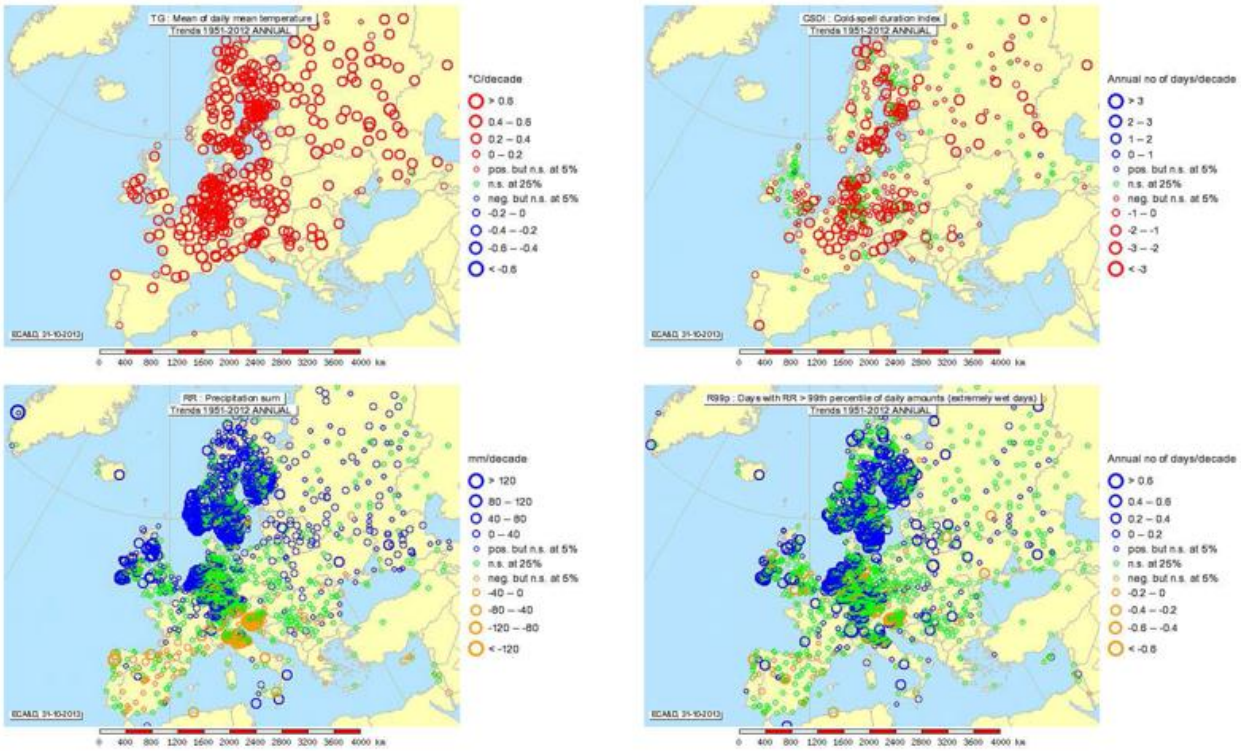

Fig. 2.54: *Trends of Selected Climate Indices 1951 to 2012 (Source: ECA&D, http://www.ecad.eu):*
Upper left: TG (Mean of daily temperature),
Upper right: CSDI (Cold spell duration index),
Lower left: RR (Precipitation sum),
Lower right: RR99p (Days with RR>99th percentile of daily amounts (extremely wet days)

Long-term temporal development of related phenomena

Fig. 2.55 and 2.57 illustrate phenomena that are closely related to the temporal development of the air temperature.

In Fig 2.55 a ranking of the North Sea surface temperature since 1969 is shown. Note that the 'year' in this case refers to December to November. Presented are the ranks of the years 1969 to 2012. From 1988 until now most (all except 5 years) values are warmer than the median while before 1988 most values were colder. 2012 was on the warm side and warmer than 2011..

In Fig 2.56 the anomalies (reference 1971-2000) of the mean sea level at the station Wladyslawowo in Poland is shown. A positive trend of 0.22 cm per year results from this time series. The rising mean sea level is a climate indicator for global warming. The sea level increase is caused by melted ice and warmer water. Sea level is observed in many countries with coastal stations. For instance Sweden has 23 stations for observation and the longest series is Stockholm with measurements since 1774. Though a graph is not available for 2012 consistent results are for instance presented on the Web (http://www.smhi.se/polopoly_fs/1.8963!Swedish_Sea_Level_Series_-_A_Climate_Indicator.pdf).

DMI has observed the surface air temperature (SAT) at Summit in the middle of the Greenland ice cap in 3.2 km altitude since 1991 (Fig 2.57). DMI's observations show that the temperatures typically range from -60 to -50°C in winter and from -10 to 0°C in summer. It is not unusual to observe positive temperatures on a few days during a year. It is a fact in 10 different years out the 18 years of observations. Observations from July 2012 (Fig. 3.29 in the monthly survey) showed that temperature for several days in a row exceeded 0°C, not seen before. In the days of 11 - 14 and 16th July the temperatures were above 0 °C. The observations confirm the NASA satellite observations of melting in these days.

Socio-economical Impacts of Extreme Climate or Weather Events:

Countries have reported socioeconomic impacts of climate extremes or weather events. This was done partly in a given structure (WMO guiding table for country submission of information on extreme climate events) or the information is part of the regular monthly reports on the internet or it was seperately reported. Still this information is heterogeneous and does by far not give a complete overview. Not only do the administrative structures differ so that the information cannot easily be gathered but also many kinds of impact is difficult to be estimated. In the following only a short extract will be given.

Figure 2.58 shows the percentages of casualties (fatalities or injured persons) due to 6 kinds of events. Numbers of casualties were the only numbers that can be presented in form of a diagram. Conclusions should be drawn only with caution. The total number of cases for the figure was 511 which will be certainly underestimated. Moreover the reported numbers were in some cases not fix but like 'hundreds' or 'few'. In this case '100' resp. 'zzz' was taken to produce the graph. The economic damage was estimated as well by some countries but the information is not sufficient to be presented with any reliability of representativeness. The figures of economic damages will be summarized individually below.

The largest portion in Figure 2.58 is 'Flood'. This includes floods by all kinds of causes as precipitation of longer duration, influence of snow melt or extreme precipitation with high intensity. The report of Russia contributed the largest number here. The next large portion is 'Cold'. Reports came from Bosnia and Herzegovina, Poland, Czech Republic, Germany, Austria and Romania. This was mainly the intense and spatially extended cold spell in January/February and had probably in 2012 a much greater portion than in other years but the reports do certainly not cover all victims. 'Heat' on the other hand is surely underestimated in the graph because only one country reported a vague number. 'Lightning' was relatively often reported by several countries (Germany, Georgia, Turkey). 'Storm' includes storm depressions of synoptic scale as well as tornadoes. Two severe tornadoes (Portugal and Poland) make most of this number in 2012. 'Snow' includes snowload and snowdrift. The report came from Bulgaria.

Much economic damage is usually connected with floods, storm, cold spells (all kinds of frost, snow or ice), hail, drought or extreme heat. There are some figures which are summarized in the following but much of this kind of damage cannot be estimated.

- Thunderstorms with hail or lightnings caused nearly 100 Mio Euro damage in Georgia and Austria, most of it in Georgia (90 Mio).
- Flooding caused about 12 Mio Euro together in Finland (6 Mio), Austria and Bulgaria
- Economic damage by drought was estimated by Hungary to 1.8 Mio Euro.
- Economic damage due to forest fires was reported by Bosnia-Herzegovina with 65 Mio Euro.
- Economic damage due to snow was estimated by Austria to 32 Mio Euro.
- Economic damage due to local storm was estimated by Cyprus with 40 000 Euro.

The economic damage especially of drought cannot be given in reliable figures. The only figure stems from Hungary. But many other countries reported of unfigured damage on the agricultural sector. Beside the agricultural sector drought as well caused water shortages for households, hampered shipping on rivers or affected live in rivers or lakes due to lack of oxygen. Also in the case of forest fires there are other kinds of descriptions of the impact that cannot easily be transformed into Euro: Bulgaria reported a burned area of 63 Mio km² and Greece reported a burned area of 18 Mio km².

No figures are available for instance for the economic impact caused by snow and ice upon the sector of traffic (on railway, roads or in the air).

Turkey is the only country that gives graphs of percentages of the occurrence of types of extreme climate or weather events in 2012 (Fig. 2.60) as well as a time series of the development of weather related damages starting in 1940 (Fig. 2.59). 'Weather related damages' is here given in number of cases not in a monetary value.

RCC-CM has developed a 'Knowledge database on euROpeaN climatE extRemes' (KRONER) which integrates information from several already existing and well-known databases and completes them. Figure 2.61 shows the relation of the four kinds of reported events 'Cold', 'Flood', 'Heat' and 'Drought' in 2012 as extracted from this database. 60 country-specific events (mainly taken from EM-DAT) build the collective. Cold spells (37 countries) have the greatest relative part in 2012 followed by floods (14 countries), heat (6 countries) and drought (3 countries).

KRONER gives also numbers for fatalities for 'Cold' (855) and 'Flood' (33). This makes the uncertainty of figures for socioeconomic impacts obvious: the figures based upon the reports of NMHSs were 144 resp. 198.

Seasonal Survey

Winter

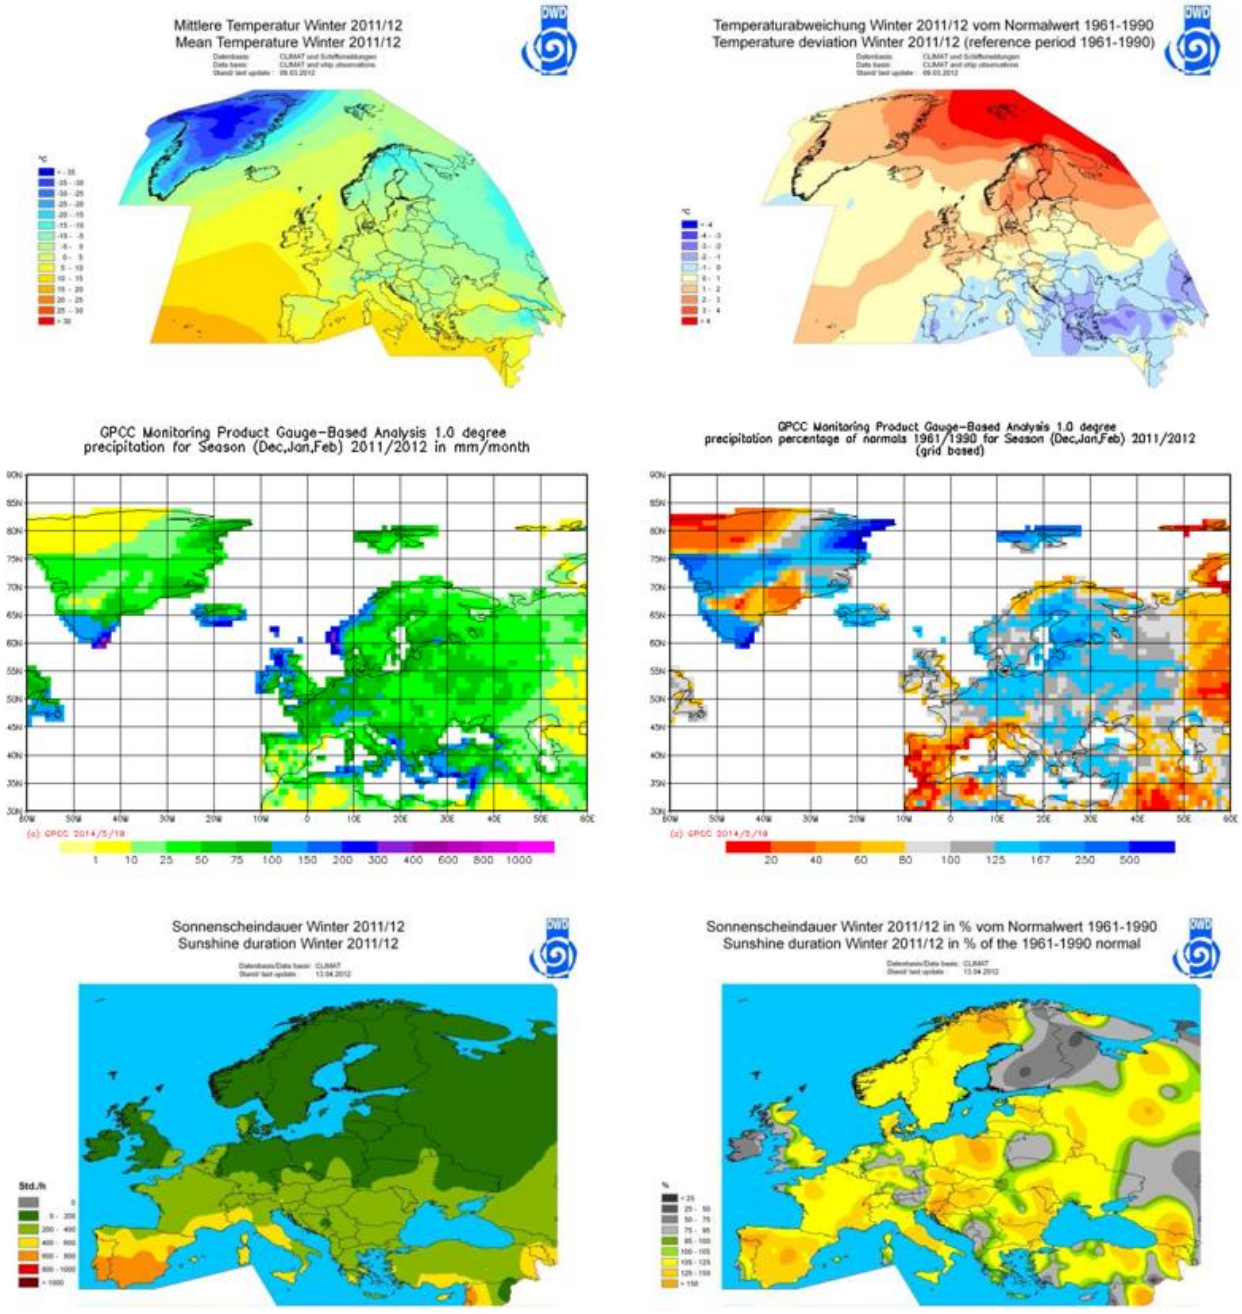

Fig. 2.62: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in winter 2012*
Source: http://www.dwd.de/rcc-cm

Temperature:

Winter was warmer than normal as a mean over Europe according to the analysis from E-OBS data but only on rank 32 in the time series from 1951 to 2012 for the mean daily mean of the temperature. With respect to the daily maximum and minimum temperature winter 2011/2012 was on rank 36 resp. 26. The spatial mean of the daily mean temperature was 0.7°C +/- 0.54. With respect to the defined subregions 'Central and western Europe' had the greatest negative anomaly with -0.9 K followed by 'Nordic and Baltic countries' with -0.8 K. The subregion 'Middle East' had the highest positive anomaly of +0.5 K and the 'Mediterranean, Italian and Balkan Peninsula had a mean positive anomaly of +0.3 K. The anomaly fields for the temperature changed completely during winter 2012. In December 2011 there were positive anomalies over Russia, continental Europe, Scandinavia and the Arctic. In January 2012 there were mostly everywhere positive anomalies, especially in the Arctic, except in the Mediterranean Sea area. And in February there was an extent area of negative anomalies covering Russia, continental Europe and the Mediterranean. Again it was very warm in the Arctic and warm over the North Atlantic. The winter mean shows negative anomalies in southern Europe and the Middle East and warm anomalies northward with values of >= 4 K in the Arctic region. From the last decade of January 2012 to mid of February lasted a severe and extended cold spell which cost about 600 people their lives. The anomaly of the cold spell index for the complete winter shows impressively the surplus of cold spell days. But during the 2nd half of February it became very warm so that winter 2012 is characterized by a great temperature range. In UK for instance between 11 February (-15.6 °C) and 23 February (+17.7 °C) the rather unusul difference of 33.3 K was recorded at Lincolnshire. Austria reported an even larger range of -23.5 °C for the minimum temperaturea on 8 February to +20.9 °C for the maximum temperature on 24 February (a difference of 44.4 K) at the station Güssing. In some parts of eastern Spain it was the most important cold wave since February 1956.

Precipitation:

The winter season had drought conditions especially on the Iberian Peninsula, southern England and the western Mediterranean Sea region. For instance Portugal had precipitation totals for the period October 2011 to February 2012 mostly below 75 percent of the 1971-2000 reference (Boletim climatologico mensal - fevereiro 2012), February 2012 was the driest February since 1931 and winter 2011/2012 was the driest since 1931 in Portugal as well. As well in southern and eastern UK the winter precipitation totals were below 70 % of the norm.(http://www.metoffice.gov.uk/climate/uk/2012/winter.html). Under influence of the North Atlantic Ireland and Scotland as well as the westcoast of Scandinavia received much precipitation as well as the central and the eastern Mediterranean Sea. Also central Europe, eastern Europe and the Balkan Peninsula were wetter than normal. In Latvia winter 2011/2012 in total was the wettest in the last 90 years.

Sunshine Duration:

Winter 2011/2012 was sunny to very sunny in most of Europe with exception of Finland and northern Russia, parts of Belarus, parts of Germany, the western Alps and the southern Adriatic Sea, Ireland and western UK, and the Middle East and southern Russia. Eastern England and the British Midlands had one of their sunniest winters on record, while Ireland had one of its dullest. In the Netherlands the 1st decade of February was the sunniest in more than 100 years. Sunshine duration in Denmark was nearly 50 % above normal making winter 2011/2012 the sunniest in 49 years and the 2nd sunniest since 1920.

Drought

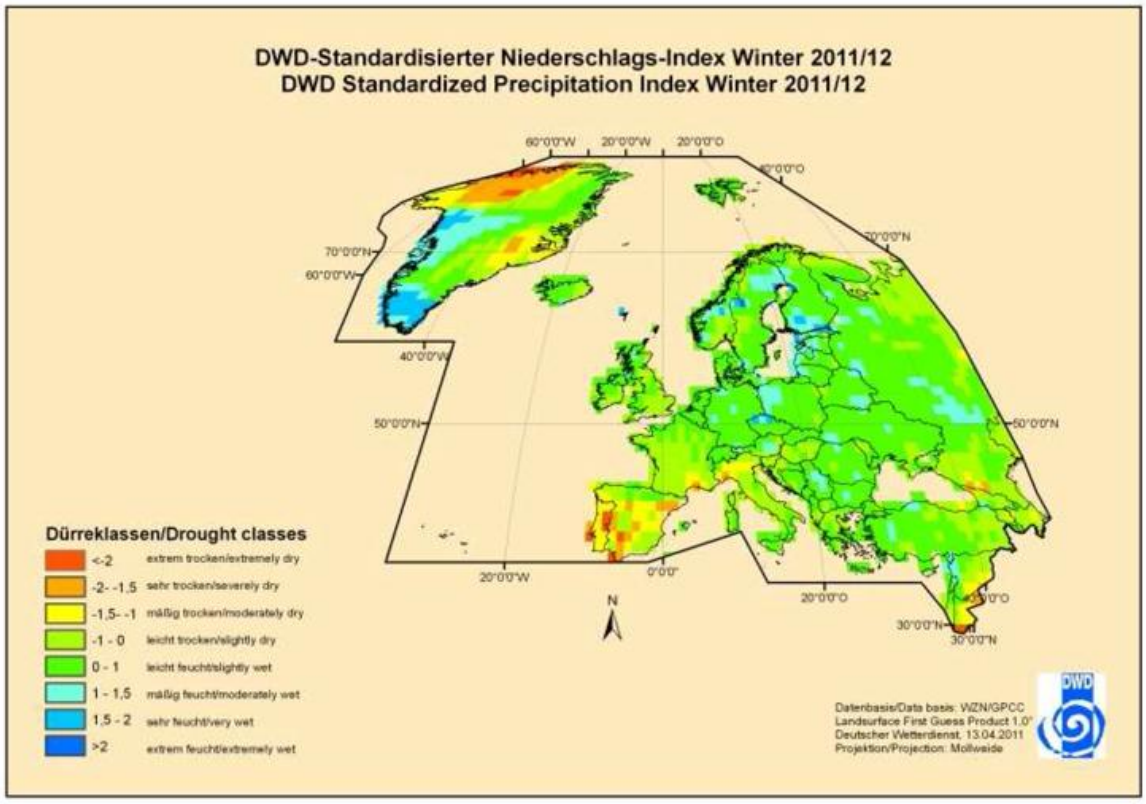

Fig. 2.63: Means of the modified Standardized Precipitation Index (DWD-SPI), winter 2012

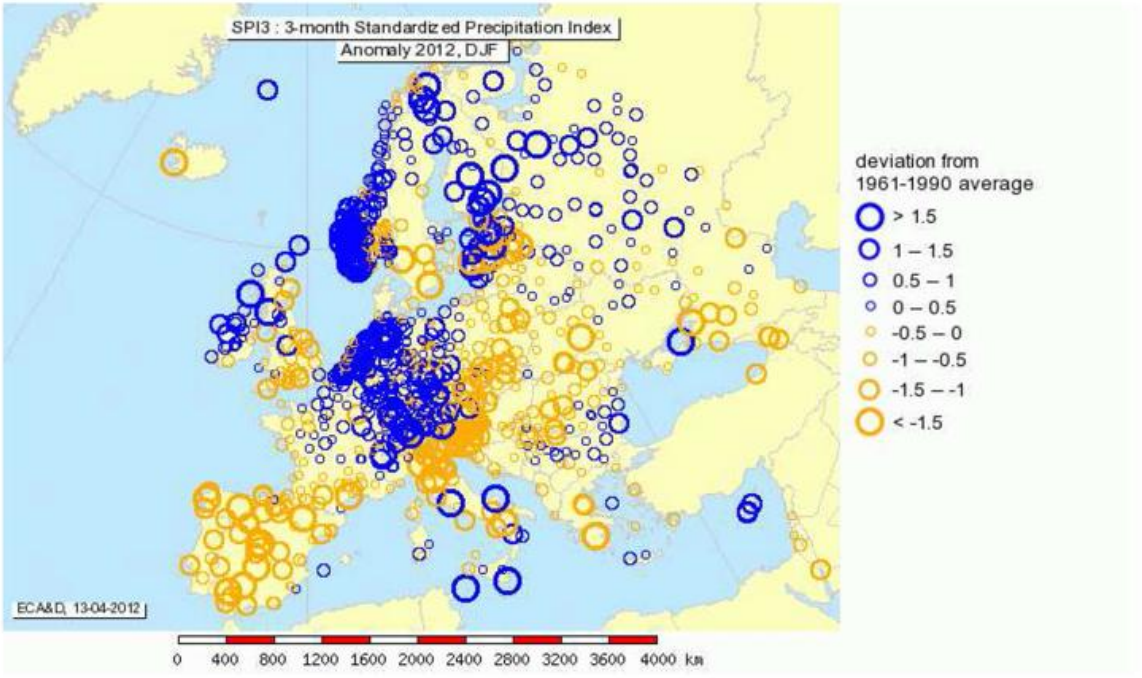

Fig. 2.64: Anomalies of the 3-month SPI (ECA&D) in Winter 2012

The winter season had moderate to partly extreme drought conditions especially on the Iberian Peninsula, southern France,Middle East and southern Eastern Europe.

- Portugal reported the driest February since 1931 and the driest winter since 30 to 70 years for some stations.
- In European Russia the vast area, from the White Sea to the southern Ural, received below-normal precipitation. Substantial precipitation deficit (5-30% of monthly normal) was recorded in the Ural region in February.Yekaterinburg received as little as 14mm of precipitation for the entire winter. This is the second time, when such low-snow winter is recorded for 120-year observations.

On the Iberian Peninsula the drought is mostly anomulous (Fig. 2.63, 2.64).

Spring

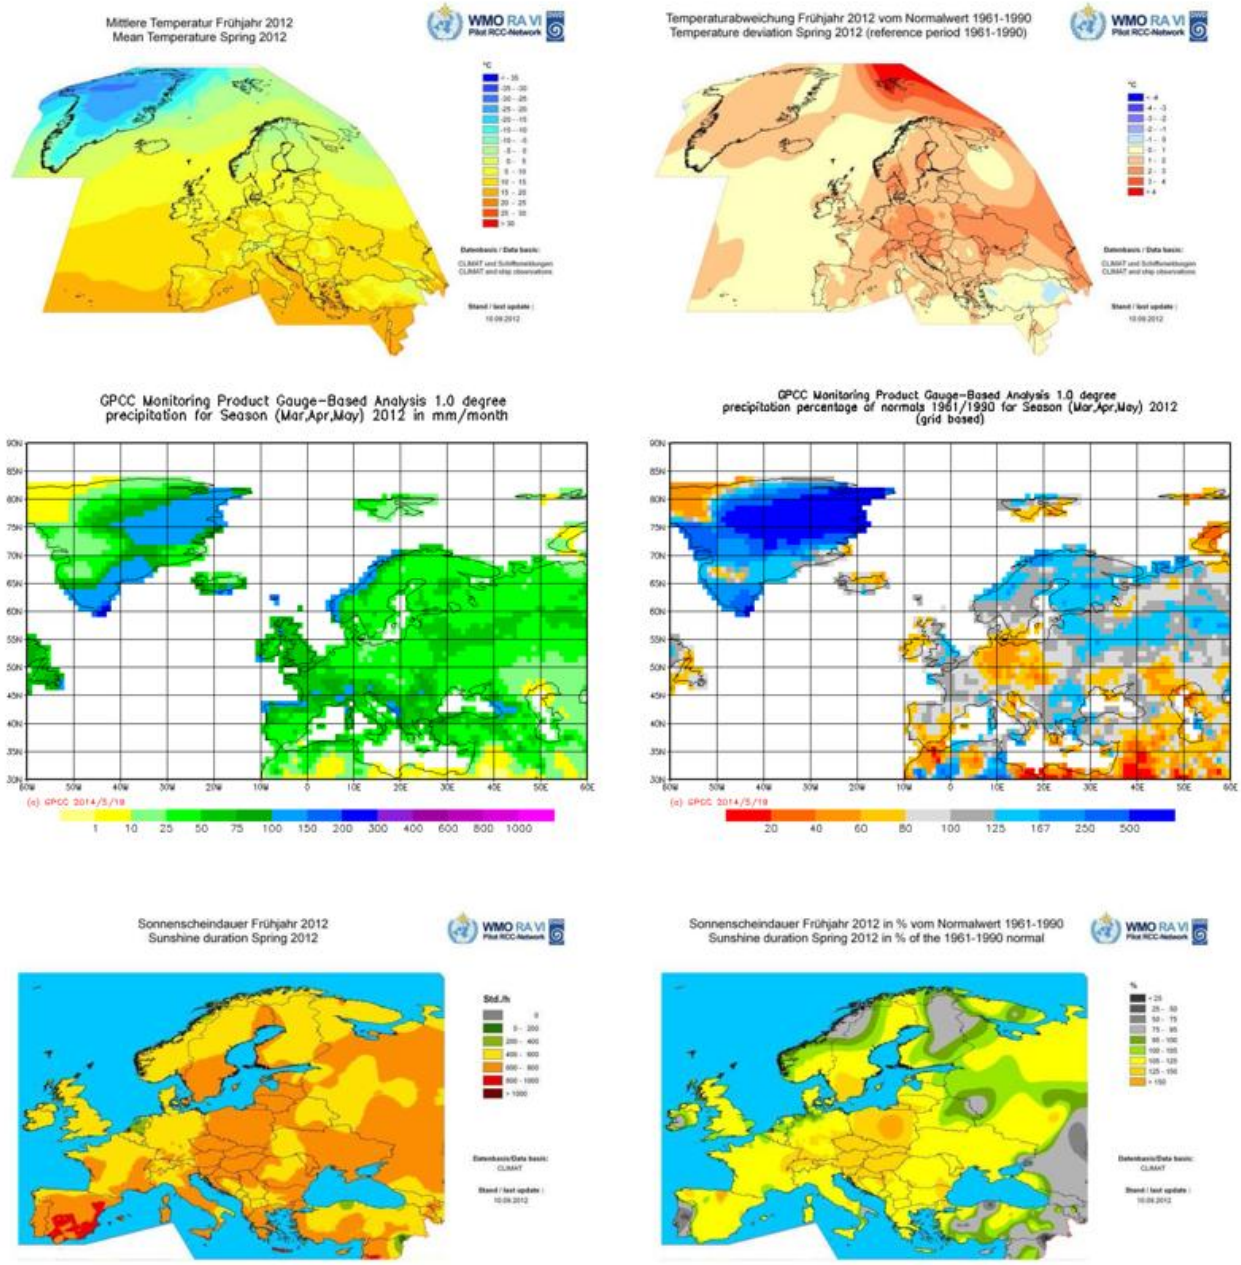

Fig. 2.65: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in spring 2012*
Source: http://www.dwd.de/rcc-cm

Temperature:

Spring 2012 was warmer than normal over the whole RA VI area.According to the E-OBS analysis spring 2012 was on rank 6 of the spring daily mean temperature since 1950. The mean daily maximum temperature as well as the mean daily minimum temperature were on rank 5. The anomalies ranged from 0.3 K to 4 K for the individual countries (result of the DWD temperature analysis). According to the DWD temperature analysis the highest positive mean anomaly for spring 2012 was computed for the region 'Mediterranean, Italian and Balkan Peninsula' with +2.3 K. With +2.0 K the positive anomalies of the regions 'Middle East' and 'Eastern Europe' were the next warmest. The 'Nordic and Baltic countries' were relatively slightly warmer than 'Central and western Europe' with anomalies of +1.5 K resp. +1.2 K. The smallest positive anomaly is computed for 'Iberia' (+1.0 K).

In Norway spring 2012 was the 15th warmest spring since 1900. Warm days occurred remarkably more often than normal . Much less frostdays than normal were registered in Denmark. Extraordinarily warm was **March 2012** in many countries. In Lithuania March was remarkable by its higher warmth (2.3° warmer than normal), and especially in the middle, when daily temperature rose to a record high. Sporadic high temperature records were observed also in April and May. The coldest nights of spring in Lithuania, as appropriate, were observed in early March (locally to -17 °C). In the end of April the absolute maximum temperature record of Lithuania was exceeded (31 °C measured in Alytus). Switzerland reported summer temperatures with locally record-breaking values in **April 2012** while **May 2012** on the other hand brought low temperatures and snow even in 600 m asl. Southern Russia had the warmest May since 1891 and new records for the daily maximum temperature at stations were reported by Sweden and Romania.

Precipitation:

Spring 2012 was drier than normal in central, northwestern and southwestern Europe and the Middle East. Wetter than normal were the Balkan Peninsula, Norway, the Baltic region, parts of Russia as well as partly the western Mediterranean Sea region, UK and France.

Spring was the second wettest in Estonia since 1961.

March 2012 was drier than normal in most of the Region except in Norway as well as the Baltic States, European Russia and the Caucasus region. In several countries March 2012 was one of the driest March months for many years. In UK it was provisionally the driest March since 1953 and the fifth driest since 1910. In Germany March 2012 was on rank 4 of dry March months since 1881. Central Europe, the Balkan Peninsula and the Middle East as well as much of Norway were drier than normal also in **April 2012** when the other parts of the region were wetter than normal, especially western and southern Europe. In **May 2012** again central Europe but also southwestern, western and eastern Europe were drier than normal while southeastern Europe, especially the Balkan Peninsula was wetter than normal. Thus central Europe remained drier than normal troughout the whole season.

Sunshine Duration:

Spring 2012 was a sunny season in most of the RA VI area except the Middle East and some regions in the northwest, north and northeast. The map of sunshine duration and the maps of the number of fair or dull days correspond nicely. The sunshine surplus of the season was mostly determined by March and May. **March 2012** was unusually sunny especially in UK, southern Scandinavia, France, Germany, Austria, Switzerland, Italy, Poland, the Czech Republic, Slovakia, Hungary, Croatia and the Balkan Peninsula. Shannon Airport in Ireland recorded the highest spring sunshine duration since 1938 (when the station opened) and on **25 May 2012** its highest daily sunshine duration of 15.6 hours.

Drought

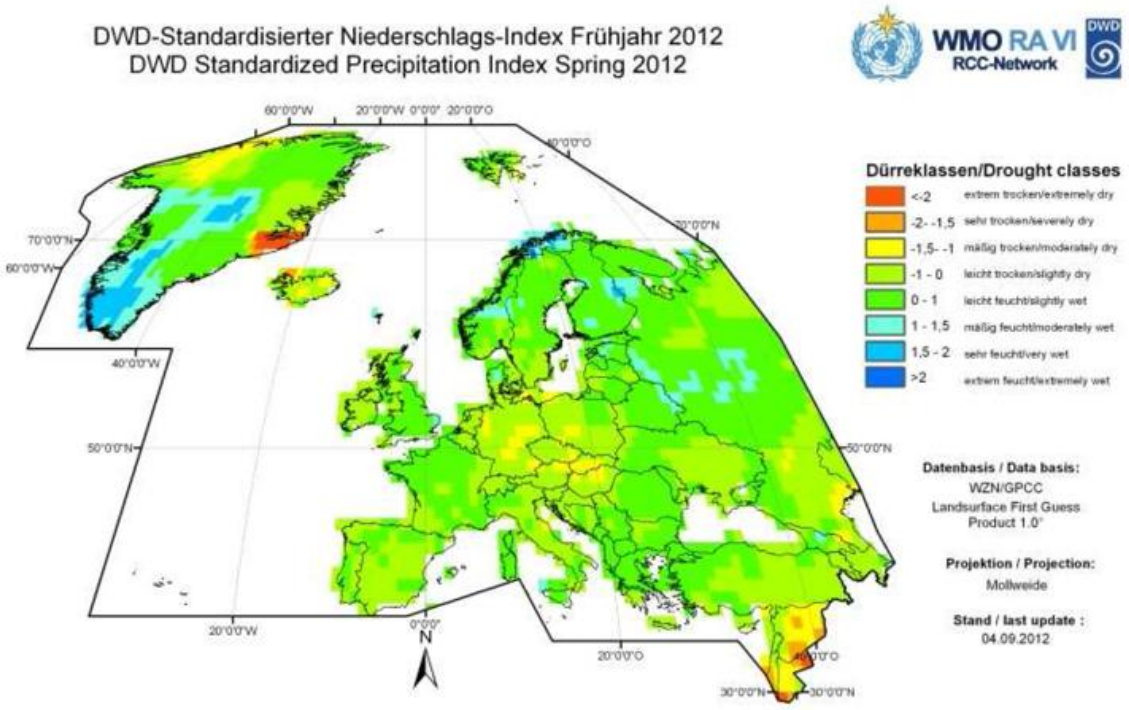

Fig. 2.66: *Means of the modified Standardized Precipitation Index (DWD-SPI), spring 2012*

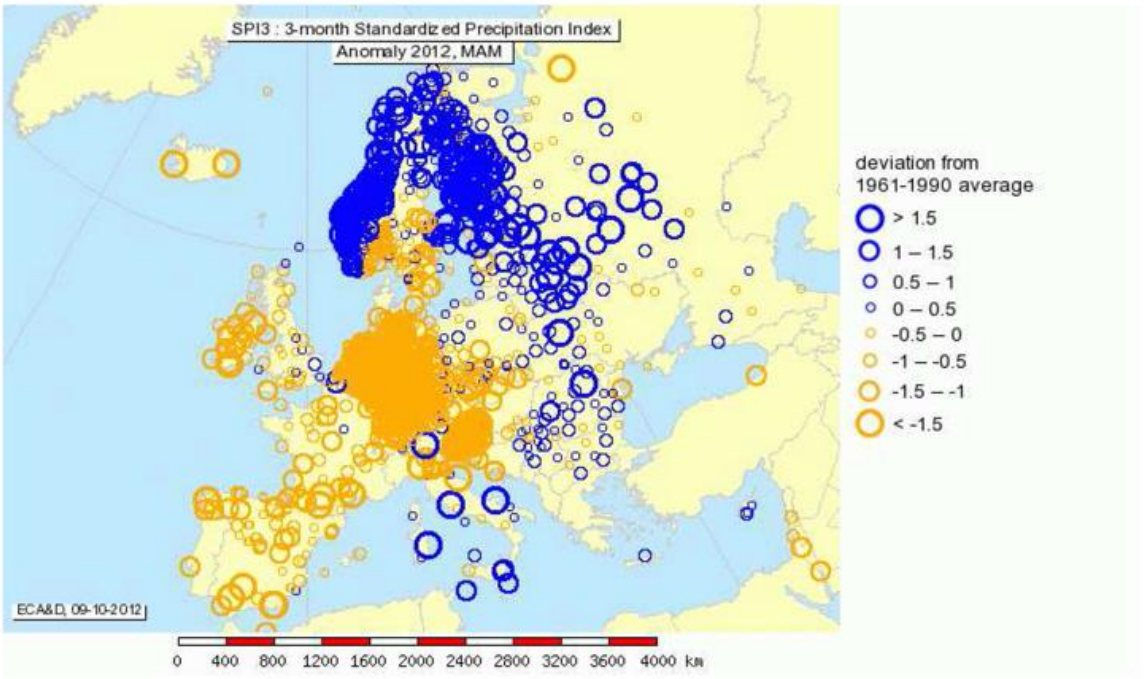

Fig. 2.67: *Anomalies of the 3-month SPI (ECA&D) in Spring 2012*

Spring 2012 was slightly to moderately dry in parts of Central Europe and southern Eastern Europe as well as on Iceland and slightly dry on the Iberian Penisula and on Ireland. It was moderately to severely dry in Middle East (Fig.2.66). Overall western, southwestern and central Europe and southern Scandinavia were anomalously dry in spring 2012 (Fig. 2.67).

Summer

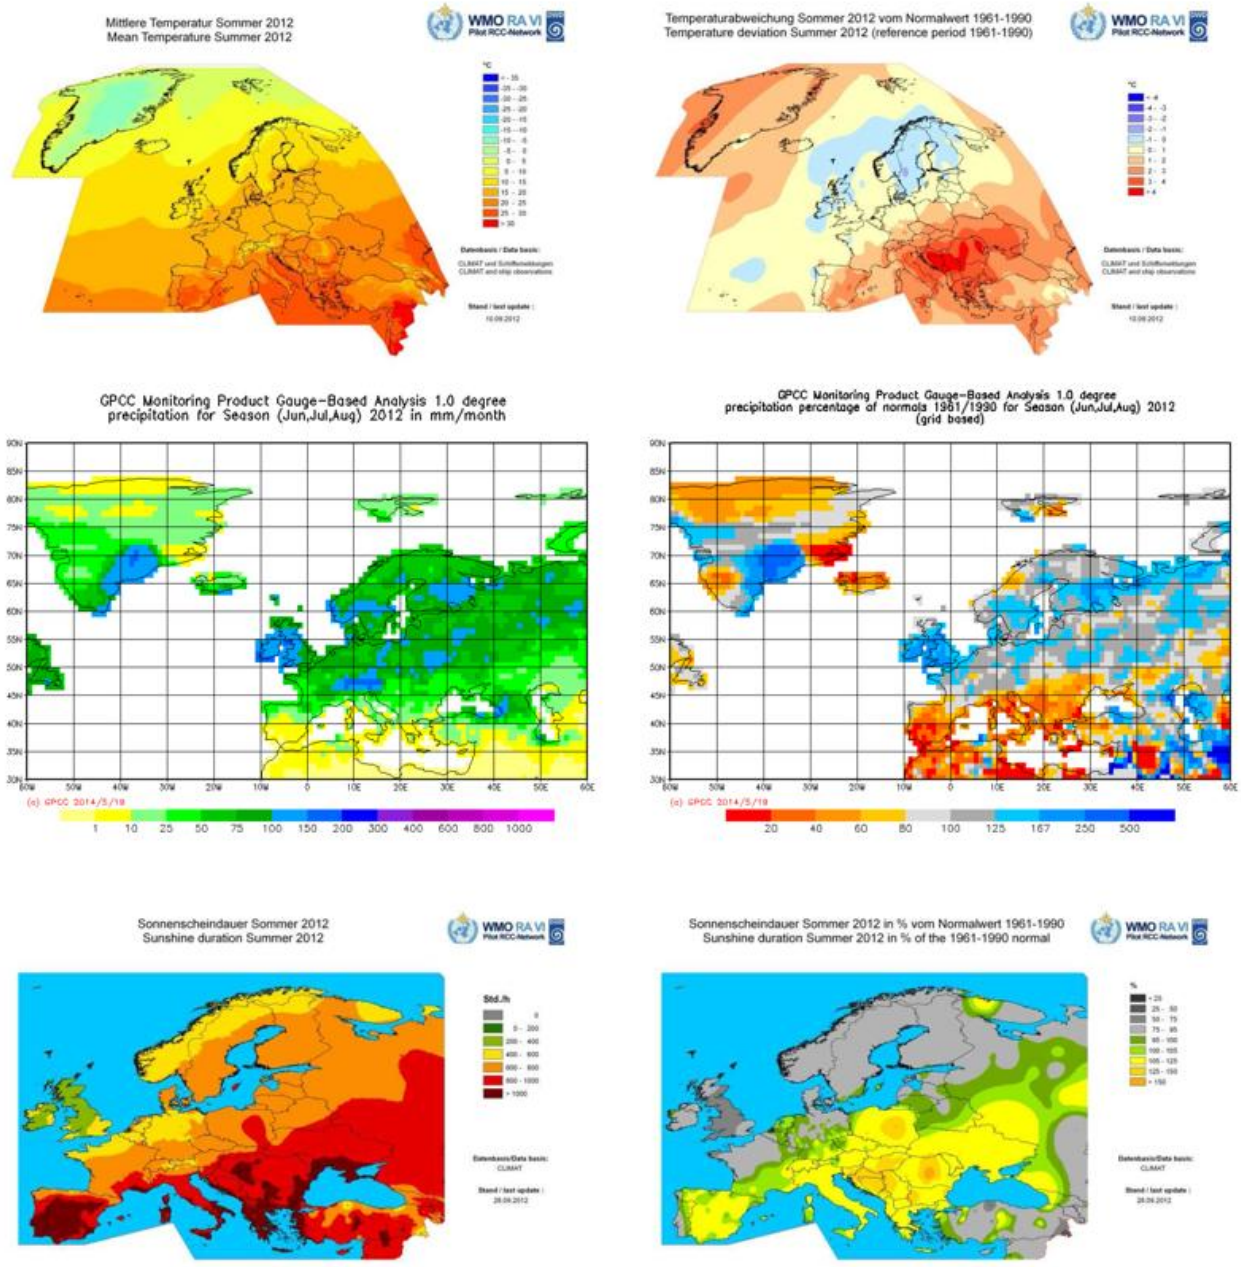

Fig. 2.68: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in summer 2012*
Source: http://www.dwd.de/rcc-cm

Temperature:

Summer 2012 was warmer than normal in southern, southeastern Europe and Middle East as well as on Greenland and the northwestern North Atlantic. The positive anomalies were highest in Italy, the Balkan Peninsula and the Ukraine. According to the E-OBS analysis summer 2012 was on rank 3 since 1950 for rthe daily mean temperature as well as for the mean minimum teperature. For the mean maximum temperature it was on rank 6. According to the DWD analysis the mean anomalies of summer 2012 for the subregions were highest for 'Central and western Europe' (+3.1 K) and lowest for 'Middle East (+1.4 K). The positive seasonal anomalies were mostly determined by June and August. Summer 2012 was especially unusual warm in Greenland. Record breaking and near to record breaking summer and single months occurred in many places (in Upernavik (20.3°C) and Ittoqqortoormiit (18.6°C) in July), but also a single record breaking cold June 2012 at Tasiilaq at the east coast were seen! In August it became really hot in Switzerland when hot days were recorded in locations up to 500 m asl during a heat wave. Moldova was characterized by an abnormally hot summer. On August 7, on 50% of the area was recorded the highest maximum temperature of +37,2°C to 42,4°C for the entire observation period in the summer season which is 0,2-0,9°C higher than the former absolute highest values.

In Turkey 31 stations had broken their extreme maximum temperature record in summer 2012. Tropical days have occurred (Tmax >30°C) in 122 stations. Moreover in 40 cities, maximum temperatures exceeded 40°C. The summer 2012 was the warmest on record together with the summer of 2010 in Israel. Slightly colder than normal were large parts of Scandinavia and the northern British Isles, the northern North Atlantic and northern central Europe where June and July were relatively cold and only August was warmer.

Precipitation:

Summer 2012 was drier than normal in the Mediterranean region including the Iberian Peninsula as well as the Balkan Peninsula. It was as well dry on Iceland and the northern part of Greenland. A significant lack of precipitation during summer 2012 in south-east Greenland was also observed (e.g. 0 mm at Tasiilaq, 0.7 mm at Narsarsuaq and 21.6 mm at Qaqortoq in June 2012, and only 1.4 mm at Tasiilaq in July 2012). In Tasiilaq the summer precipitation was the third lowest on record (since 1895). In Danmarkshavn in north-east the summer precipitation was 8.2 mm, the second lowest on record (since 1949) together with summer 2003. It was on the other hand wetter than normal or close to normal in western, central, northern and eastern Europe and much of the Middle East. 5-daily precipitation totals fairly above the normal values occurred in the north around the Baltic Sea as well as in the drier Mediterranean region (Northern Italy and the Alps as well as on the Balkan Peninsula.

Sunshine duration:

Summer 2012 was sunnier than normal on the Iberian, the Italian and Balkan Peninsulas as well as eastern central Europe and the southwestern parts of eastern Europe. Northern and northwestern Europe and the Middle East on the other hand had less sunshine than normal. The dullest region was the United Kingdom except the northernmost and southeasternmost areas. More sunshine than normal was registered in southern Europe through all 3 months. The Balkan Peninsula received more sunshine than normal especially in June and July. On the British Isles and in central Europe especially June 2012 was the month with a high deficit of sunshine.

Drought

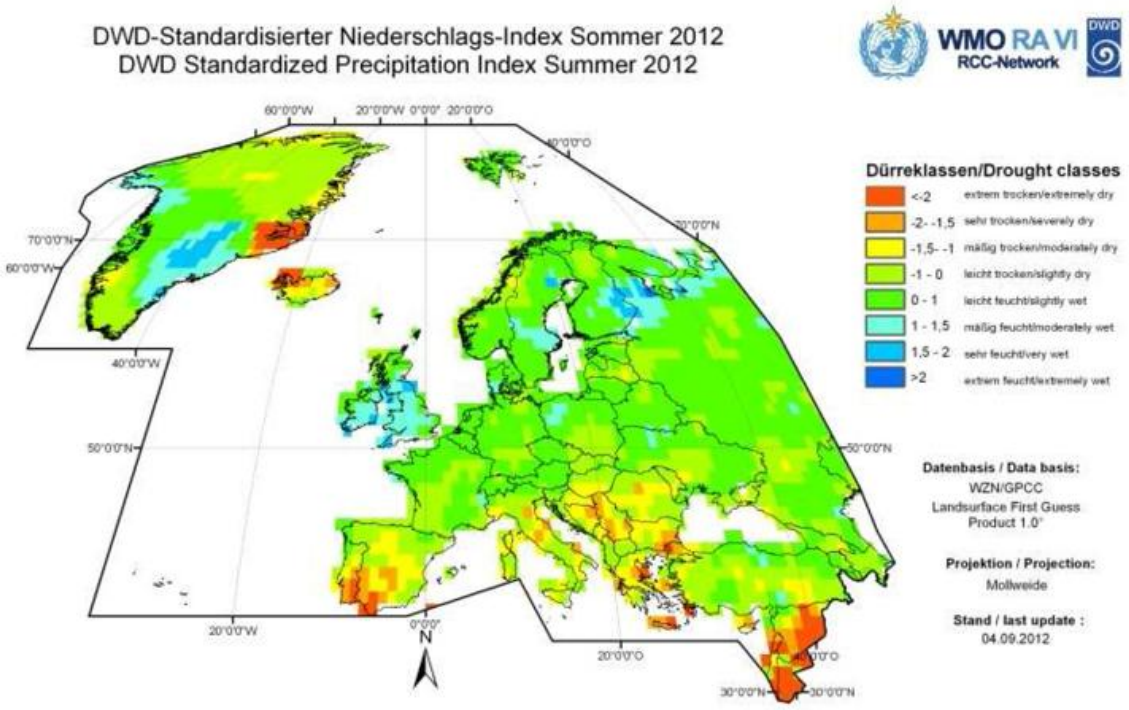

Fig. 2.69: *Means of the modified Standardized Precipitation Index (DWD-SPI), summer 2012*

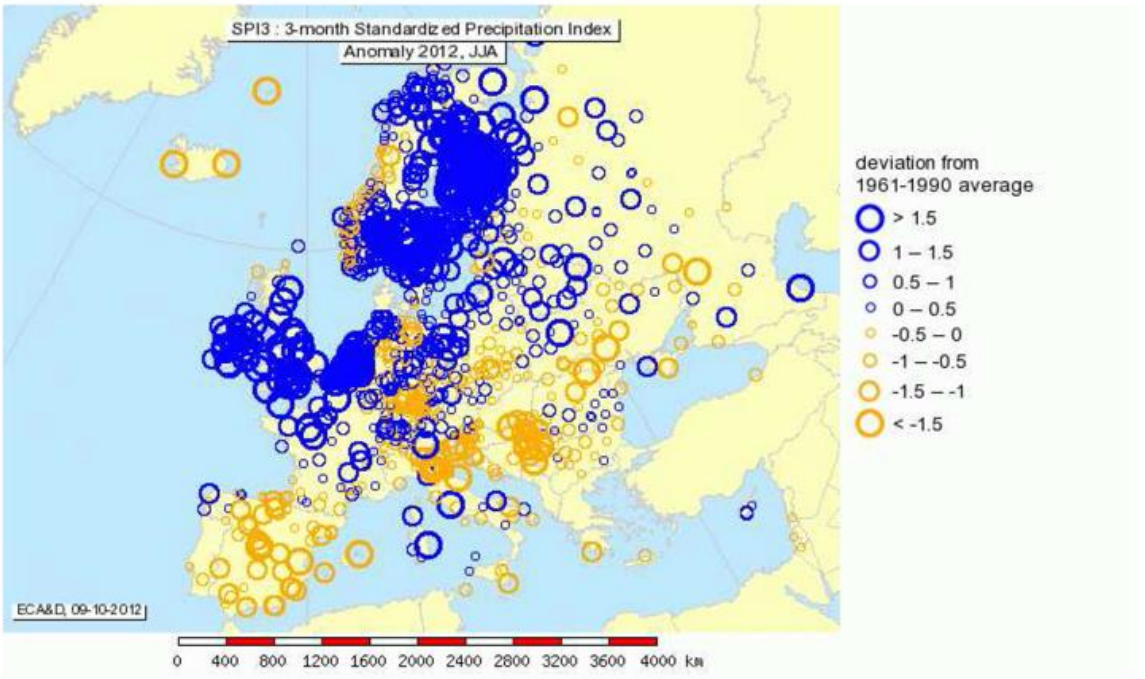

Fig. 2.70: *Anomalies of the 3-month SPI (ECA&D) in Summer 2012*

Summer 2012 was severely to extremely dry on Iceland, the southern Iberian Peninsula, partly the Italian and the Balkan Peninsula and in Middle East (Fig 2.69). It was overall on the Iberian Peninsula, on most of the Italian and Balkan Peninsula and also in parts of central and eastern Europe as well as on Iceland and the western coast of Scandinavia drier than normal. The anomalies of the 3-month SPI in the dry regions showed considerable dry deviations from the normal (<-1.5) on the Iberian Peninsula and the Mediterranean Sea region, the Alpine region, the Balkan Peninsula and southeastern Europe but also partially in central Europe.(Fig.2.70). In Moldova the total duration of rainless days per season reached 60 days, and the longest duration of continuous rainless days 26 days.

Autumn

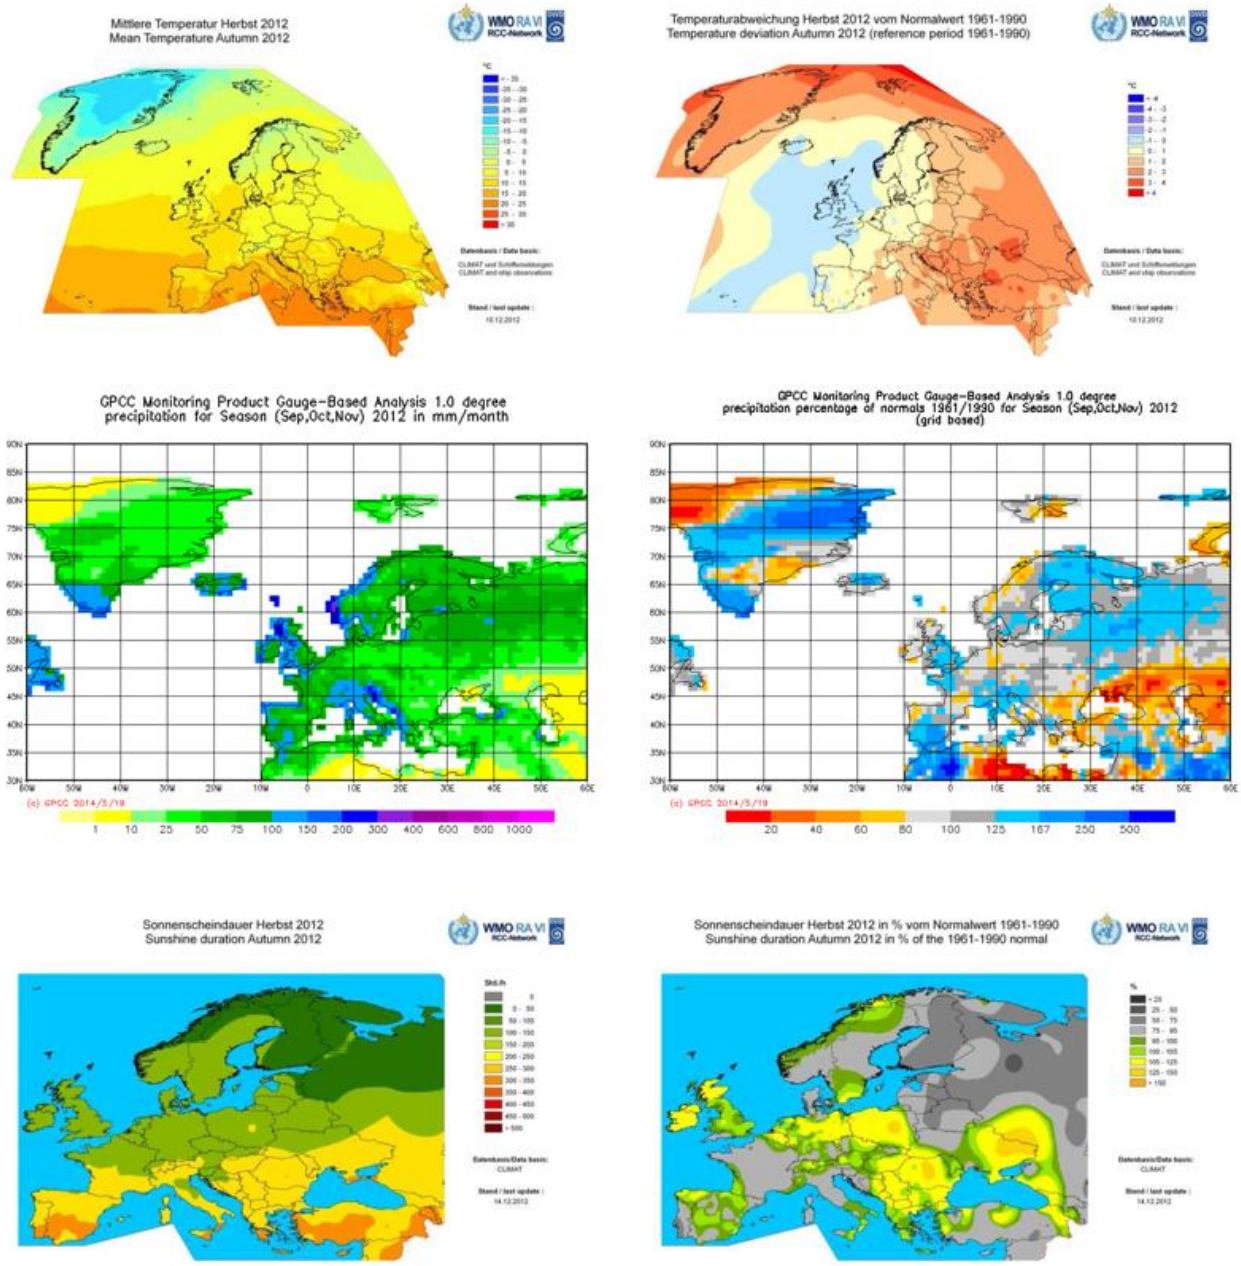

Fig. 2.71: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in autumn 2012*
Source: http://www.dwd.de/rcc-cm

Temperature:

In **autumn 2012** Greenland, the Arctic and most of continental Europe except the westernmost parts were warmer than normal while only the eastern North Atlantic with the British Isles and Iceland was colder. All 3 months were not very different concerning the anomaly pattern.

According to the E-OBS analysis autumn 2012 was on rank 2 since 1950 for the mean daily temperature, the mean maximum temperature and the mean minimum temperature as well.In Armenia autumn 2012 ranked 3rd warmest autumn on record. The highest positive anomaly was computed from the DWD analysis for the subregion 'Eastern Europe' (+2.2 K) closely followed by 'Central and western Europe' and 'Iberia' with +2.1 K. The smallest positive anomaly was computed for the subregion 'Nordic and Baltic countries' with +0.6 K.

September 2012 brought high maximum temperatures of more than 30 °C for instance in Austria, Poland and Moldavia. UK reported the provisionally coldest October since 2003.

Precipitation:

Autumn 2012 brought more precipitation than normal to the southeastern British Isles as well as to the southern Iberian Peninsula, the central and partly the eastern Mediterranean Sea area and to northern Europe as well as the Middle East. This surplus was caused to a good part by extremely wet days, resp. extreme precipitation events as the "map of anomalies of the precipitation fraction due to extremely wet days" shows. There is a special report on the extreme events in the Mediterranean Sea area for autumn 2012 available (see the list of links below). This coincides with the distribution of the mean sea level air pressure that shows low pressure centered over the Norwegian Sea reaching far southward over central Europe and only weak high pressure over the central North Atlantic and over southeastern Europe. Thus the dipole of the Icelandic low and the Azores high is poorly developed and nearly the whole European area had less than normal pressure. Relatively dry conditions occurred mainly in southern Russia, the Carpathian region and on the Balkan Peninsula and western Turkey.
Autumn was the wettest since 2001 in Denmark.

In **September 2012** especially in the Mediterranean Sea area some places received heavy to extremely heavy precipitation for 2 or 3 consecutive days so that large precipitation totals amounted within relative short time. In the Alps September brought early snowfall. **October 2012** in the northernmost part of the Swedish east coast the month of October was the rainiest on record with some local flooding.In the Mediterranean Sea region several phases with extremely heavy precipitation occurred in connection with low pressure systems. Switzerland reported that in mid-October the eastern slopes of the Alps had an uninterrrupted snow cover above 800 m asl and end of October snow height at some stations reached new October records. In **November 2012** many extremes of precipitation totals occurred in several episodes on different time scales from high several-day totals to extremely high daily totals especially in the Mediterranean Sea area and on Madeira but also for instance in England, were one week in November was the wettest since 50 years. Austria reported on 11 November 2012 125 mm in 24 hours at the station Loiblpass which is more than half of the month's normal. Switzerland reported heavy snowfall end of November so that the winterseason 2013 started with rather deep snow cover even at southern places.

Sunshine Duration:

Autumn 2012 was sunnier than normal for the British Isles, partly the Iberian Peninsula, central, eastern and southeastern Europe eastern Ukraine and southwestern Russia. For Poland the station Warszawa reported the highest seasonal total of 424.2 hours. elsewhere it was dull or close to normal. Autumn 2012 was the least sunniest autumn in Denmark since 2001.

Drought

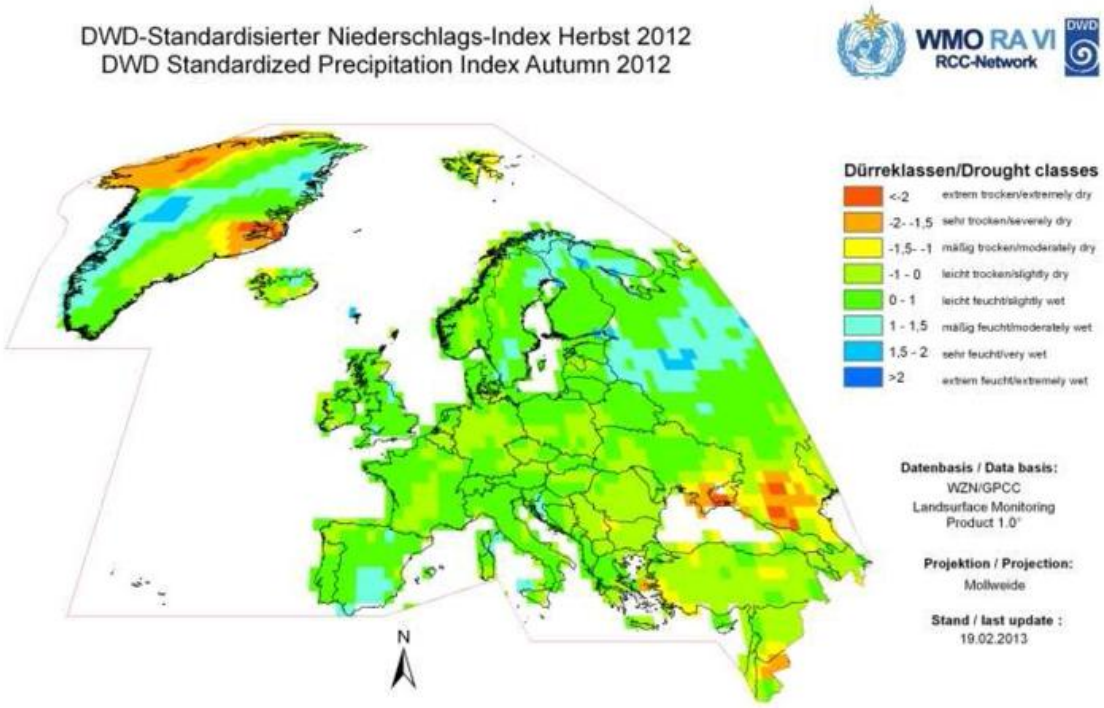

Fig. 2.72: *Means of the modified Standardized Precipitation Index (DWD-SPI), autumn 2012*

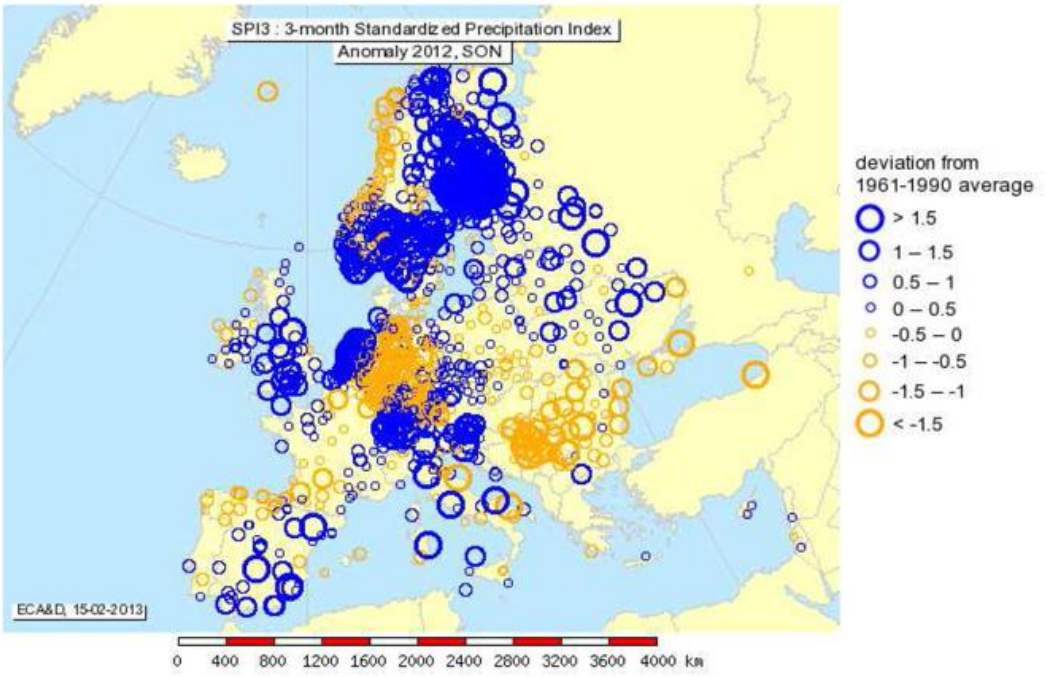

Fig. 2.73: *Anomalies of the 3-month SPI (ECA&D) in Autumn 2012*

Autumn 2012 was severely to extremely dry in the south of Eastern Europe and partly in Middle East (Fig. 2.72). This is severely drier than normal according to Fig. 2.73. Autumn 2012 was also slightly dry - and clearly drier than normal - in central Europe and on the Balkan Peninsula.

Monthly Survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2012 on the Climate in WMO Region VI - Europe and Middle East - which are available on Internet under http://www.dwd.de/rcc-cm.

January

Highlights:

- ***In the Arctic Sea region, western Greenland and northern Russia positive temperature anomalies exceeded 4 K. In southeastern Europe the negative temperature anomalies were partly below -3 K.***
- ***Very wet January 2012 in Israel. Outstanding daily precipitation total at Ny Alesund.***
- ***Positive sunshine duration anomaly for much of the European area***

Overview:

Temperature:

January 2012 was warmer than normal mostly except in the southeast and partly in the southwest. In the Arctic Sea region, western Greenland and northern Russia it was particularly warm. Anomalies here exceeded 4 K. On the other hand it was colder than normal in southeastern Europe. The anomalies were partly below -3 K.Very low temperatures occurred on the eastern Balkan Peninsula and the eastern Mediterranean Region.

Precipitation:

January 2012 was wetter than normal in central, eastern and southeastern as well as much of northern Europe but drier than normal in the west and southwest, in the south and in the north and northeast. It was particularly wet in eastern Central Europe parts of the Baltic states and western Central Russia, on the Balkan Peninsula and in Turkey. It was on the other hand drier than normal in western and southwestern Europe inclusively the western Mediterranean region, in the Middle East in the east and at the northwesterly coasts of Scandinavia though anomalously many very wet days also occurred here as well as in southern Norway. Portugal reported for Madeira the driest December and January in the series since 1950 and a comparable dry total for October to January like 1983.

Sunshine:

The sunshine duration anomaly was in January 2012 positive for much of the European area though this seems partly surprising in central and northern Europe compared to the areas of precipitation surplus. But is has to be considered that these areas do not have much sunshine in wintertime generally so that a small absolute surplus makes a high positive anomaly expressed in percentages.

Events:

- In late January the air pressure in Moscow attained 1025 hPa. The former record of 1024 hPa occurred in January 1946.
- The highest daily precipitation total of the Norwegian Arctic stations occurred on 30 January at Ny Alesund with 98 mm. This event has an estmated return period of 200 years.
- Storm depression ULLI on the British Isles, Germany and Denmark
- Storm depression ANDREA from the British Isles over central Europe to the Balkan Peninsula
- Cold wave in Europe at the end of the month (continuing in February)
- In northwestern Israel 27 consecutive rainfall days occurred (4 to 31 January)

January 2012

February

Highlights:

- ***A severe cold spell during the first half of the month over central, western, eastern and southwestern Europe placed February 2012 among the 15 coldest February months of the last 130 to 150 years in central Europe.***
- ***Below 30 % of normal February precipitation in the Ural region caused the 2nd lowest snow winter since 120 years there.***
- ***The 1st decade of February was the sunniest in more than 100 years in the Netherlands with more than half of the normal monthly total.***

Overview:

Temperature:

February 2012 was a cold month in most of continental Europe, Russia and the Middle East.Negative anomalies of -4 K or more occurred in France, the Alpine region, Poland, the Baltic states, Belarus, Ukraine, the Balkan states, parts of Russia and in Turkey. It was for instance on rank 10 of coldest February months since 150 years in Switzerland and on rank 15 of coldest February months since 1881 in Germany. Only the British Isles and southern Scandinavia were on the warm side. The Arctic Sea region had the highest positive anomalies of +4 K and more.

Precipitation:

In February 2012 it was dry in western, southwestern, and most of central Europe as well as southern Scandinavia. But the Scandinavian west coast as well as the central and eastern Mediterranean coast received partly remarkable precipitation surplus.

Sunshine:

Sunshine duration in February 2012 was nearly everywhere over the normal except most of the British Isles, the western Balkan Peninsula and southern Italy.

Events:

- Severe cold spell continuing until mid of February (see Fig. 3.7 and 3.8)
- On 1 February Haparanda reported a surface pressure of 1058.0 hPa which is a new Swedish record for February
- In the Netherlands the 1st decade of February 2012 was the sunniest since more than 100 years with more than half the monthly total
- Severe Aegean depression JULIA 6 to 8 February with storm, snow and floodings

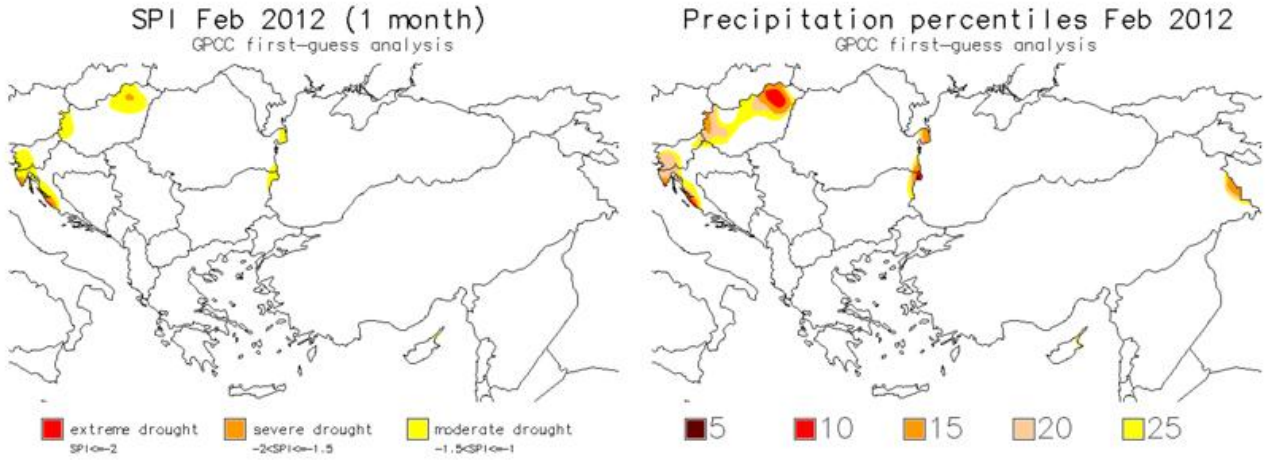

***Fig. 3.10** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
February 2012

March

Highlights:

- ***March 2012 one of the 3 warmest March months on record in many European countries***
- ***One of the 5 driest March months since about 100 years or more in western and central Europe.***
- ***One of the 5 sunniest March months in western and central Europe since 60 to 130 years.***

Overview:

Temperature:

Compared to the situation in February March 2012 was warmer than normal over most of Europe, Scandinavia, the northern North Atlantic inclusively eastern Greeland and in the Arctic Sea. Only the Middle East and European Russia were colder. In many European countries March 2012 was one of the 3 warmest March months since their timeseries started. In Norway it was the warmest March since 1900:

```
Norway:          rank 1  since 1900
United Kingdom:  rank 3  since 1910
France:          rank 3  since 1900
Germany:         rank 3  since 1881
Austria:         rank 3  since 1767
Denmark:         rank 4  since 1874
Netherlands:     rank 3  since 1900 (together with March 1957)
Switzerland:     rank 1  since 1864 in the southern parts
Sweden:          rank 1 on record in the central parts
```

Precipitation:

Most of western, southern, southeastern and central Europe as well as southern Scandinavia were dry. For UK it was the driest March since 1953, resp. the 5th of the dry March months since 1910. In Portugal March 2012 was on rank 6 of dry March monts since 1931 and in Spain it was the driest March since 1997. Also in Austria it was one of the driest March months since the records started. In Carinthia water shortage occurred. In Germany March 2012 was on rank 3 of dry March months since 1881. This precipitation deficit prolonged the drought situation for the UK (where water shortage was reported) as well as on the Iberian Peninsula and the western Mediterranean. More precipitation than normal fell on the other hand in Norway as well as the Baltic States, European Russia and the Caucasus region.

Sunshine:

March 2012 was also unusually sunny especially in UK, southern Scandinavia, France, Germany, Austria, Switzerland, Italy,Poland, the Czech Republic, Slovakia, Hungary,Croatia and the Balkan Peninsula. Some ranks of sunny March months are listed below.

```
United Kingdom: rank 1  since 1929
Austria:        rank 3  since 1880
Denmark:        rank 9  since 1920
Germany:        rank 5  since 1951
France:         rank 3  since 1950 (together with 1961 and 1953)
```

Events:

- High temperatures and low precipitation promoted wildfires in Bulgaria and in Austria as well
- High temperatures caused mud flows by snowmelting as well as avalanches in Austria
- A new record for daily maximum temperature for March occurred on 22 March in Uppsala, Sweden (19°C). The old record was of 1840.

Monthly Means or Totals and Anomalies :

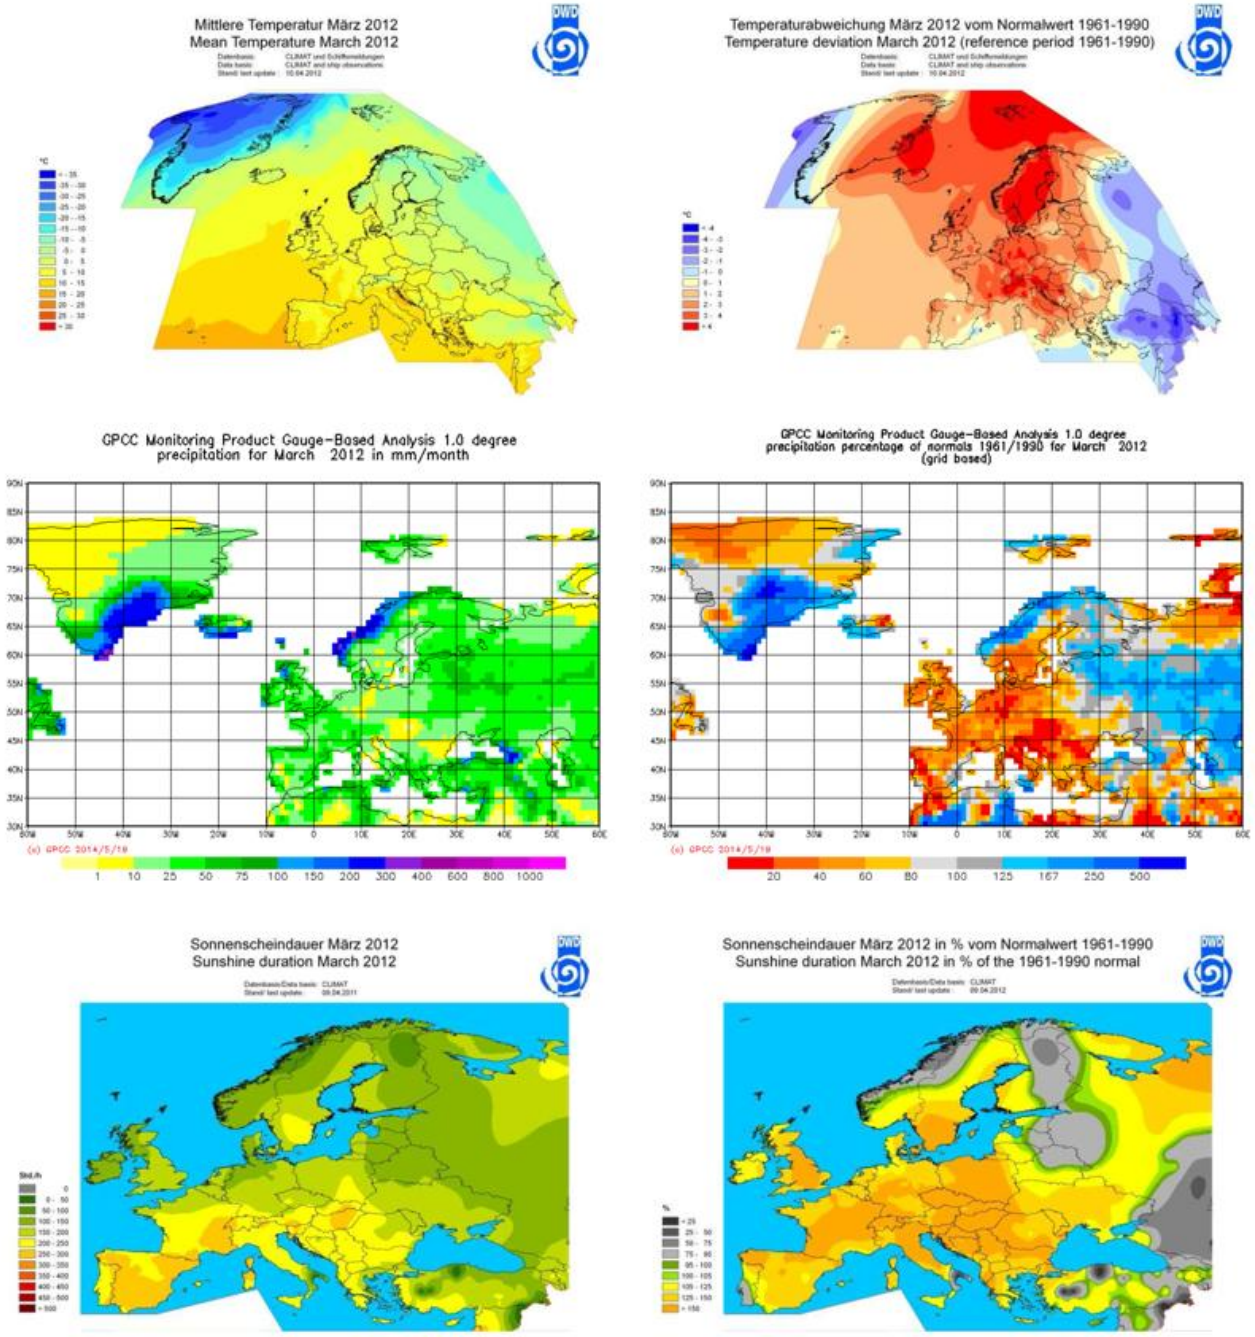

Fig. 3.11: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in March 2012*

Monthly Climate Extremes and Events:

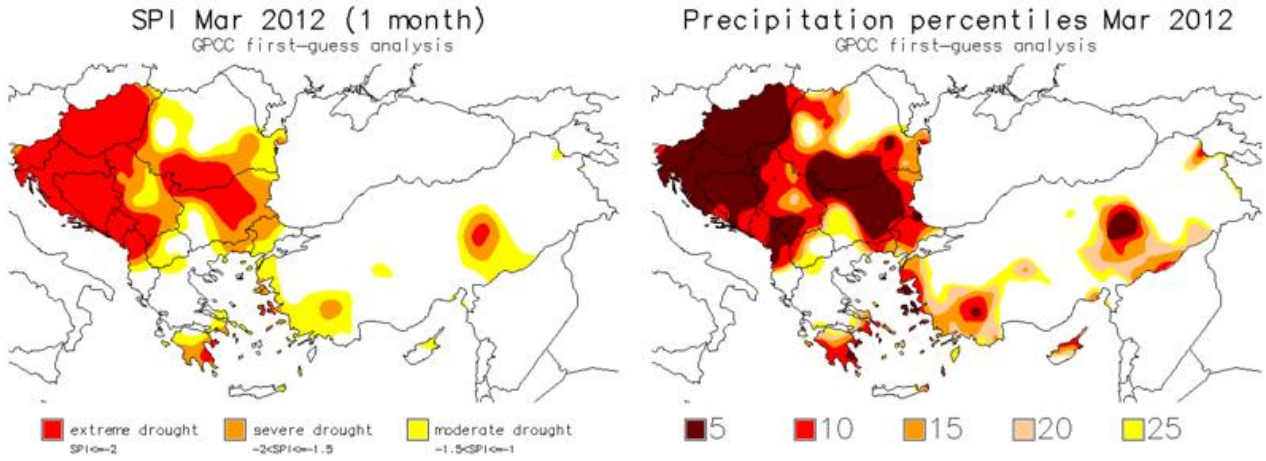

***Fig. 3.14** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
March 2012

April

Highlights:

- ***Western Europe colder than normal but new records of the daily maximum temperature at many single stations in European Russia, Lithuania, Romania and Austria.***
- ***Wettest April since 1766 in England and Wales but one of the driest April months since 70 years in northern Israel.***

Overview:

Temperature:

In April 2012 the northern and eastern North Atlantic and the western parts of Europe including much of Norway, the British Isles, western France and the western Iberian Peninsula were colder than normal. Eastern Europe, the Middle East and the Mediterranean were warmer than normal. The positive anomalies exceeded 4 K in southern Russia and the eastern Caucasus. The negative anomalies were regionally between -2 and -1 K in Portugal and Spain.

Precipitation:

Most of Europe received more precipitation than normal in April 2012. Exceptions were the Middle East, southern Russia, the Caucasus and the Black Sea Region, which were rather dry, as well as central Europe and the west of Norway and southern Spain. The surplus of precipitation was highest on the southern British Isles and western France, northern Spain, southeastern France and around the southern Adria.

Sunshine Duration

Sunshine duration anomalies in April 2012 were mostly negative in western Europe, positive in eastern central Europe, the Baltic states, the Balkan Peninsula, Turkey, the Ukraine and the Caucasus and slighly negative in the east and northeast.

Events:

- At the end of April several new records of the daily maximum temperature occurred: in Moscow, Russia: 28.9°C; in Alytus, Lithuania: 31°C; at Waidhofen/Ybbs in lower Austria; 32°C and as well at 52 Romanian stations

April 2012

May

Highlights:

- ***Highest mean May temperature since 1891 in southern European Russia and new records of daily maximum temperatures for May at stations in Romania and Sweden.***

Overview:

Temperature:

In May 2012 it was warmer than normal with few exceptions over the North Atlantic (especially the Northern North Atlantic with the greatest negative anomaly of -1 to -2 K at the northern Norwegian coast,Faroer Islands: anomaly of -0.9 K), western Turkey and locally Italy and Bosnia and Herzegovina. The positive anomalies were highest in the southern Ukraine (+3 to +4 K). Southern Russia had the warmest May since 1891. A secondary maximum (+2 to +3 K) is located in Spain. Portugal reported record-braking maximum temperatures for several stations and night temperatures well above 20°C during 14-16 May. The warm anomalies of May 2012 were not only restricted to Europe but extended globally. Norway, Sweden and Romania reported new records of the maximum temperatures for May at stations. Denmark reported 3 consecutive summerdays during the 3rd decade of the month. Ireland recorded the highest maximum temperature of 27.8 °C since 1938 on 25 May at Shannon Airport .In the Netherlands on 22 May the first summer day of 2012 was registered at De Bilt and on 23 May even a hot day was registered in eastern parts of the country.

Precipitation:

Higher than normal precipitation totals were registered on the Balkan Peninsula, western Turkey and the Caucasus region as well as partly in Scandinavia and in northern Russia. Much of this precipitation fell as heavy rain. With local exceptions it was drier than normal or close to normal elsewhere.

Sunshine Duration:

May 2012 was mostly sunnier than normal with a surplus up to >150% in central Poland and southern Russia. Less sunshine than normal occurred mainly on the Balkan Peninsula, Turkey and the Caucasus region as well as parts of Sweden, Norway, southern UK and Ireland and Portugal.

Events:

- On 29 May 2012 a new record for the highest temperature ever recorded on Greenland occurred at Ivittuut/Narsarsuaq: 24.8°C.

Monthly Means or Totals and Anomalies :

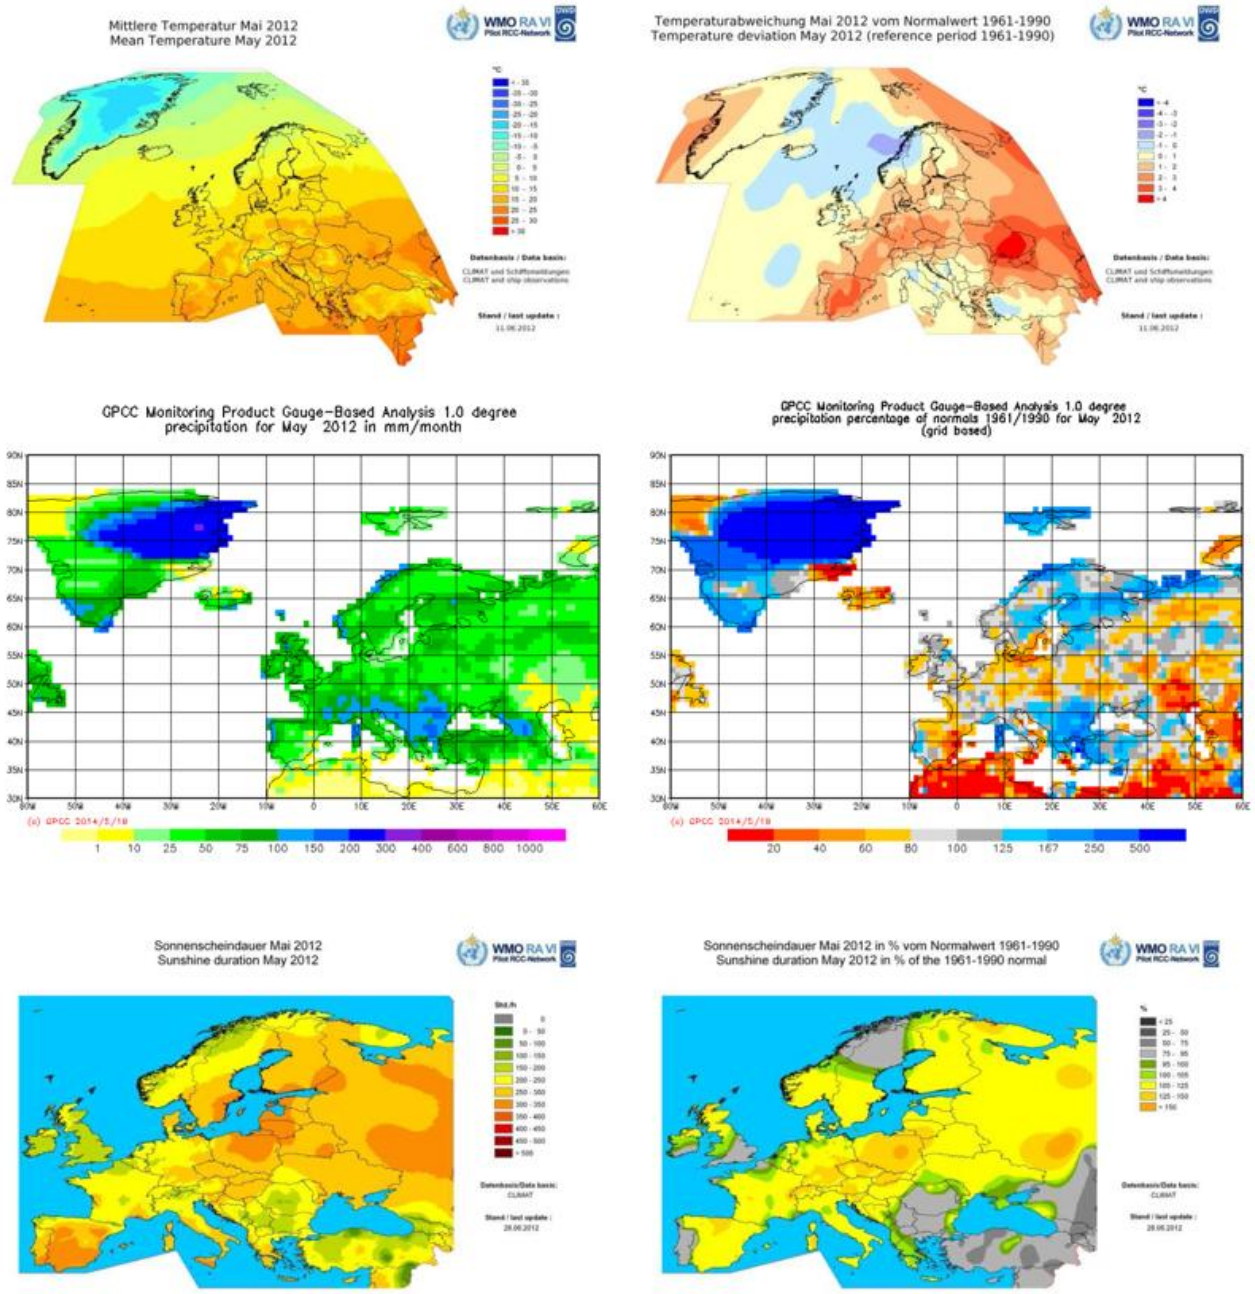

Fig. 3.19: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in May 2012*

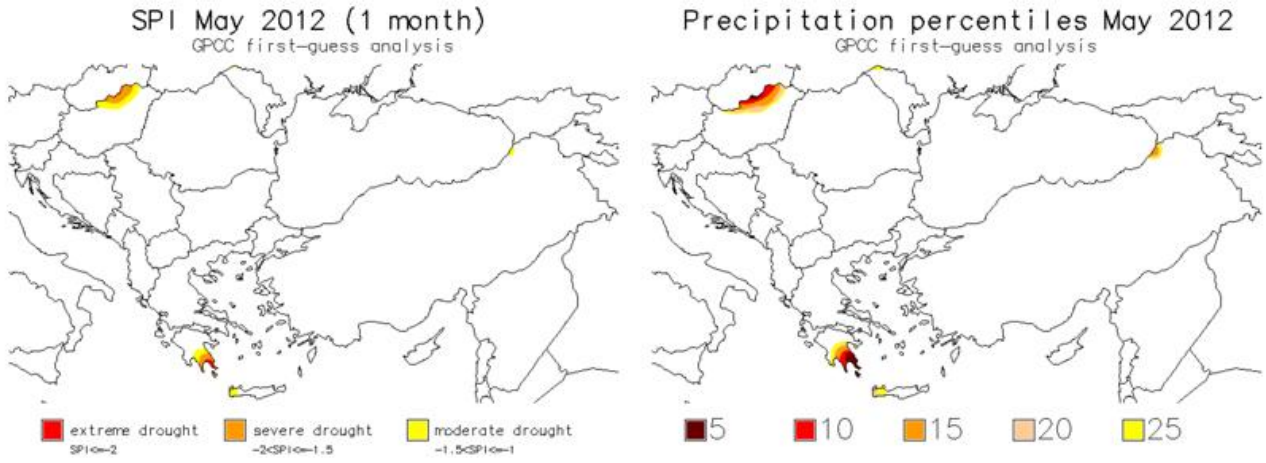

***Fig. 3.22** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
May 2012

June

Highlights:

- ***Unusually hot in Israel in mid of the month with maximum temperature up to 45°C in the Jordan valley and minimum teperatures around 30°C at the Dead Sea.***
- ***Wettest June since 1766 in England and Wales and widespread rainfall with unusually high totals in southern Israel.***
- ***Dullest June since 1929 in UK but up to more than 150 percent of the normal in Romania.***

Temperature

June 2012 was colder than normal in the northwest, north and northeast, warmer than normal in the south, southeast and east and in the Arctic region. The highest maximum temperatures were mostly below the normals in Scandinavia, Ireland, UK, Denmark and Germany. It was the coolest June since 1991 in UK and in Denmark as well as for 2 stations in Ireland. Stockholm registered its coolest June weekend in 84 years at the beginning of the month. Denmark reported rimfrost with a minimum temperature of 1.1°C near Aarhus on 15 June. On the other hand on the Iberian Peninsula, in the Mediterranean Sea region, partly on the Balkan Peninsula and around the Black Sea many stations had more tropical nights (minimum temperature above 20°C), and there were clearly more summer days (maximum temperature above 25°C) than normal. Maximum temperatures of 40°C occurred often.

Precipitation

June 2012 was wetter than normal in the west, north and northeast with exception of the coastal regions of the northern North Atlantic, Norwegian Sea and Arctic Sea. It was drier than normal around the Mediterranean Sea and the Black Sea region. Locally the Middle East was wetter than normal. It was by far the rainiest June on record since 1786 in Stockholm, Sweden. It was the wettest June across the UK in the series from 1910 (wetter than June 2007), and the equal-wettest June in the England and Wales series from 1766 (shared with June 1860). In Ireland the majority of stations across the country reported their wettest June on record. More days with very heavy rain (>=20 mm) than normal were recorded at many stations on Ireland and northern England, in Sweden, in the Alpine region and Belarus and western Russia. Highest 1-day precipitation amounts were partly remarkably above the normal values. On the other hand in the Mediterranean Sea region, the Iberian Peninsula, the Balkan Peninsula and most of the Black Sea area and southern Russia the monthly precipitation totals were often below 25 mm, on the southern Iberian Peninsula and the Mediterranean Sea and Middle East below 10 mm or partly even below 1 mm.

Sunshine Duration

June 2012 was sunnier than normal mainly around the western Mediterranean Sea, on the Balkan Peninsula and the southern Ukraine. Romania with partly more than 150 % of the normal was sunniest, but overall also the Balkan Peninsula was very sunny. Elsewhere it was close to normal or dull. In UK it was provisionally the second dullest June in the series from 1929. The far north-west of Scotland was the sunnier exception. Germany for instance had the 12th dullest June since 1951.

Events

- On 8 June hail with diameters between golf ball to tennis ball at Wieselburg (district Scheibbs) in Austria caused estimated economic damage of 3 millions Euro.
- A heat wave from 14 to 18 June in Israel brought maximum temperatures of 43°C to 45°C around the Dead Sea and Arava region, 40°C to 42°C in the Jordan Valley and 38°C to 40°C in the Negev and 35°C to 37°C in the mountains. On 17 to 18 June minimum temperatures fell only to 26°C to 28°C and around the Dead Sea and Eilat to 30°C to 32°C. Only 3 times during the last 60 years higher night-time minima occurred.
- On 16 June cloudbursts occurred in the southeast of the Moscow region. The places Kolomna and Kashra received 116 mm and 89 mm within 12 hours.
- On 22 June it rained in northeastern Israel, around the Dead Sea and in the Negev. Precipitation totals of 10-20 mm were recorded widely and the higest daily total was 35mm
- On 28 June severe thunderstorms brought locally torrential rain, large hailstones and flooding to parts of the Midlands and northern England with 40 to 50 mm within 2 to 3 hours at some places

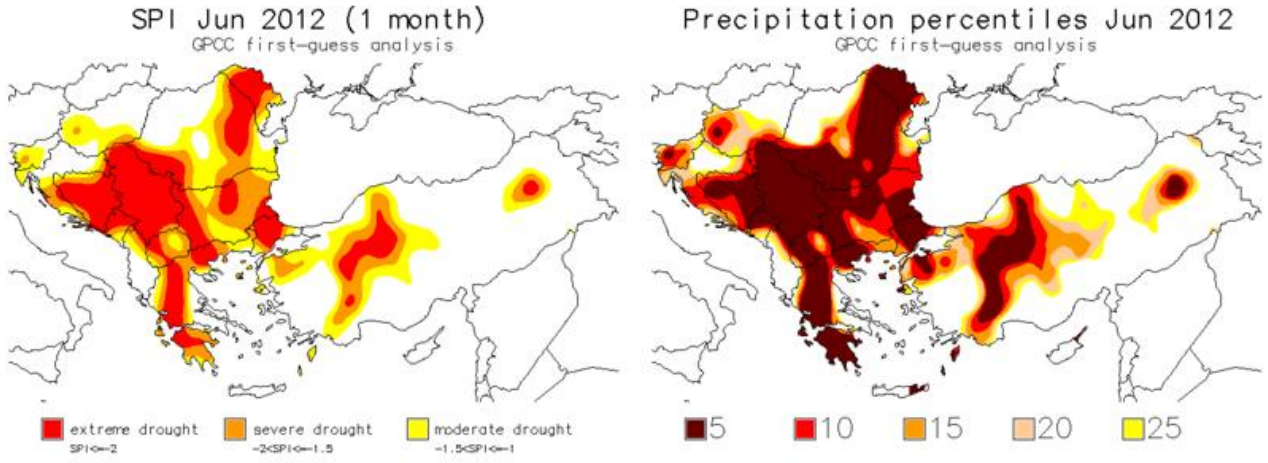

***Fig. 3.26** : Monthly Drought Indices (1-month SPI and low precipitation percentiles) as provided by the Drought Management Centre for Southeastern Europe (DMCSEE)*
June 2012

July

Highlights:

- ***Several days with temperatures above 0°C in Kangerlussac on Greenland.***
- ***Unusually extreme rainfall events in Sweden, in Austria and in southern European Russia.***

Temperature

On the whole Northern Hemisphere most of the land area and the western North Atlantic were warmer than normal.

Warmer than normal conditions were prevailing except in the west and north of Europe under the influence of the North Atlantic. Most striking was the positive anomaly of more than 4 K on the Balkan Peninsula and Ukraine. Also where the positive anomalies were less or it was overall colder than normal, partially more warm days than normal occurred. Many hot days and days with more than 40°C occurred in southern and southeastern Europe.It was the warmest July on record in Hungary as well as in parts of Israel. Several days with temperatures above 0°C occurred on Greenland (Kangerlussaq).

Precipitation

It was wetter than normal in western, central, northern and northeastern Europe as well as the Middle East and drier in the southwest, south, east and southeast. The relatively wettest areas are on the British Isles, northern and eastern parts of Central Europe and the eastern Alps, northern parts of Russia, the central Mediterranean and partly the Middle East. It was the 3rd wettest July since 1858 in Austria. At many Austrian stations, predominantly in the south and southeast new records for the July precipitation totals were achieved. In Mallnitz (Carinthia) July 2012 brought 325 mm, 82 mm more than in 2005. The series started 1895. Much of the surplus was caused by more than usual wet days. It was on the other hand very dry especially around the Mediterranean Sea except the region around southern Italy and the Thyrranean Sea.

Sunshine Duration

Sunshine duration was above normal in southern and southeastern Europe. The greatest positive anomalies occurred on the Balkan Peninsula and in Poland. This corresponds to the low number of dull days and in the Mediterranean Sea and on the Iberian Peninsula to the high number of fair days. This of course supported the high temperatures in the area.

Events

- Rain and several days of thaw have been registered at the Arctic ice cap with high temperatures late June and several days in a row in July above 0°C. mm (see Fig. 3.29).
- 20 of 31 days with weather-related damages in Austria with one of the most intense hailstorms (hailstones of up to 8 cm in diameter) in recent years in Austria on 8 July
- On 20 July large parts of the district Lietzen (in Styria, Austria) were a desaster area after long-lasting heavy rainfall. A mudslide buried 70 houses of St. Lorenzen in the Paltental. Vehicles piled up to 10 meters high. The entire infrastructure, drinking water and electrcity supply was detroyed. The cleaning and rebuilding work lasted until the end of the year.
- Torrential melting waters destroyed a bridge in Kangerlussac, Greenland
- 163 mm daily precipitation total on 7 July in Hinshult, southeastern Sweden; the 5th highest daily amount ever recorded in Sweden.

- Destructive flooding in the Krasnodar territory with daily totals of the order of six-month totals for the region. On 6 July 2012 Gelendzhik received 253 mm. Novorossisk and Krymsk received 187 resp. 156 mm.
- In Romania the Thermal Heat Index (THI) reached or exceeded a critical value almost every day.

Monthly Means or Totals and Anomalies :

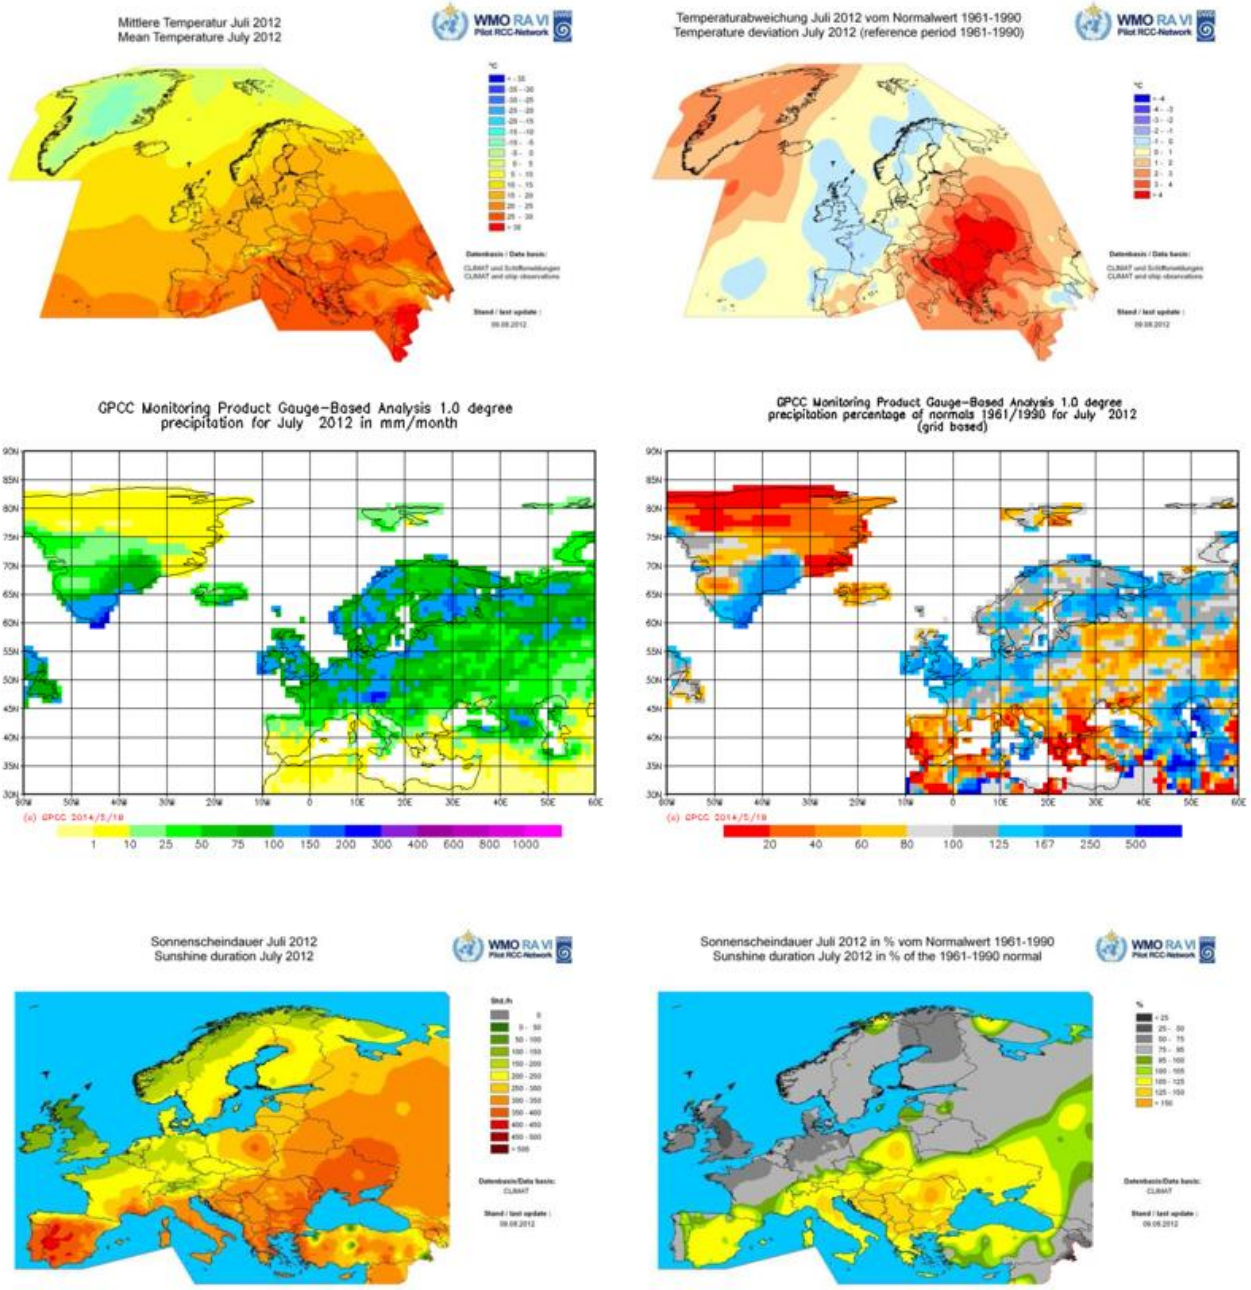

Fig. 3.27: *Means and anomalies (reference 1961-1990) of temperature, precipitation and sunshine duration in July 2012*

Monthly Climate Extremes and Events:

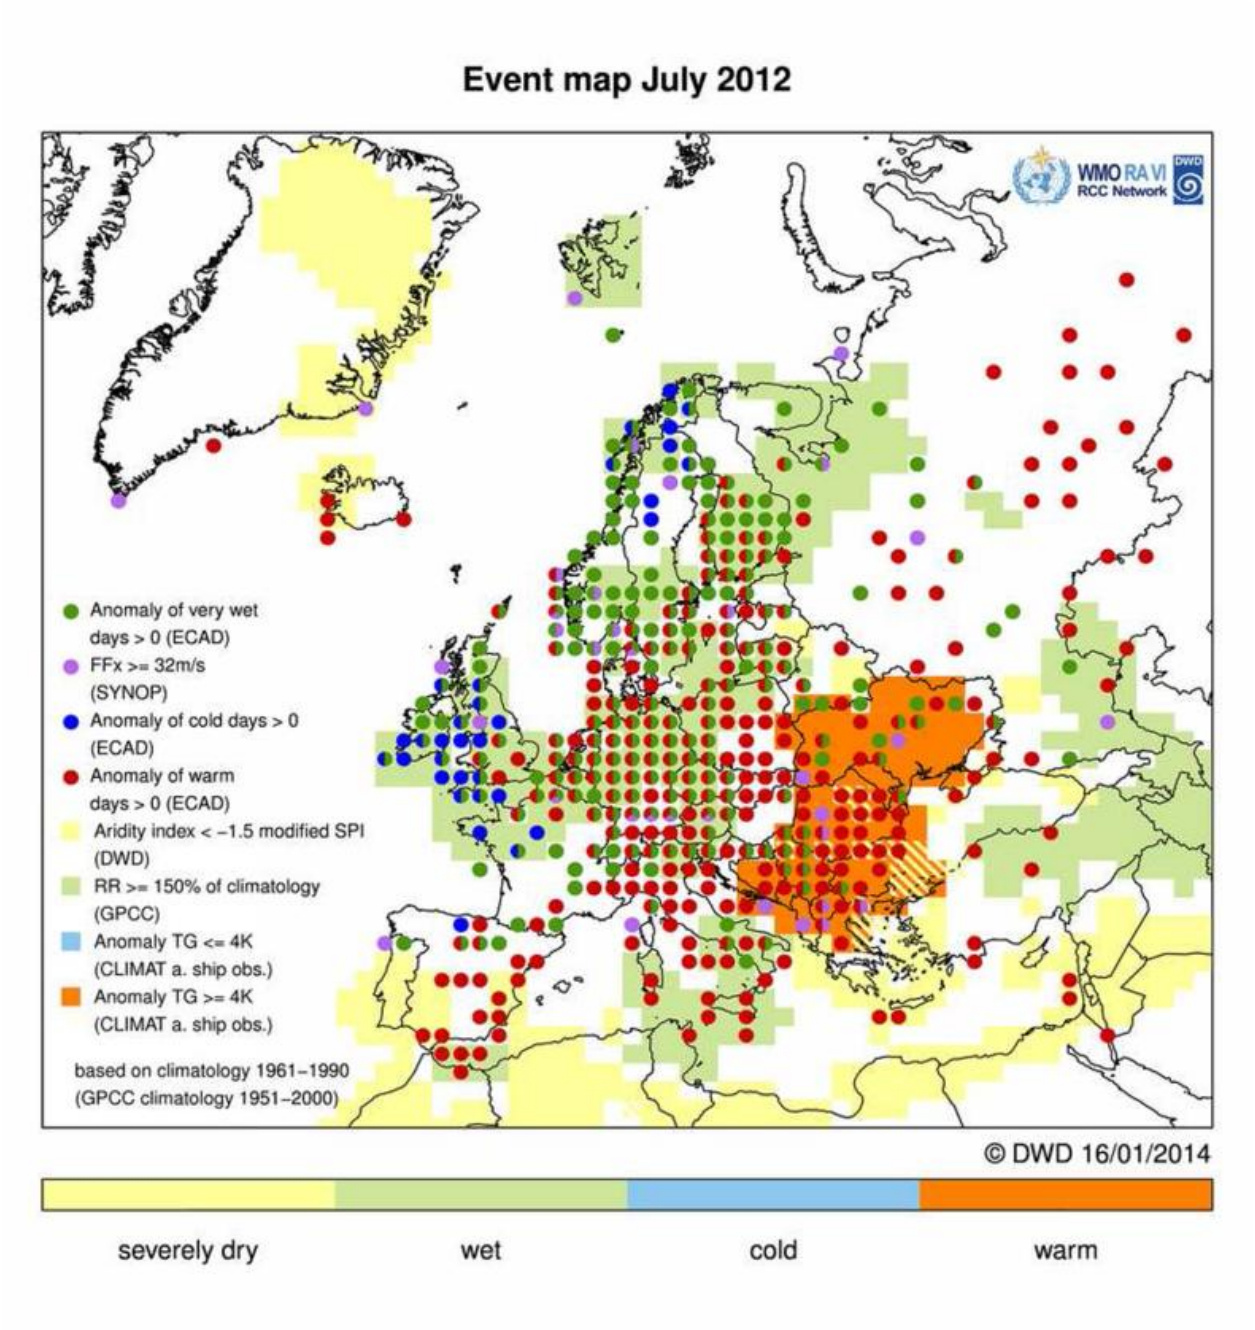

***Fig. 3.28** : Monthly Map of Climate Extremes and Events July 2012*

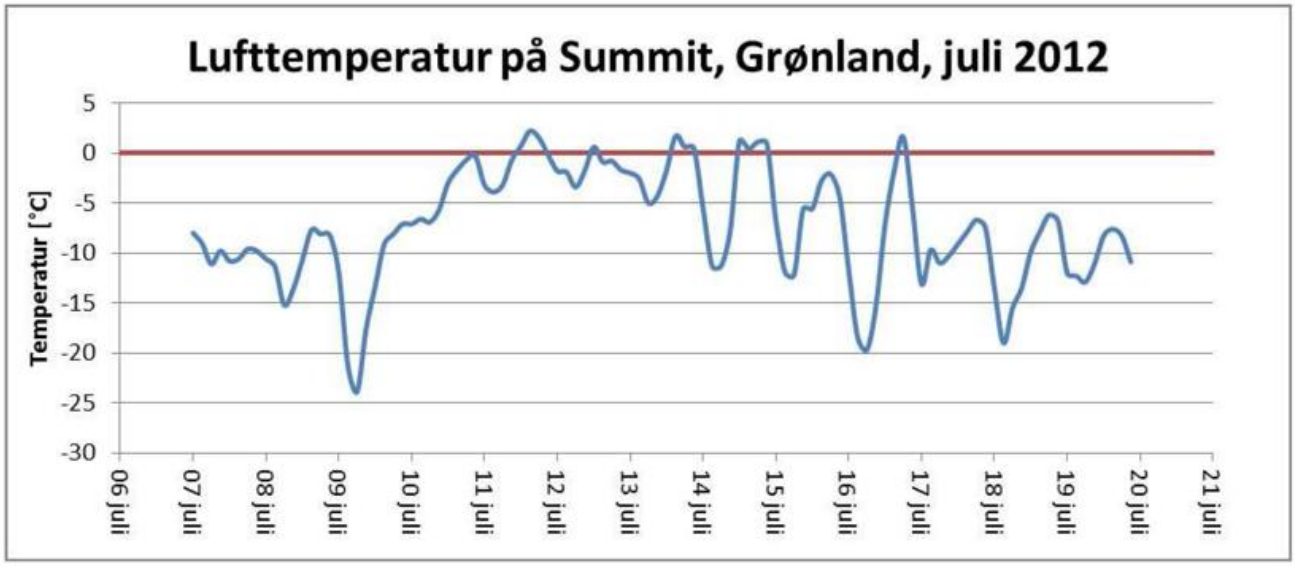

Fig. 3.29 *: DMI has observed the surface air temperature (SAT) at Summit in the middle of the Greenland ice cap in 3.2 km altitude since 1991. DMI's observations show that the temperatures typically range from -60 to -50°C in winter and from -10 to 0°C in summer. It is not unusual to observe positive temperatures on a few days during a year. It is a fact in 10 different years out the 18 years of observations. Observations from July 2012 (lower figure) showed that temperature for several days in a row exceeded 0°C, not seen before. In the days of 11 - 14 and 16th July the temperatures were above 0 °C. The observations confirm the NASA satellite observations of melting in these days. July 2012*

Monthly Temperature and Precipitation in the Eastern Mediterranean Subregion:

July 2012

August

Highlights:

- ***In 24 countries in the region daily maximum temperatures of 40°C or more were reached or exceeded, highest maximum of 45.9°C in Spain.***
- ***Lowest rainfall total for July since 1901 in Hungary***

Overview:

Temperature

August 2012 was warmer than normal nearly in the whole area with exception of slightly colder areas on the North Atlantic, the Norwegian Sea, the Baltic countries and parts of northern Russia and Finland. The positive anomalies reached or exceeded 4 K on the Balkan Peninsula and the Adriatic Sea and in Italy as well as parts of eastern Spain. In many countries (24 in the region) on the Iberian Penisula, the Balkan Peninsula, in the eastern Mediterranean region as well as in Italy and in France daily maximum temperatures of 40°C or more were reached or exceeded (see Fig 3.34 for the heat wave in France). Most of the other countries had at least one station with a hot day (30 °C or more) with exception of Ireland, the Faroer Islands, Greenland, Iceland, Norway, Finland, Estonia and Latvia.

Precipitation

In August 2012 it was very dry on the Balkan Peninsula, in Italy, southeastern France and northwestern France, most of the Iberian Peninsula except the west coast, parts of the eastern Mediterranean and Middle East. Precipitation totals were below 20 percent of the normal in the driest areas especially on the Balkan Peninsula, much of Italy and the Iberian Peninsula. It was the driest August since 1901 in Hungary. Less than normal precipitation was as well observed in central Europe, northern Norway and Finland, partly around the Baltic Sea and in northern Russsia. Also Iceland and southern Greenland were very dry. Wetter than normal were western and northern parts of the British Isles, Netherlands and Denmark, southern Scandinavia, the Alps, Poland, and much of Russia as well as some areas in Greece and Turkey.

Sunshine

In August 2012 it was sunnier than normal in most of the western, central and southern European continent and in northern Scandinavia. It was on the other hand very dull in parts of the Turkish Black Sea area and rather dull in southwestern UK.

Events

- Spain reported the highest maximum temperature of 45.9°C.

August 2012

September

Highlights:

- ***Extremely heavy precipitation in southern Spain and Italy***

Overview:

Temperature

Most of the region was warmer than normal except the North Atlantic and the adjacent countries: northwestern France, the British Isles and southwestern Scandinavia. The Balkan Peninsula in the southwest and the Arctic region and Greenland in the north had the highest positive anomalies of +2 to +3, partly over +3 K.

Precipitation

Much of central, eastern and southeastern Europe and the Middle East were drier than normal. The Mediterranean Sea area especially in its central part as well as the southern Iberian Peninsula and northern and northwestern Europe partly received more precipitation than normal. This surplus was often caused by extremely heavy precipitation. Especially in the Mediterranean Sea area some places received heavy to extremely heavy precipitation for 2 or 3 consecutive days so that large precipitation totals amounted within relative short time.

Sunshine Duration

It was sunnier than normal mostly in central, western, southeastern and southern Europe except the central Mediterranean Sea region. It was less sunny on the other hand in most of the north: northern Germany, Scandinavia except southern and central Sweden and northern Russia. The sunniest country was Poland with positive anomalies up to more than 150 percent of the normal.

Events

- Valencia in Spain recorded a daily total of 188.9 mm on 28 September.
- Extremely heavy rain events in Tuscany, Italy on 19 and 30 September 2012

September 2012

October

Highlights:

- ***New records of October maximum temperatures at stations in Sweden, Latvia, Austria, Romania and European Russia***
- ***For some stations in northeastern Sweden the rainiest October on record for more than 100 years.***

Overview:

Temperature

In October 2012 it was mostly colder than normal or close to normal on the eastern North Atlantic, the British Isles, the western Iberian Peninsula, Norway and Sweden except the farest north, Netherlands, Denmark, Germany, Poland and much of the Baltic Sea area. Ireland and northern UK as well as large parts of Norway and western Sweden were coldest with anomalies up to -3 K. UK reported the provisionally coldest October since 2003. It was on the other hand warmer than normal in the south, southeast, east, north and northwest with the highest positive anomalies above 4 K in the Black Sea area and above 3 K from the Aegean Sea northeastwards to southern Russia, southern Ukraine and the Caucasus region as well as in the Barents Sea and northern Greenland.

Precipitation

October 2012 was wetter than normal on most of the western, southern, northern and eastern to northeastern continent, except the eastern Black Sea, the Caucasus region and the Caspian Sea region, the Atlantic region, parts of the Mediterranean Sea region and central Europe (mostly Germany), which were drier. Much more precipitation than normal fell in western France, on the southern Iberian Peninsula, at the Adriatic coast, in the northern Baltic Sea region and in the eastern parts of European Russia as well as in southwestern Greenland. Sweden reported that "in the northernmost part of the Swedish east coast the month of October was the rainiest on record (since more than 100 years) with some local flooding". Especially in the Mediterranean Sea region several phases with extremely heavy precipitation occurred in connection with low pressure systems. Heavy to very heavy precipitation also occurred in the north.

Sunshine Duration

October 2012 was sunnier than normal on the British Isles, the southern Iberian Peninsula, central and eastern central Europe, partly southern and western Scandinavia and on the Italian and Balkan Peninsulas. Elsewhere it was close to normal or dull. Lesser sunshine than normal was especially observed in northwestern France and southeastern UK, partly in Portugal, in northeastern Russia as well as in Finland, the eastern Baltic Sea region and Belarus.

Events

- New records of October maximum temperatures occurred on 1-2 October in Romania, on 20 October in Sweden, Latvia and Austria and end of October in European Russia.
- Heavy rain led to exceptional autumn flooding in western parts of Finland
- During 10 to 13 October heavy to extremely heavy rain in the Adriatic Sea and western Balkan Peninsula accumulated to 3-day totals between 50 and 200 mm.
- On 20 October the cave of Lourdes in France became flooded after heavy rain
- During a storm a maximum windgust of 43.9 m/s was recorded on 30 October 2012 in Izaña (Teneriffa).

October 2012

November

Highlights:

- ***Previous records of November maximum temperature were broken at stations in European Russia (9°C in Ufa on 8 November) and in Romania (Calimani on 12 November).***
- ***Many events of extreme heavy precipitation***

Overview:

Temperature

November 2012 was warmer than normal in the Arctic region and on most of the continent except the westernmost parts of the British Isles, France and the Iberian Peninsula. It was colder than normal on the Atlantic. The positive anomalies were higher than +4 K in the Arctic region and at many stations above +3 K in Slovakia.

Precipitation

It was wetter than normal on the southern Iberian Peninsula, the Middle East, northern Italy and the Alpes, northern parts of European Russia and Finland as well as southern Scandinavia and the southern British Isles. Drier than normal on the Balkan Peninsula around the Black Sea and in southern Russia as well as on the northwestern European continent and parts of Scandinavia. Many extremes of precipitation totals occurred in several episodes on different time scales from high several-day totals to extremely high daily totals especially in the Mediterranean Sea area and on Madeira but also for instance in England, were one week in November was the wettest since 50 years.

Sunshine Duration

November 2012 was sunnier than normal on the northern part of the Balkan Peninsula and north of the Black Sea (partly more than 150 percent of the normal) as well as over the Alpes, parts of Germany and the Netherlands, the westernmost parts of the continent and southeastern and northern UK and Ireland and as well parts of western Scandinavia. It was mostly dull elsewhere with less than 50 percent of the normal in the east.

Events

- A strong blizzard in the southern parts of Finland and the Gulf of Finland with significant wave heights of 5.2 meters which was above the previous record.
- A F3/T6 tornado in the Algarve region in Portugal (at Lagoa, Silves) with wind in the range 256-295 km/h resp. 71.1-81.9 m/s.
- Extensive flooding in Slovenia on 5 to 6 November.
- On 6 November an extremely low air pressure (728 mm Hg resp. 970.6 hPa) was recorded in Moscow.
- A '100-year' flooding of the river Drau on 11 November in Austria, district Wolfsberg. The water stood 2 m high in the city of Lavamünd.
- Flooding in Tuscany and northern Italy, with precipitation totals of 320 mm during 6 to 13 November (compared to a mean monthly total of 80 mm) in the area of Florence. the 6th highest water level in Venice since 1872.
- Extremely heavy precipitation with a daily total of 200 mm (170 mm within 3 hours) in Carrara, Italy, on 27 November

November 2012

December

Highlights:

- ***A severe cold spell in eastern Europe and the warmest Christmas since 60 years in Austria.***
- ***Wettest December in Belgium, December the wettest month of the year in the Netherlands and new records of daily rainfall totals at stations in Western Galilee, Israel***

Overview:

Temperature

December 2012 was warmer than normal in the Arctic, the North Atlantic, the western, central and southwestern European continent and the Middle East. It was colder than normal in Scandinavia, Russia, the eastern central European continent, the Balkan Peninsula and Italy. The warm anomalies in the Arctic exceeded +4 K and the cold anomalies in Russia exceeded -4 K. In eastern Europe the cold came unexpectedly early and strong.

Precipitation

While December 2012 was drier than normal in northern and western Scandinavia, northern Russia, the Baltic states and the Caucasus, the Iberian Peninsula and western Mediterranean, it was partly remarkably wetter than normal elsewhere. In eastern UK, northern France, Belgium and the Netherlands it was about twice of the normal and in eastern Romania and southern Ukraine as well as in parts of the Middle East more than 250% of the normal were observed.This was the wettest December so far in the records of Belgium. In the Netherlands December 2012 was the wettest month during the year.

Sunshine

Sunshine duration was clearly higher than normal for Poland, the Czech Republic and partly the eastern Alps as well as in Russia while most of central Europe, te western Iberian Peninsula, moste of Scandinavia, the western Balkan Penisula, the baltic states, Belarus, Ukraine and the Middle East were dull.

Events

- On 20 December stations in Western Galilee, Israel received daily rainfall totals of 135-140 mm. These were the highest daily totals ever recorded.

1 Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Climate and the State of the Climate Article published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ amongst the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collection Centre (GCC), run by Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), run by Deutscher Wetterdienst
- Sunshine: CLIMAT data.
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

Subregional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC) and the Southeast Drought Management Centre (DMCSEE)

The following subregions are used in this Bulletin:

Central and western Europe: *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, Netherlands, Poland, Slovakia, Switzerland, United Kingdom*

Nordic and Baltic Countries: *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden*

Iberia: *Portugal, Spain*

Mediterranean, Italian and Balkan Peninsula: *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Serbia, Slovenia, Macedonia, Montenegro, Turkey*

Eastern Europe: *Belarus, European Russia, Moldova, Romania, Ukraine*

Middle East: *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, western Kazakhstan*

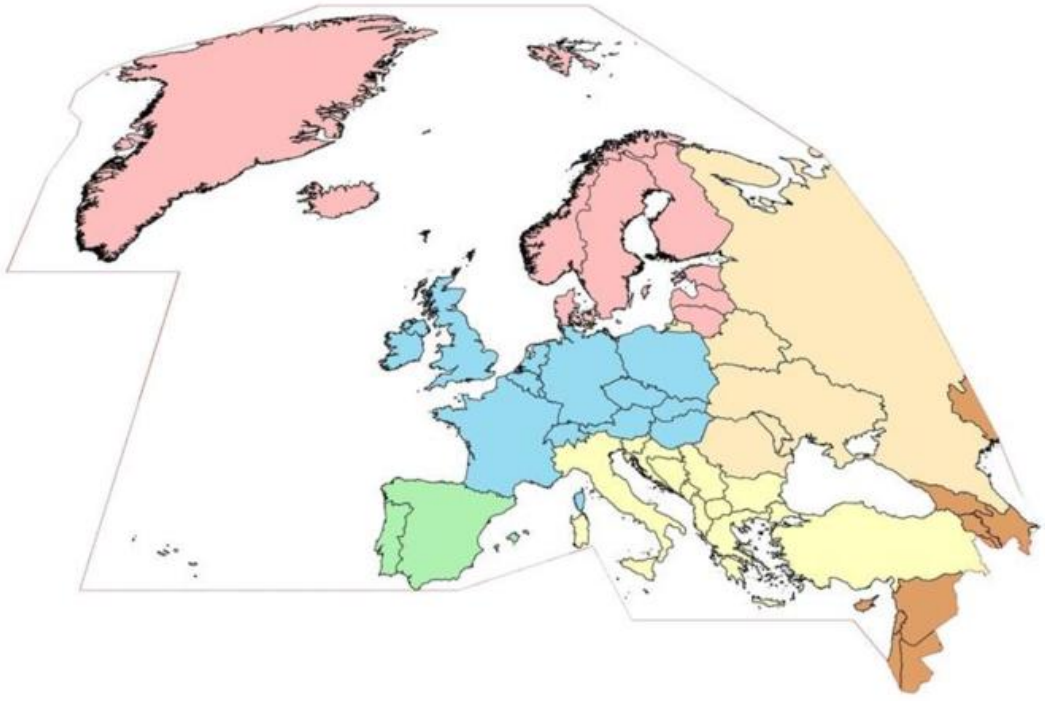

Figure 1.1: Definition of the 6 subregions used in this bulletin.

Box 1

Notable anomalies and events 2013

Anomalies

Temperature

- A record breaking warm March (since 1948) at Pituffik/Thule AFB on Greenland.
- Winter comeback in March in Central and North Europe,
- New station record temperature record for Greenland with a peak value of 25.9°C in July at Manitsoq, West Greenland coast.

Precipitation

- Catastrophic flooding in Central Europe in May-June 2013 followed by an
- Extreme drought for nearly the same region
- The driest July since 1853 in Austria

Sunshine Duration

- Highest sunshine duration in July since 1884 in Austria.
- Record lack of sunshine winter 2012/2013 since 1951 in Germany.
- Record lack of sunshine January-May since 1864 in Switzerland at station Zurich.

Other Anomalies

- Strong negative phase of North Atlantic Oscillation (NAO) in March,
- Highest monthly mean sea level pressure for March since 1962 over Iceland.
- A record-breaking period with 594 days without storm winds (>= 25 m/s) in Sweden ended on 28 October when Hallands Väderö recorded a mean wind speed of 31 m/s.

Events:

- Hail storm on 28 August in Germany near Reutlingen with hail stones of 14 cm diameter and a weight of 360 g.
- Catastrophic flooding in Romania and Ukraine in September 2013
- Severe autumn storm cyclone CHRISTIAN in the North Sea on 28 October 2013
- Depression CLEOPATRA in the western Mediterranean Sea with extreme flooding on Sardinia in November 2013 caused 18 fatalities.
- 3 Severe winter storm depressions (XAVER, DIRK, ERICH) in December 2013

2 Annual survey

The climate of 2013 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2.5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2013 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea surface pressure, surface temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for each participant countries. More detailed insight to the long-term variability of the mentioned parameter from the individual participant countries offers sub-section 2.2. Trends in temperature and precipitation indices are given in sub-section 2.2.4.

2.1 Annual averages and anomalies of selected essential climate variables

2.1.1 Sea level pressure

Generally, long-term mean annual sea level pressure distribution over the Region VI is dominated by a low pressure trough in the polar area (with exception Greenland) with the Icelandic low centred near Iceland and by the subtropical high pressure belt extended from the centre over Azores (Azores high) across southern, western and central Europe to European Russia.

2013 the mean sea surface pressure differs in some extend from the long-term mean with a reduced pressure especially within the subtropical high pressure belt and higher values over northern Europe. This is visible in the anomaly field for 2013 in respect to the normal period 1961-1990 (Figure 2.1 right). The anomaly configuration resemble especially the unusually pressure distribution in later winter and early spring (for more details cf. section 3.1.1 and 4.1).

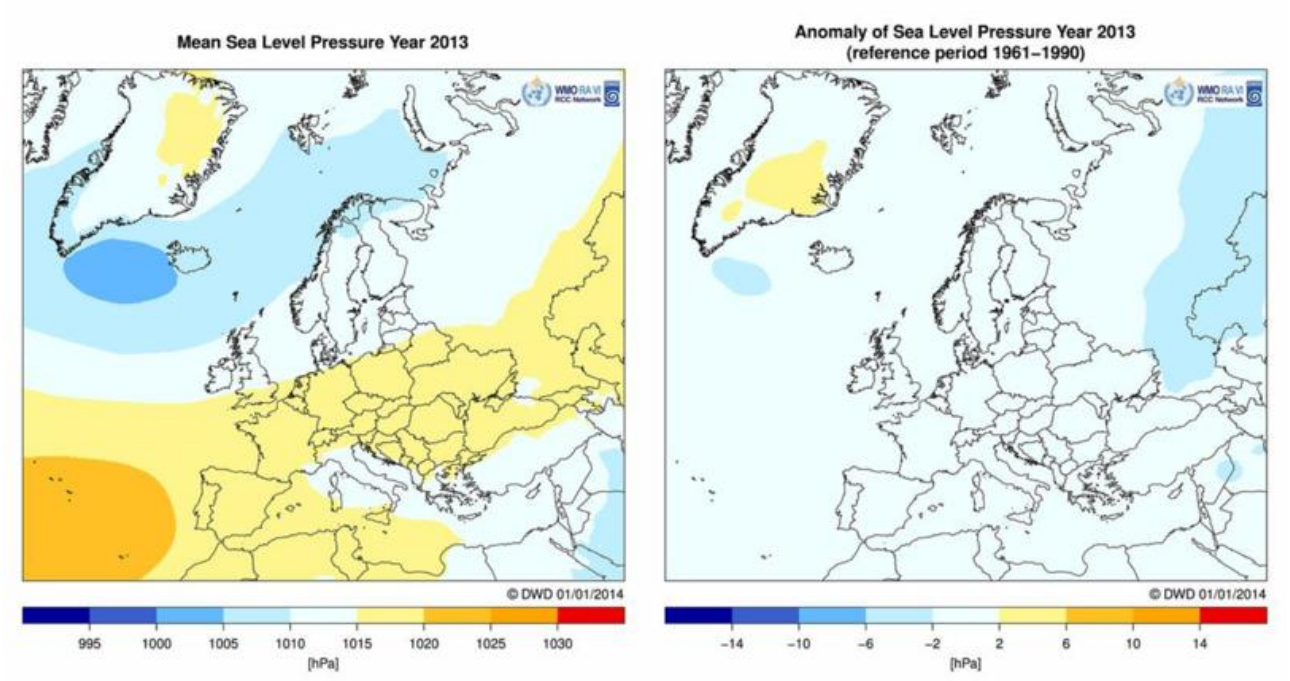

Figure 2.1: Annual mean of sea level pressure (left) and anomalies (right) for the year 2013 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.2 Temperature

Generally, the year 2013 was overall warmer than normal. It ranked on place 6 in the time series of E-OBS for the land area between 35°N and 75°N and 25°W and 45°E and the period 1950-2013 (van der Schrier et al., 2013). The mean temperature was calculated to 10.8°C. This value was very close to that of the year 2009 on rank 7. Warmer than 2013 were the years 2007, 2008, 2000, 1989 and 2011. The result for 2013 was mainly influenced by the warm summer and autumn 2013 (cf. section 3.1.2).

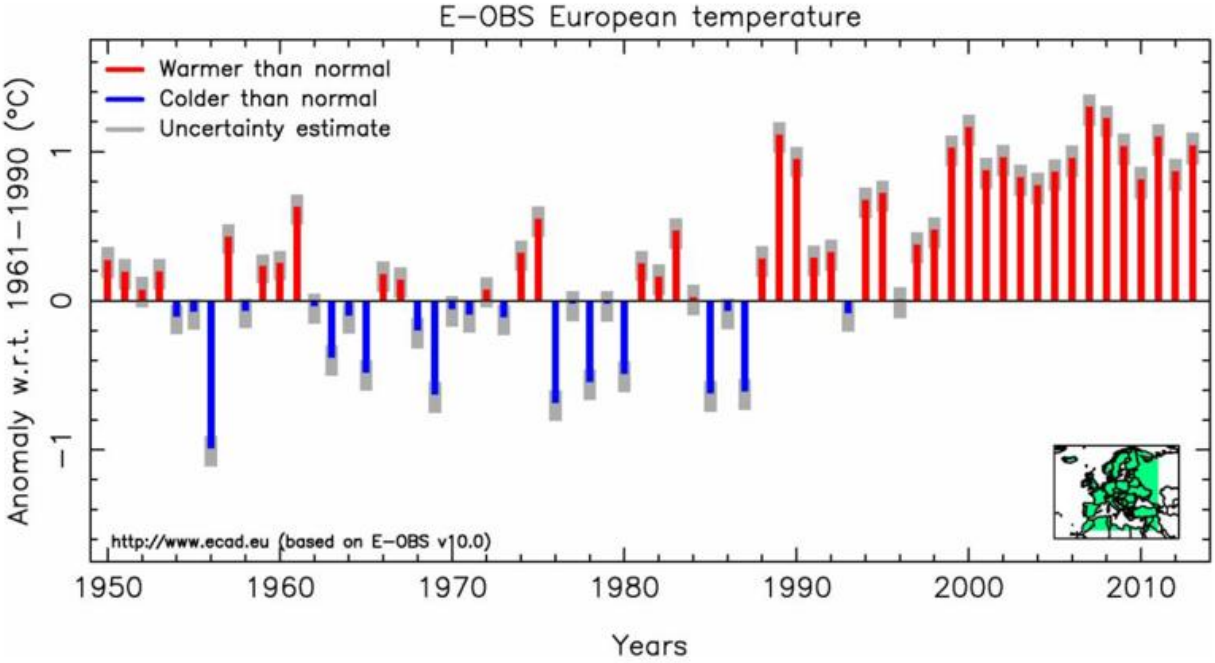

Figure 2.2: Mean annual temperature anomalies 1951-2013 for Europe (land area; 35°N - 75°N and 25°W - 45°E, source: **www.ecad.eu**, van der Schrier et al. 2013)

The mean annual temperature distribution is generally characterised by South-North temperature gradient. The spatial pattern of the annual temperature anomalies in 2013 related to the normal period 1961-1990 was dominated by negative or normal values in central and western Europe as well as positive values in northern and eastern Europe (cf. **Table 4.2**).

In many countries 2013 ranked within the top ten warmest years since the beginning of observations e.g.:

- In Bulgaria the 2nd warmest year since 1901.
- In Armenia the 2nd warmest year since 1935.
- In Finland the 5th warmest year with anomalies of 1°C - 2°C related to the period 1981-2010.
- In Serbia the 7th warmest year since 1951.
- In Austria the 9th warmest year since the start of record in 1767.
- In Hungary the 9th warmest year since 1901.

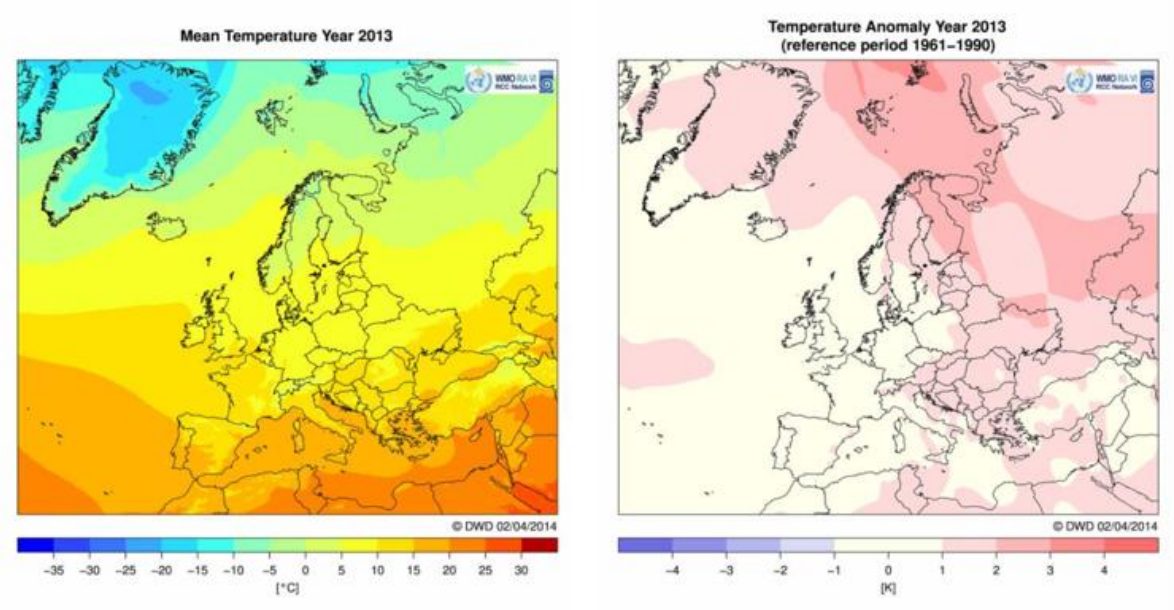

Figure 2.3: Mean annual temperature in °C (left) and anomalies (right) for 2013 (reference period 1961-1990). (Source: http://www.dwd.de/rcc-cm)

2.1.3 Precipitation

The annual precipitation totals of 2013 were overall close to normal like in the year 2012. The existing anomalies ranged between -30 and 30 mm. Only south-eastern Europe was drier than normal. This pattern (Figure 2.4) understated the situation in south-eastern Central Europe where in May and June, after heavy precipitation and floods a dry period in June and July occurred.

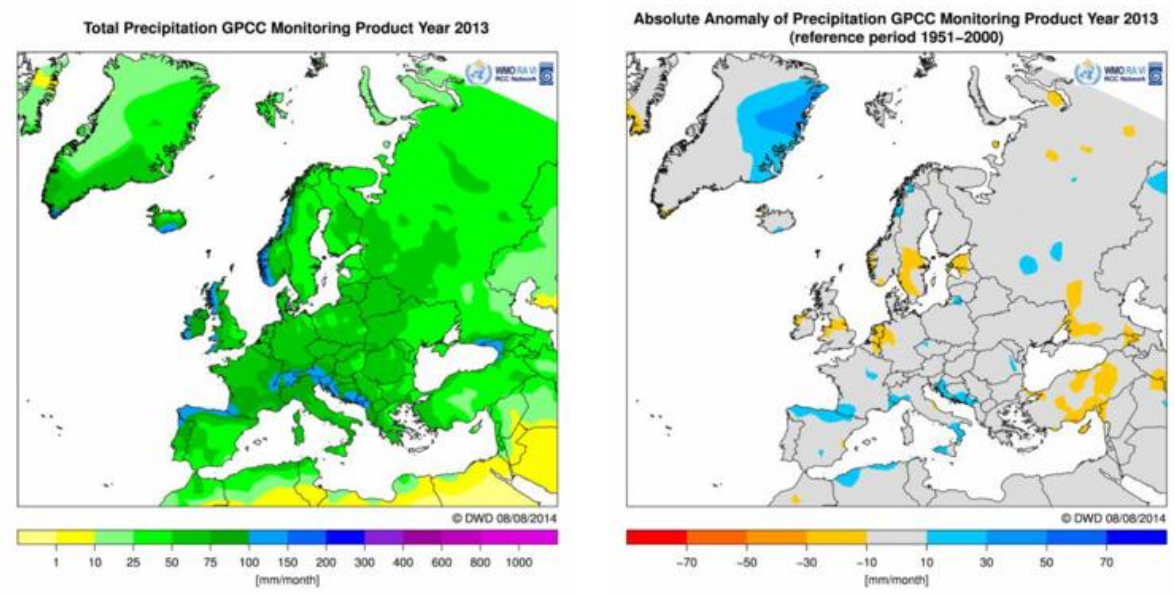

Figure 2.4: Total precipitation (left) and absolute anomalies (right) for 2013 in mm/month (reference period 1951-2000). (Source: http://www.dwd.de/rcc-cm)

- In Germany 2013 was the 65th wettest or the 69th driest year since 1881.
- Turkey mean total precipitation in 2013 was 564 mm and this amount is 13% below normal (646 mm for 1971-2000).

- The average precipitation for the year 2013 (Jan-Dec) in Cyprus is 291 mm which is the fourth highest yearly average precipitation ever recorded since 1902.

2.1.4 Annual extreme values of temperature and precipitation

Absolute annual extreme values for 2013 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5-day precipitation for each country are given in Figure 2.5.

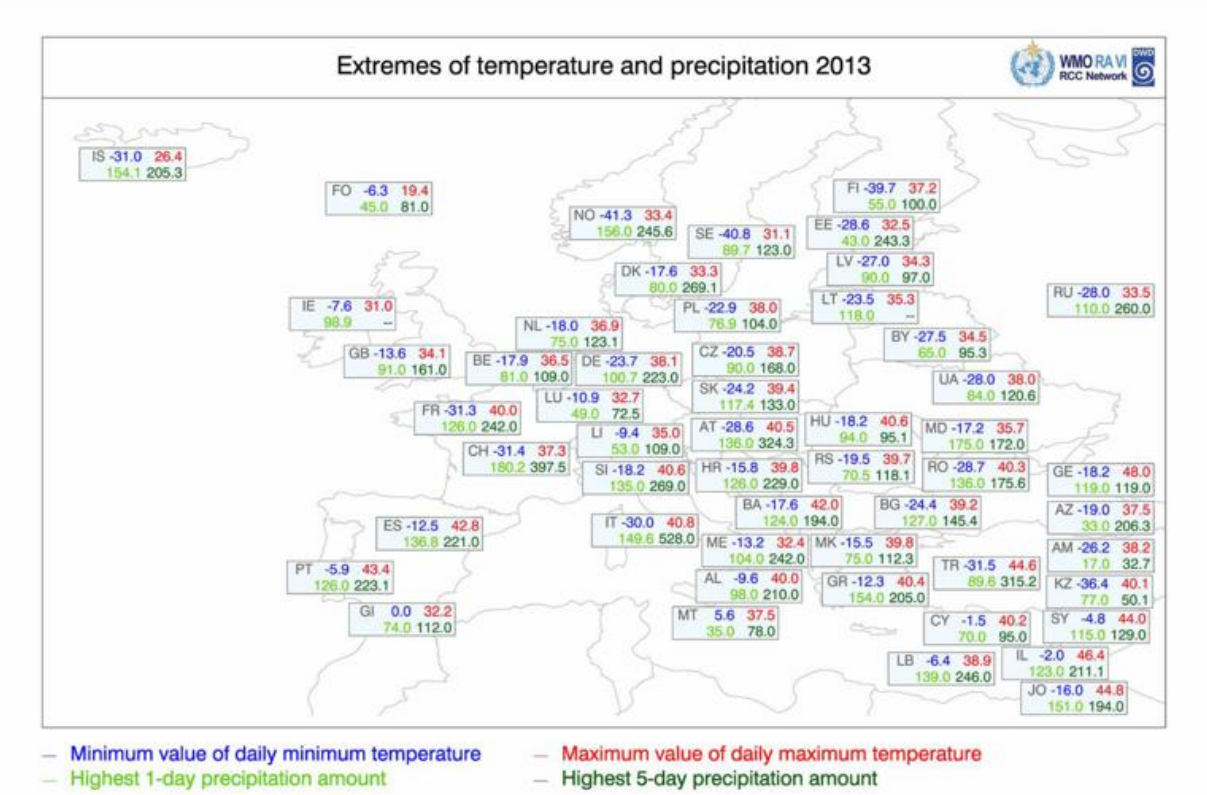

Figure 2.5: Annual extreme values for each country: highest daily precipitation (mm), highest 5-daily precipitation totals (mm), highest daily maximum temperature (°C) and lowest daily minimum temperature (°C) in 2013.
Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their Internet country codes. (Source: http://www.dwd.de/rcc-cm)

2.1.5 Sunshine duration

As expected, the annual sum of sunshine duration 2013 showed from the South to the North generally gradual decreasing values. More than normal sunshine hours have been primarily noted in northern eastern and southern Europe.

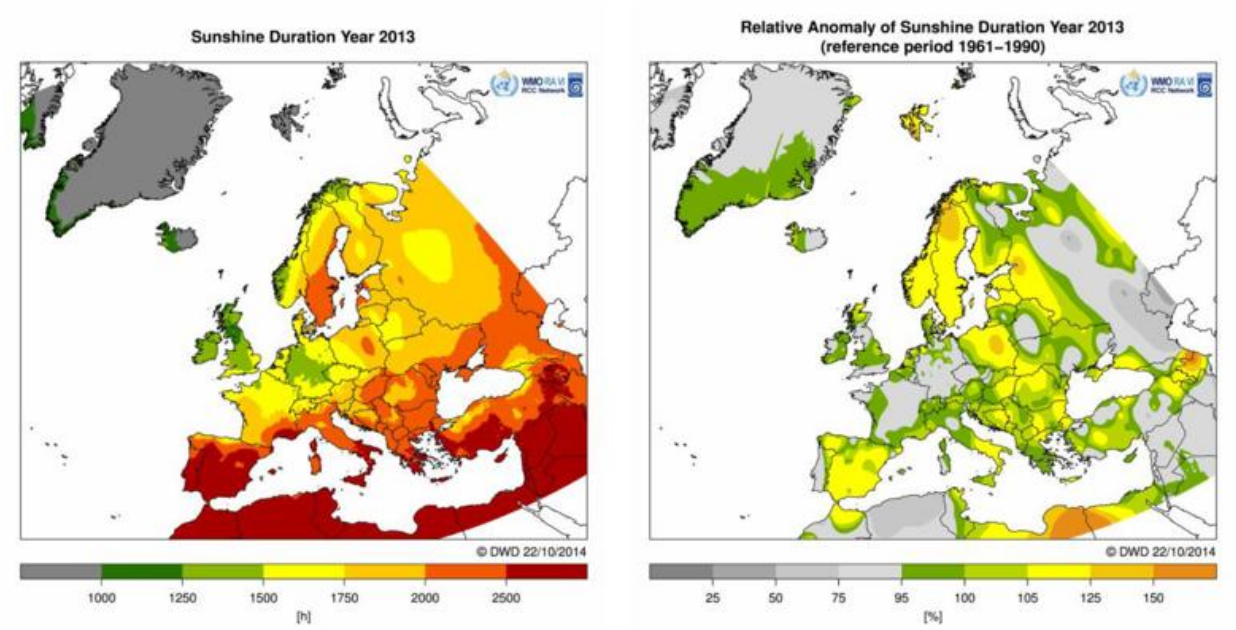

Figure 2.6: Annual sum of sunshine duration (left) and relative anomalies (right) for the year 2013 in hours with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

- The annual sum of sunshine duration in 2013 in Poland was in some areas more than 200% above the normal for the period 1971-2000.
- In Sweden 2013 was the sunniest year on record at several stations for example Karlstad and Uppsala.
- 2013 has been the 15th poorest year in sunshine since 1951 in Germany and therefore falls into the lower third of the distribution for this parameter.

2.1.6 Drought situation

The year 2013 as a whole showed no significant droughts. Longer drier periods occurred in July 2013 in southern Scandinavia and eastern Central Europe. The drought in eastern Central Europe affected several countries: Austria, Germany, Hungary, Poland, Rumania, Slovakia and Slovenia. There was also a drought in Portugal in November.

For details see section 3.1.5.

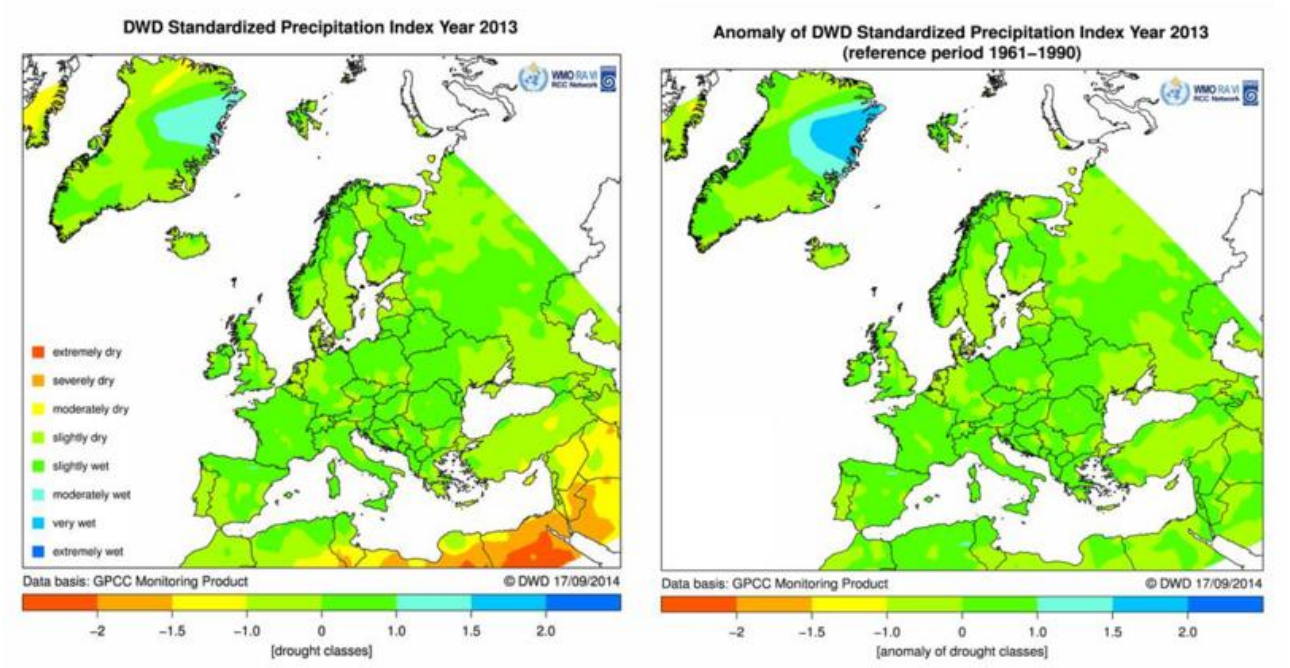

Figure 2.7: Annual modified Standardized Precipitation Index (DWD-SPI) for the year 2013 (left) and its anomalies (right) with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.7 Snow cover

For an assessment of the snow cover occurrence and duration, the time span from 1st September 2012 to 31st August 2013 is used. Apart from the mountains regions, the first snow in October was recorded from the south part of Germany across Austria and Poland to the central and northern Russia. In this area the snow cover lasted 5-6 months.

Annual snow cover extent (SCE) over Eurasia lands averaged 14.6 million km^2 in 2013 (from 31.2 in January (rank 6) to 0.2 million km^2 in August (rank 38), Rutgers Laboratory, 2013).

Between February 5th and 11th there was persistent snowfall, especially in the south and in the west of Austria. Station Bregenz (Vorarlberg) recorded 52 cm fresh snow within 24 hours (maximum value within 48 years).

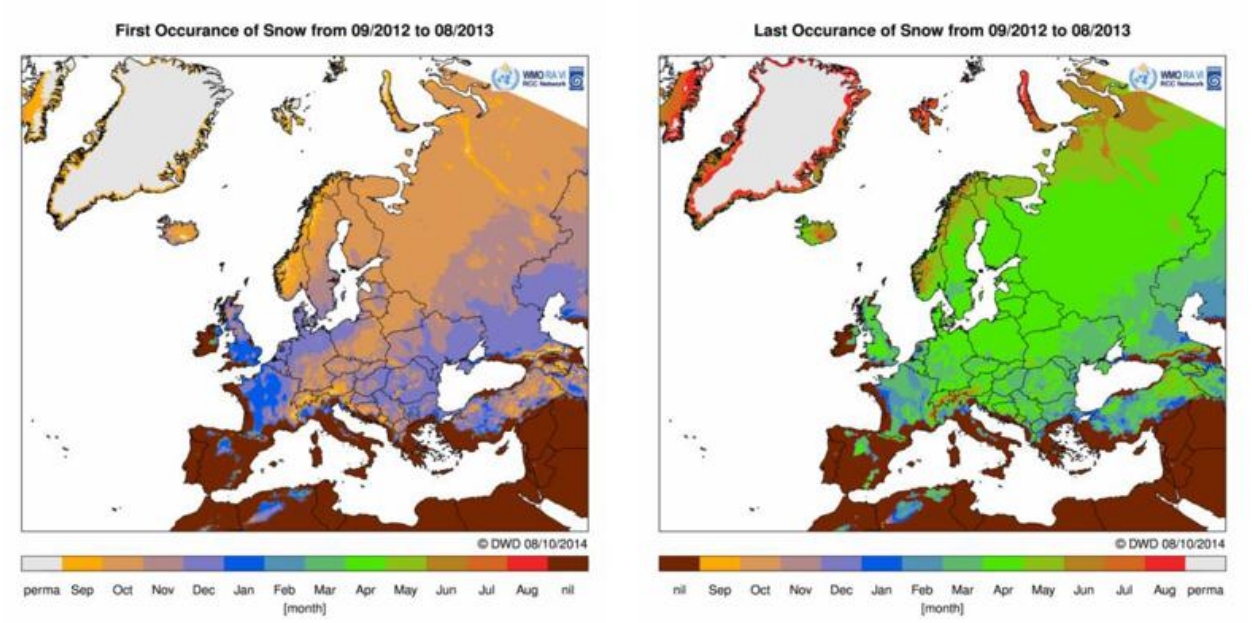

Figure 2.8: First occurrence of snow (left) and last occurrence of snow (right) during the snow-season 2012/2013. (Source: http://www.dwd.de/rcc-cm)

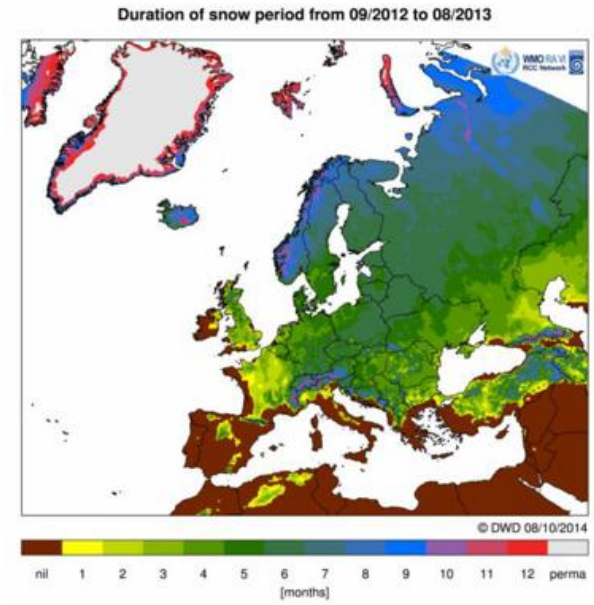

Figure 2.9: Duration of snow cover in the snow-season 2012/2013. (Source: http://www.dwd.de/rcc-cm)

2.2 Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the national meteorological services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 subregions defined above (Figure 1.1). The table below informs about the lengths of the time series shown as well as whether they refer to spatial means of the country or single stations. Most are temperature time series. Each subregion is at least represented by one country. Time series of precipitation totals are fewer but including a time series of the maximum daily precipitation total for the Upper Galilee in Israel there is as well each subregion represented with at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries and they belong to different subregions. Some countries contributed time series which were not available in 2012. Other time series that were available in 2012 are not available in 2013 on the other hand.

Following this section, trend maps representative for the elements temperature and precipitation are shown. As reference period for these trend maps 1951-2013 was chosen. After this, we present examples of the temporal development of other temperature related phenomena, such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Wladyslawowo.

Table 2.1: Availability of the long-term records of temperature, precipitation and sunshine duration from some participant countries.

		Temperature		Precipitation		Sunshine Duration	
Subregion	**Country**	**Spatial Mean1**	**Single Station**	**Spatial Mean**	**Single Station**	**Spatial Mean**	**Single Station**
Central and Western Europe	Belgium		1833				
	France	1900					
	Germany	1900		1900		1951	
	Luxembourg	1947					
	Poland	1951					
	Switzerland	1864		1869		1959	
Nordic and Baltic Countries	Denmark	1873		1873		1920	
	Finland	1900					
	Greenland		1873				
	Latvia	1924		1924			
	Lithuania	1961

Middle East - precipitation anomalies

Georgia

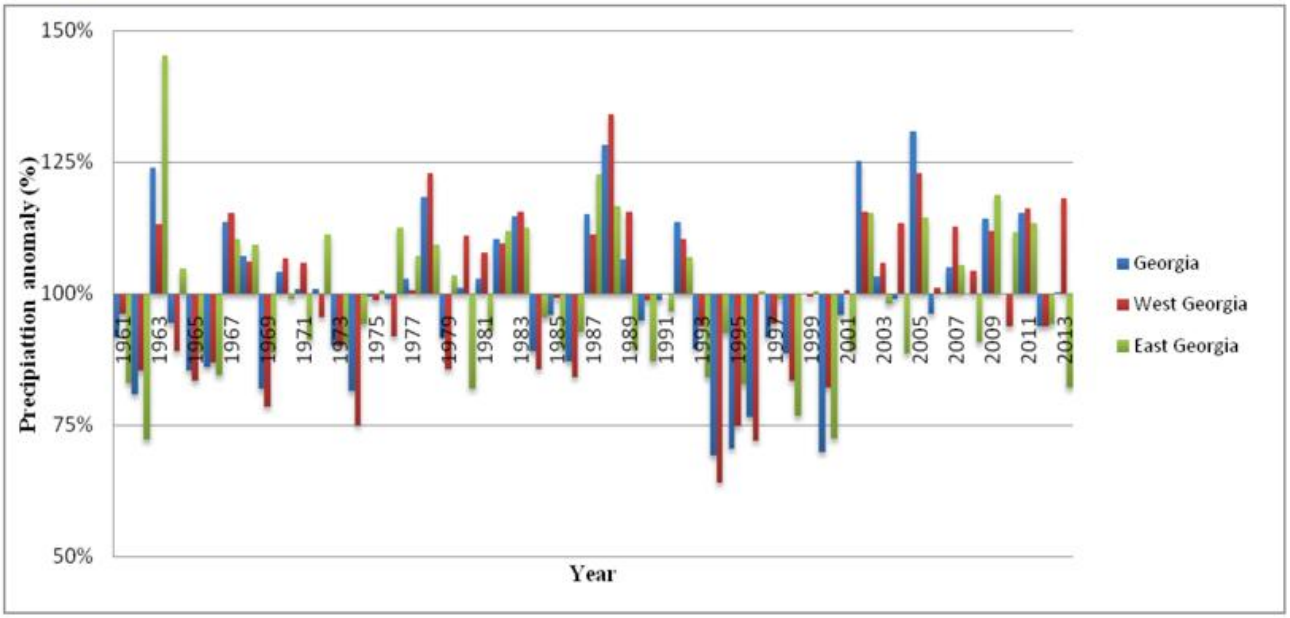

Figure 2.46: Time series of relative annual precipitation anomalies for Georgia (reference period 1971-2000; diagram as provided by the NHMS)

2.2.3 Sunshine duration

Central and Western Europe - sunshine duration anomalies

Germany, Switzerland

Germany

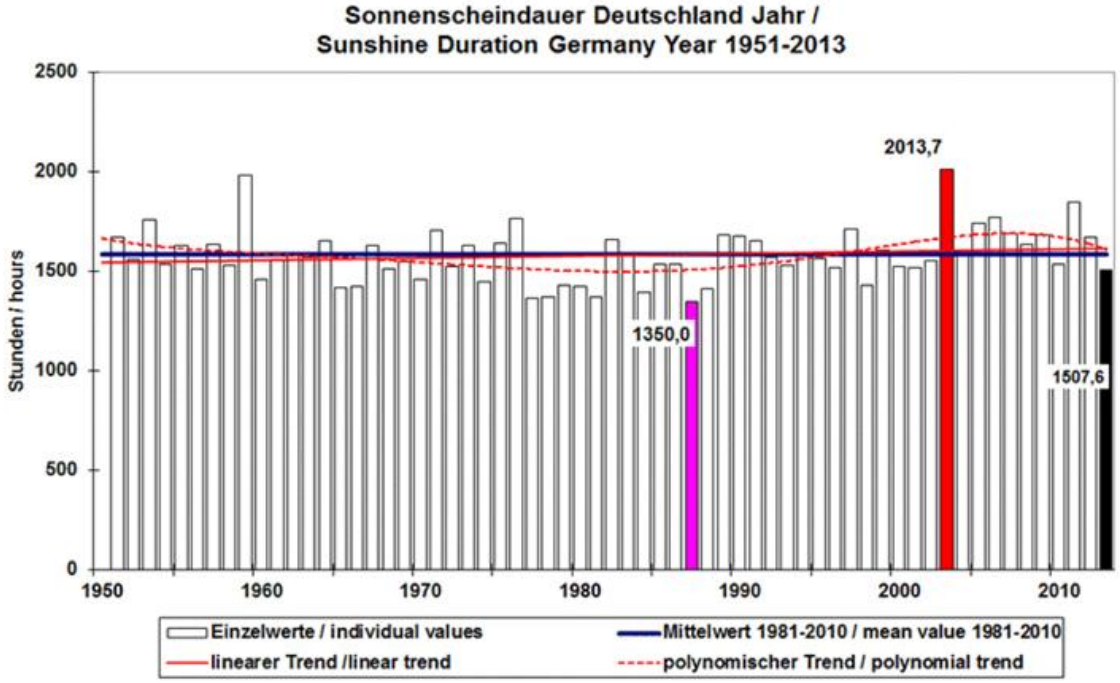

Figure 2.47: Time series of annual sum of the sunshine duration in hours for Germany (Diagram as provided by the NHMS)

Northern and Southern Switzerland

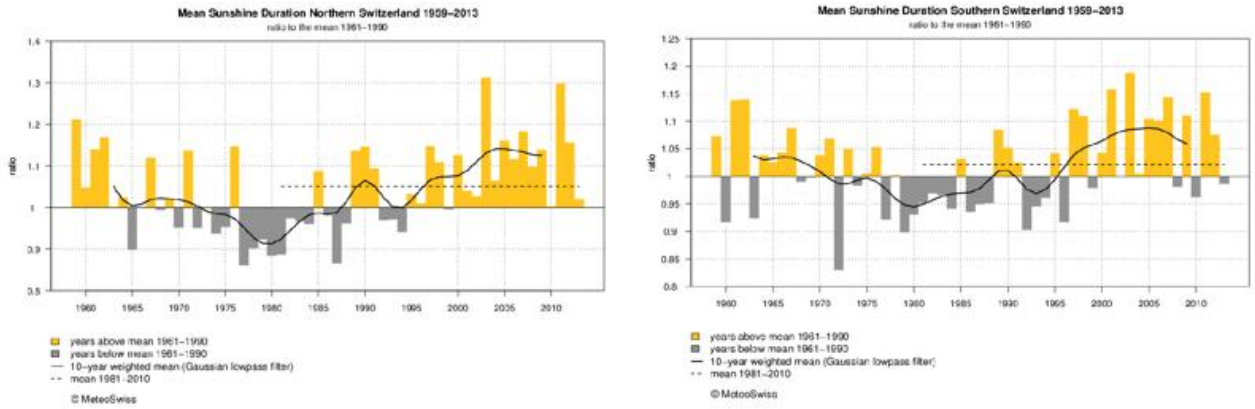

Figure 2.48: Time series of annual sunshine duration anomalies as ratio of the mean 1961-1990 for Northern (left) and Southern (right) Switzerland (reference period: 1961-1990; diagram as provided by the NHMS)

Nordic and Baltic Countries - sunshine duration

Denmark

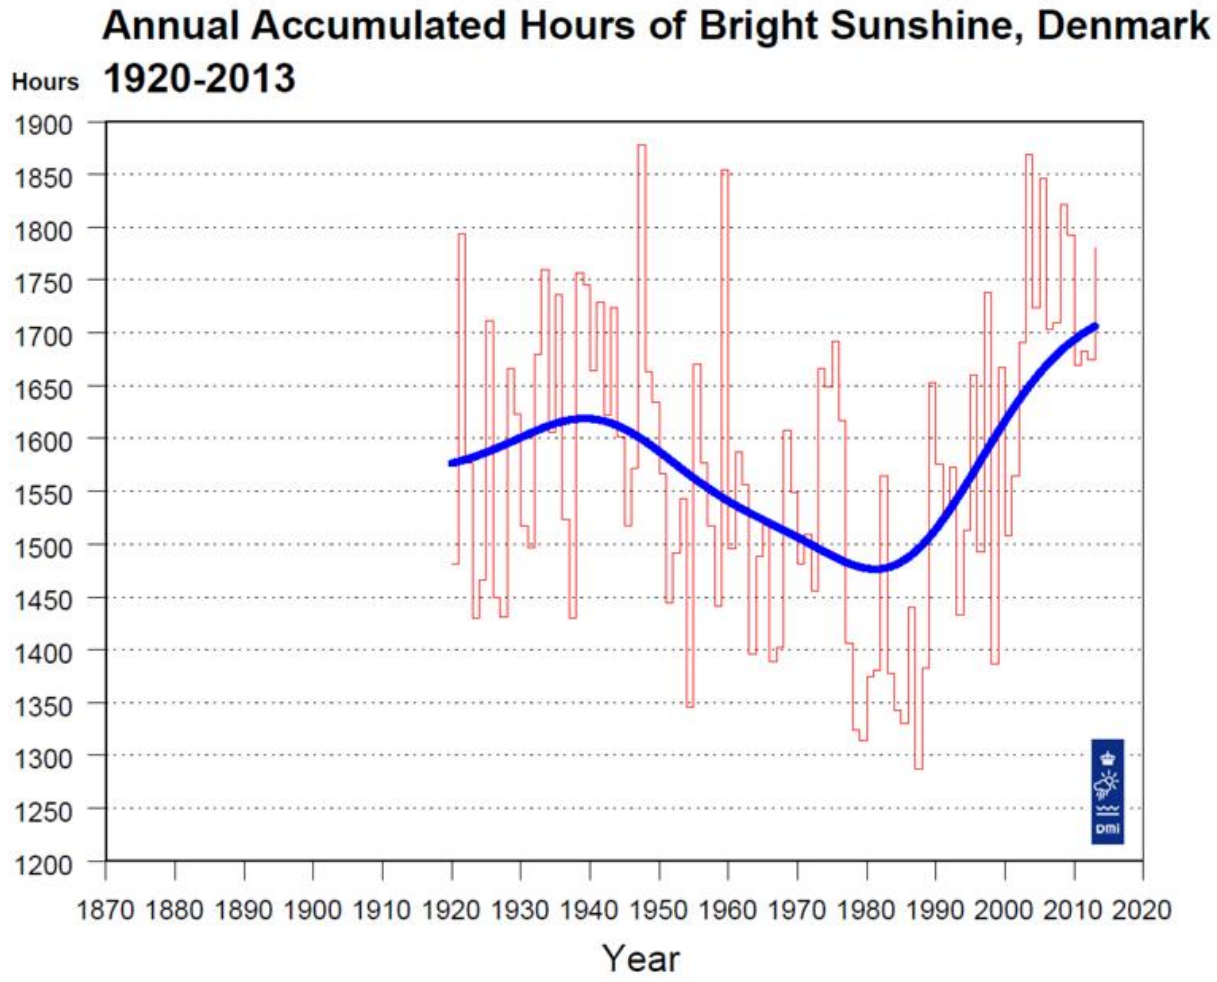

Figure 2.49: Time series of annual sunshine duration in hours for Denmark (Diagram as provided by the NHMS)

Note: DMI observed since 2002 the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. It should also be noted that all values before 2002 are adjusted in the best way possible ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990. http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf

2.2.4 Trends of temperature and precipitation indices 1951-2013

2.3 Socio-economic impacts of extreme climate or weather events

Several countries reported socioeconomic impacts of climate extremes or weather events. This was done partly given in a standardized structure (WMO guiding table for country submission of information on extreme climate events) or the information was part of the regular monthly reports on the internet or it was separately submitted. However, this information is heterogeneous and does by far not give a complete overview. Not only do the administrative structures differ so that the information cannot easily be gathered but also many kinds of impact are difficult to estimate. In the following only a short extract will be given.

Figure 2.55 shows the number of observed extreme weather or climate event as reported by the NMHSs in 2013 that can be presented in form of a diagram. Conclusions should be drawn only with caution because some of the events were reported by several countries. The total number of cases for this figure was 196. No diagrams were shown for the injured persons and fatalities as well as the economic losses because the number of reports were too few (about 3, 9 resp. 5). In some cases the reported numbers were not fix but like 'hundreds' or 'few'. The economic damage was estimated as well by some countries but the information is not sufficient to be presented with any reliability of representativeness. The reported of economic damages will be summarized individually below.

The most frequent events in 2013 were according to Figure 2.55 'Heat Waves' with 26% that occurred in most of the countries, Serbia reported 6 and Israel 7 heat waves. The second one with 20% is 'Extreme Precipitation' that also happened in most of the countries. The third often event were 'Wind Storms' that mainly occurred in the Nordic countries together with extreme precipitation. About 8 % of the extreme events were 'Floods' and 'Droughts'. One major flood event from the end of May until beginning of June 2013 occurred in eastern Central Europe and affected 6 countries. Afterwards most of these countries reported a drought with less agricultural production.

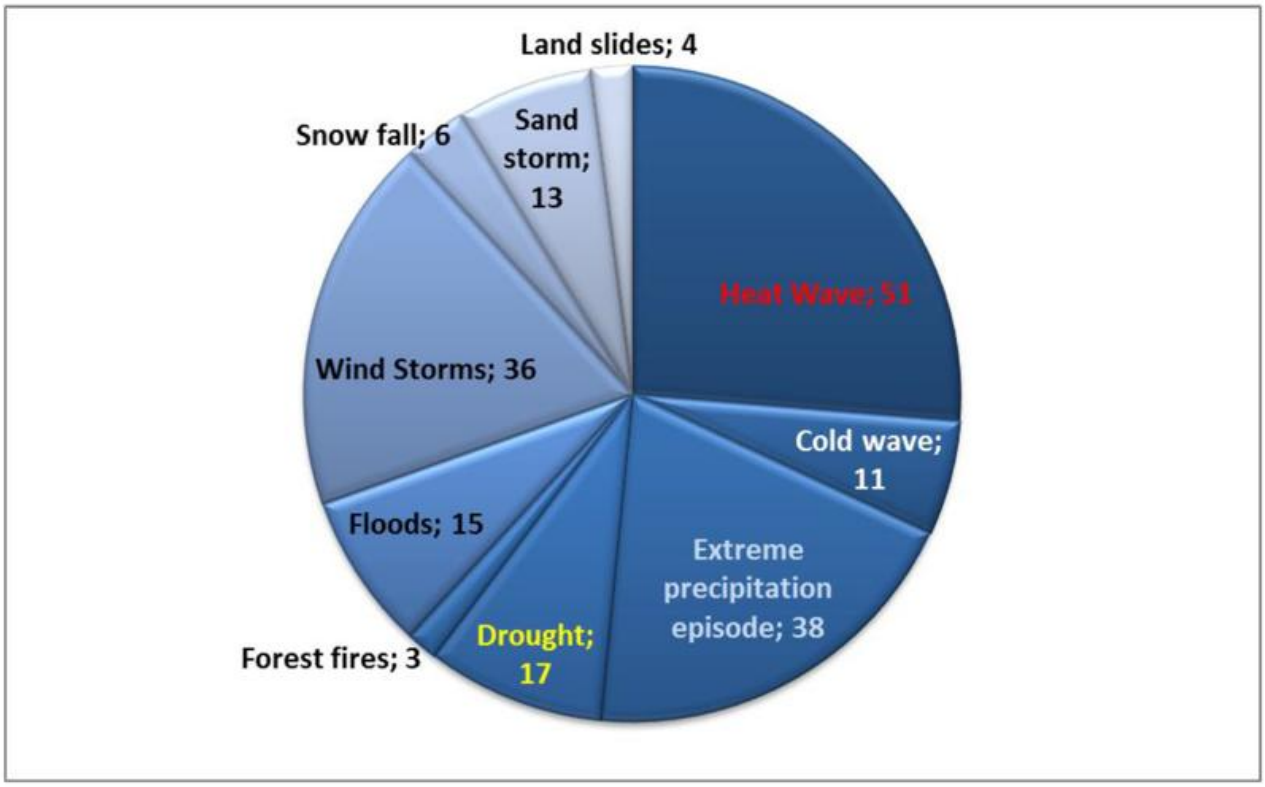

Figure 2.55: Relation of observed extreme weather or climate events in 2013 based on 36 reports from NMHSs (total events reported for 2013: 196)

Much economic damage is usually connected with floods, storm, cold spells (all kinds of frost, snow or ice), hail, drought or extreme heat. There are some figures which are summarized in the following but much of this kind of damage cannot be estimated (by meteorologists).

- The snowfall in **Austria** during the Easter holidays esp. on 30th and 31st March caused many trees to break due to wet snow. The falling trees cut power lines too. Because of the unusual long-lasting wintry weather conditions, the fully saturated meadows and fields could not be cultivated.
- The flood in **Latvia** was due to temperature rising in the second 10-days of **April**, thick snow melted very quickly – in 6-9 days. The heat was rapidly breaking up ice and forming ice jams in rivers as well. These effects together resulted in a significant increase in water level and intense and extensive flooding. The highest water level rise was observed in the Ogre River near the town of Ogre. Estimates suggest that the maximum water level (24.5 m, which is 4 meters above the long-term average) had a probability of 0.5%, i.e. once every 200 years. Economic losses due to floods in Latvia were estimated of 5.2 million €.
- On **22 May**, the Tula Region, **Russia**, was attacked by windspout that wrecked significant destruction: roofs torn down, trees toppled and power transmission lines broken. Twenty two people, including five children, were injured. The damage was estimated to be 150 million rubles (~2 million €).
- The rainfall of the last few days in **May** and beginning of June 2013 led to one of the worst floods and flood disasters in recent years in east **Central Europe** with 6 countries involved. In Lower Austria, the Danube reached north of Vienna a water level of 11 meters. On 4th June 2013 the flooded regions along the rivers Inn and the Danube reached its greatest extent and the flood-bearing rivers, the highest water levels. The river Inn reached in Upper Austria a water level of 10.7 meters (in 2002 there was the value 8.7 meters - the standard level of the Inn is there 4 meters). Communities were flooded up to four meters high. On 6th June along the rivers Danube and Morava a water level of 7.44 meters was recorded (in comparison in the year 2002 there was a water level of 7.28 meters). The total flood damages were estimated by 100 million € in the Danube Valley of Lower Austria, alone (Trachte et al. 2014). On the fields around Vienna there was a crop failure by 30 percent.
- **July** 2013 was marked by very dry and warm weather conditions in **Austria**. During the third decade of July, the prevailing drought caused huge agricultural losses. One third of the fields in the states of Salzburg, Styria and Carinthia had drought damage. The pastures were suffering from the drought. On the fields around Vienna there was a crop failure by 30 percent. The other involved countries also reported less agricultural production after the flooding and the drought period in August.

Turkey is the only country that gives graphs of percentages of the occurrence of types of extreme climate or weather events in 2013 (Figure 2.56) as well as a time series of the development of weather related damages starting in 1941 (Figure 2.57). 'Weather related damages' is here given in number of cases not in a monetary value.

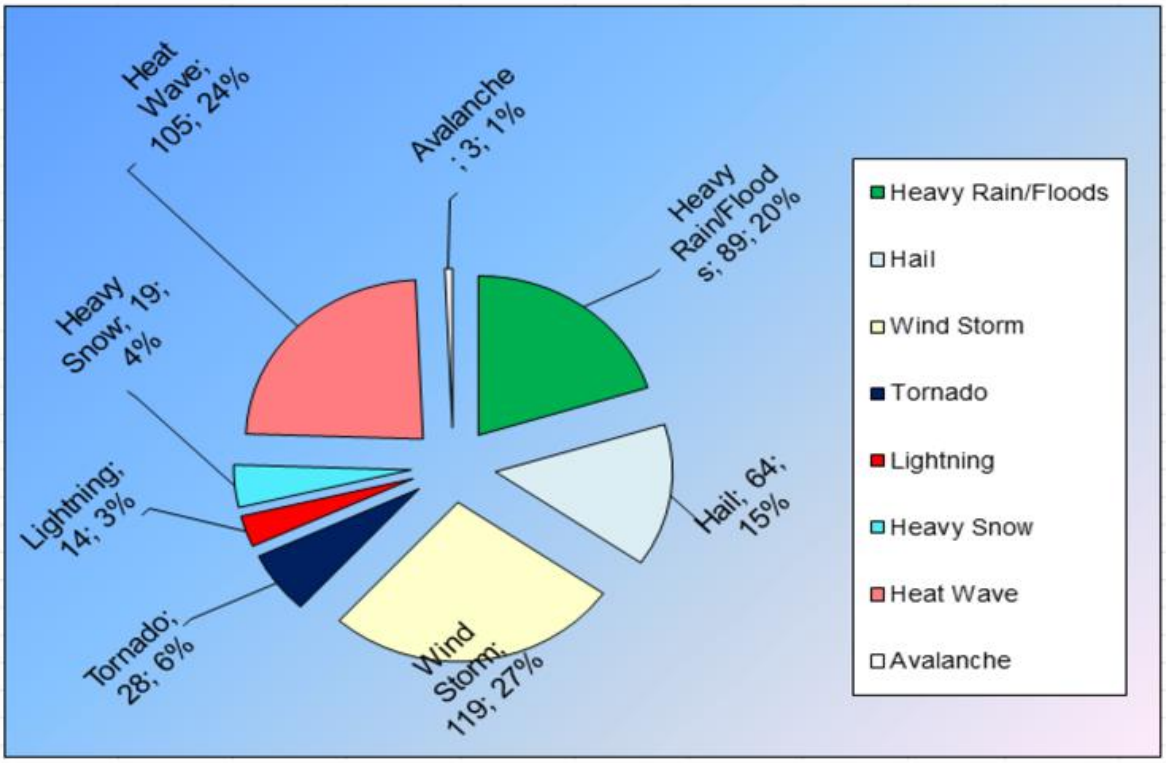

Figure 2.56: Percentages of the occurrence of extreme climate or weather events in the year 2013 in Turkey (Source: Turkish State Meteorological Service http://kardelen.mgm.gov.tr/BultenGenel/Klima/fevkGlnYeni.aspx)

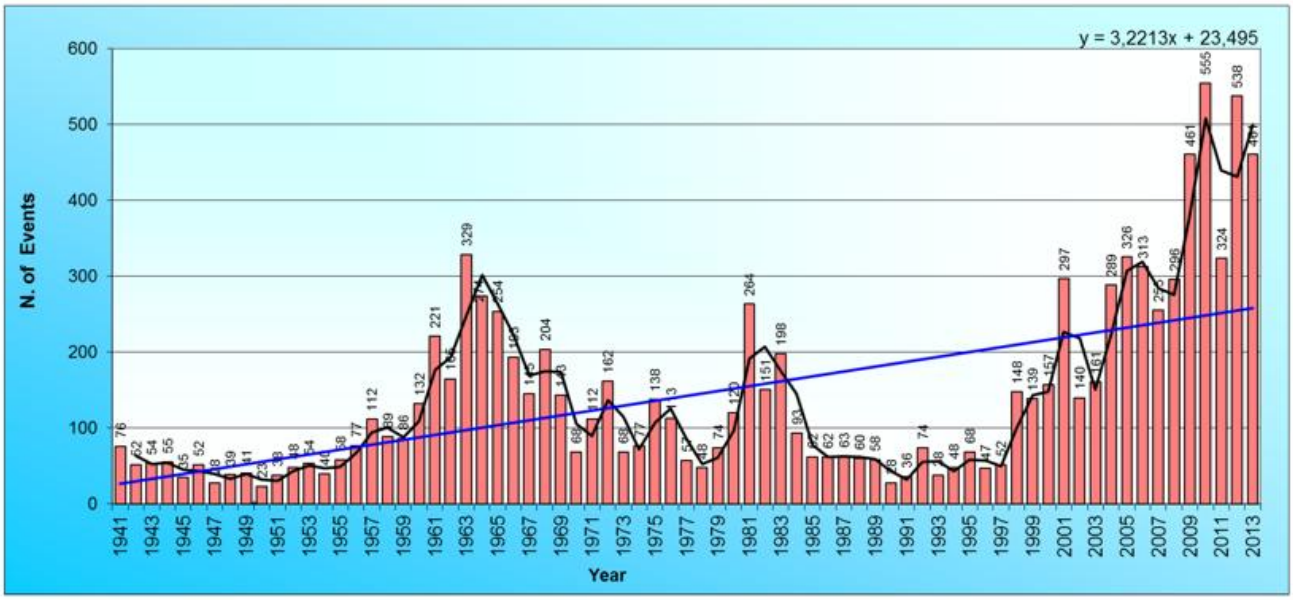

Figure 2.57: Temporal development of the occurrence of weather-related damages in Turkey for the period 1941-2013 (Source: Turkey http://kardelen.mgm.gov.tr/BultenGenel/Klima/fevkGlnYeni.aspx)

3 Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2013 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea surface pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1 Seasonal averages and anomalies of selected essential climate variables

3.1.1 Sea surface pressure and circulation indices

The seasonal sea surface pressure anomalies show in some extent unusually spatial patterns. **Winter** pattern was dominated by a stronger Azores high extended to western coast of Europe and a more intensive high pressure centre over Russia separated by a band of lower than normal pressure from Scandinavia across Central Europe to Italy and Balkan Peninsula.

Increased pressure in the polar low depression and a broad, diagonal from western Europe to southern Russia oriented, band of negative anomalies were the most prominent features of the **Spring** sea surface pressure anomalies pattern.

Summer was characterised by a north-south contrast of anomalies: more intensive as normal polar low depression and increased pressure in the belt from Central Europe including North Sea and Scandinavia across eastern Europe to Russia.

In **Autumn** dominated a west-east contrast in the pressure anomalies pattern: Positive anomalies over East Atlantic southwards of Iceland including western Europe and Iberian Peninsula, negative anomalies over East Europe and Russia. The polar low pressure trough was displeased more to the North. Remarkably was the anomalies pattern over South-East Europe: Positive anomalies over Turkey, negative anomalies over eastern Mediterranean and Balkan region.

In terms of the seasonal mean values of the circulation indices, the circulation over the Region VI was not very different from long-term mean (Tab. 2.1). However, the moderate, negative AO and negative NAO index in **winter** and **spring** indicated prevailed north-easterlies over Central and West Europe. The NAO and AO reached in March their strongest negative phase (cf. Tab. 4.1). The positive SCA phase reflected positive pressure anomalies especially in February over Scandinavia. The negative POL index in **spring** resulted from a weaker than average polar vortex. EA/EW negative phase in **summer** was associated with higher than normal pressure anomalies over Russia.

Table 3.1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2012/2013	-0.33	0.57	-0.57	1.03	-0.39	**-1.12**
Spring 2013	-0.30	0.40	-0.05	-0.40	**-1.17**	-0.79
Summer 2013	0.88	0.54	**-1.47**	-0.18	-0.11	0.23
Autumn 2013	0.10	0.30	-0.28	0.12	0.58	0.61

NAO = North Atlantic Oscillation, EA = East Atlantic Pattern, EA/WR = East Atlantic/West Russia Pattern, SCA = Scandinavia Pattern, POL = Polar/Eurasia Pattern, AO = Arctic Oscillation.
Note that all values are standardized with the reference 1981-2010; bold: index values > |±1| corresponds to moderate positive/negative phase of the leading NH circulation modes.
(Definition and sources: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

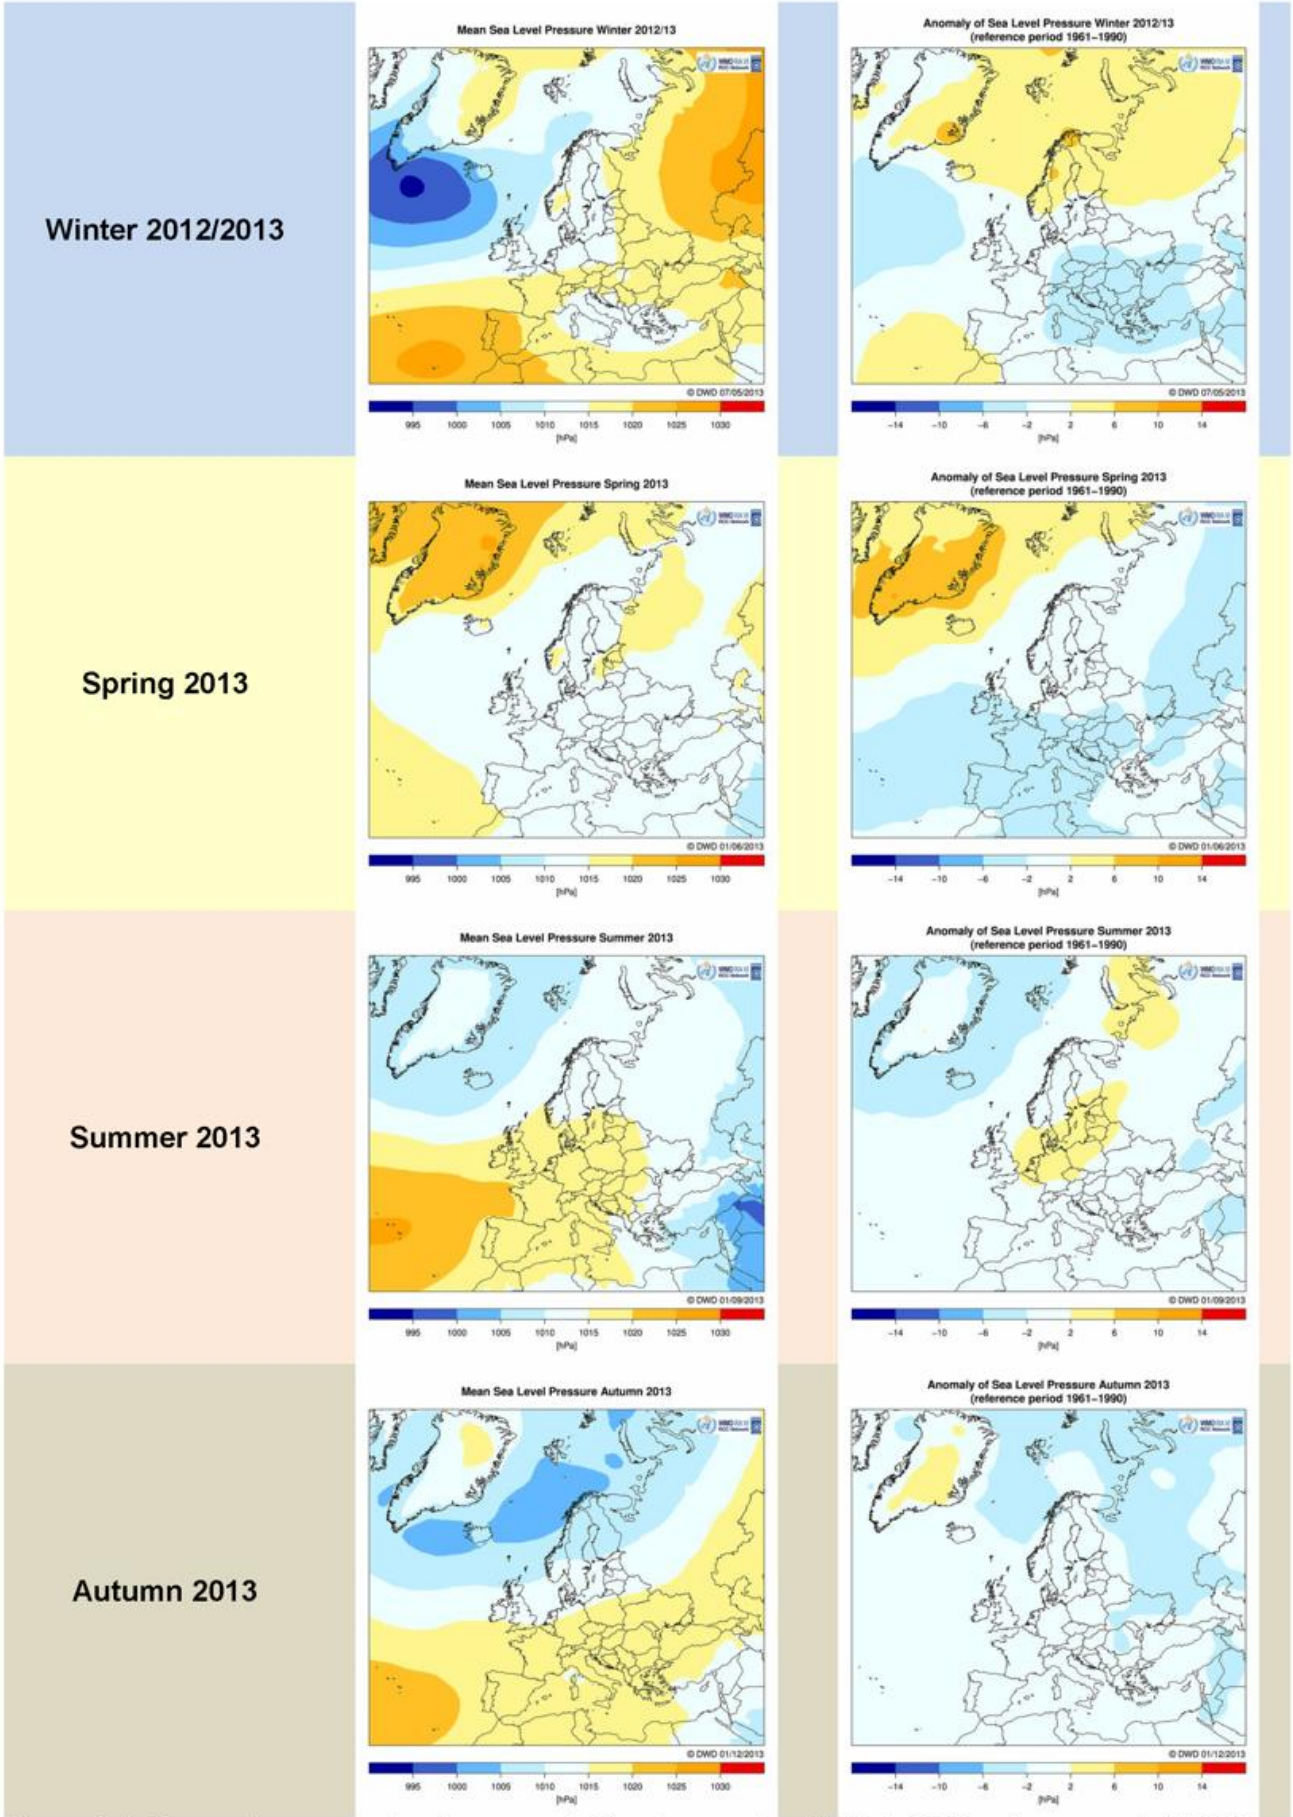

Figure 3.1: Seasonal mean sea level pressure (left) and anomalies (right) in 2013, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.2 Temperature

In average of the whole Region VI the winter 2012/2013 was warmer, the spring cooler, the summer and autumn warmer in respect to normal period 1961-1990. In regional view, however, some differences existed (Tab. 3.2).

Table 3.2: Seasonal and annual areal average of temperature anomalies in °C for each sub-region in the year 2013 (reference period: 1961-1990)

Region	Winter 2012/2013	Spring 2013	Summer 2013	Autumn 2013	Year 2013
Central and western Europe	0.08	-0.67	1.52	0.81	0.57
Nordic and Baltic countries	1.55	0.91	0.89	1.25	1.30
Iberia	0.40	-0.03	1.08	0.86	0.48
Mediterranean, Italian and Balkan Peninsula	0.71	1.40	1.78	1.33	1.40
Eastern Europe	1.47	0.55	2.06	1.64	1.89
Middle East	1.90	1.76	0.80	0.76	1.19

Data source: Gridded data (result of spatial analysis of CLIMAT and SHIP data; http://www.dwd.de/rcc-cm)

Winter 2012/2013 was colder than normal in central, northern, southern and partly western Europe while it was warmer than normal in the northwest, in the Arctic and in the east and southeast. The negative anomalies were largest (-1 to -2 K) in southern Norway and the positive anomalies were largest (more than +4 K) in the Arctic region. Remarkable were for instance the negative anomalies of frost days on Iceland and the Balkan Peninsula.

Spring 2013 was colder than normal on the northern North Atlantic, the British Isles, and the western and northern European continent including the south of Scandinavia. The strongest negative anomalies of -1 to -2 K occurred on the British Isles, northern France, Belgium, the Netherlands and northern Germany as well as parts of northern Russia. Mainly the month of March dominated the seasonal mean. Warmer than normal were the Arctic and Greenland as well as the eastern Mediterranean Sea, the Balkan Peninsula, Southern Russia and the Middle East.

Summer 2013 was warmer than normal over the continent and only on the North Atlantic partly slightly colder than normal. Warmest overall was the Northeast. Between 2 to 3 K warmer than normal were parts of the Alps, parts of the Balkan Peninsula and parts of eastern Europe. It was the 7th warmest summer since 1864 in Switzerland and the 3rd warmest summer since 1813 in south-eastern Austria. Also in Germany it was one of the 10 warmest summers since 1881. Especially in the Mediterranean and Black Sea region there were much more tropical nights than normal. The warm spell duration index was clearly higher than normal for northern Italy, the eastern Alps and the Balkan Peninsula.

Autumn 2013 was again warmer than normal nearly over the whole Region VI. Generally, the autumn temperatures varied considerably. Some countries in northern or central Europe registered even maximum temperatures of 30°C on single days which is unusual in autumn. For instance, in Austria on 6 September in Innsbruck 30.3°C were observed and also De Bilt (Netherlands) recorded on the same day 32.7°C. In Germany autumn 2013 was the 23th warmest since 1881. In Estonia it was the 5th warmest since 1961 with a seasonal mean of 8.2°C. On the other hand, it gave already frosty weather and first snowfall in the Alps for few days in September and October. The lowest temperature in autumn 2013 occurred in Austria on 27 November with -26.9°C at the station Brunnkogel (3438 m asl).

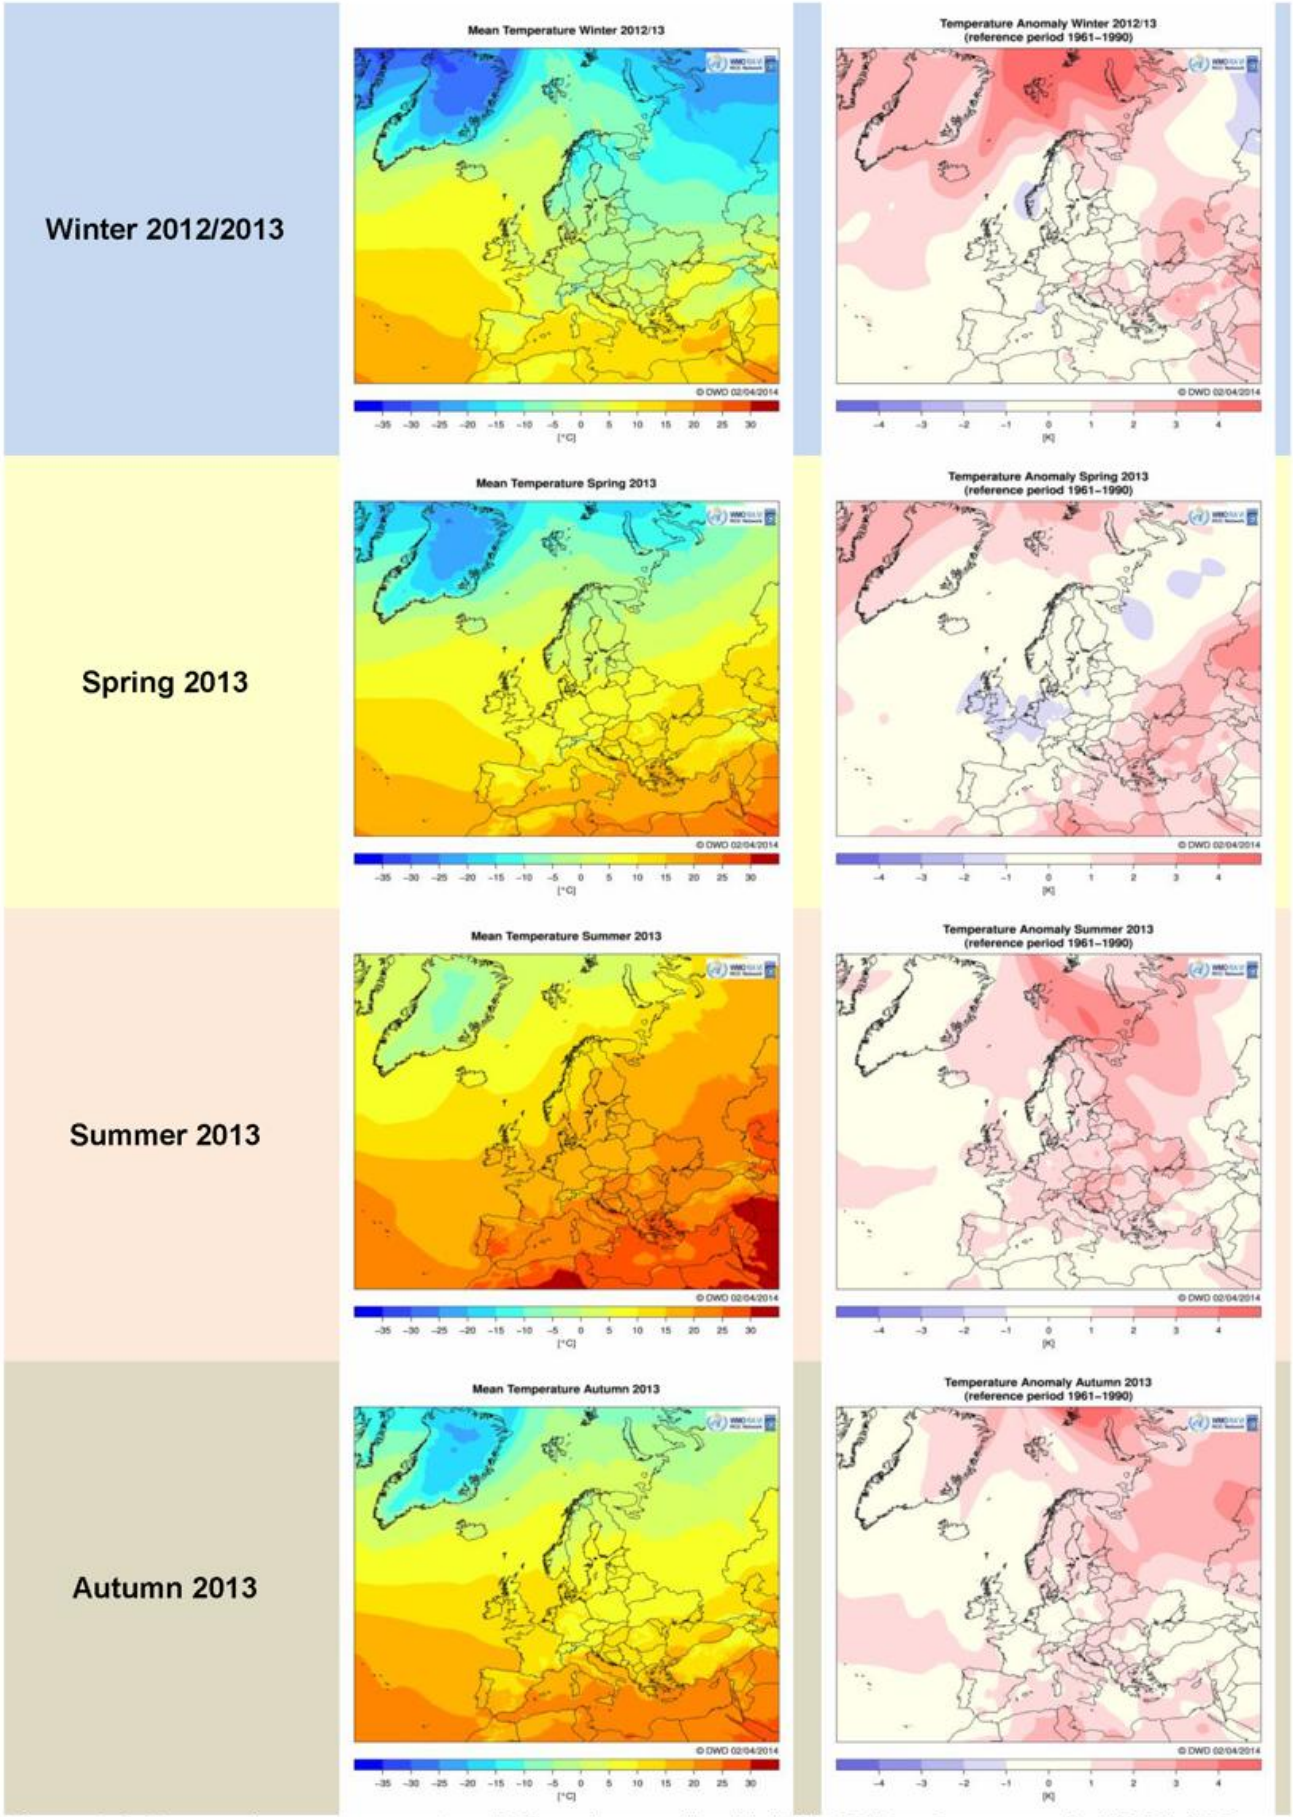

Figure 3.2: Seasonal mean temperature (left) and anomalies (right) in 2013, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.3 Precipitation

In winter, predominantly close to mean conditions with more than normal precipitation especially in eastern Mediterranean, northern Spain and western France were observed (Figure 3.3). Dominant for spring was a belt of higher than normal precipitation extended from Iberia to central-northern Russia, accompanied by bands of drier conditions northwards and southwards. In summer the basic pattern of precipitation anomalies opposite to spring spatial existed. Autumn was characterised by predominantly wetter or close to normal conditions.

In **winter** 2012/2013 especially the Balkan Peninsula and southern Europe as well as Middle East received more precipitation than normal. The Italian Peninsula had locally more very wet days than normal. Generally only Scandinavia, the western Mediterranean with the eastern Iberian Peninsula and southern France as well as the Caucasus area received less precipitation than normal. In combination with the low temperatures there was partly much snow (which is not well reflected in the anomaly maps due to the partly coarse station coverage).

In **spring** 2013 the Iberian Peninsula, southern France, the western Mediterranean, the Italian and Balkan Peninsula and Eastern Europe as well as locally Norway were wetter than normal. Some Norwegian stations recorded new records of March precipitation since 100 years. March was as well dominant for the seasonal precipitation anomalies. Drier than normal were the northern parts of the European continent, most of Scandinavia and the eastern Mediterranean Sea and Middle East.

The **summer** 2013 was wetter than normal in the Arctic region, on eastern Greenland and Norway, partly also in Italy, the Black Sea region, the eastern Ukraine and southern and northern Russia. It was drier than normal on the British Isles, the Iberian Peninsula, in most of central Europe, on the Balkan Peninsula and in eastern Ukraine, eastern Mediterranean and Middle East as well as in central parts of European Russia. In eastern Central Europe, which was effected by an extraordinary flooding at the beginning of the season, the seasonal totals were slightly above the normal. The 1-month SPI (DWD adjusted SPI) was highest on the western Balkan Peninsula, in the eastern Mediterranean and Middle East. The 3-month SPI index was remarkably below the mean on the whole Iberian Peninsula, in southern UK, and in the Netherlands, and northern Germany, on the Balkan Peninsula and in parts of Italy and parts of the Alps.

In **autumn** 2013 it was wetter than normal in western, central and eastern Europe, in southern parts of eastern Europe and locally in the Mediterranean Sea area as well as in parts of Middle East. In the Netherlands autumn 2013 was the 5th wettest since 1906, in Germany it was the 18th wettest since 1881. Precipitation surplus was partly caused by remarkable precipitation events. In Denmark the highest daily total in autumn 2013 was 55.5 mm at Oby. It was drier than normal partly on Iceland and Ireland, on the southern and eastern Iberian Peninsula and on the southern French coast, in the eastern Mediterranean, in most of Turkey and much of Middle East. It was as well drier than normal in southern Scandinavia and in parts of the Baltic Sea states. Most of the British Isles, the northern half of the Iberian Peninsula and western France, northern and eastern Europe and the Balkan Peninsula were close to normal.

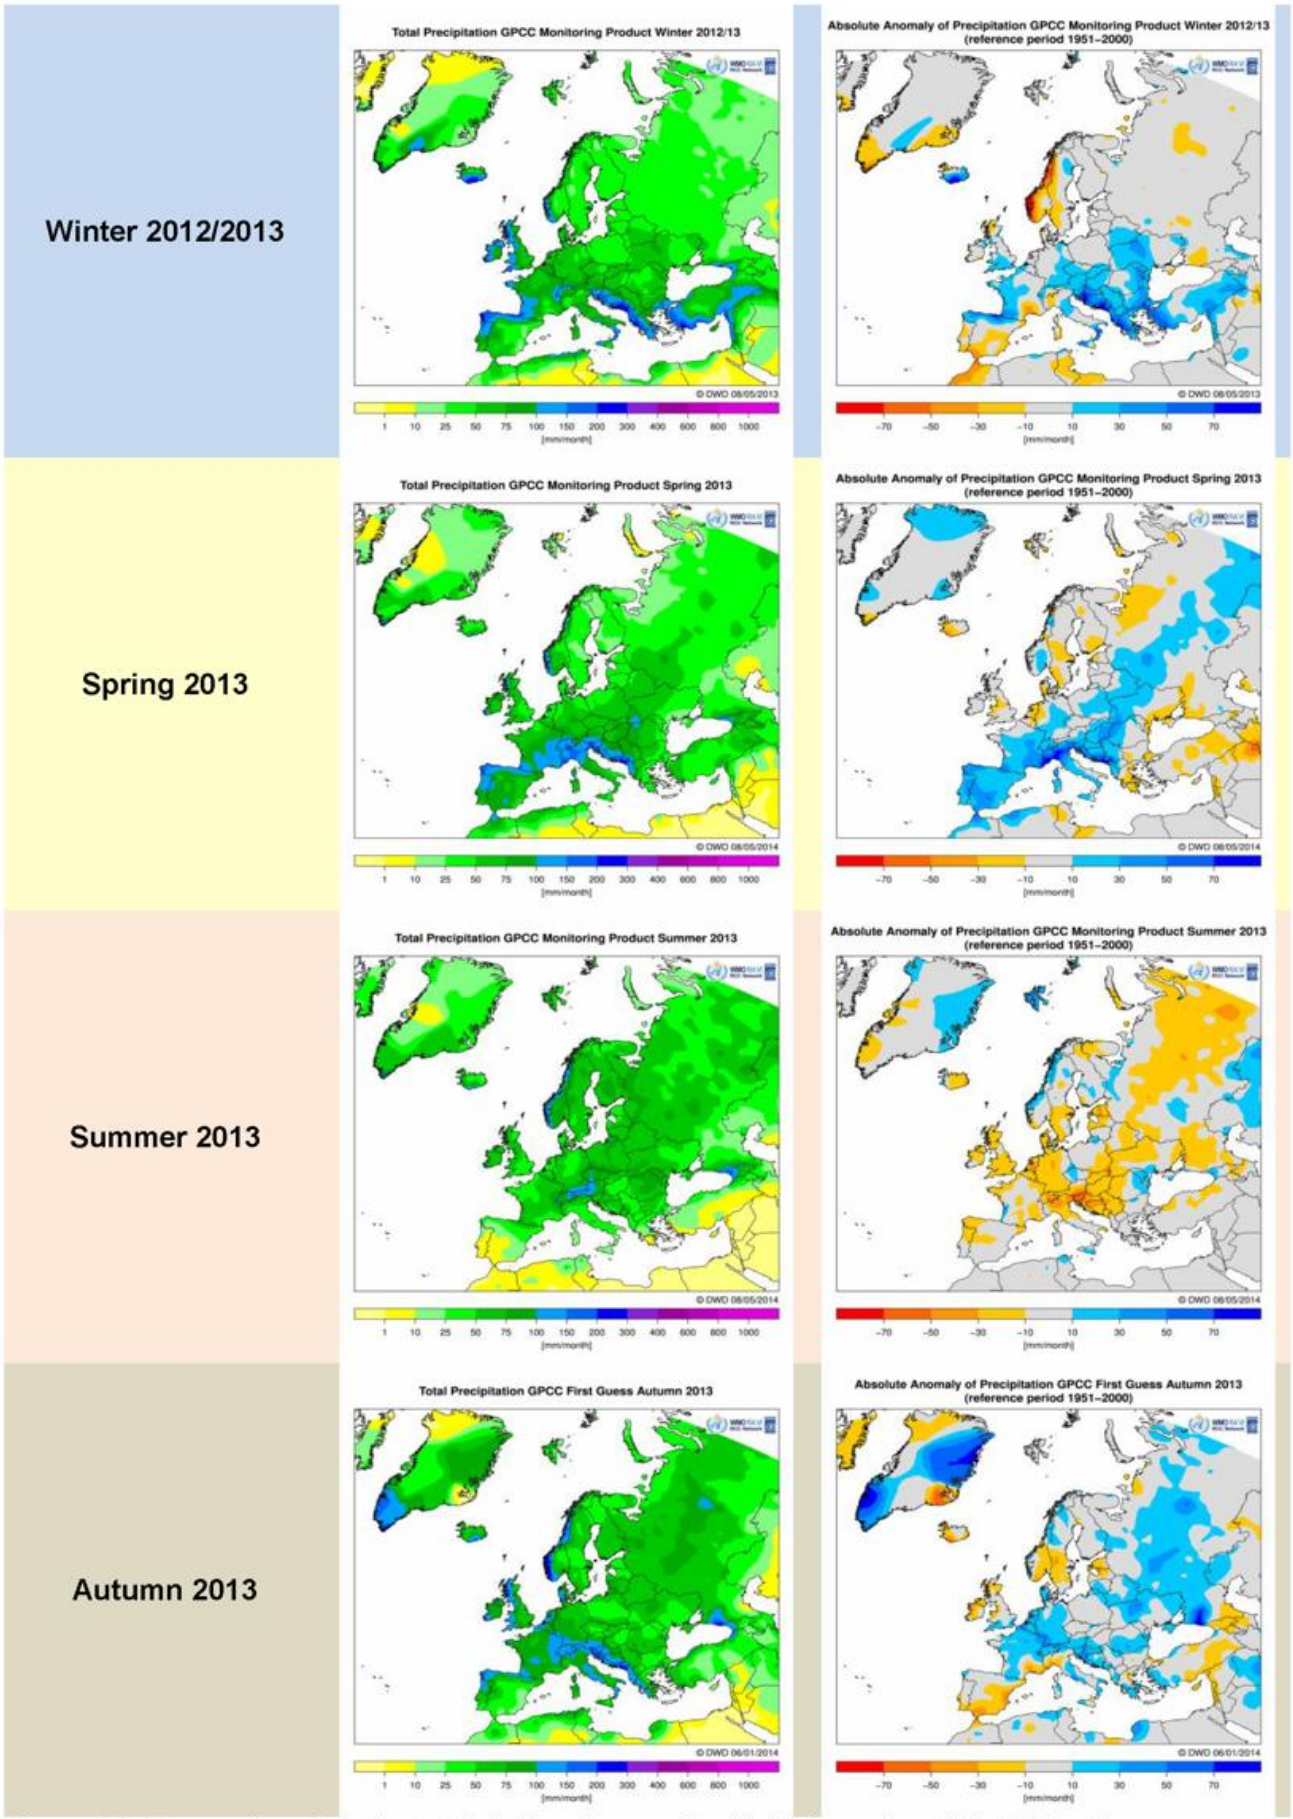

Figure 3.3: Seasonal precipitation totals (left) and anomalies (right) in mm/month in 2013, reference period1951-2000 (Source: http://www.dwd.de/rcc-cm)

3.1.4 Sunshine duration

In most parts of Europe cloudy weather conditions dominated in winter and continued in spring in Central Europe. In contrast, eastern Europe and Russia received more than normal sunshine. The summer was sunnier in whole Europe. In autumn large part of western and eastern Europe observed deficits of sunshine duration, while in the areas from Scandinavia over Poland to the Balkan Peninsula positive anomalies of sunshine duration occurred.

In **winter 2012/2013** the low sunshine duration was remarkable in central Europe. This is as well reflected in the anomaly map of the number of cloudier days which are much more frequent than normal.

Spring 2013 was sunny in Scandinavia, the Baltic countries and northern Russia and cloudy in western Europe especially in UK, partly over Iberian Peninsula, southern Russia and the Caucasus region.

Summer 2013 was sunniest in Poland and the eastern Alps with more than 125% of the 1961-1990 normal. In Poland it was locally even above 150%. With respect to a 1971-2000 reference it exceeded there even 175%, with a seasonal total of 1064 hours at Warsaw. In Austria summer 2013 was on rank 1 together with 1887 and 1904 in the north, in the southeast and on the summits it was the 2nd sunniest summer. It was generally sunnier than normal with patchy regional exceptions over the continent. It was cloudy in the eastern Mediterranean and Middle East. On the coast and in central Slovenia summer 2013 was the second sunniest summer so far.

In **autumn 2013** the relative sunshine duration was below normal or close to normal over large parts of the area except in Spain, Scandinavia, Denmark and the northern part of the British Isles, most of Turkey, the Caucasus area and a narrow band from Poland southwards to the Balkan Peninsula. In Germany autumn 2013 was the 13th cloudiest autumn since 1951. The relative surplus in Spain of 105 to 125% resp. in southern and middle Sweden of 105 to 150% corresponds to an absolute surplus of up to 20 to 50 hours. In Poland and on the Balkan Peninsula the absolute surplus did not exceed 20 hours. Most of eastern Europe was clearly cloudier.

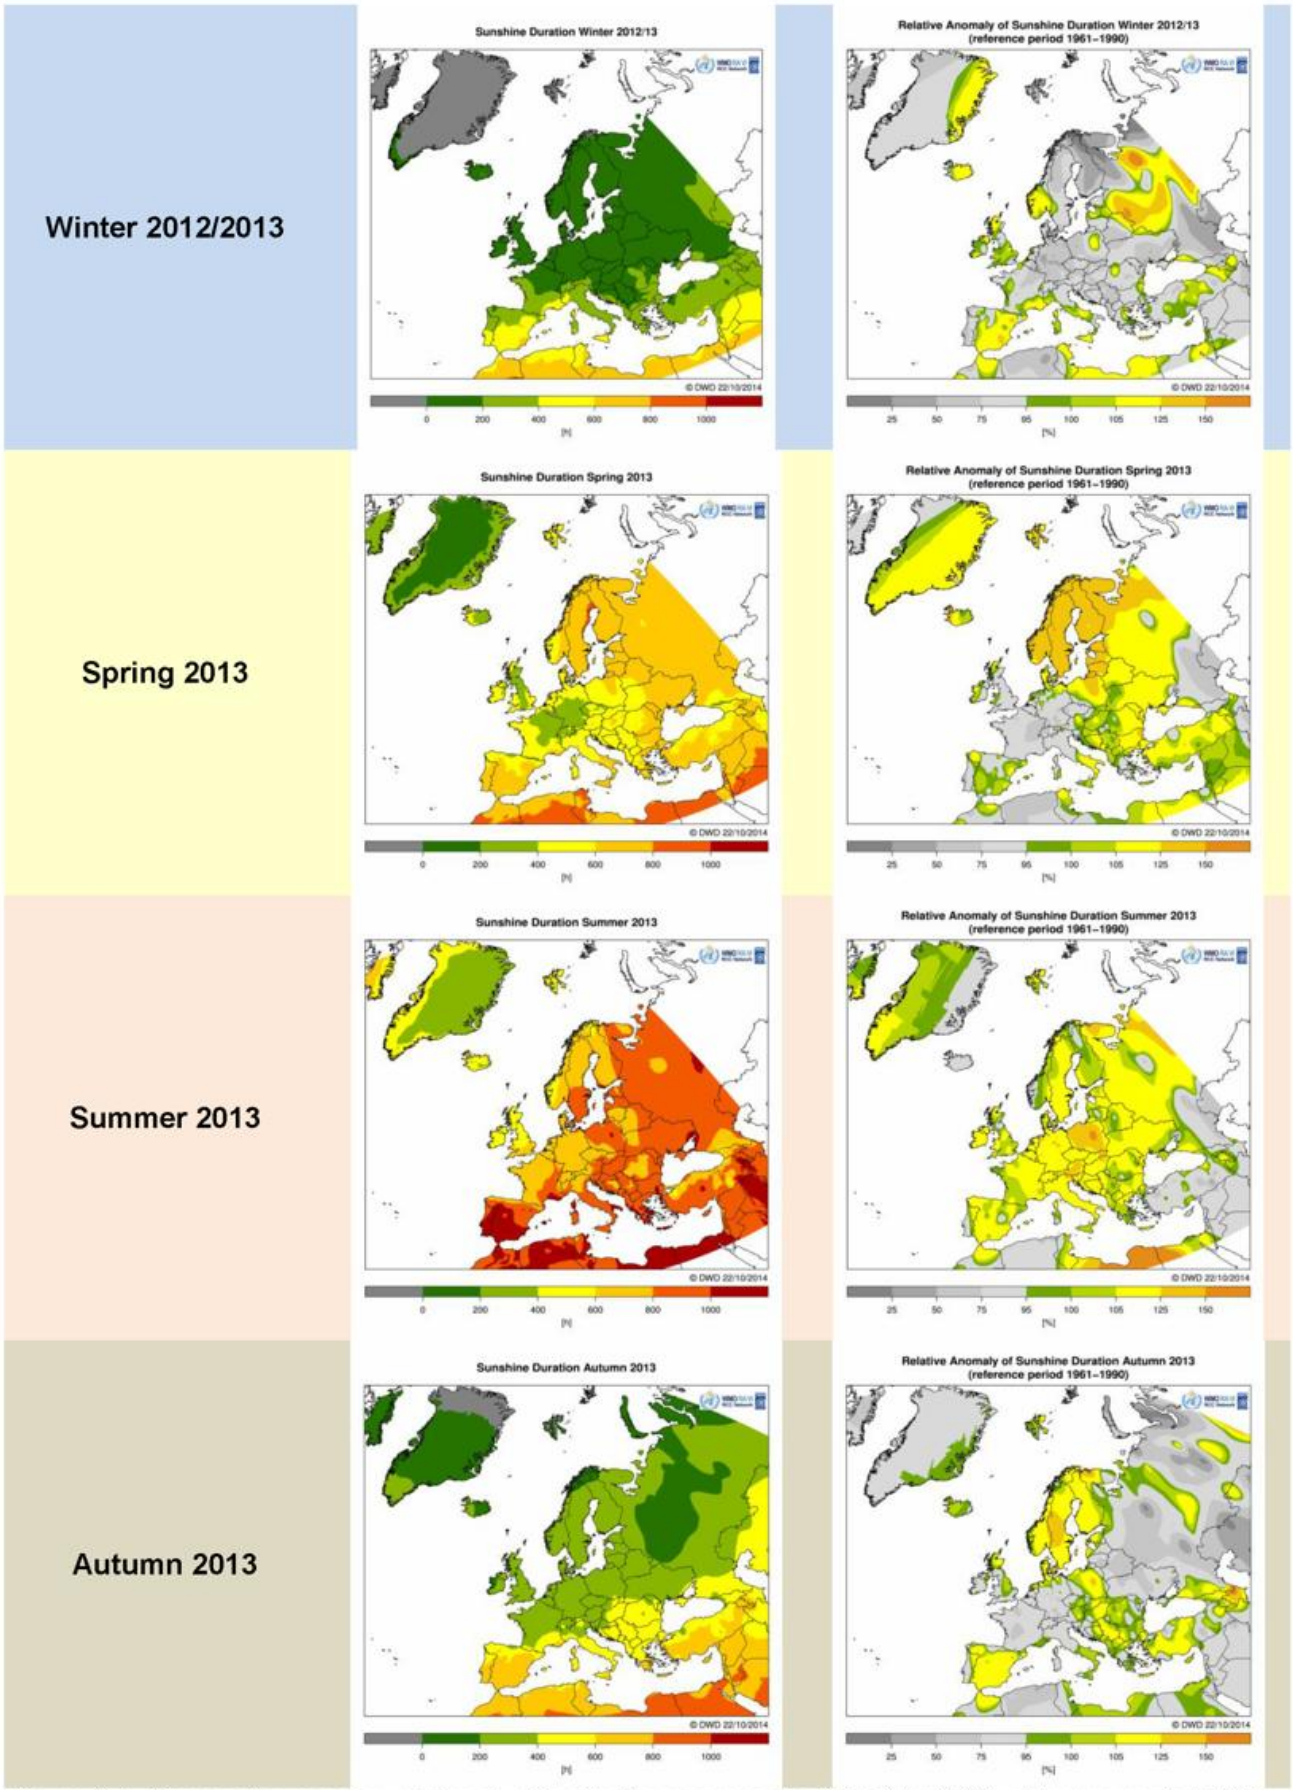

Figure 3.4: Seasonal sums of sunshine duration (left) and anomalies (right) in 2013, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.5 Drought

Reports on longer lasting dry periods from the National Meteorological and Hydrological Services:

Denmark received in July 2013 only 19 mm rain as an area mean. It is 47 mm or 71% below the normal for 1961-1990. A comparison with the past 10 years-normal 2001 to 2010 of 77 mm also provides a very dry July 2013 the entire 58 mm or 75% below. It was the fourth driest July since the nationwide precipitation measurements began in 1874.

Although in **Hungary** the precipitation amount in 2013 was 114% of the average amount of 1971-2000 all three summer months were drier than usual, especially July, which was the 6th driest on record with only 37% of the normal amount. The end of the year was again extremely dry: some regions had no precipitation at all in December, which was the second driest on record with only 8% of the average amount.

In **Austria** July 2013 was the driest since 1853, the precipitation sum was 65% lower than normal. Though the precipitation in May and June was unusually high, combined with floods, the absence of rain in July led to a drought that caused serious damages in agriculture.

The drought in **Slovakia** was most significant in western and central part of the country. Mean monthly precipitation amount was 26% of the average and the lowest in the last 50 years.

The year 2013 in **Slovenia** was marked by abundant precipitation in the first 3 months, and catastrophic drought in summer. The summer drought coincided with the extreme heat period. The most critical period for drought was from 11 June to 10 August.

Portugal notified the 4th driest November of the last 83 years. In the 2nd half of the month no precipitation was recorded in almost the whole territory.

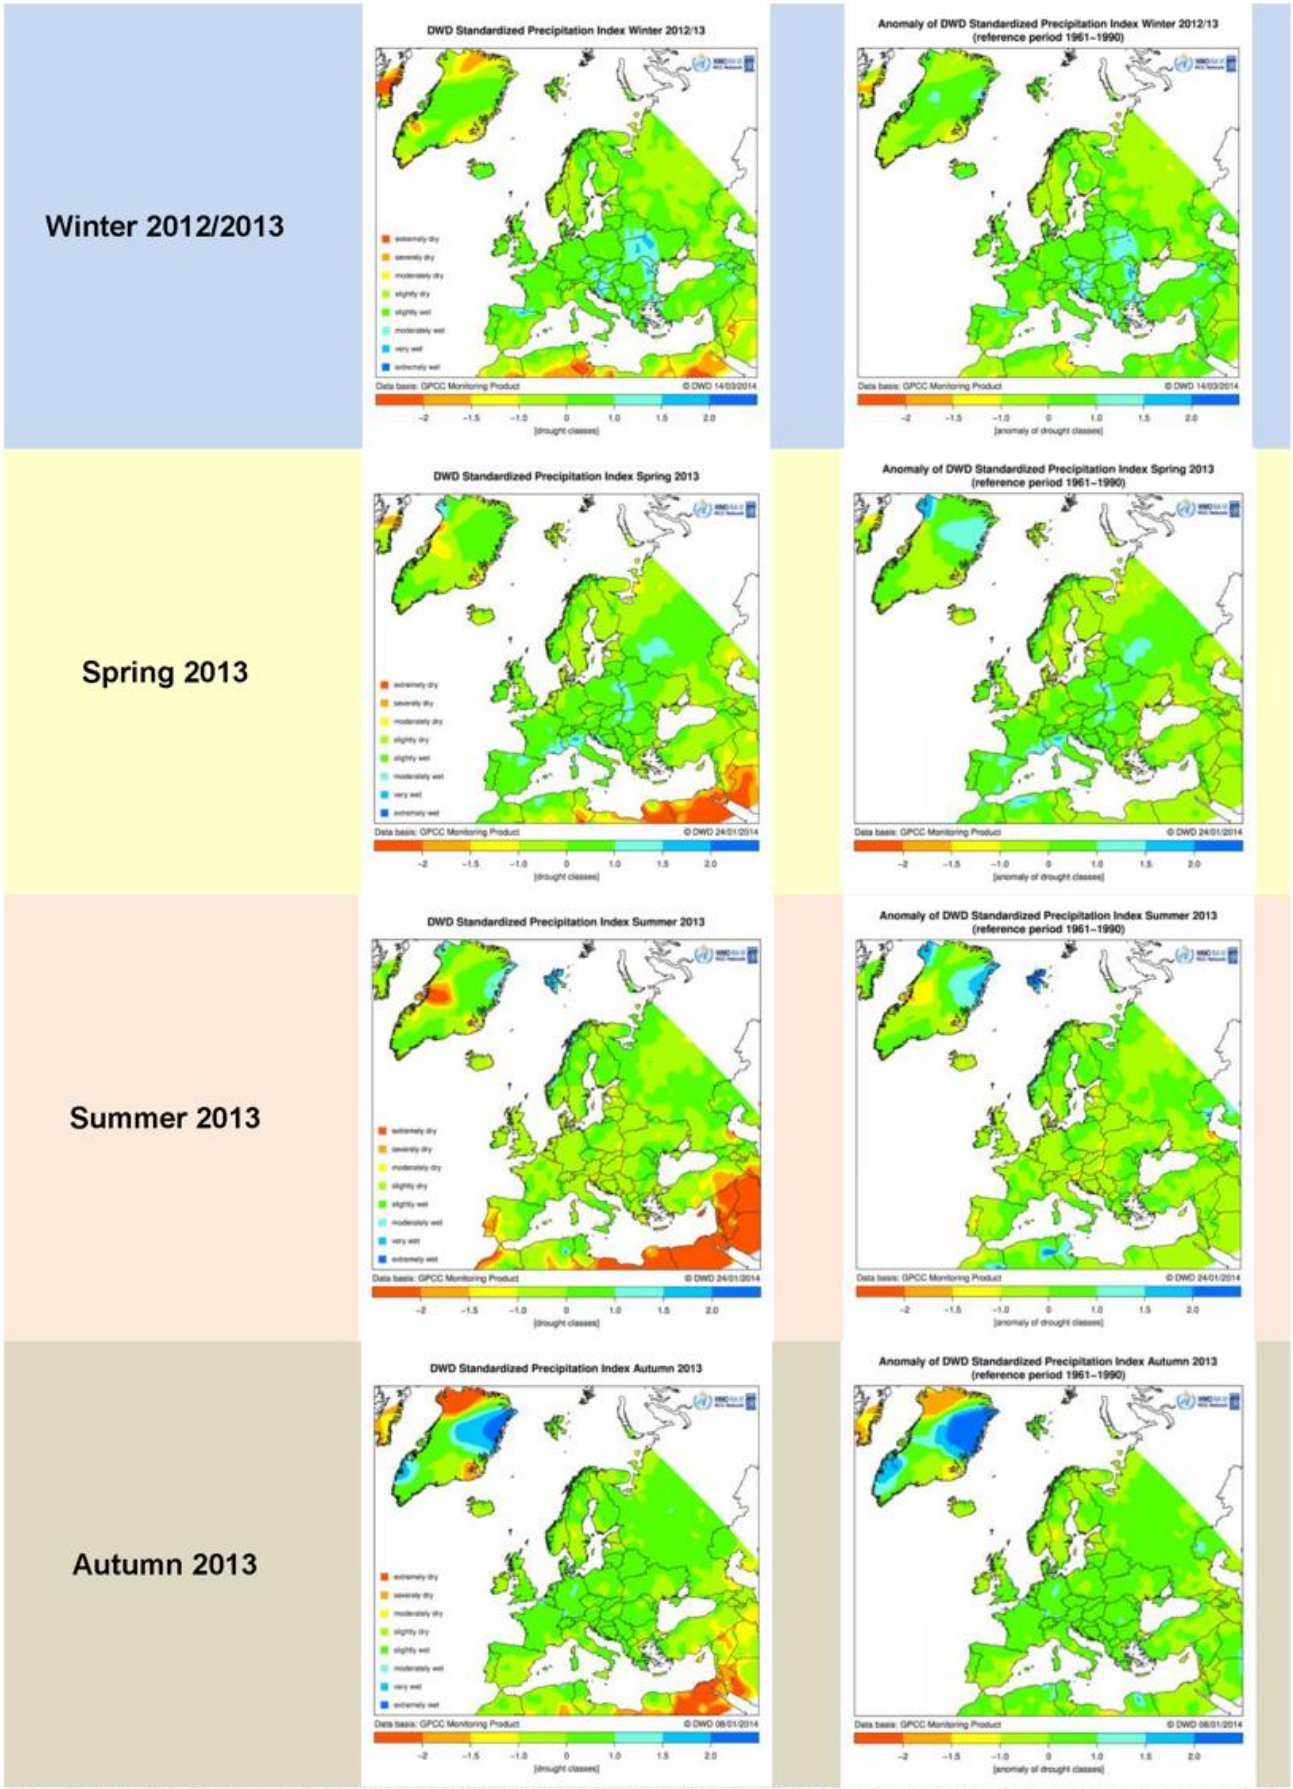

Figure 3.5: Seasonal mean of the modified Standardized Precipitation Index (DWD-SPI, left) and anomalies (right) in 2013, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

4 Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2013 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation, sunshine duration for each months as well as monthly overview of extremes and notable events.

4.1 Sea surface pressure and circulation indices

This chapter about the atmospheric circulation provides information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based upon the Monthly Bulletins on the climate in WMO RA VI and the Global Climate Bulletin (MeteoFrance) and completed by reports of NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4.1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the AO, for January 2013 to December 2013

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2013	1	-0.11	0.88	0.46	0.08	-1.86	-0.61
2013	2	-0.96	0.14	-1.28	1.00	0.34	-1.01
2013	3	**-2.09**	-0.24	**2.31**	-0.57	-1.90	**-3.19**
2013	4	0.60	1.31	-0.40	-1.10	-1.64	0.32
2013	5	0.58	0.14	**-2.06**	0.48	0.02	0.49
2013	6	0.83	0.66	**-2.30**	0.30	-0.01	0.55
2013	7	0.70	0.63	-0.17	-0.03	-0.30	-0.01

2013	9	0.38	-0.57	-0.58	0.38	-1.59	-0.46
2013	10	-0.88	1.39	0.63	0.67	0.75	0.26
2013	11	0.81	0.09	-0.88	-0.70	**2.58**	**2.03**
2013	12	0.79	1.20	-0.36	-0.73	-0.83	1.48

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

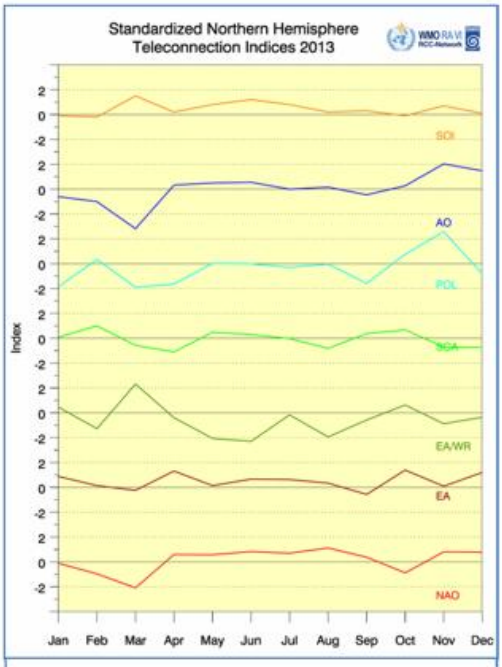

Figure 4.1: Annual course of relevant Teleconnection Indices 2013

In **January** 2013 the anomaly of the sea-level pressure was negative nearly over the whole area of interest except in the Norwegian Sea and over western Scandinavia and on the North Atlantic, west of northern Africa with a center north of the Canary Islands where it was positive (+4 to +8) giving an monthly mean in the range of +1025 hPa to 1030 hPa. The lowest mean for the month was 990 hPa south of Greenland where the anomalies ranged from -8 hPa to -12 hPa. The mean gradient between both mean pressure centres was strongest on the northern North Atlantic in the area west of the British Isles, roughly between 40°W and 20°W and 45°N to 55°N. The negative anomalies ranged between -4 and -8 hPa in Russia and southeastern Europe and around the Italian Peninsula. The NAO- and AO-indices were relatively small but the Polar/Eurasian Pattern

had a negative value, indicating high pressure north of Alaska. There was only weak to medium blocking around the 0 meridian during the month (source: http://www.cpc.ncep.noaa.gov).

Lower than normal sea-level pressure prevailed over southern and southeastern Europe and Middle East in **February** 2013. The largest negative monthly anomalies ranged from -4 to -8 hPa in the Tyrrhenian Sea. Northern and western Europe had on the other hand positive anomalies in the range of +4 to +8 hPa on the North Atlantic from the Norwegian Sea southwards close to the Azores. Westward the anomalies were negative again with up to -4 hPa southeast of Greenland. This refers to a low pressure system south of Greenland while Iceland was on its eastern edge. There was increasing blocking between 0 and 30 E from about 9 to 18 February and - more intense - around 0 E from 19 to the end of the month (see http://www.cpc.ncep.noaa.gov). The pressure pattern corresponds quite well with the observed anomalies of temperature and precipitation. The NAO index, EA/WR and AO were of the same order of magnitude of -1.0.

March 2013 is characterised by high pressure over Greenland, Iceland and Scandinavia and low pressure on the mid-latitude North Atlantic with anomalies of -12 to -16 hPa in the Azores region and -8 to -12 hPa over southern Russia and more than +16 hPa over Greenland. Since both centers of action were less intense the NAO index was -2.09 and the AO index -3.176. Remarkable was the value of the EA/WR mode with 2.31.

During **April** 2013 the lowest negative sea-level pressure anomalies occurred west of the British Isles and the Norwegian Sea that ranged between -4 and -8 hPa. The Icelandic Low was shifted to the north-east. On the North Atlantic, over the North Sea and Scandinavia, over western North Africa and the western Mediterranean Sea as well as in the Middle East and Eastern Europe negative anomalies prevailed. Positive anomalies occurred on the western North Atlantic. The NAO index changed around the middle of the month from negative to positive values consistent with the temperature changes in western and central Europe. Therefore the NAO for the whole month was not well developed. The negative anomalies in the western and eastern Mediterranean Sea correspond with phases of intense precipitation. The gradient over the Norwegian Sea were not very high but the pressure distribution allowed the development of storm tracks normal for the season. The East Atlantic Pattern (EA) and the Polar/Eurasia Pattern (POL) were in opposite phase.

The NAO index was positive during the first half of **May** 2013. This reflects the strong Icelandic low and Azores high especially during that time. In fact, a first cooling in central Europe started around 10 May (Ice Saints), when the NAO index reached its maximum. The second cooling period in western and central Europe, which was even more intense than the first one came in the last third of the month when the circulation pattern became more meridional, which is displayed by a switch to a negative mode of the NAO. The AO index was also positive during the first half of the month, which means relatively little exchange of air masses between the polar region and mid-latitudes. In the second half of May, the AO oscillated around normal. Both the Icelandic low and the Azores high were stronger than normal, and the Icelandic low was extended eastwards to the North Sea. As a result, there was a strong north-westerly flow of cold and moist air to the western half of Europe. Large parts of central Europe and adjacent areas had prevailing cyclonic conditions, explaining the high positive anomalies of precipitation. On the other hand, high pressure dominated over north-eastern Europe. At the south-eastern flank of that high pressure area, warm and dry air moved far to the north.

In **June** 2013 the NAO index was positive most of the month, resulting in a slightly positive monthly mean of 0.83, similar to April and May 2013. This reflects both the more intense Icelandic low and Azores high. The AO index, too, was mostly slightly positive, indicating relatively small air mass exchange between polar and central latitudes most of the month.

In **July** 2013 the Azores high was extended northeastwards over the northwestern, central and southwestern European continent. The anomalies were positive from Scandinavia and northern Russia over the northwestern, central, southern and southeastern continent and the central Mediterranean region and negative on the Atlantic, including the Iberian Peninsula, in the eastern Mediterranean, the Middle East, the Caucasus region and Russia except the north.

In **August** 2013 the Icelandic low and the Azores high were well pronounced. The Azores high was extended northeastwards over the European continent to western Russia. The positive anomalies

were in the range of 0 to +4 hPa. Over the northern (including the northern British Isles) and western Atlantic Ocean, the southern North Atlantic, the eastern Mediterranean Sea, the Middle East and southern Russia the anomalies were negative, mostly in the range of 0 to -4 hPa. The negative anomalies over Iceland ranged -4 to -8 hPa. The NAO index was positive with 1.12.

The sea-level pressure in **September** 2013 was below the normal over most of the European continent and the Mediterranean Sea. The strongest negative anomalies in the range of -4 to -8 hPa were located in southern Russia and southeastern Ukraine. Negative anomalies occurred as well over Iceland and over the western North Atlantic. Positive anomalies were over the northern UK and Ireland, Scandinavia and northern Russia with the highest values in the range of +4 to +8 hPa over northern Scandinavia and northern Russia. The NAO index was 0.38 and the AO index was -0.461.

In **October** 2013 there were negative anomalies over the central North Atlantic including the Azores of up to -12 hPa and slightly positive anomalies over Greenland and the northern North Atlantic including Iceland as well as over the southern North Atlantic, northern Africa and most of the Mediterranean Sea and further northward over the Balkan Peninsula and most of the Black Sea to Poland. The high pressure corresponds with the dry weather in northern Africa and much of the Mediterranean as well as on the Balkan Peninsula while low pressure corresponds to the wet conditions in western, central, northern and northeastern Europe. The NAO-index was below zero during 12 to 25 October and the negative values were below the mean minus 1 sigma. It turned positive at the end of the month. At that time the AO was positive well above the mean plus 1 sigma.

November 2013 was dominated by a strongly positive AO of 2.03 and a positive NAO of 0.81. A strong mean depression with its center north of Scandinavia had a mean sea-level pressure below 995 hPa. It dominated the north of the area from west of Greenland to Russia. High pressure on the North Atlantic with its center over the Azores and east of them (mean sea-level pressure 1025 to 1030 hPa) and high pressure over Kazakhstan and southern Russia with a mean pressure of 1020 to 1025 hPa were connected by a high pressure bridge over western, southern central and southeastern Europe and Middle East. Most of the Mediterranean Sea except the western part had slightly low pressure below 1015 hPa. The anomalies were mostly negative except over the North Atlantic where they were positive with 2 to 6 hPa over the British Isles western France and the western Iberian Peninsula and 6 to 10 hPa west of the European continent. In the Arctic the negative anomalies exceeded -10 hPa and even -14 hPa in the polar region. Negative anomalies below -2 hPa reached from west of Greenland to central European Russia and as well over the central and eastern Mediterranean Sea, the Italian and Balkan Peninsula and Middle East.

December 2013 was characterised by intense and extended low pressure centered over Iceland with a mean sea-level pressure below 995 hPa reaching from southern Greenland to northern Norway and high pressure in the south and southeast from the Azores (mean pressure in the range 1020 to 1025 hPa) eastwards and northeastwards. The highest mean pressure of 1025 to 1030 hPa was over the Iberian Peninsula and over the northern Balkan Peninsula. Lower pressure but not very low (1015 to 1020 hPa) was over the eastern Mediterranean Sea and adjacent southern and eastern countries. The highest positive anomalies of 6 to 10 hPa was over the central Mediterranean, the Balkan Peninsula and the Black Sea whereas the highest negative anomalies of -14 hPa and lower occurred around Iceland. The strongest gradients between the low and the high pressure occurred between northern France and Scotland and the gradient zone remained rather sharp also over northern central Europe and northern Sweden. The frequent and strong winter storms in December are closely related to this. Many low pressure cyclones accompanied the frequent far southward reaching troughs and brought heavy to extremely heavy precipitation to the Mediterranean Sea and Balkan Peninsula. The NAO index for December 2013 of only 0.79 reflects the large extent of the low pressure in the north. A higher positive value of 1.475 resulted for the AO index.

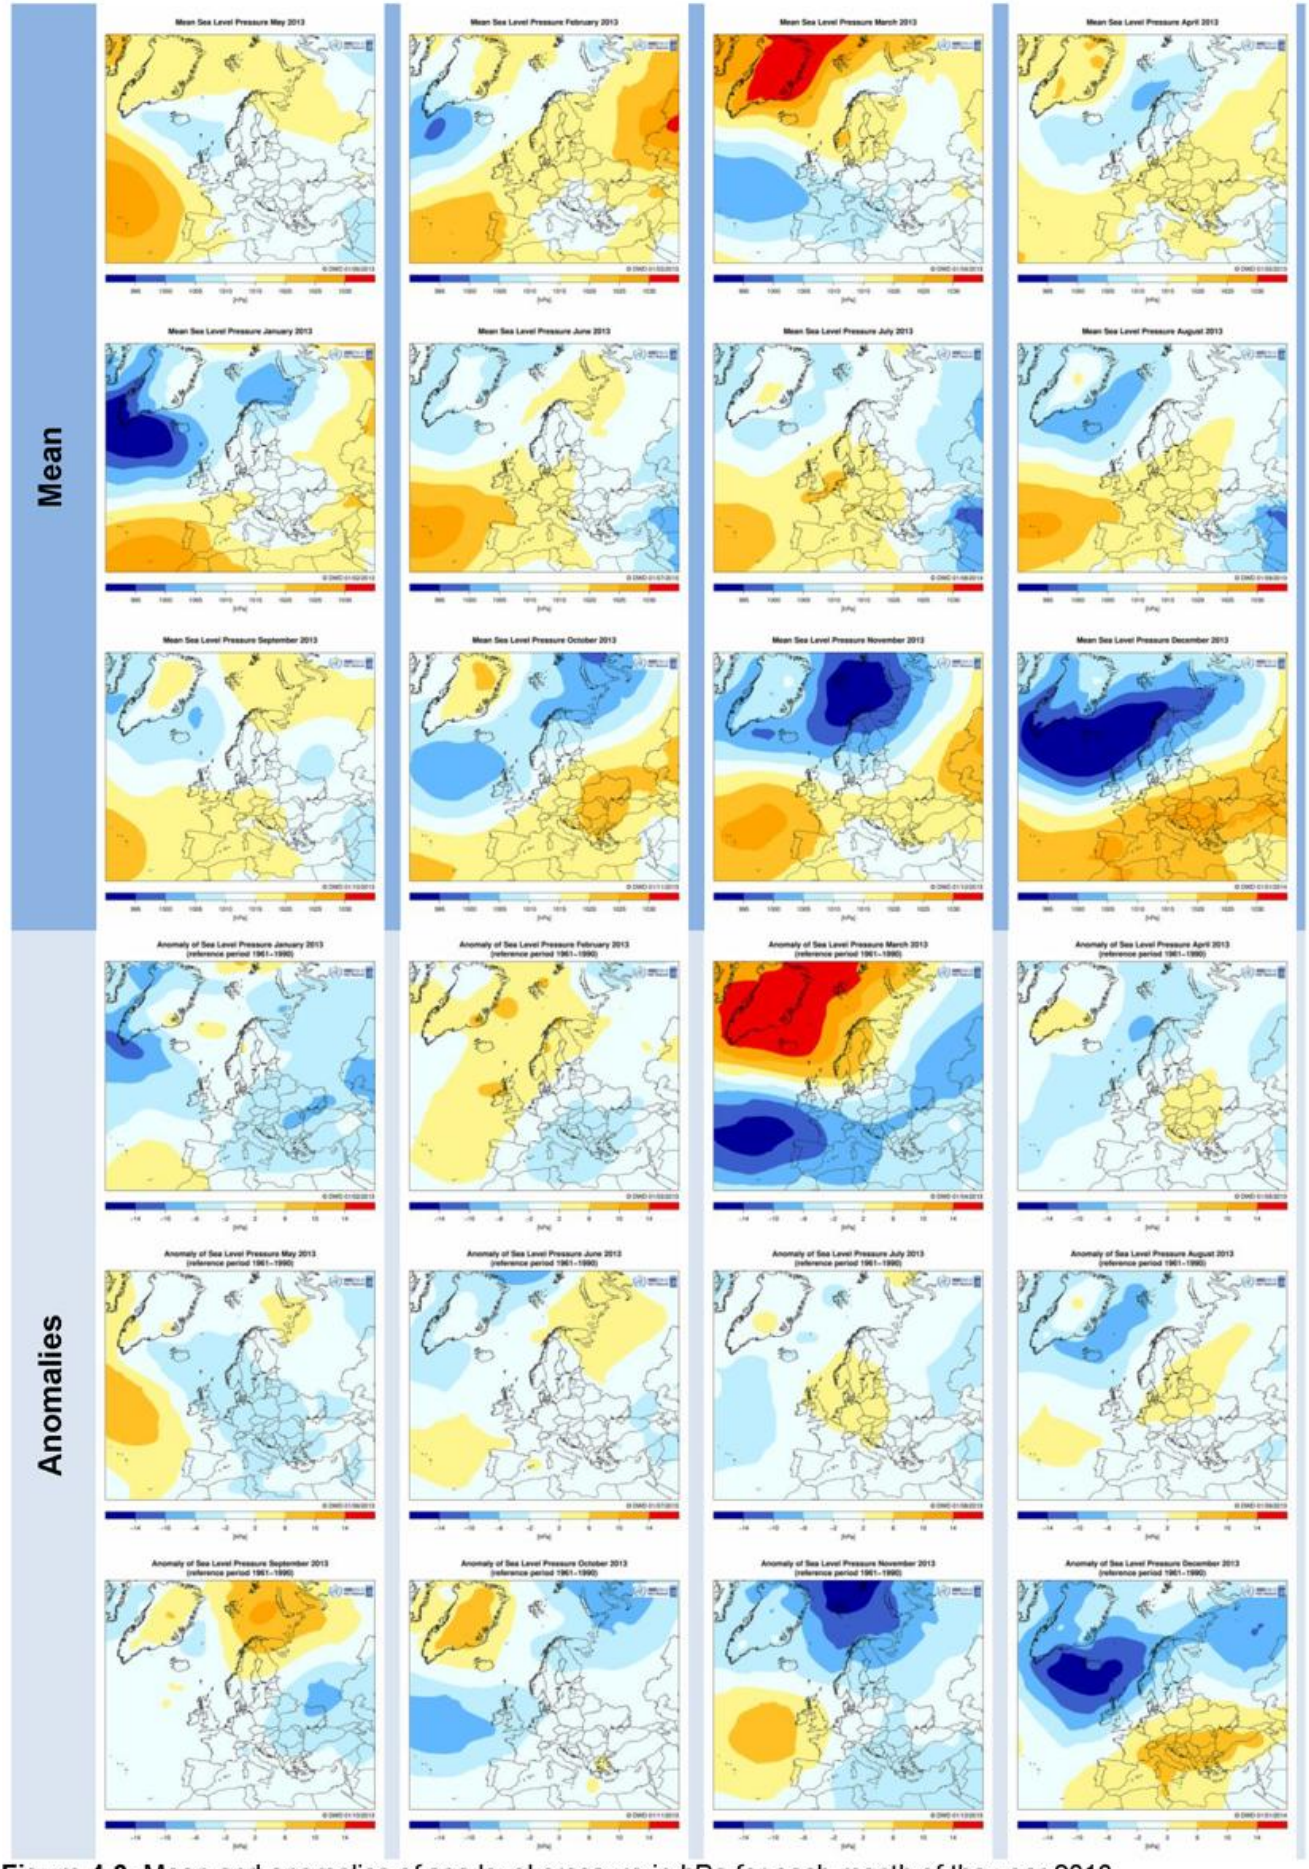

Figure 4.2: Mean and anomalies of sea level pressure in hPa for each month of the year 2013.

4.2 Temperature

In most of the months and subregions 2013 was warmer than normal except of March.

Table 4.2: Monthly and annual area average of temperature anomalies in °C for each sub-region in the year 2013 (reference period: 1961-1990)

	year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.

January 2013 was colder than normal in the North Sea with the adjacent countries western UK, northern France, Belgium, the Netherlands, north-western Germany and southern Norway and in the Baltic countries with southern Sweden, north-eastern Poland and most of Belarus. As well colder than normal were parts of southern France. Elsewhere it was warmer than normal, with anomalies of more than +4 K in the Arctic and northern Norway and northern Russia and more than +3 K on Iceland, in southern Russia and in Austria and parts of Bosnia and Herzegowina and Serbia.

February 2013 was colder than normal in western, central and southern Europe. The largest negative anomalies spread over western and south-western France with anomalies in the range of -2 to -3 K and locally more than -3 K. Negative anomalies in the range of -2 to -1 K extended remarkably far southward in the Mediterranean Sea. Northern, eastern central, eastern and south-eastern Europe and the Middle East were warmer than normal. Positive anomalies of +4 K and more were observed from Finland southward to the Caucasus area. Warmer than normal was as well the Arctic Sea with +4 K for Spitsbergen and +2 to +3 K on Iceland and south-eastern Greenland. Iceland reported February 2013 to be the 2nd to 4th warmest February since observations started in the 19th century.

March 2013 was colder than normal in most of Europe except the central and eastern Mediterranean, the Middle East and the Caucasus area. The negative anomalies were larger than -4 K in northern Russia and the eastern Baltic States as well as in large parts of Germany and Poland. In Germany March 2013 was on rank 4 of cold March months since 1901 and on rank 5 since 1881. In Ireland some locations recorded the coldest March of the last 50 to 70 years. In the Netherlands March 2013 was on rank 7 of the coldest March months since 1901. UK recorded the 2nd coldest March since 1910 and the coldest since 1962. In France it was the coldest March for 25 years. It was as well the coldest March since the start of the series in 1980 together with March 1996 at the station Ekofisk in the Norwegian Sea. In Latvia rivers and lakes had an ice cover of 20 to 28 cm. In Minsk, Belarus, March 2013 was on rank 8 of the cold March months since 1945. The second half of March 2013 was extremely cold in the entire territory of Slovakia. At Hurbanovo the mean temperature of the period of 16 – 31 March 2013 was the second lowest recorded since 1901 with deviation 5.4°C below the 1961 – 1990 average.

April 2013 was still colder than normal on the Northern North Atlantic and southern Scandinavia and the Baltic states, while it was warmer than normal in the Arctic region, in eastern Europe and in south-eastern and most of southern Europe. Temperatures rose by the middle of the month corresponding to the change of the NAO regime (see the graphs of the time series below). Interesting is again the good correspondence of the anomalies of the vertically integrated water vapour (Total precipitable water, TPW, see in http://www.dwd.de/rcc-cm under products - water vapour).

Cold polar air moved frequently to the western parts of Europe in **May**, whereas warm tropical air masses flowed into the eastern parts far to the north. The highest negative anomalies below -2°C were recorded in France and northern Spain. It was the coldest May in Switzerland since 1991, in the United Kingdom and Ireland since 1996, in Spain since 1985; France recorded its lowest maximum temperature since 1984. On the other hand, there were very high positive anomalies above +4°C in the Ukraine and western Russia, and even in northern Scandinavia, where temperature records for May were broken at several stations. The difference between west and east was especially extreme in the last week of the month, when minimum temperatures in western Europe fell near to the freezing point, while maxima in Finland exceeded 30°C.

June 2013 was at least +1°C warmer than normal in the Arctic region and in eastern Europe. In eastern parts of the European Arctic region, anomalies exceeded +4°C. It was the warmest June since 1999 in Finland. Highest maximum in Finland this June was 32.4°C. In Belarus the return time of such a warm June is about 20 years. Northern Norway recorded its third warmest June with a highest daily maximum of 29.8°C. Akureyri in northeastern Iceland had its warmest June since 1953 with 11.4°C on monthly average, and maxima exceeded 20°C in places. Turkey had some new local June maxima records (35-40°C) around 5 June. Parts of the western half of Europe and the North Atlantic were slightly cooler than normal. This concerns especially the sea areas of the North Sea, eastern regions of the North Atlantic and the western Mediterranean, and the corresponding coastal regions. Anomalies were mostly between 0 and -1°C, only few exceptions below -1°C, e.g. locally in the Pyrenees region. Spain had its coldest June since 1997. This happened for the first time since 1985. However, in the United Kingdom, the previous two Junes were even colder than this one. Central Europe was slightly warmer than normal due to an intense but short heat wave with maxima up to above 35°C, which also affected most of the other parts in Europe. Some local records occurred around 19 June in central Europe. The heat wave ended after arrival of a cold front causing an abrupt temperature decrease at the end of the month.

July 2013 was warmer than normal on the European continent except partly in Turkey and the Caucasus area. The mean monthly anomalies exceeded +2 K in central and western Europe and were in the range of +3 to +4 K in parts of France, Germany, eastern Austria and its neighbours and locally in UK and north-western Spain. In France the heat wave of 13 days (15 to 27 July) was moderate but its length was on rank 6 since 1947. In Spain it was the 5th warmest July since 1961 and Norway reported the 5th warmest July since 1900. UK reported July 2013 as the 3rd warmest since 1919, France as well. Germany had the 6th warmest July since 1901.In Ireland it was the warmest July at several places for more than 60 years and at the Valentia Observatory it was the warmest since 1893. Hot days occurred in all central, southern, south-western and south-eastern Europe except in the high mountains and as well in southern UK. Summer days occurred on the whole continent except on the higher mountains, northern Scandinavia and Russia. Days with maximum temperatures over 40°C occurred in south-western Spain and Portugal as well as in parts of Italy, south-eastern Europe and the Middle East, mainly Syria (see the table). The highest temperature in Spain was 41.8 °C in Jerez de la Frontera. Tropical nights occurred not only in southern Europe but also in eastern Germany, in Poland and in easternmost Austria and its neighbouring countries.

August 2013 was warmer than normal, especially on the Balkan Peninsula as well as in the eastern Arctic Sea. Tropical nights occurred rather often in the Mediterranean Sea region (compare also the map of sea surface temperatures) and in the northern Black Sea region but as well in northern Germany, Denmark and the Baltic States. Hot days occurred in central, western, southern and south-eastern Europe, the Middle East and southern Russia and the Caucasus except in the higher mountains. On the southern Iberian Peninsula, in Greece and western and southern Turkey as well as in Syria, Lebanon, Israel and Jordan and in southern Russia more than

25 days of the month were hot days. Extremely hot days (above 40°C) occurred mainly in southern Spain and in Syria and Jordan but locally also in other countries. 17 of 58 countries reported that a maximum temperature of 40 °C or more was registered in August 2013. The highest value occurred in Jordan with 45 °C. In Spain 44.1 °C was the highest value. Only a few frost days occurred in the Alps at higher locations but more often in the mountains of southern Norway and Sweden. The high temperatures partly caused deformations of streets (i.e. Portugal, Germany, Austria).(Consider that temperatures close to the surface may exceed the air temperatures arbitrarily under sunshine conditions). Together with the dry conditions they lead to forest or bushfires especially in the southern regions (Portugal, Austria).

September 2013 was warmer than normal over the Arctic region with positive anomalies of +3 to +4 K. It was as well warmer than normal in western Europe and the Mediterranean region. September 2013 war colder than normal in eastern Europe and Middle East with negative anomalies of -1 to -2 K on the eastern Balkan Peninsula, in southern Poland, in the Ukraine and southwestern Russia. Southeastern Ukraine had the strongest negative anomalies (-2 to -3 K).

In **October** 2013 it was warmer than normal with exception of the eastern Mediterranean and Middle East as well as the northeastern Arctic region and parts of the North Atlantic south of Greenland. In Spain it was the 6th warmest October since 1961, in places even the warmest October since 1869. It was also the 6th warmest October since 1900 in France. Several places had their highest monthly mean since the last 90 years. Cap Corse (Haute-Corse) had a monthly mean of 20.8 °C (record since 1917). In the Netherlands it was the warmest October in De Bilt since 1901. In Germany it was the 11th warmest October since 1881 as a mean over the country.

November 2013 was warmer than normal in the Arctic and on Greenland, in northern, eastern central, in eastern and south-eastern Europe and in Middle East. A large area over most of European Russia and parts of Belarus, the Ukraine and Moldova had positive anomalies of 4 K or more. It was only slightly colder in most of western and western central and south-western Europe and on the North Atlantic. In north-eastern Portugal partly 13 to 15 days (2nd half of the month) had minimum temperatures of 0°C or below.

December 2013 was warmer than normal on most of the northern, western, central and eastern part of the continent and colder than normal in Turkey and Middle East. The highest positive anomalies of more than 4 K occurred over eastern Norway, Sweden, Finland, the Baltic States and the northern part of European Russia. Also the Arctic regions had partly positive anomalies above 4 K. The negative anomalies in Turkey and the Middle East were above -4 K partly as well. The month therefore has been the 10th warmest December since the beginning of the 20th century and also since 1881 in Germany. In Denmark it was the 2nd warmest December since 1874. In the Netherland December 2013 was the 6th warmest December since 1901. In Ireland it was the warmest December at single stations since 22 to 25 years. On 12th December Malin Head recorded its highest maximum temperature for December since 58 years (15.2°C).In UK it was the warmest December since 1988. In Norway December 2013 was the 8th warmest December for the whole country since 1900 with an anomaly of 4.2 K (locally 6-8 K). In the region Ostland it was the 3rd warmest after 2006 and 1924.

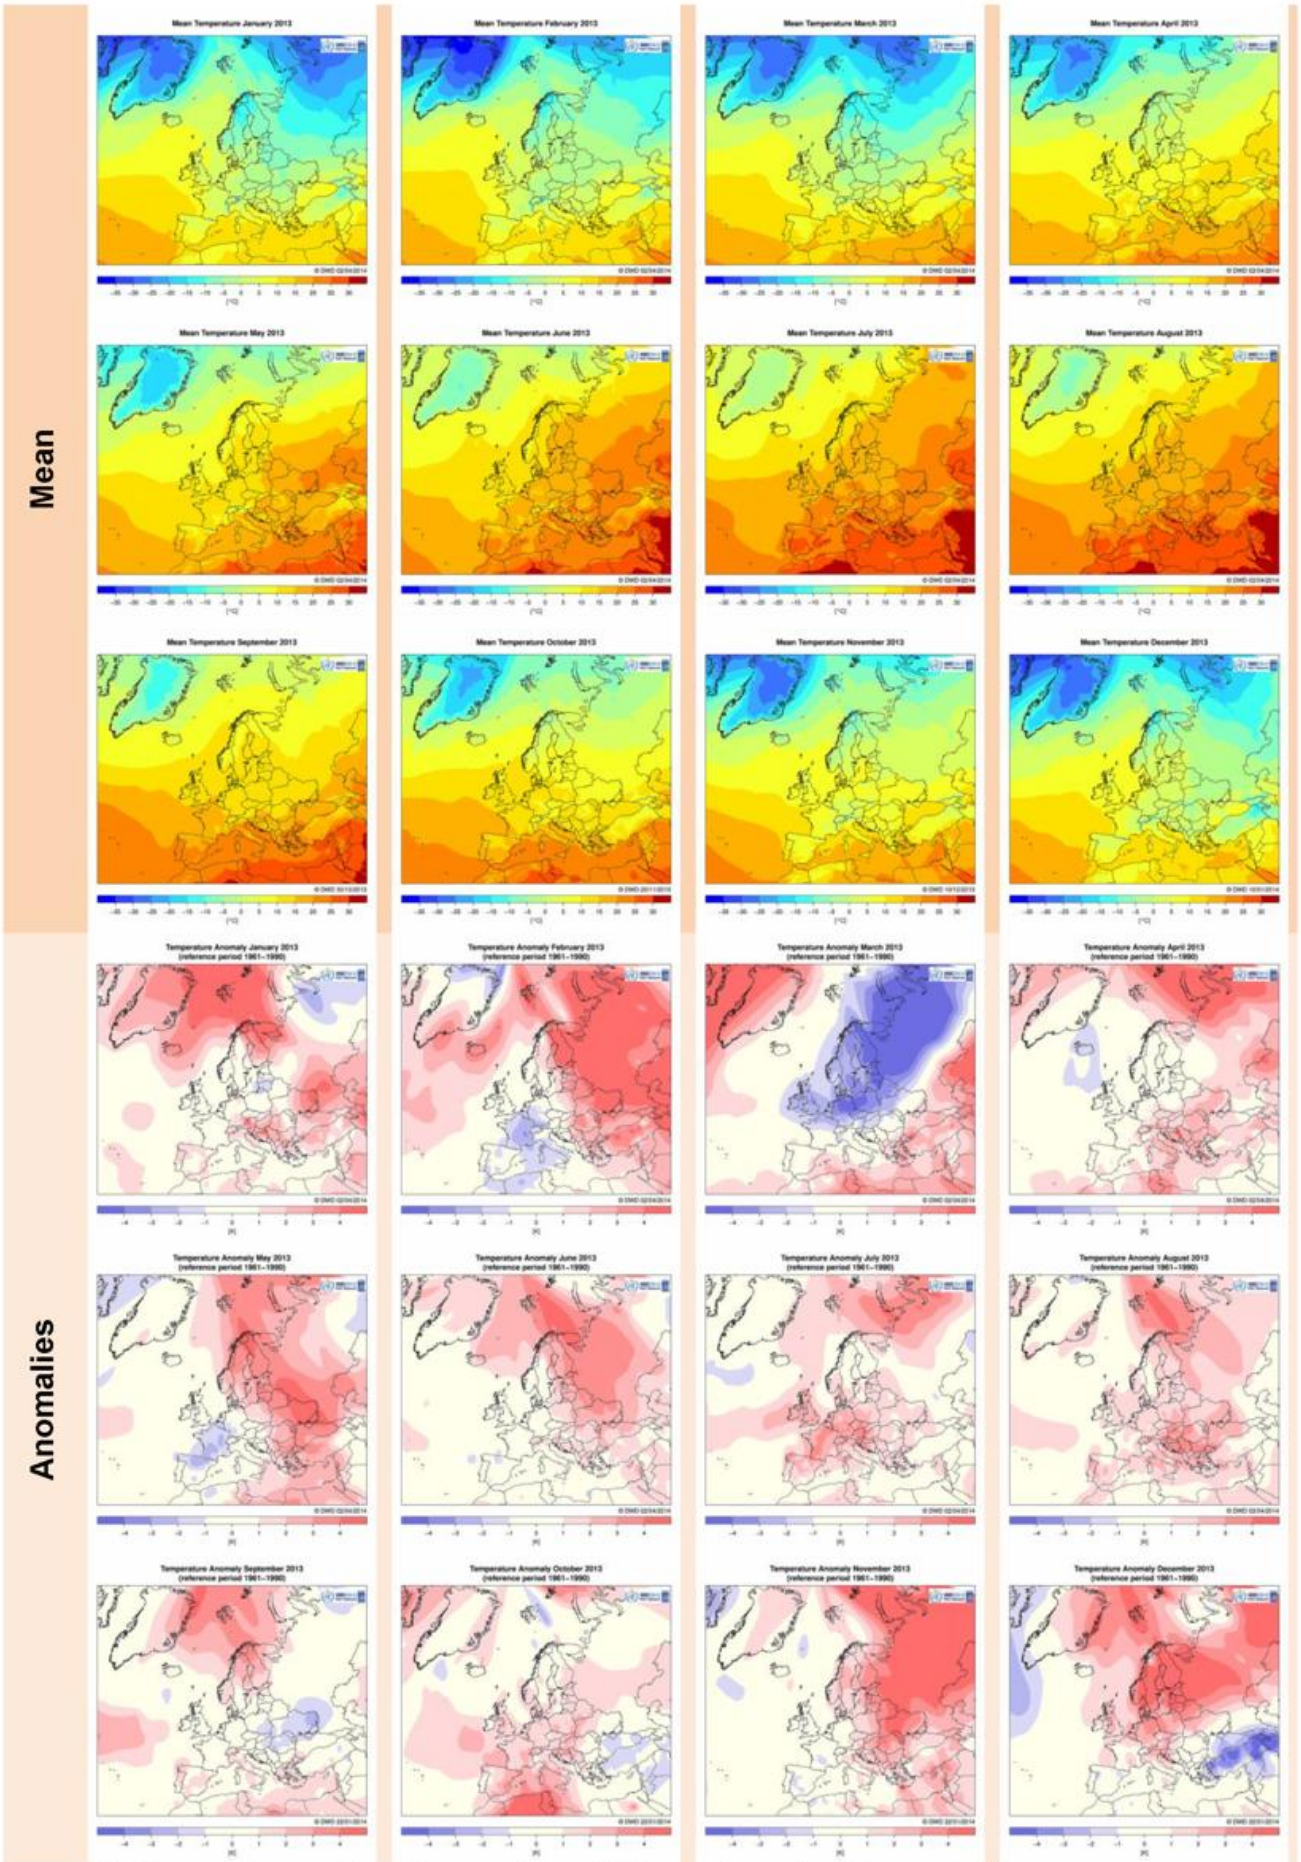

Figure 4.3: Mean and anomalies of temperature in °C for each month of the year 2013.

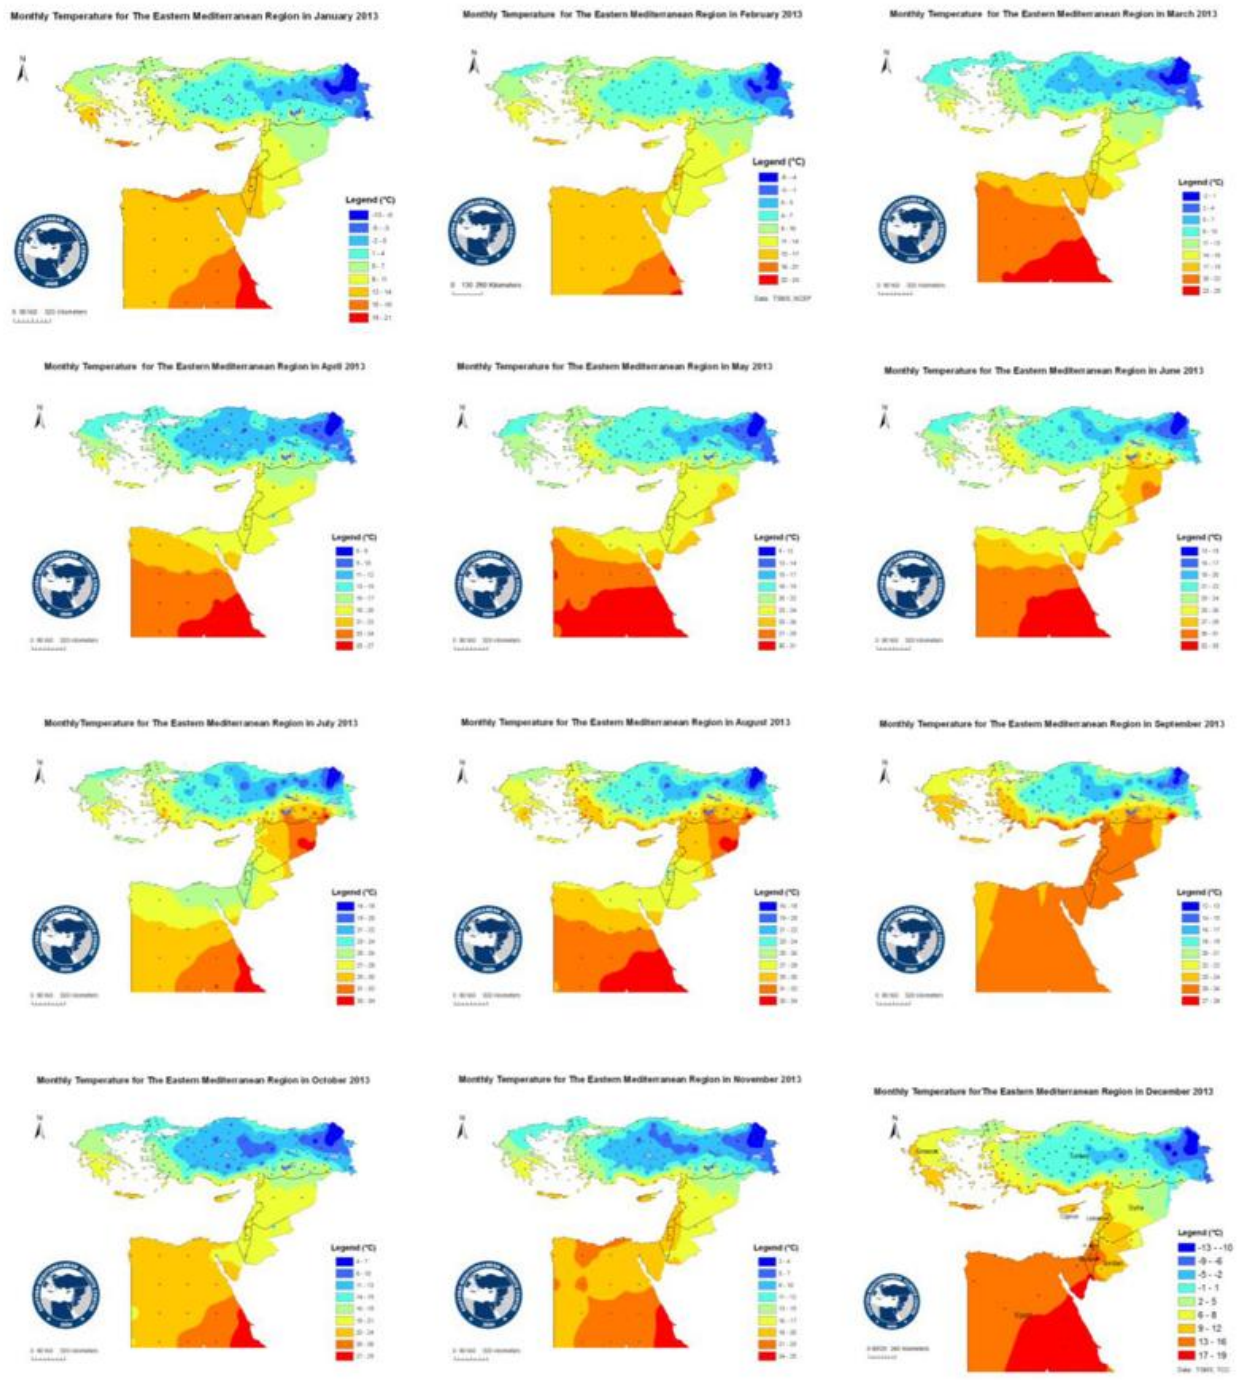

Figure 4.4: Monthly mean temperature (°C) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC)

4.3 Precipitation

In **January** 2013 the countries under the influence of the Atlantic as well as in the central and eastern Mediterranean Sea and in Middle East received partly much more precipitation than normal. More precipitation than normal was as well registered in eastern and south-eastern Europe and southern Russia. On the other hand much of UK, southern Scandinavia, the western central Europe, the western Mediterranean region, southern Turkey and northern Russia and Finland had less precipitation than normal. This pattern is widely consistent with the circulation anomalies.

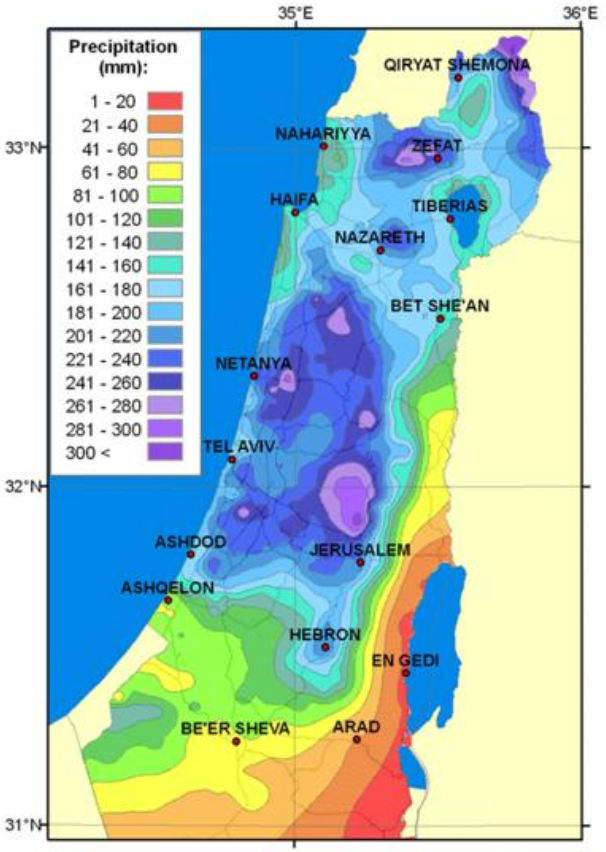

Figure 4.5 Precipitation totals (mm) in Israel for the episode 4 to 10 January 2013

Wetter than normal conditions existed in **February** on the northern Iberian, the Italian and western Balkan Peninsula as well as in western Turkey. Drier than normal were northern, western and central Europe as well as southern Russia and the Caucasus, the eastern Mediterranean area and the Middle East.

In **March** 2013 there was a broad band of higher than normal precipitation from the Iberian Peninsula over the western Mediterranean Sea, Italy, the Balkan Peninsula, the Ukraine and the Black Sea region to Russia. Also southern UK and northwestern France as well as the northwestern coast of Scandinavia were partly wetter than normal. Dry was on the other hand Iceland, most of UK and Ireland, Scandinavia, Denmark, Germany, Poland, the Baltic States, northern Russia as well as the southern and eastern Mediterranean Sea and the Middle East. In Spain it was the wettest March since 1947 with about 300% of its normal value. Also in Norway some stations recorded new records of March precipitation totals since 100 years or more.

In **April** 2013 there were positive anomalies of precipitation totals in the western Mediterranean Sea and southern (and central) France, in the eastern Mediterranean Sea, at the Atlantic coasts (except Portugal), especially in Scotland and southern Norway. As well regionally positive anomalies can be found in northern Scandinavia, the Baltic states and in Russia. Drier than normal were Portugal, UK except Scotland, northern central Europe, the Balkan states, Italy, the Ukraine, the Caucasus and southern Russia and the Middle East except the Mediterranean coasts. The surplus of the precipitation is partly related to events of heavy precipitation, see the events part below. Dry regions in northern Germany, in southern Scandinavia and in the east of the Black Sea coincide with regions of negative soil moisture anomalies (http://www.cpc.ncep.noaa.gov/).

Most of Europe, especially western and central Europe and even parts of the east saw a wet **May 2013**. Monthly totals exceeded 100mm or 125% of the May normal over much of that area. Particularly high precipitation fell in the Alpine region. Germany recorded its second wettest May since 1881 behind 2007, and Austria had one of the 5 wettest months of May since beginning of measurements. There was much rainfall throughout most of the month, but especially in the last week heavy precipitation caused an extreme flooding situation in eastern central Europe. Another area of high precipitation was located over the North Atlantic, affecting especially southern and southeastern coasts of Greenland and Iceland, northwestern Scotland and Ireland, and southern Norway (reaching new precipitation records there). Also in the Middle East there was more precipitation than normal. The northernmost parts of the European continent, on the other hand, were relatively dry, and so was also Iberia and areas around the Black Sea. Some locations north

of the Black Sea and in west Kazakhstan received less than 10mm of monthly precipitation, which was less than 20% of the normal; also southern Sicily was very dry.

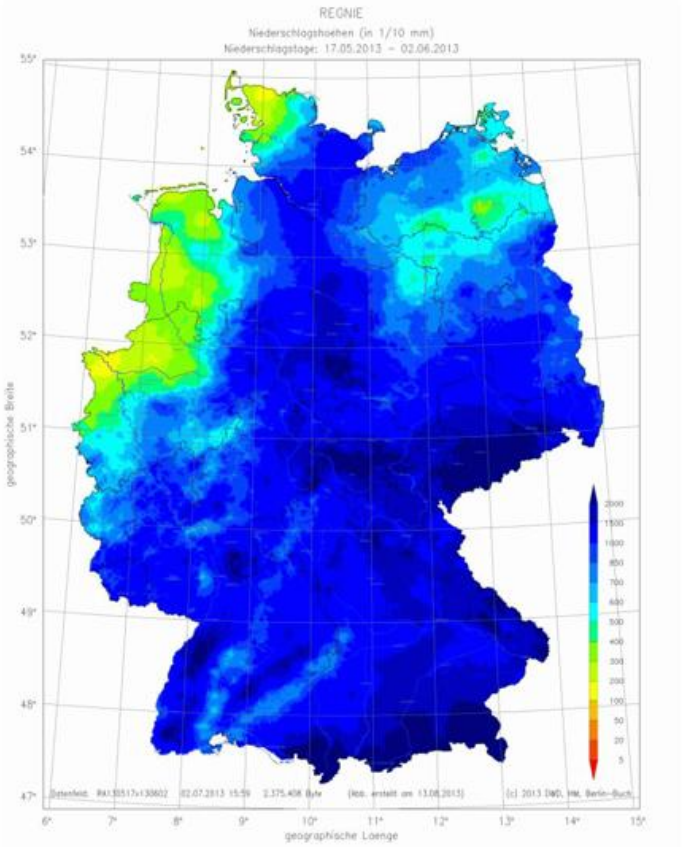

Figure 4.6: Precipitation totals (mm) in Germany for the period 17 May to 2 June 2013

Figure 4.7: High water marks in Passau, 2013, the second from the top (provided by Mrs Helga Nitsche, 10/08/2014)

Due to an extremely heavy precipitation situation with flooding especially in the Elbe and Danube River catchments at the beginning of **June**, monthly totals were very high especially in eastern central Europe, and new local records were achieved in several places. 48-hour totals on 2-3 June reached at least up to 275mm in Germany, exceeding clearly the normal for the whole June. Also some heavy rain after thunderstorms in the last third of the month contributed to a wet month there. Highest monthly totals fell in northern Austria with a local maximum of 475mm in Bregenz and new local June records. It was also very wet west of the Black Sea, in Scandinavia and over the eastern Atlantic and its coasts in southern Ireland, western France and northern Spain with monthly totals above 100 mm, locally above 150 mm or around twice the normal; in Bulgaria locally more than 300% of the normal, partly accompanied by large hail. Norway and the northern half of Austria received each 160% of its normal June total. It was the third wettest month on record in eastern Norway behind 2011 and 1987. In south-western France, much of the rain was contributed by heavy thunderstorms on 17-20 June. In Moldova, more than 100 mm fell on 30 June within a few hours. On the other hand, there were some quite dry areas as well that month, such as Iceland, United Kingdom, the Azores islands, most of Iberia, the Mediterranean and also large parts of eastern Europe, although several thunderstorms with heavy precipitation and large hail occurred in Russia and other parts of eastern Europe. Southern Iberia and southern parts of the Mediterranean regions received less than 10 mm that month, which was locally less than 20% of the June normal. It was also very dry near to the southern slopes of the Alps. Villach in southern Austria had its driest June since beginning of measurements in 1888. Turkey had less than 80% of the normal rain; however, it was not so dry like in June 2012.

July 2013 was drier than normal in Central Europe, on the Balkan Peninsula, on most of the Iberian Peninsula and most of the Middle East. It was wetter than normal in the northern North Atlantic/Arctic Ocean and adjacent countries, partly in eastern Europe and partly in the

Mediterranean countries. Highly convective situations with heavy to extremely heavy precipitation were often, not only in the wetter-than-normal areas. There are as well reports of extreme precipitation intensities of more than 50 mm within one or two hours (France). The convective events were partly accompanied with hail of up to 10 cm size especially in the last week of the month (Germany, France).

August 2013 was mostly drier than normal except in the Arctic Sea region, the western Mediterranean Sea region, and parts of Russia. Drought contributed to the development of forest fires. As well drought-related damages to agriculture occurred as reported for instance by Austria. Surplus of precipitation in the western Mediterranean, partly in the Alps and Germany, in Norway, northern and southern Russia in eastern central Europe and parts of the Middle East was often caused by heavy to extremely heavy precipitation.

September 2013 was wetter than normal in most of central and eastern Europe, in parts of the Mediterranean Sea and of the southern Iberian Peninsula and in parts of Greenland. It was on the other hand drier than normal in most of Scandinavia (except parts of Sweden), northern Russia, the British Isles, most of the western and the eastern Mediterranean Sea and Middle East. Especially around the Black Sea extremely heavy precipitation occurred and caused flooding. On September 13 at station Cahul, Moldova, 172 mm during 12 hours were registered, which is rank two for the entire observation period. At the same station during the 11-13.September 246 mm (50% of annual rate) the greatest amount of precipitation on the territory of Moldova during 1-3 days were measured, for the entire observation period the amount was 282 mm. A series of cyclones brought excessive rainfall in many areas of the Ukraine - from 265 % - 390 % of monthly normals. In some areas the monthly rainfall exceeded the rate of 4-5 times. The highest rainfall was recorded in Kyiv - 211 mm, and Zhytomyr – 202 mm. Wind gusts reached 15-23 m /s.

October 2013 was wetter than normal in northern Scandinavia and northern European Russia, on the British Isles except northern Scotland and western Ireland (Mullingar recorded its wettest October since the station opened in 1950), in western and central Europe, around the North Sea and in Denmark and southern Sweden, on the western Iberian Peninsula, northern Italy, around the Black Sea and in western Turkey, the eastern Balkan Peninsula and southern European Russia. In De Bilt, Netherlands October 2013 was one of the 5 wettest October months within 100 years. It was drier than normal in central Scandinavia, in the western Mediterranean and around the Adriatic Sea, in eastern central Europe and western central European Russia and the Baltic states and in Middle East.

November 2013 was drier than normal on Iceland, the British Isles, most of the Iberian Peninsula, the eastern Mediterranean Sea, around the Black Sea, in southern Russia and in western Kazakhstan. It was wetter than normal in Norway, western and partly southern continental Europe, Italy and the western Balkan Peninsula, the Middle East and northern European Russia. 200 to 300 mm and locally more than 300 mm fell at the Norwegian coast, in northern Spain, at the Adriatic coast and in southern Italy. Norway reported many new records of November daily precipitation totals. Most of them occurred on 16 November. Monthly totals of less than 10 mm were recorded in parts of the Iberian Peninsula, at the eastern Mediterranean coasts, in the southern Ukraine, in southern Russia and eastern Kazakhstan.

December 2013 was wetter than normal on Greenland (except the southernmost part), on the British Isles, in Scandinavia and northern Russia. It was also wetter than normal in eastern European Russia and the Middle East. In Denmark it was the 2nd wettest December since 1874. In Ireland it was the wettest December at single stations since 7 to 24 years. In Norway December 2013 was the 2nd wettest since 1900 (after 1975) for the whole country and in the region Agder it was the wettest. In Scotland it was the wettest December since 1910. Precipitation totals and precipitation surplus were partly remarkable with above 300 mm resp. above 167 % in some areas. On the other hand much of central Europe and most of southern, eastern central and south-eastern Europe was drier than normal. Montenegro reported only 2% to 35% of the climatologically mean. In the Mediterranean Sea area the spatial variability between wetter and drier regions was great. In the dry areas on the Balkan Peninsula and Middle East partly monthly totals were below 10 mm.

A severe storm with high precipitation totals and significant snowfall amounts occurred in **Israel** on 10-14 December, 2013. An upper air trough, with extremely cold air from North Russia and a low level depression, affected the Eastern Mediterranean. These systems prevailed for 3 days, enabling the conditions for significant rainfall and snowfall.

The precipitation was more significant in the central and southern parts of the country with amounts of 150-250 mm. In the southern coastal plain, 250-300 mm were measured, with a few stations receiving more than 300 mm. In the northern parts of the country the rainfall amounts were 70-150 mm (**Figure 4.8**).

Comparison of this event's accumulated rainfall to the accumulated rainfall (for 4-5 days) in previous years, reveals that in most stations in the southern coastal plain and the Judean Mountains, similar or more significant rainfall occurred only once since records began in the 1940s-1950s. That happened in late November through early December 1991.

In addition, significant snowfall occurred in the mountain regions. In central Israel mountains (the Judean mountains, Jerusalem and part of Samaria) the snow began in the morning hours of December 12th, ceased later and then resumed during the evening hours. The snowfall continued throughout the night and the following day, December 13th, with extremely low temperatures. It continued until December 14th. The snow depth in Jerusalem reached 50 cm (elevation of 800 m). In higher places like the Hebron Mountains and surroundings (elevation of 900-1000m) the snow depth was 50-70 cm, and in the peaks of northern Judea and Samaria, there were reports of 70-90 cm of snow (**Figure 4.9**).

The snowfall was very unique regarding its depth and the time of the year it occurred. Snowfall does occur in the mountain regions every year or two, but usually its depth is no more than a few cm. 10-30 cm of snow is less frequent and falls, generally, in January or February.

Snowfall reports in Jerusalem date back to the 19th century and since then such a significant snowfall has not been recorded in the first half of December (it happened only once at the end of the month, on the 28-29th of December 1879). Regarding all the winter months, there were only three other events with similar or more significant snow depth since the beginning of the 20th century (1920, 1950 and 1992, all in February).

In the northern mountains, the snow fell mostly on December 13, reaching a depth of 40-60 cm in the northern Golan and 30-50 cm in the Upper Galilee. There were also reports of 1 meter of snow in the peaks of the Upper Galilee. In all regions, temperatures remained very low after the storm had ceased, resulting in a slow melting rate of the snow, which remained on the ground for more than a week after the end of the event. The severe amounts of snow caused heavy infrastructure damage, including power outages in tens of thousands of homes and road closures with many drivers stranded.

During the event, extremely low temperatures were measured. On December 13th, the maximum daily temperatures were 12-13°C below December's daily maximum average, reaching as low as 7-8°C in the coastal plains and about 0°C on the northern and central mountains picks. This deviation from the monthly mean was very exceptional taking into account the maritime characteristics of the Mediterranean climate. In Zefat - Har Kenaan, temperatures were below 0°C all day long (minimum -1.2°C and maximum -0.3°C). Since records began in 1939, there were only three occasions in Zefat with lower or similar maximum daily temperatures, none of them in December (February 1950, January 1992 and February 1992).

After the storm passed and the sky cleared, a rapid nighttime cooling occurred and in the early morning of December 15th, extremely low minimum temperatures were measured. In the Merom Golan Picman station (in the Golan Heights), the minimum temperature was as low as -13.6°C, a record-breaking low since records began there in 1978 .

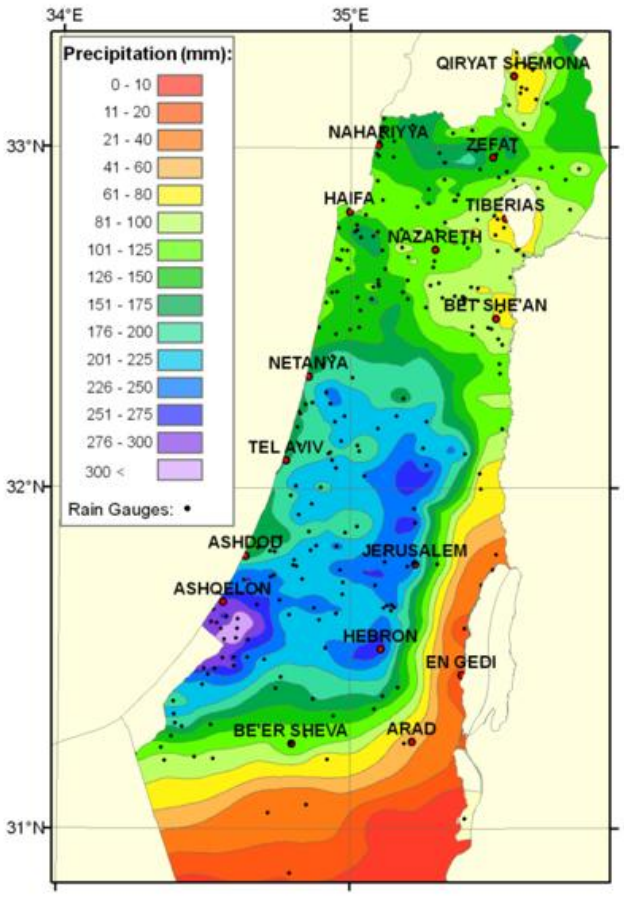

Figure 4.8: Accumulated precipitation (mm) in Israel on 10th-14th December 2013.

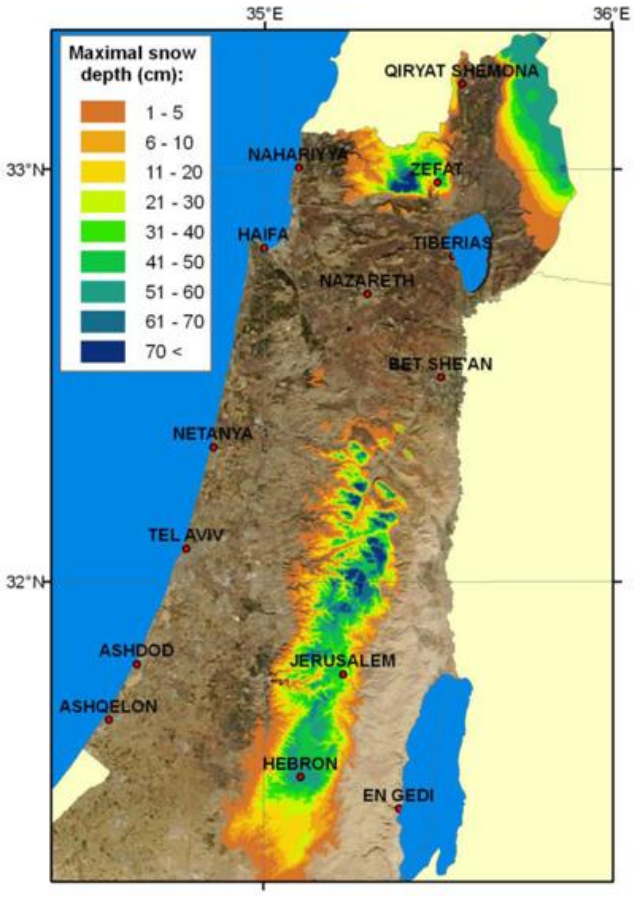

Figure 4.9: Maximal snow depth (cm) 11-14 December 2013

The map in **Figure 4.9** is based on a model that links between altitude and snow depth according to reports of about 50 observers. This basic model underwent minor changes especially in the marginal areas of the snow, based on reports regarding the presence or absence of snow in these areas. (for more information see http://www.ims.gov.il/IMSEng/TRAINING/Reports+and+Publications/Reports+and+Publications

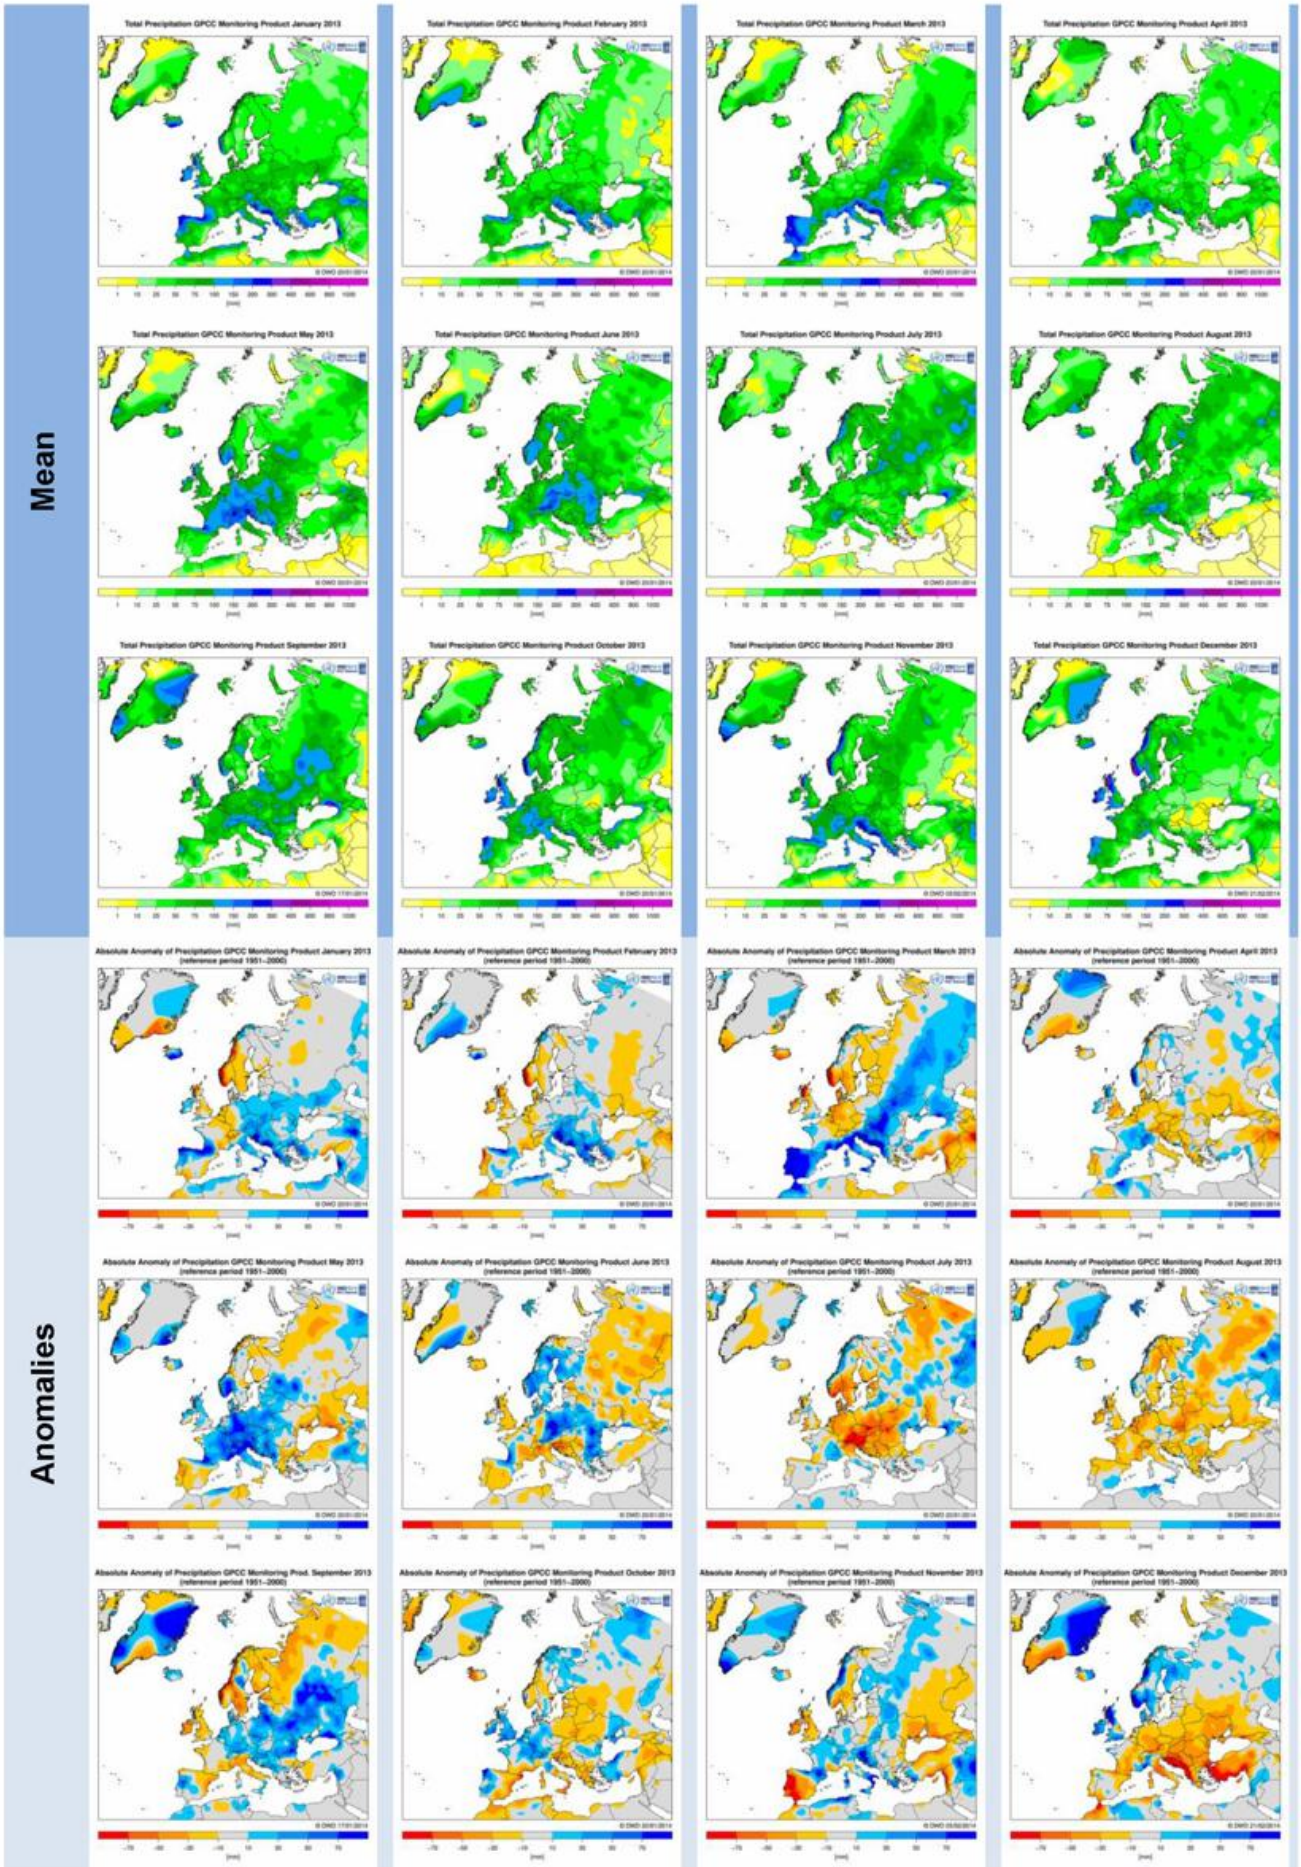

Figure 4.10: Monthly precipitation totals and anomalies in mm/month for each month of the year 2013.

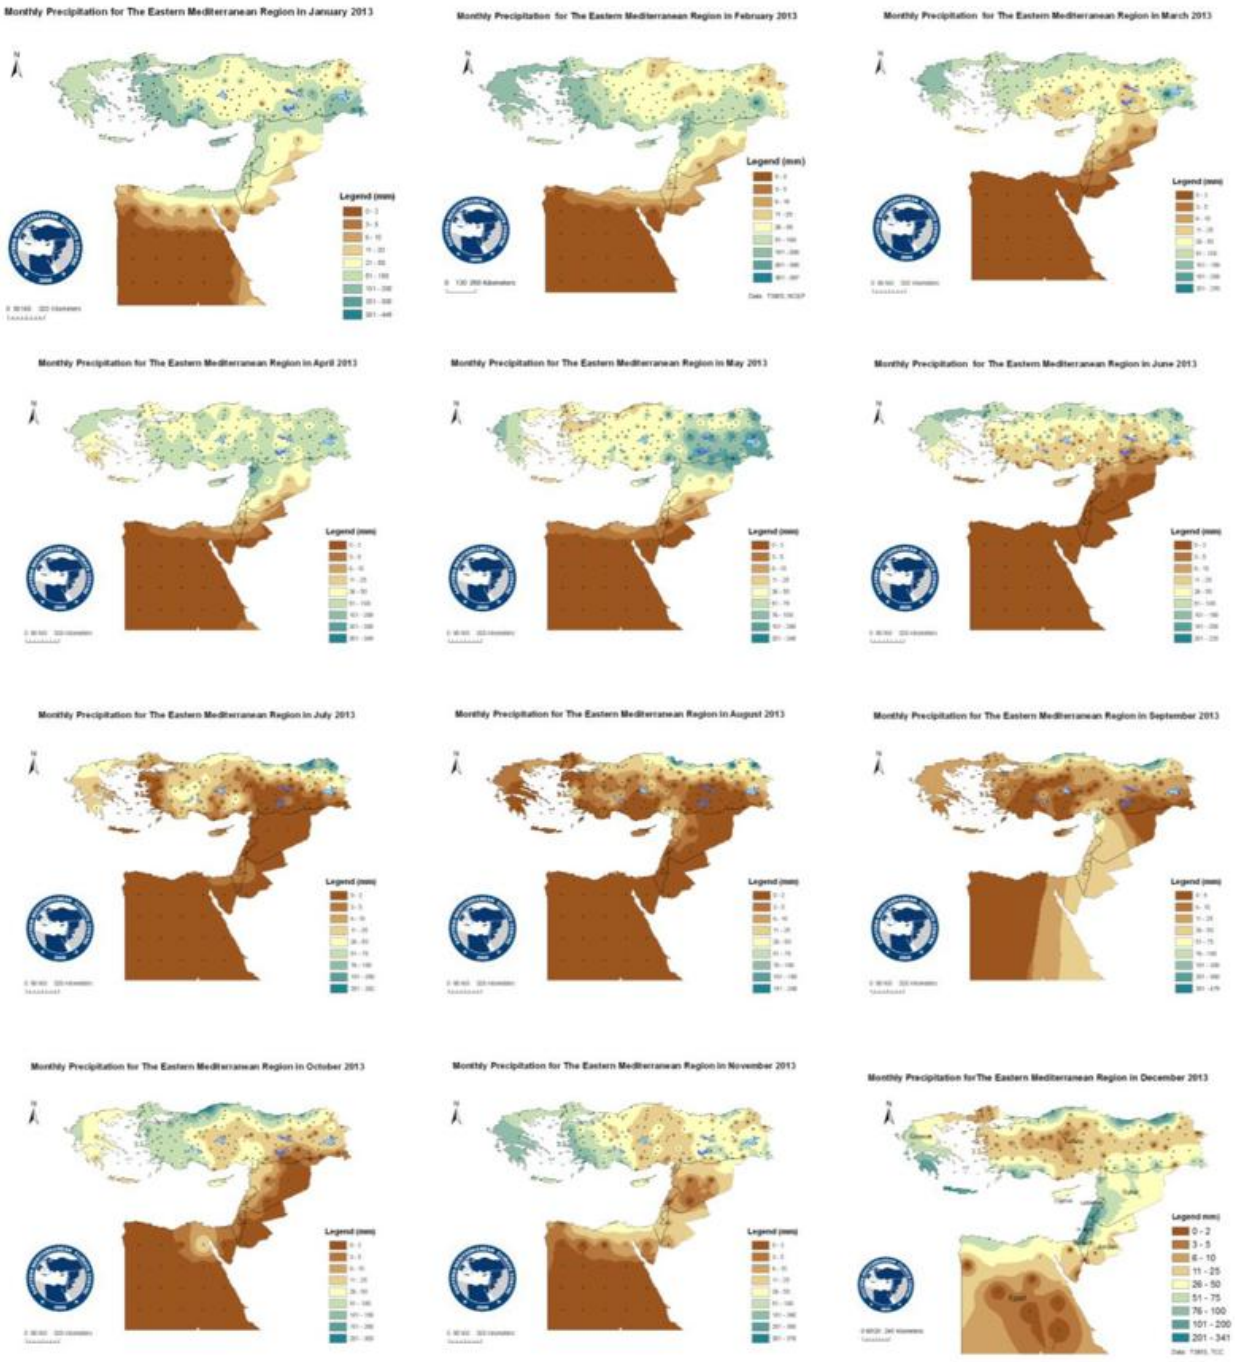

Figure 4.11: Monthly precipitation totals (mm) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC)

4.4 Sunshine duration

January 2013 was remarkably dull in Europe except in the Mediterranean region and Middle East, central and eastern Europe, the north of Europe and the southern Ukraine had less than 25 percent of the normal while the south-eastern Iberian Peninsula, southern France and partly Middle East received 150 % of the normal. In France January 2013 was one of the dullest January months since 1950, together with January 2004and January 1970. In Germany January 2013 was the dullest since 1951.

February 2013 was dull in most of the area with few exceptions: more sunshine than normal was recorded on the British Isles, most of the Iberian Peninsula and south-western France, southern and northern Norway, the Baltic States and Turkey. The dull areas over central and eastern central Europe as well as in northern Russia correspond to a monthly mean of 7 to 8 octas for the cloud cover. Remarkable is the 'sunny' area in northern Norway and Sweden which corresponds to an area of less than 2 octas of cloud cover as a monthly mean. This value is comparable to the Mediterranean Sea but in this season the monthly totals remain here below 50 hours.

In **March** 2013 the north with Scandinavia, the Baltic States and northern Russia as well as northern Germany and Denmark, Poland and the Ukraine had higher than normal sunshine. Most of the other countries were close to normal or partly dull. The dullest area was southern Russia. It was also the sunniest March on record at several Swedish stations.

Less than normal sunshine duration in **April** 2013 was measured over southern France, Switzerland, north-western Italy, central and southern Germany and western Czech Republic corresponds to the low pressure in the western Mediterranean Sea. The monthly mean of the cloud cover here was 6 octa or more (www.dwd.de/rcc-cm, products-cloud cover).The regions with higher than normal sunshine duration correspond to not more than 10 dull days. In Denmark April was very sunny, the second sunniest since 1920.

Due to frequent cloudiness with precipitation, **May** 2013 was very dull throughout western and central Europe. Especially most of France, Switzerland and Germany received less than 150 hours of sunshine, which is less than 75% of the normal, locally less than 100 hours or 50%. More than half of France had new records of low sunshine in May. In contrast, it was sunnier than normal in most of northern and eastern Europe and in the Middle East, partly also in southern Europe. Highest durations of sunshine in Europe were recorded in eastern Sweden and at the northern coasts of the Black Sea with more than 350 hours or more than 125% of the normal.

It was very sunny in most of eastern Europe and the Arctic region, locally with more than 125% of the climate mean. On 6 **June** 2013, sunshine duration in northern Lapland was nearly 24 hours. Also parts of central Europe, the western Mediterranean, Iberia and southern Ireland saw a relatively sunny month. Sunniest areas were in Russia and southern Iberia, both with more than 350 hours of sunshine. In contrast, it was mostly dull over north-western and western Europe. Reykjavik (Iceland) had the dullest June since 1995. Turkey and the Middle East, too, were much duller than normal.

July 2013 was mostly sunnier than normal on the European continent except partly in the Mediterranean countries and in northern Scandinavia and the Baltic countries. Less sunshine than normal occurred partly in the eastern Mediterranean countries and the Middle East and in western European Russia. The sunshine surplus reached exceptional values in some countries, for instance in the northern parts of France (45 to 63 percent, based on the 1991-2010 reference). In Germany July 2013 was the 2nd sunniest July since 1951. Slovakia reported an absolute record in monthly sunshine duration in its observational history at station Bratislava with 390 hours.

August 2013 was mostly sunnier than normal except on the British Isles, the eastern Mediterranean Sea and the Middle East and parts of Russia. The surplus of sunshine duration was most impressive for Poland where the absolute anomaly amounted up to 60 hours. Also rather high positive anomalies occurred in Scandinavia around the northern Baltic Sea as well as in the northernmost regions of Russia.

September 2013 was sunnier than normal in northern Europe except northern Sweden and in Spain and southern France and Italy. It was dull in eastern Europe, especially in Russia where only less than 50 percent of the normal sunshine duration or even less were achieved in the central parts. It was as well dull in most of central and western Europe.

October 2013 was sunny in most of Scandinavia, from Poland southward to Greece and southern Italy, in Spain and in Turkey and Middle East. Elsewhere it was dull or normal.

November 2013 was relatively sunny for most of Scandinavia, the British Isles, Denmark and northern Germany as well as northern parts of the Baltic States, on most of the Iberian Peninsula, most of Turkey, eastern Hungary, Romania and Moldova, south-eastern Ukraine and southern Russia. Elsewhere it was mostly relatively dull. The dullest area covered northern Russia with partly below 50 or locally even below 25 percent.

In good consistency with the mean sea surface pressure **December** 2013 was sunnier than normal from most of the Iberian Peninsula over the western European continent and south-eastern UK, central, southern, south-eastern and parts of eastern continental Europe. It was less sunny than normal over Ireland and northern UK, Denmark and southern and northern Scandinavia, most of Russia and Middle East. December 2013 has been the 7th richest December in sunshine since 1951 in Germany. Relative sunshine surplus was above 150 percent in parts of the sunnier-than-normal area whereas northern Russia received less than 25 percent of the 1961-1990 normal.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 52 individual countries) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Climate and the State of the Climate Article published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ amongst the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes 4 parts: the annual, seasonal and monthly survey of the climate state in 2014 as well as contributions of the NMHSs to the long-term variability of selected parameters up to 2014 (section 5).

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collection Centre (GCC), run by Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), run by Deutscher Wetterdienst
- Sunshine: CLIMAT data.
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

Sub-regional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC).

Box 1

Notable anomalies and events 2014

Anomalies

Temperature

- A record breaking year in many European countries (see **Table 2.1)**.
- This year was globally the warmest year on record, according to four independent surface temperature observational analyses.

Precipitation

- Record snow south of the Alps in January and February of up to 7 meters
- Long drought within the rainy season in Israel and Jordan.
- 12th-17th May extremely heavy precipitation over the Balkan (Croatia, Bosnia and Herzegovina, Slavonia, Serbia) with catastrophic floods.
- In September Italy was affected by frequent thunderstorms and heavy convective precipitation. The country reported a record-breaking monthly rainfall total of 479.3 mm along the Adriatic coast and on 3rd September a record-breaking daily total of 167.2 mm.

Sunshine Duration

- Sweden experienced its sunniest September on record, with 243 sunshine hours observed in southern and central Sweden.

Other Anomalies

- In January and February the western and northern coasts of the Iberian Peninsula were affected by strong winds and high swell waves of up to 15 m, on 9 February, caused by a storm whose core pressure was falling ~29 hPa in 24 hours.
- 12 winter storms form December 2013 until February 2014 over the North Atlantic affecting Western Europe (Ireland, the UK, northern Iberia and western France) with damages, heavy precipitation and flooding.
- Catastrophic flood over the Balkans in 12–20 May 2014. From the flood in the lower Sava river basin eastern Croatia, northern Bosnia and Serbia were affected.

Events:

- On 2nd March an intense dust storm occurred over the eastern Mediterranean Sea and was visible in satellite images.
- On 8th and 11th March Norway and Sweden were affected by two storms within a few days, with wind gusts of up to 49.6 m/s at station Tarfala (in Sweden on 8th March).
- Extreme precipitation and floods recorded in southern France during 16–20 and on the 29th September 2014 (Montpellier 299.5 mm/24 hours on the 29th).

The following sub-regions are used in this Bulletin:

Central and western Europe (14 countries): *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, United Kingdom*

Nordic and Baltic Countries (9 countries): *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden*

Iberia (2 countries): *Portugal, Spain*

Mediterranean, Italian and Balkan Peninsula (12 countries): *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia, Turkey*

Eastern Europe (5 countries): *Belarus, European Russia, Moldova, Romania, Ukraine*

Middle East (9 countries): *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, western Kazakhstan*

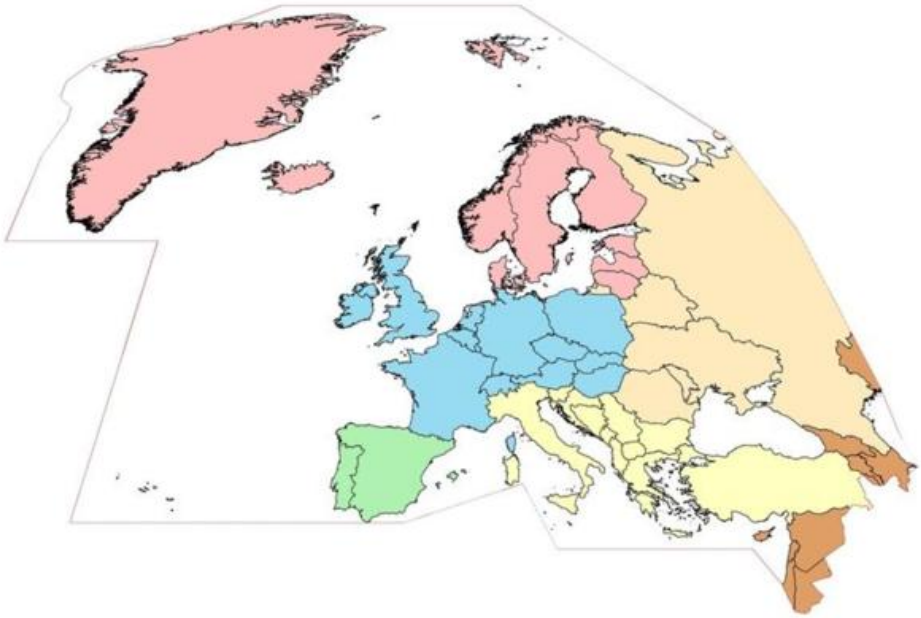

Figure 1.1: Definition of the 6 sub-regions used in this bulletin.

2. Annual survey

The climate of 2014 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2.5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2014 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea surface pressure, surface temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for each participant country. Long-term trends in temperature and precipitation indices were offered in section 2.2.

More detailed insight into the long-term variability of the temperature and precipitation and also some other parameters from the individual participant countries are presented in the section 5.

2.1. Annual averages and anomalies of selected essential climate variables

2.1.1. Sea level pressure

Generally, long-term mean annual sea level pressure distribution over the Region VI is dominated by a low pressure trough in the polar area (with exception Greenland) with the Icelandic low centred near Iceland and by the subtropical high pressure belt extended from the centre over Azores (Azores high) across southern, western and central Europe to European Russia.

2014 the mean sea surface pressure differs in some extend from the long-term mean with a reduced pressure especially in a region from Greenland to the British Isles with anomalies of -2 to -6 hPa and higher values over northern Europe (of more than 2 hPa). This is visible in the anomaly field for 2014 in respect to the normal period 1961-1990 (Figure 2.1 right). The anomaly configuration resemble especially the unusually pressure distribution in autumn (for more details cf. section 3.1.1 and 4.1).

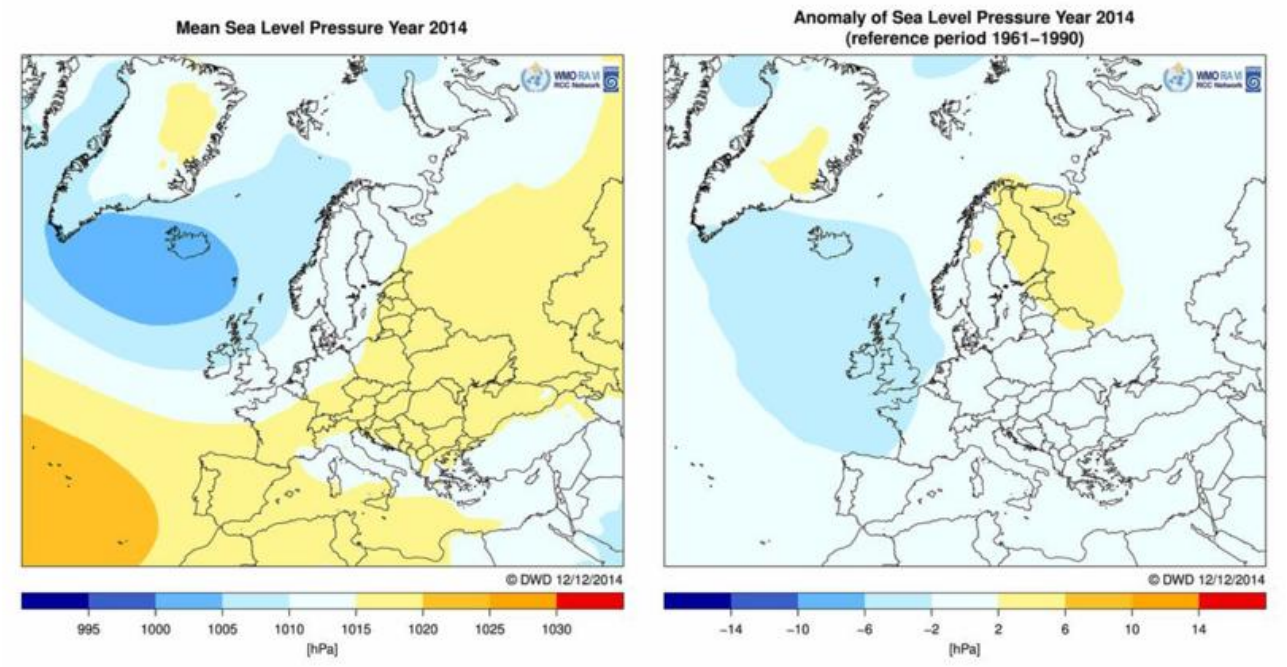

Figure 2.1: Annual mean of sea level pressure (left) and anomalies (right) for the year 2014 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

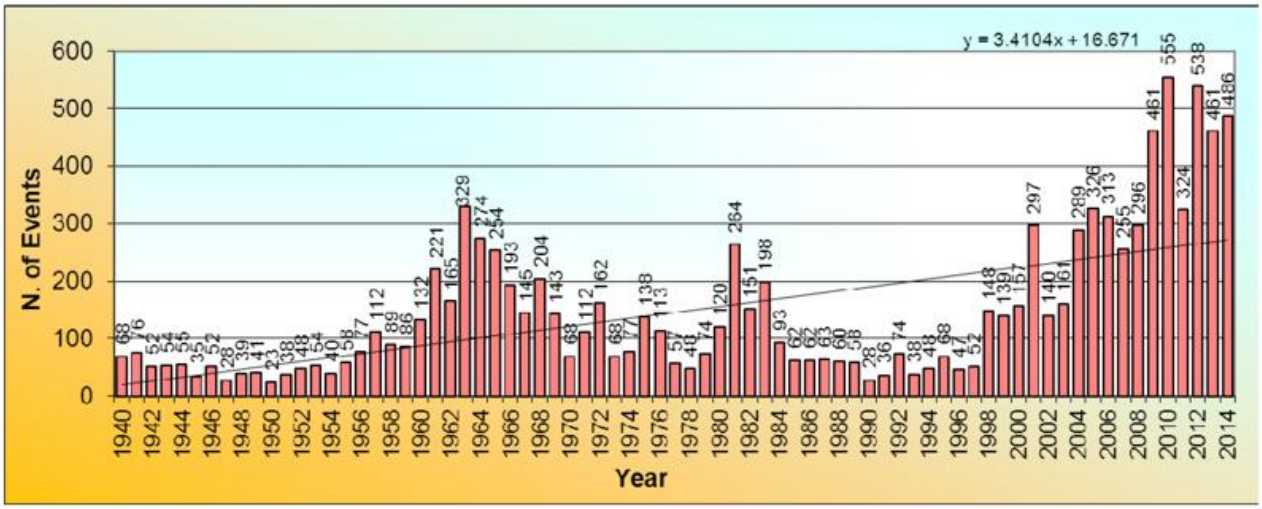

Figure 2.12: Annual count of extreme events occurred in Turkey from 1940 - 2014 (Diagram as provided by the NHMS).

The number of extreme events in 2014 has been reached to 486. (Figure 2.12). There is an increasing trend in extreme event (34events/decade).

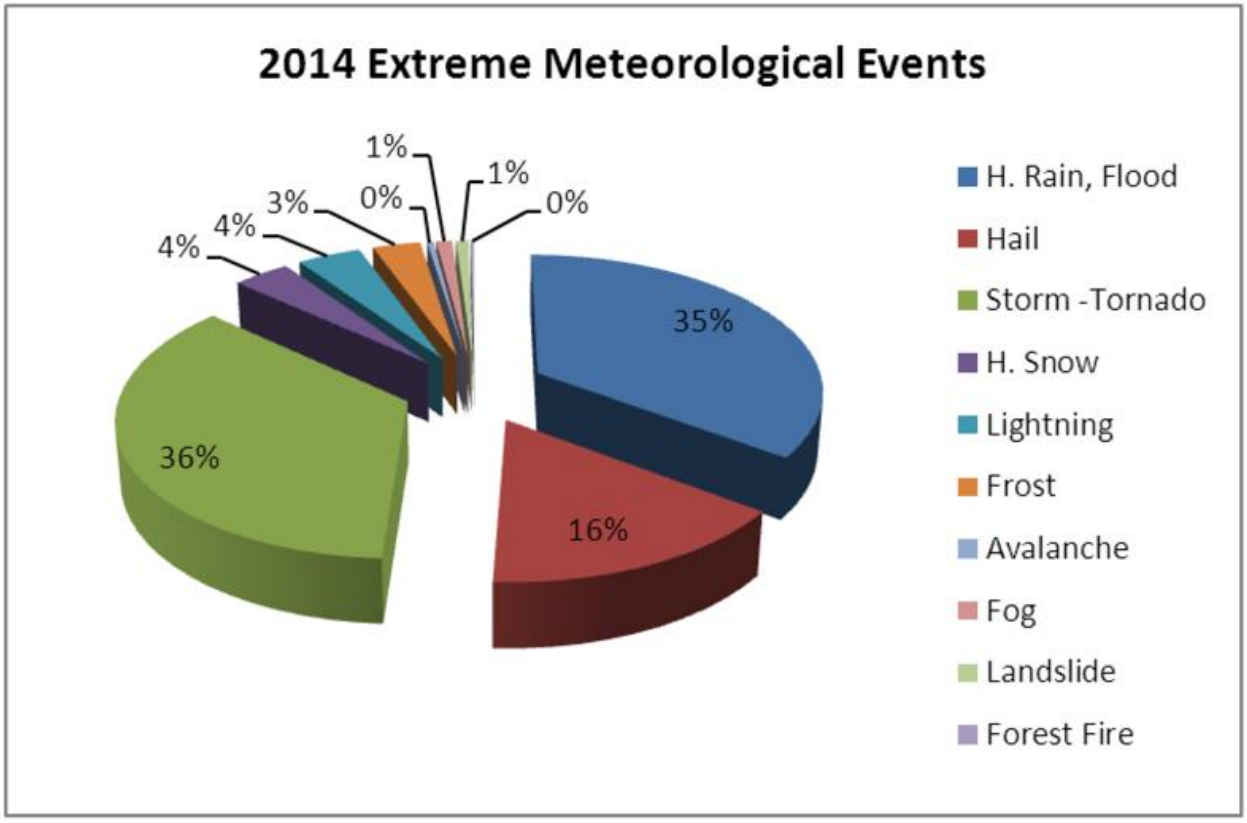

Figure 2.13: Distribution of extreme events occurred in Turkey in 2014.

During the year 2014 most hazardous extreme events in Turkey have been wind storm-tornado (36%), heavy rain/flood (35%), hail (16%), heavy snow and lightning (4%) and frost (3%) respectively (Figure 2.13). Although it's occurring rarely, 2 avalanches and 4 landslides also occurred in 2014.

2.1.2. Temperature

In the entire European region (35°–75°N, 10°W–30°E) the year 2014 was the warmest since 1950 with an anomaly of 0.9°C above the reference period 1981–2010 and of 1.46 related to 1961-1990. Many of the European countries reported new records (Table 2.1).

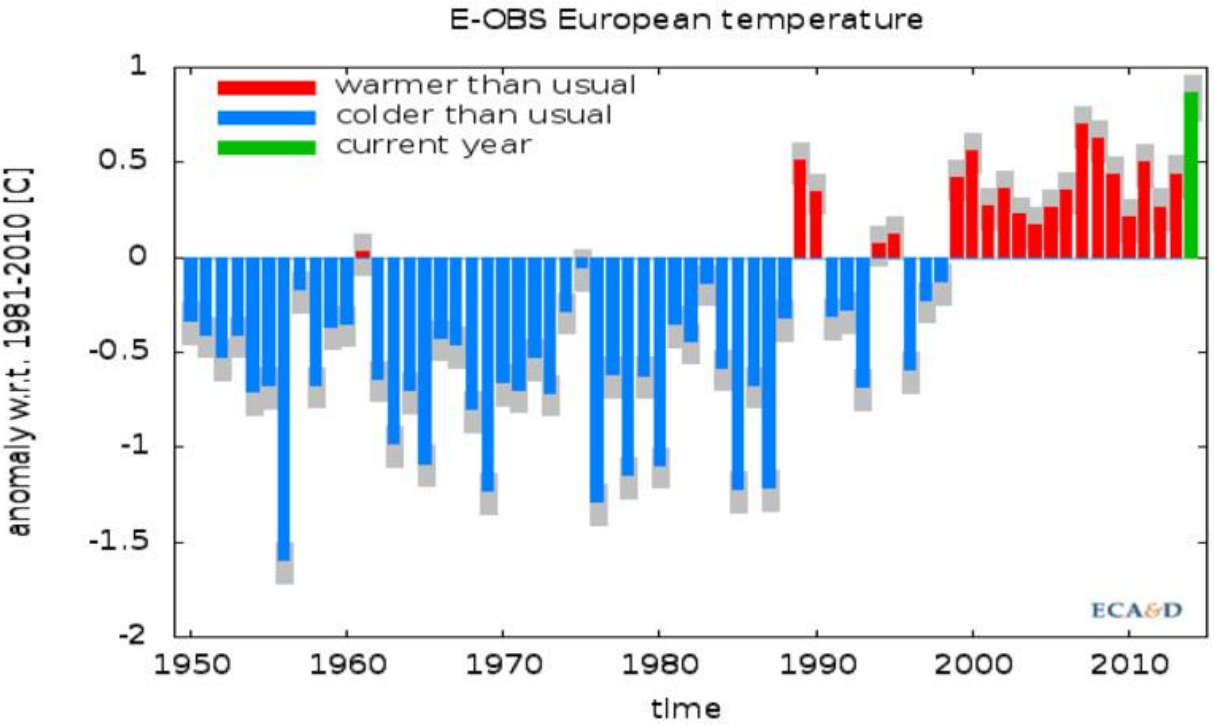

Figure 2.2: Annual temperature anomalies 1950-2014 for Europe (land area; 35°N - 75°N and 25°W - 45°E, reference period 1981–2010; source: www.ecad.eu, van der Schrier et al. 2013)

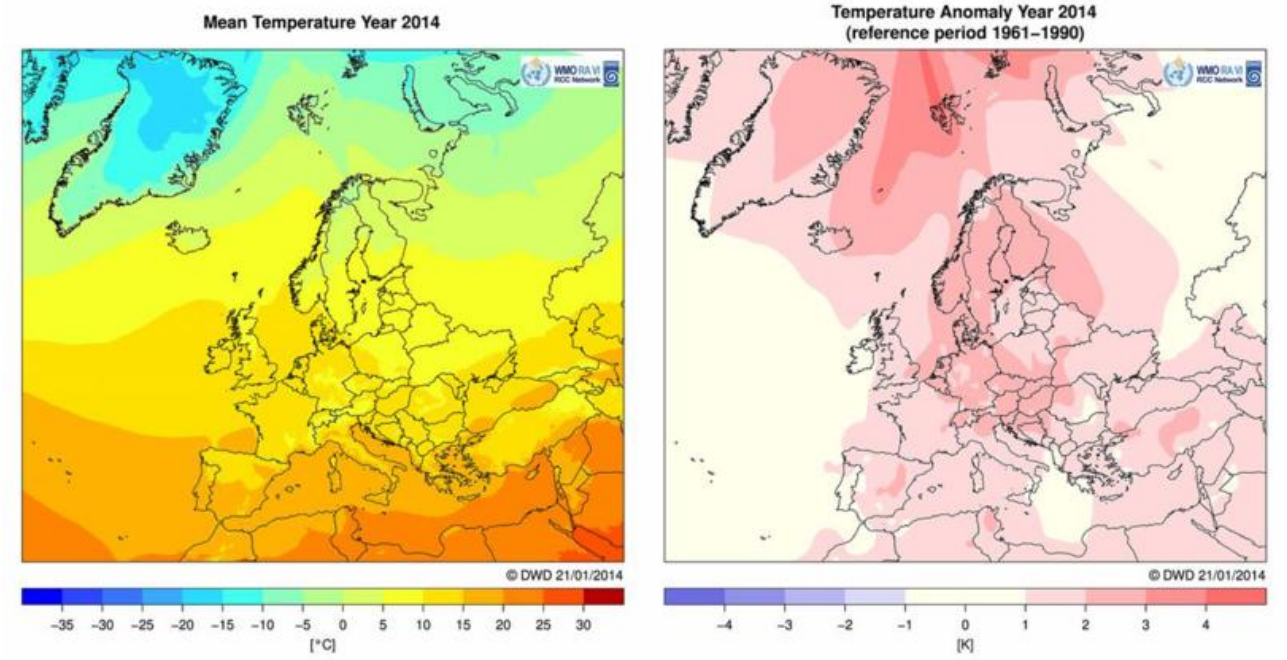

Figure 2.3: Mean annual temperature in °C (left) and anomalies (right) for 2014 (reference period 1961-1990. source: http://www.dwd.de/rcc-cm)

The highest annual anomaly of 2.09°C referred to 1961-1990 has been observed in the sub-region Nordic and Baltic countries followed by Central and western Europe (1.85°C) the Mediterranean,

Italian and Balkan and sub-region Eastern Europe (about 1.6°C). The sub-region Middle East showed the lowest anomalies of 1.26°C (Table 3.2). Nearly all months of the year were warmer than normal (1961-1990) with remarkably consistent deviations of +2 to +3°C especially in winter and spring across Central and Eastern Europe as well as Scandinavia (cf. section 3.1.2 and 4.2).

The global annual temperature average for 2014 increased also to a record high 0.57 ± 0.09 °C above the 1961–1990 average (WMO 2015, Blunden und Arndt 2015)

A summary of the annual temperature time series and the historical rating can be drawn from section 5. The rank statistics are listed together with the start of the time series and the anomaly for the year 2014 as provided by the as provided by the NHMS.

Table 2.1: Rank statistics and anomalies of annual temperature in 2014 from some participant countries as reported by National Meteorological and Hydrological Services (NMHSs).

Country	Rank of annual temperature in 2014	start of time series	Anomaly in °C	Reference period
Europe (35°–75°N, 10°W–30°E, E-OBS)	**1**	**1951**	**1.46**	**1961-1990**

Spain	2	1961	0.7	1981-2010
Sweden	1	1860		1961-1990
Switzerland	1	1864	2.1	1961-1990
Turkey	2	1971	1.4	1981-2010
United Kingdom	1	1910	1.6	1961-1990

2.1.3. Precipitation

The annual precipitation amount was close to normal over most of the continental Europe except for the Balkan region and parts of Italy, where significantly higher totals (>150% of normal) were recorded. Parts of northern and eastern Europe, eastern Spain, South Caucasus, and the Middle East showed drier conditions (totals <80%, locally <60% of normal). The annual figures of the year 2014 give only rough hints of the regions with outstanding precipitation events. Detailed descriptions such as the flood in Balkan in May 2014 can be found in the seasonal (3.1.3) and monthly survey (4.3).

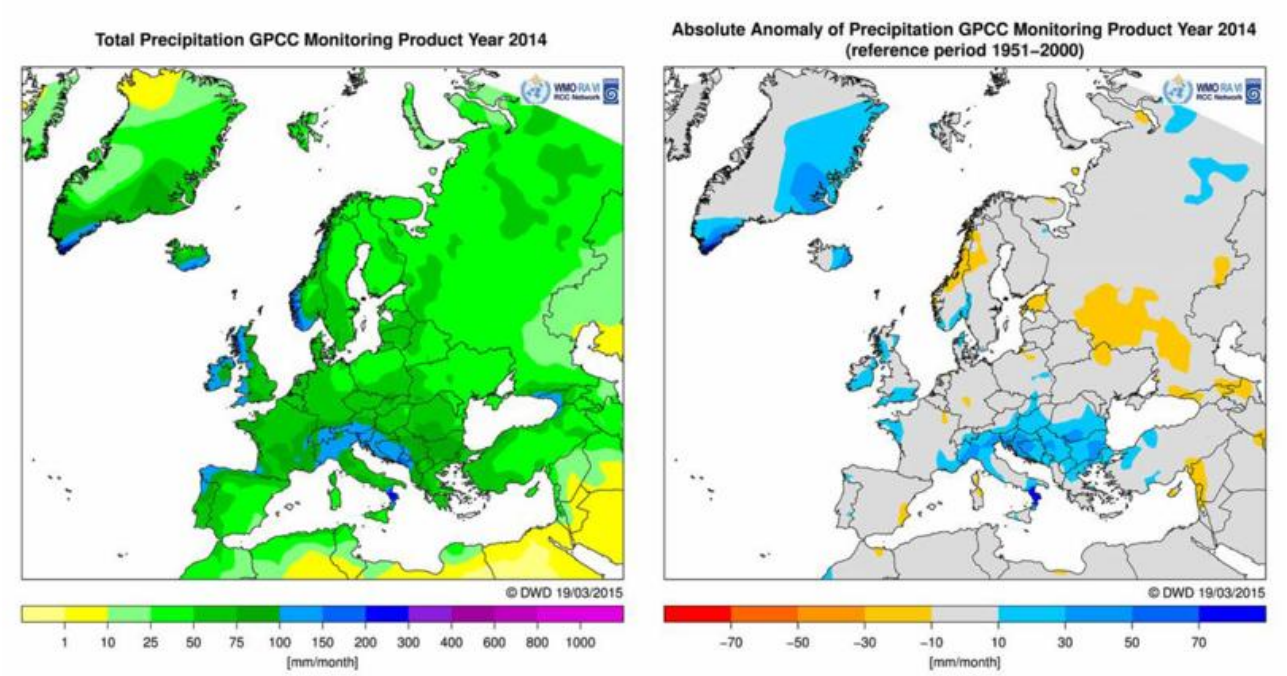

Figure 2.4: Total precipitation (left) and absolute anomalies (right) for 2014 in mm/month (reference period 1951-2000; source: http://www.dwd.de/rcc-cm)

2.1.4. Annual extreme values of temperature and precipitation

In this section an overview is given for the temperature spread and the extreme precipitation for each country. Absolute annual extreme values for 2014 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5 consecutive days with precipitation for each country in the WMO Region VI are given in Figure 2.5.

The spatial pattern of extreme temperature corresponds roughly to those of the temperature anomalies of 2014. The highest extremes (above 40°C) occurred primarily in sub-regions Middle East, Mediterranean, Italian, Balkan and Iberian Peninsula. Maximum temperature higher than 35°C are reported from most of the countries in central and western Europe, but also from some of Nordic and Baltic Countries. The one-day precipitation total (RX1) of more than 150 mm for individual countries documented in several sub-regions; the highest values occurred in France (299 mm/day) and Italy (330 mm/day). Highest total precipitation from 5 consecutive days (RX5) (above 300 mm) had been measured in Switzerland (476.6 mm), Italy (358 mm) followed by Austria (350 mm).

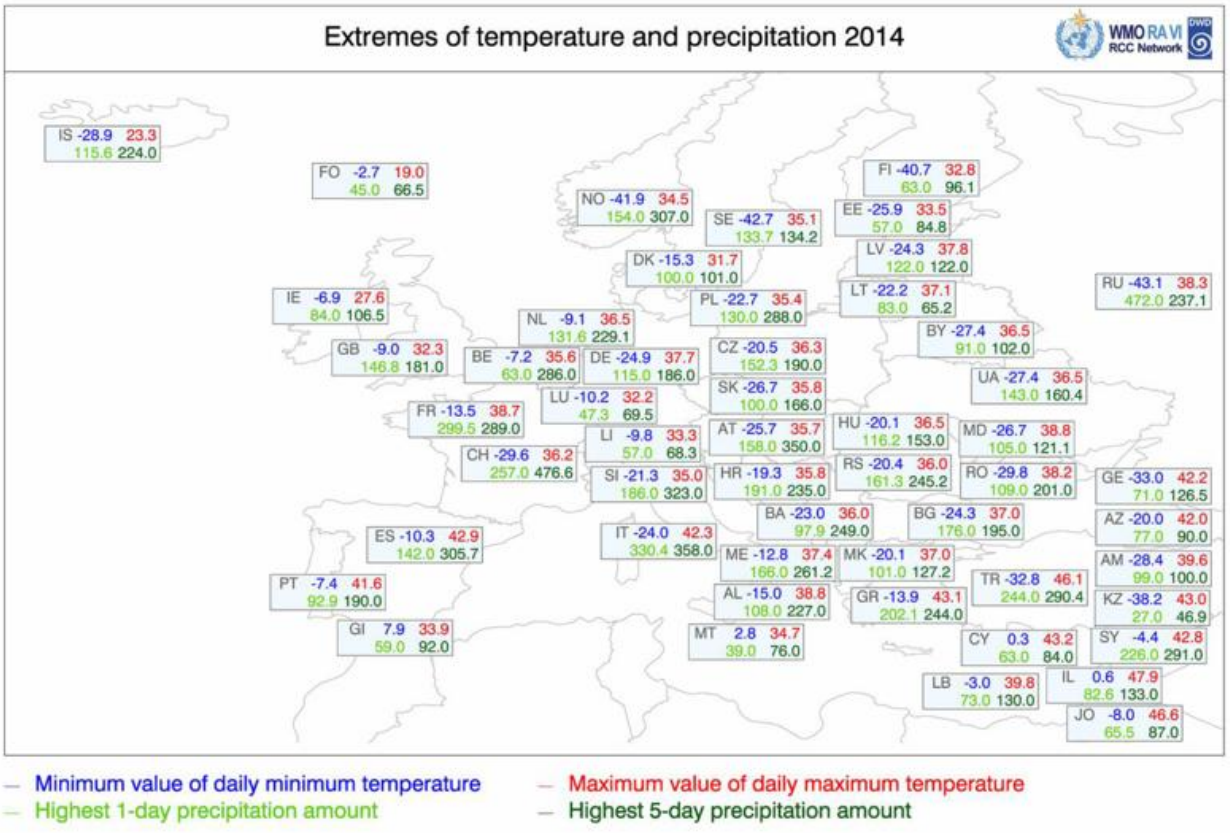

Figure 2.5: Annual extreme values for each country in 2014: first row: Internet country code, lowest daily minimum temperature (in °C, blue) and highest daily maximum temperature (in °C, red); second row: maximum daily precipitation totals (in mm, light green) and maximum 5-daily consecutive precipitation totals (in mm, dark green).

Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their Internet country codes. (Source: http://www.dwd.de/rcc-cm)

2.1.5. Sunshine duration

As expected, the annual sum of sunshine duration 2014 showed from the South to the North generally gradual decreasing values. More than normal sunshine hours have been primarily noted in most parts of Europe except in Portugal, northern and central Italy as well as in south-eastern and north-eastern Europe. Poland, Belarus and Ukraine showed in every season above normal sunshine.

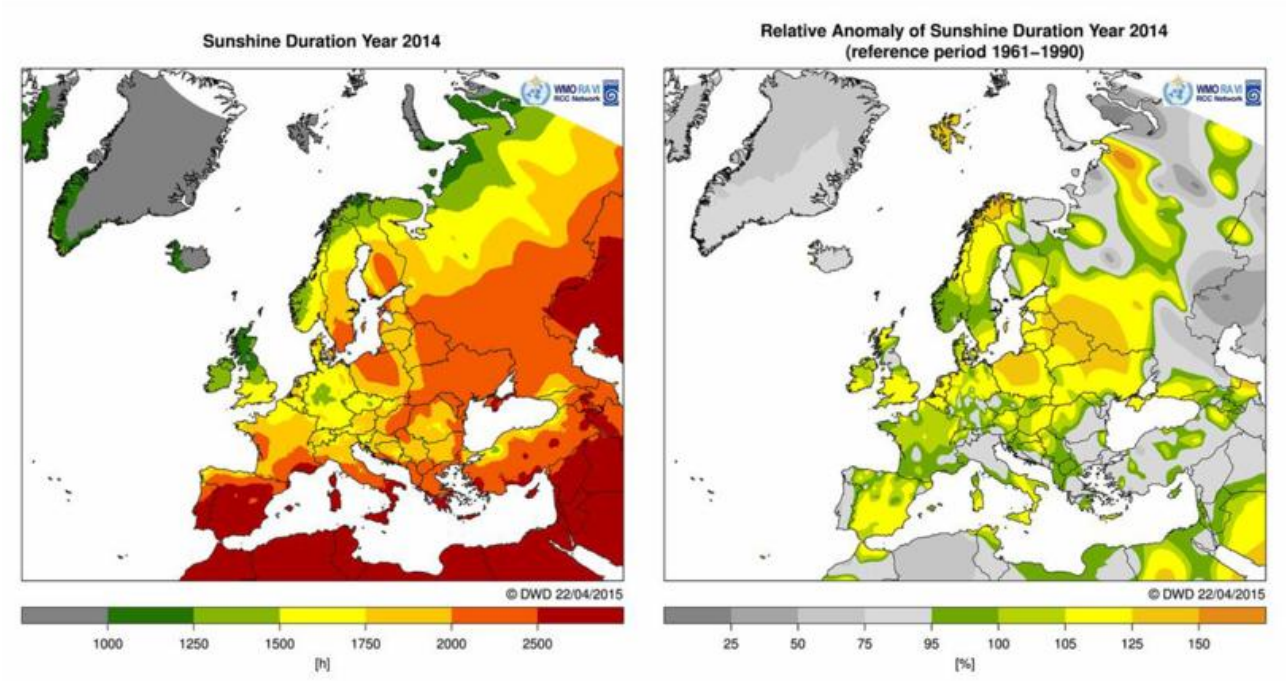

Figure 2.6: Annual sum of sunshine duration (left) and relative anomalies (right) for the year 2014 in hours with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.6. Drought situation

The drought index (SPI) in 2014 differs only slightly from its normal values. The anomalies in Central and Eastern Europe were slightly below normal and the Balkan region and northern Italy were moderate wet. In these areas annual precipitation was above normal linked with floods.

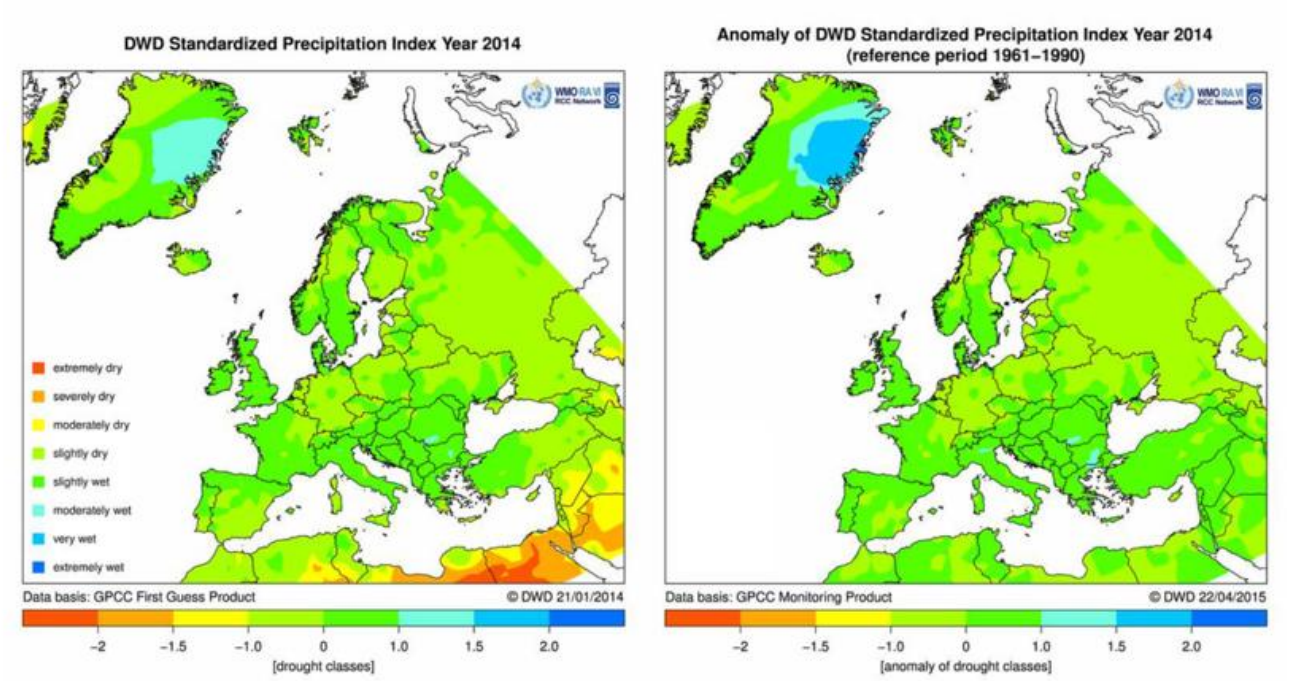

Figure 2.7: Annual modified Standardized Precipitation Index (DWD-SPI) for the year 2014 (left) and its anomalies (right) with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.7. Snow cover

The snow-season 2013/2014 (September 2013–August 2014) was warmer than normal. Therefore in many low land areas in west and south Europe no snow occurred at all. Apart from mountain areas, in the central Europe the partly occasional snow fall events occurred in January and February. As expected, towards the northern and eastern Europe the snow cover duration was longer and ended in early summer.

However, remarkable snow conditions prevailed in Austria and Switzerland.

The snow cover over most parts of **Austria** was well below average. Except in the upper parts of Carinthia and East Tyrol the snow conditions in January and February were remarkable. At some locations the amount of fresh snow was three times higher than the average.

In **Switzerland** the three winter months brought hardly any snow to the northern lowland regions. The meteorological station Zurich-Fluntern registered only 1 cm of new snow in January. It was the winter with the least amount of snow in the Zurich measurement series spanning over more than 80 years. In addition, the winter half-year ranked second in terms of lack of snow – there was only some additional snowfall amounting to 25 cm in November 2013. This was in strong contrast to the previous year when Zurich recorded a winter half-year with the most new snow for over 40 years (slightly above 2 m).

Record snow in Switzerland south of the Alps

From mid-December 2013 to February 2014 south-westerly and southerly currents were predominant in the Alpine regions. They brought enormous amounts of rain and snow to the areas south of the Alps. Lugano recorded by far the highest amount of precipitation since observations

started 151 years ago. It amounted to 698 mm - one third more than the total in the former record winter of 1950/1951. In Locarno-Monti the total even amounted to 754 mm. Here slightly less precipitation (722 mm) had been recorded in the previous record winter of 1950/1951.

As a result of the copious precipitation, a huge total of new snow was observed in higher regions south of the Alps. At the meteorological station Bosco-Gurin in the Ticino Mountains almost 7 m of new snow was recorded between December and February. This is the highest value in the measurement series available since 1961. Segl-Maria in the Upper Engadine received a total of 4 m in the three winter months, representing the second-highest value in the measurement series spanning 150 years. However, the record winter of 1950/1951 brought far higher new snow totals (up to 7 m) to these regions.

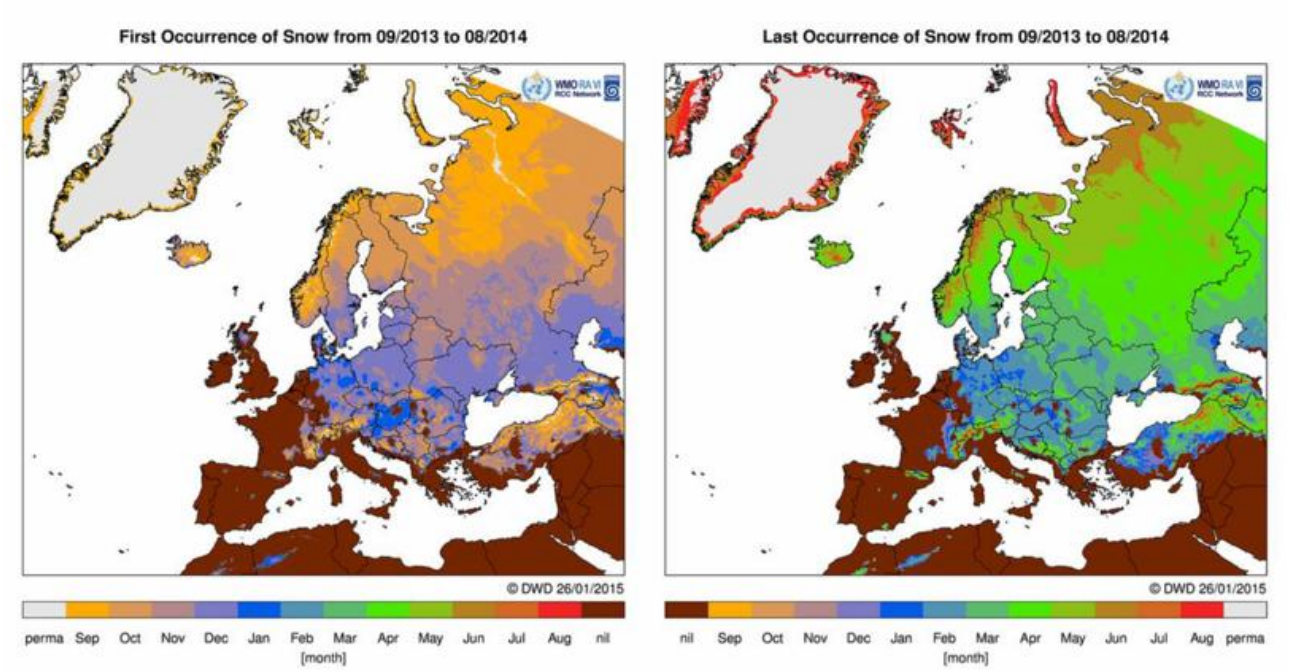

Figure 2.7: First occurrence of snow (left) and last occurrence of snow (right) during the snow-season 2013/2014. (Source: http://www.dwd.de/rcc-cm)

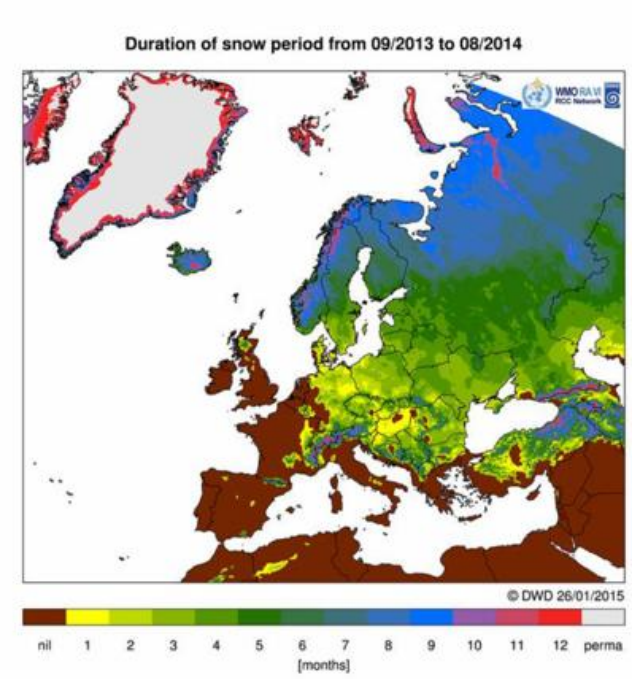

Figure 2.8: Duration of snow cover in the snow-season 2013/2014. (Source: http://www.dwd.de/rcc-cm)

2.2. Trends of temperature and precipitation indices 1951-2014

In this section, trend maps representative for the elements temperature and precipitation are shown. As reference period for these trend maps 1951-2014 was chosen.

In the north, northwest and eastern Europe most stations show an increase in the annual number of wet days (RR1) for the last 64 years while in southern Europe a decreasing trend prevails. The decreasing and increasing trend at neighbouring stations indicate inhomogeneities in the time series. The number of warm and wet days (WW) increased over whole Europe with exception of Greece. The annual number of summer days (SU) increased in Central and southern Europe while in the northwest they are not significant. The annual numbers of tropical nights (TR) show some tendencies of increasing in the south-east while in the north-west part the trends are insignificant.

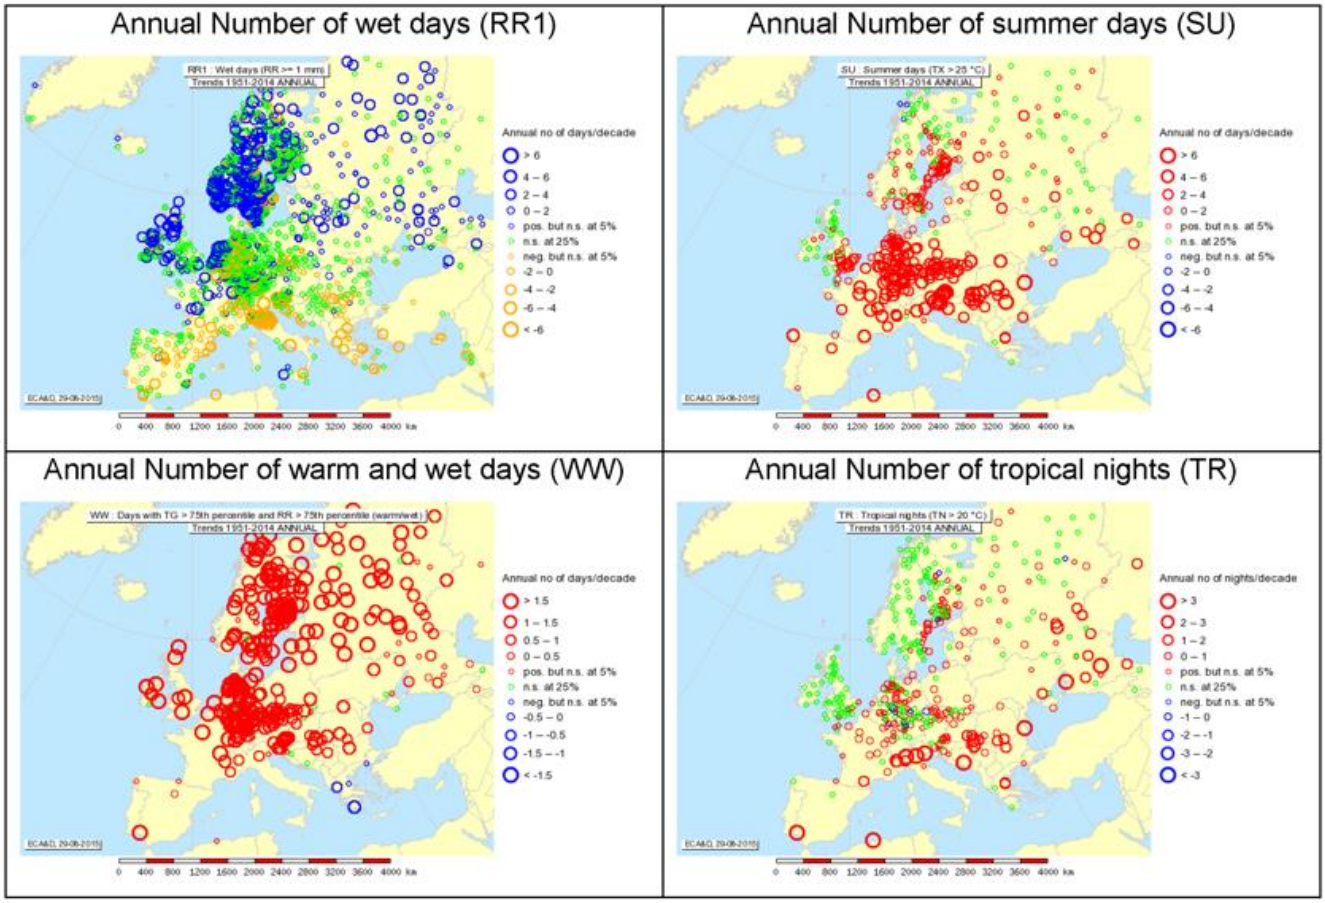

Figure 2.9: Trends of Selected Climate Indices 1951 to 2014 (Source: ECA&D, http://www.ecad.eu)

1. **RR1, Number of wet days**: count of days where RR (precipitation > 1 mm)
   Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally effected.
2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) > 25°C
3. **WW, Number of warm and wet days:** days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile
4. **TR, Number of tropical nights**: count of days where TN > 20°C

2.3. Socio-economic impacts of extreme climate or weather events

Several countries reported socioeconomic impacts of climate extremes or weather events. This was done partly given in a standardized structure (WMO guiding table for country submission of information on extreme climate events) or the information was part of the regular monthly reports on the internet or it was separately submitted. However, this information is heterogeneous and does by far not give a complete overview. Not only do the administrative structures differ so that the information cannot easily be gathered but also many kinds of impact are difficult to estimate. In the following only a short extract will be given.

The following figure (Figure 2.10) shows the number of observed extreme weather or climate event as reported by the NMHSs in 2014 that can be presented in form of a diagram. Conclusions should be drawn only with caution because some of the events were reported by several countries. The total number of cases for this figure was 399. No diagrams were shown for the injured persons and fatalities as well as the economic losses because the number of reports were too few (about 9, 10 resp. 11). In some cases the reported numbers were not fix but like 'hundreds' or 'few'. The economic damage was estimated as well by some countries but the information is not sufficient to be presented with any reliability of representativeness. The reported economic damages will be summarized individually below.

The most frequent events in 2014 were 'Extreme Precipitation' with 108 events or 27% that also happened in most of the countries with reported 30 fatalities and 138 injured. The second one with 20.5% or 82 events were 'Wind Storms' that mainly occurred in winter in the western part of Europe together with extreme precipitation. Rank three were 'Heat Waves' with an occurrence of 15% or 60 events mostly in Central, southern and eastern Europe, Serbia, Russia and Israel reported 4 heat waves. The next extreme events were 'Floods' (13 %, 158 persons injured, 10 fatalities) and 'Droughts' (7%).

Dec 2013 – Feb 2014. The area from **Spain** to **Ireland** and **United Kingdom** was hit by 12 **storm** surges. It has been the wettest winter in the England and Wales Precipitation (EWP) series going back to 1766, with 435 mm. This huge amount of rain saturated the ground and caused **landslides** and **floods**. Villages were cut off for four weeks. Munich Re estimated the damage of about 1.300 Mio. €.

13 – 30. May 2014 Parts of the Balkan Peninsula (**Serbia, Croatia, Bosnia and Herzegovina**, **Romania**) was concerned by **Floods** and **landslides** The days of heavy rainfall from a slow-moving storm led to historic widespread flooding. The floods caused land mines hidden more than 20 years ago to appear. A warning was issued to residents about the possibility of land mines uncovered by mudslides and flood waters. More than 3.1 million were affected and 86 fatalities. The overall losses were estimated to 3.300 Mio. €.

On 9 and 10 June 2014 with maximum temperature of more than 37°C in south **Germany** heavy **thunderstorms** moved from eastern France to western Poland. In the Rhine-Ruhr-Area to Kassel and Göttingen wind gusts of up to 144 km/h were measured (40m/s at station Düsseldorf Airport). Most affected were Dusseldorf and the Ruhr area, where a downdraft with heavy precipitation combined with hail and floods caused a lot of damage. In the city of Düsseldorf nearly 20 000 trees were uprooted, similar situation in other cities at the district. A total of six people were killed. About 30 people were seriously and 37 slightly injured. The damage estimated by the Munich Reinsurance Company was 3200 Mio. €.

November, 03.–19., 2014 A series of severe **storms** together with high wind speeds and **tornadoes** hit **France, Italy and Switzerland** with very high amounts of precipitation. The rainfall has exceeded 250 mm in many areas from southeast France into northern Italy and southern Switzerland. During these two weeks over 600 mm has fallen in Genoa (Italy), and 420 mm in Nice (France). In Genoa, this is almost half of the yearly average rainfall. 20 persons died and the monetary loss was about 240 Mio. €.

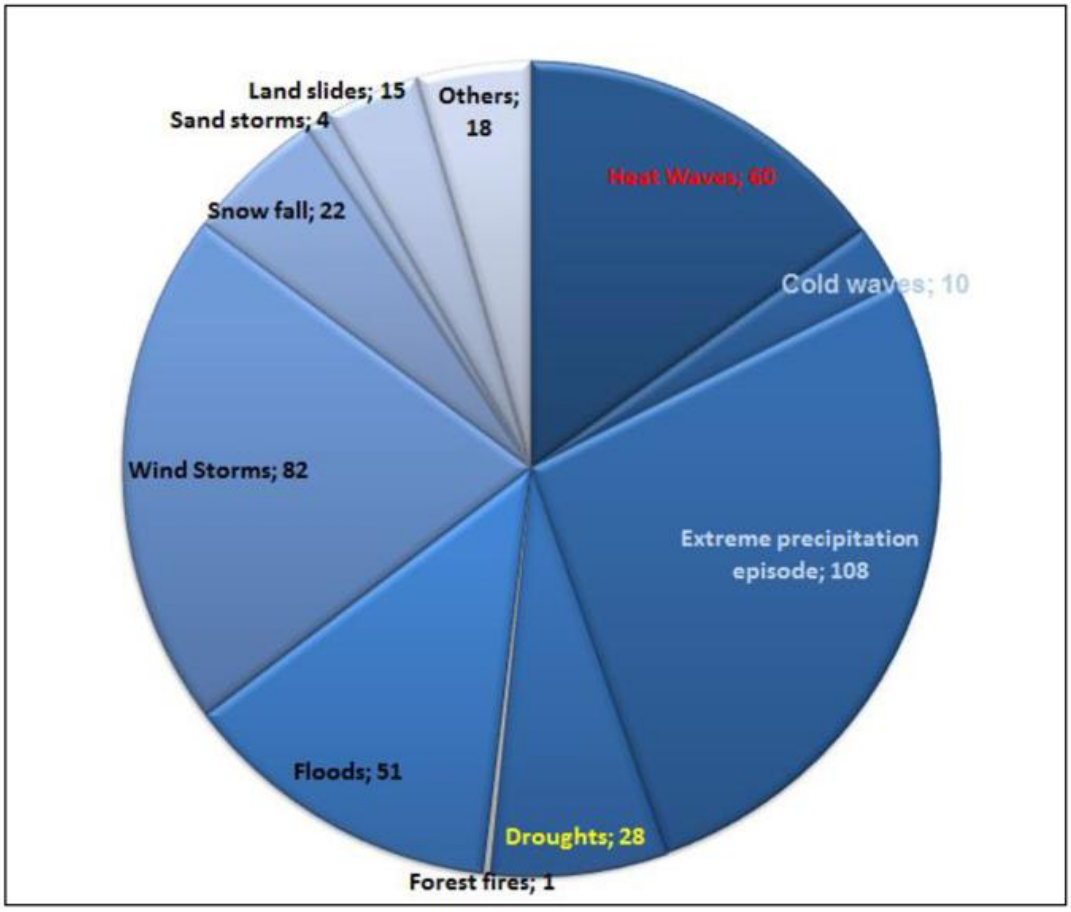

Figure 2.10: Relation of observed extreme weather or climate events in 2014 based on 35 reports from NMHSs (total events reported for 2014: 399)

Much economic damage is usually connected with floods, storm, cold spells (all kinds of frost, snow or ice), hail, drought or extreme heat. There are some figures which are summarized in the following but much of this kind of damage cannot be estimated (by meteorologists).

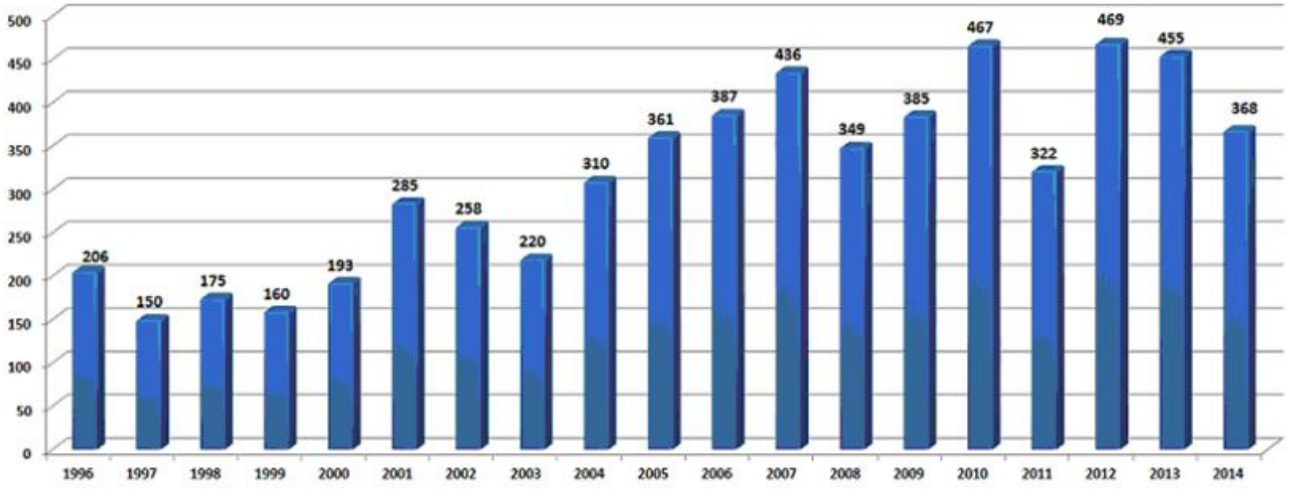

Figure 2.11: Number of severe weather events caused damage from Russia Federation, 1996-2014 (Diagram as provided by the NHMS).

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2014 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. Seasonal averages and anomalies of selected essential climate variables

3.1.1. Sea level pressure and circulation indices

Winter 2013/2014 was dominated by a strong Icelandic low with a core pressure below 995 hPa (−18 hPa sea level pressure anomalies) and was centred south of Iceland. The low pressure extended over the whole North Atlantic from the east coast of North America to the west coast of Europe and from the Norwegian Sea to southwest of the British Isles. In Ireland storm force winds occurred on 12 different days – on the 5th/14th/18th/24th/26th/27th December 2013, 3rd/25th/26th January and 1st/8th/12th February 2014. This series of storms led to an increase in rainfall amounts of between 1.5-2 times above normal and to saturated or waterlogged ground throughout the country. The most severe windstorm occurred on the 12th February 2014 and was associated with an active depression off the south coast that tracked steadily north-eastwards over the country. The Azores high was shifted south-westwards so that the Azores lay outside the centre with more than 1025 hPa mean sea level pressure. The negative anomalies exceeded an absolute amount of 14 hPa. The Azores high and the Asian high were connected over most of the European continent and the Mediterranean Sea. The positive anomalies were in the range of 2 to 6 hPa in the Azores region and in south-eastern Europe and Middle East and in the Russian Arctic region.

The lowest sea level pressure in the WMO Region VI of 948.1 hPa was registered at station Gufuskálar in the West of Iceland on 9 December.

The mean sea level pressure of **spring 2014** was close to normal. Low pressure in the Arctic Sea reached southward in the Norwegian Sea and northern Russia with negative anomalies below -14 hPa. The Icelandic low with a centre pressure below 1005 hPa was located west of Iceland and had negative anomalies below -6 hPa.

The sea level pressure distribution for **summer 2014** was quite normal. The exception was the high pressure over Greenland and the Norwegian Sea with positive pressure anomalies of more than 6 hPa over Greenland. This was the cause of the negative NAO-index. The Azores high was located above the Azores with a pressure of more than 1020 hPa.

The circulation pattern in **autumn 2014** was marked by a strongly developed Iceland low with the core located southwest of Iceland (under 1000 hPa) and a Russian-high with a central pressure from 1020 to 1025 hPa. The negative anomalies ranged from Greenland to the Iberian Peninsula with values less than -6 hPa southwest of Ireland. The Azores high was shifted west to the Atlantic. Positive pressure deviations were found over Scandinavia and northern Russia with values of more than 6 hPa.

Table 3.1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2013/2014	0.56	1.60	-1.20	0.71	-1.16	0.18
Spring 2014	-0.06	0.61	-0.11	-0.54	0.68	0.88

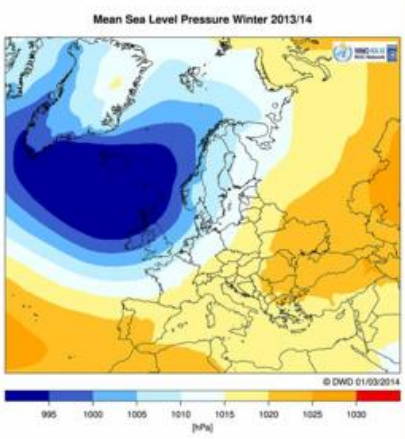
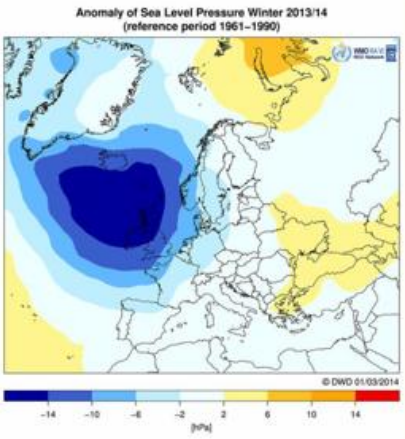
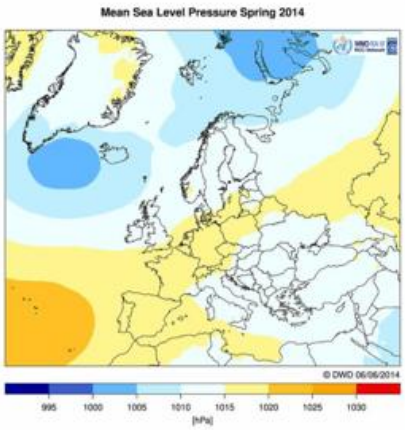
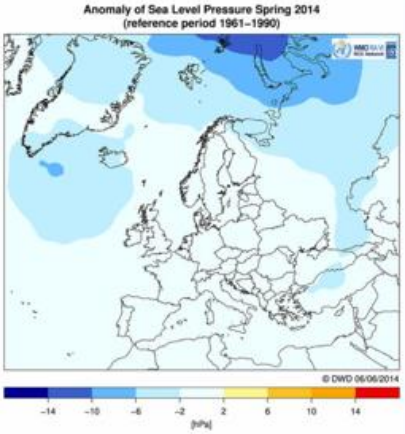
Winter 2013/2014



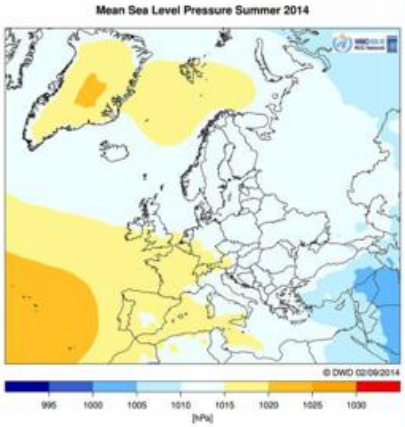


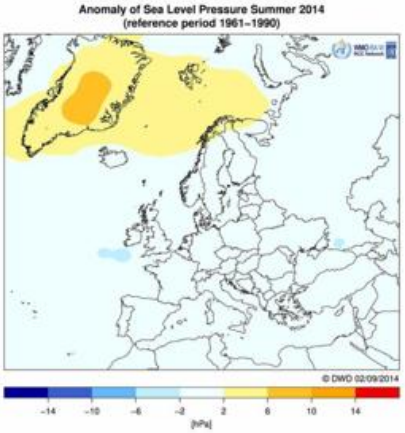
Spring 2014



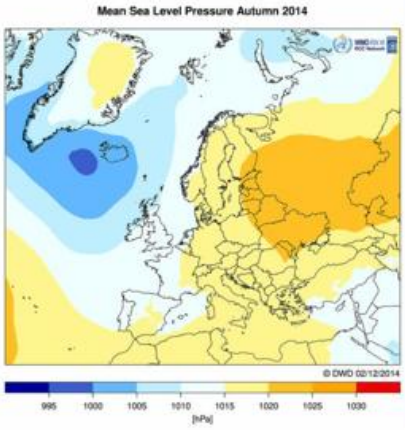


Summer 2014





Autumn 2014



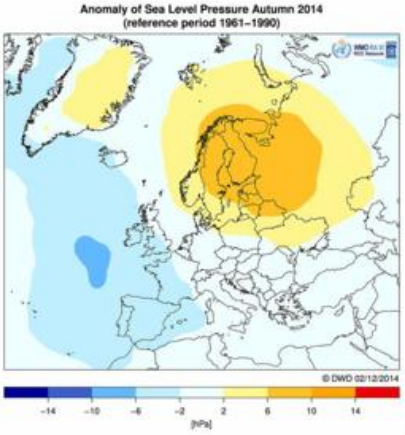


Figure 3.1: Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2013/2014, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.2. Temperature

On average for the whole WMO Region VI and sub-regions the temperature in all seasons in 2013/2014 except Eastern Europe in autumn was warmer than the normal period 1961-1990. In regional view, however, some differences existed (Tab. 3.2).

Table 3.2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2014 (reference period: 1961-1990)

Sub-Region	Winter 2013/2014	Spring 2014	Summer 2014	Autumn 2014	Year 2014
Central and western Europe	2.51	2.10	0.89	2.06	1.85
Nordic and Baltic countries	3.23	2.24	1.40	1.78	2.09
Iberia	0.69	1.98	0.73	2.03	1.39
Mediterranean, Italian and Balkan Peninsula	2.25	1.32	0.83	1.36	1.56
Eastern Europe	2.65	2.58	1.31	0.13	1.58
Middle East	0.57	2.05	1.55	-0.09	1.26

Winter 2013/2014 was warmer than normal on Greenland, the European Arctic Sea and the Norwegian Sea, Scandinavia and northern European Russia, Central and Western Europe, and most of the Mediterranean Sea and the Balkan Peninsula. Colder than normal was an area on the western North Atlantic as well as a small region in eastern Turkey and Iran as well as a part of northern Russia (already outside RA VI). The warm anomalies were partly exceptional.

Some ranks of warm winters based on web-available bulletins by NMHSs are given below:

Table 3.3: Seasonal rank statistics for winter mean temperature (2013/2014) as provided by the NMHSs.

Country	Rank	Time series available since
Europe (35°–75°N, 10°W–30°E, E-OBS)	1	1950
Austria	2	1767
Denmark	5	1874
France	2	1900
Germany	4	1881
Montenegro	1	1951
Hungary	3	1901
Luxembourg	2	1947 (together with winter 1989/1990)
Netherlands	2	1706, together with 1990
Norway	8	1900, regionally (Vestlandet) rank 1
Poland	7	1952
Portugal	15	1932
Slovakia	3	1951
Switzerland	3	1864
United Kingdom	5	1981

Croatia classified the winter 2013/2014 as very warm in the northeastern part and extremely warm in the western part (based on the normal period, 1961-1990).

Most of the region was warmer than normal during all three months. Several countries reported each month as one of the 10 warmest months in their long time-series either for the whole country of for regions or at least for stations.

Spring 2014 was overall warmer than normal and one of the warmest spring seasons in several countries (2nd warmest since 1706 in the Netherlands, the warmest since 1900 in Norway, on rank 9 of warm spring seasons since 1931 in Portugal, provisionally the UK's third warmest spring in a series from 1910, the 3rd warmest since 1880 in Germany, the 3rd warmest in Belgium since 1837, the 3rd warmest in Poland since 1951, the 7th warmest spring since 1767 in Austria, among the 10 warmest since 1864 in Switzerland). Poland and Switzerland highlighted unusually early phenological phases for spring 2014 in their seasonal bulletins. The map of the anomaly of days with night temperatures above the 90 percentile shows remarkably positive values nearly everywhere.

Summer 2014 was warmer than normal in many European countries. Anomalies of 2-3°C occurred north of Iceland, from Norway to Denmark and east of the Black Sea. For Norway the summer temperature anomaly was 1.9°C, in some parts even 3-4°C above normal.

Three heat waves in summer 2014 in Lithuania

(as provided by the NMHSs of Lithuania)

Summer was much warmer than usually (1.2°C positive anomaly). The only month that turned out to be rather cool was June (-1.2°C negative anomaly). Very warm was the month of July (even 3.5°C positive anomaly), also warm was August (1.4°C positive anomaly). The hottest day of summer was 4 August, when the absolute record temperature of that month was observed, reaching 37.1ºC.

Summer saw totally 6 severe and 1 disastrous meteorological phenomena. Most of them (3) were heat waves: on 6–10 July, 24–31 July and 2–8 August.

All heat waves (when 30ºC and higher temperature persists 3 days in a row) were related to tropic air influx to Lithuania from North Africa or Southeast Europe. *Heat wave on 6–10 July* was local-scale and mostly affected seaside and western part of the country, rising temperature to 30-32.5ºC. Such tropical heat was brought in by Azores anticyclone. The heat mostly affected people on sea shore.

The second heat wave reached Lithuania by the *end of July and was the longest, lasting for 8 days*. Such duration was determined by two anticyclones: one moving over Scandinavia pushed tropical air to the Baltic States and then merged with another southern anticyclone moving by Russia. 29 July was the hottest day of that month with maximum temperature reaching 30–34.7ºC. UV index was also high, between 5–6, and heat index showed great discomfort (perceptive temperature for humans reached 35–39ºC). That period was both hot and unsettled with thunderstorms and squalls and showers here and there every day. Prolonged sweltering heat caused people suffer.

After only a single day of relief, tropical *heat returned on 2 August* and the heat wave lasted until 8 August. Such heat was brought to Lithuania from Southeast Europe by anticyclone stopped by Southwest Russia. The temperature reached its peak on 3–4 August, when it was record-high all over Lithuania (between 32–37°C): almost all meteorological stations reached or exceeded maximum temperature records for those days. On 4 August in many places the temperature was over 35°C, and *in the south of the country (in Druskininkai) it measured as much as 37.1°C. This is an absolute temperature record in August in Lithuania*, replacing the previous 35.8°C (in 1992). Very warm were also the nights, often featuring minimum temperature falling as little as to 16-20°C, in seaside to 21–23°C.

The thermal conditions in **autumn of 2014** were divided in two parts, the western part of Europe reveales above average temperature anomalies while Russia was colder than normal. In some areas of western Europe anomalies showed values of more than 3°C.

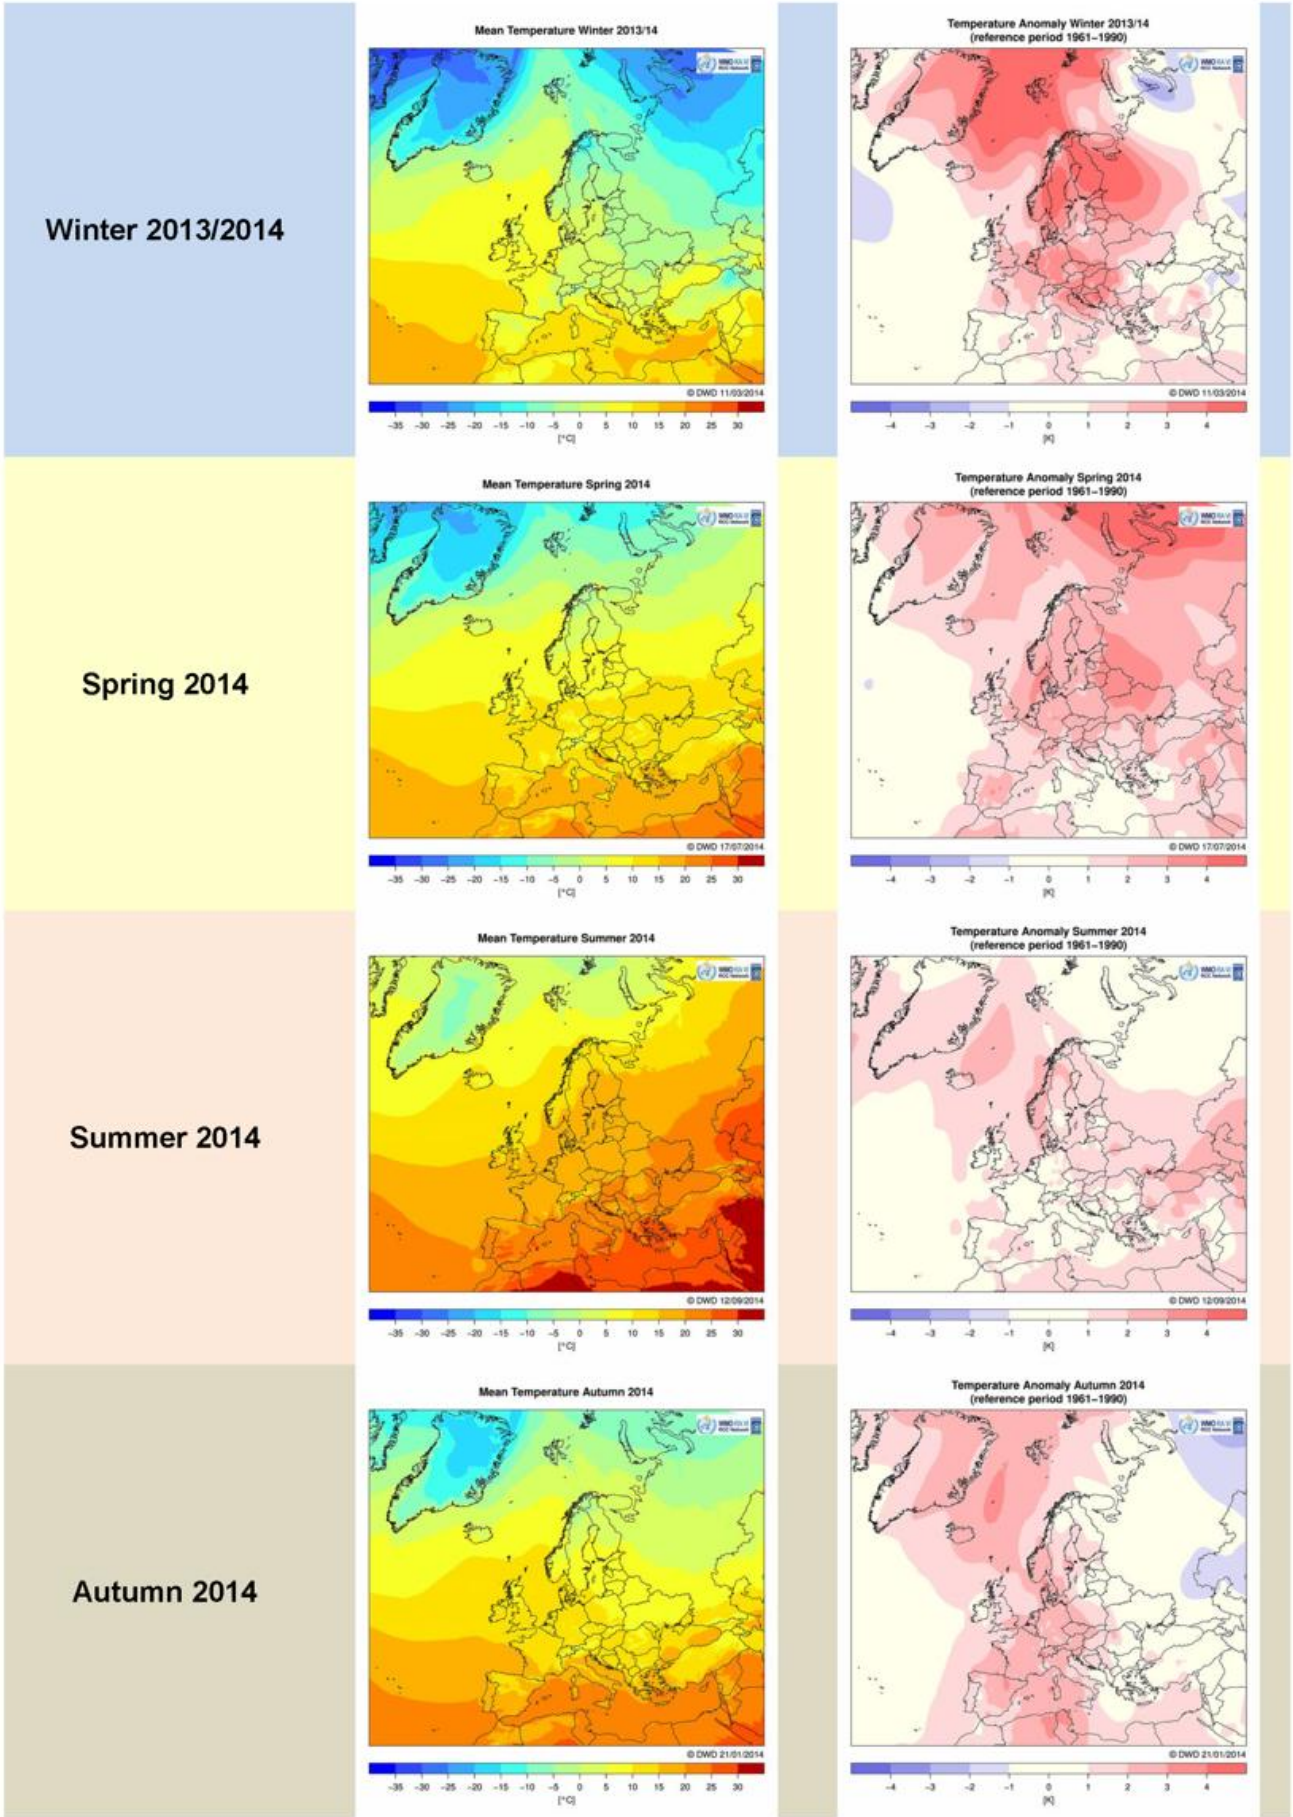

Figure 3.2: Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2013/2014, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.3. Precipitation

Winter 2013/2014 was wetter than normal in UK, western France and the northern Iberian Peninsula under Atlantic influence. It was as well wetter than normal in southern Norway, partly in southern Sweden and Denmark. Wetter than normal was also the southern Alpine region, and parts of the Adriatic coast, the western Italian Peninsula and western Sicily and partly the eastern Balkan Peninsula. Smaller parts of European Russia mostly in the north were wetter than normal as well. Drier than normal were western Iceland, parts of Norway, parts of central Europe, most of Germany, western parts of the Balkan Peninsula, eastern Ukraine and southern Russia and the Caucasus region and most severely Turkey and the Levante coast. Israel reported that the period from mid December 2013 to end of February 2014 was the driest for more than 70 years. Most other regions were around normal.

The contrasts north and south of the Alps were high: In Austria the northern parts received the lowest precipitation since the winter 1857/1858. Germany was dry, the Netherlands were drier than normal.

Table 3.4: Rankings of total precipitation (in mm) for winter 2013/2014 for some of the wettest regions.

Country	rank	total precipitation	area averaged time series since
United Kingdom	1	545 mm (177% of the 1961-1990 average)	1910
United Kingdom	1	446 mm (178% of the 1961-1990 average)	1766 for the England&Wales series
Northern Ireland	2	489 mm (159% of the 1961-1990 average)	1910
France	1	995 mm at station Guiscriff (206 % of the 1961-1990 average)	1959, for the regions Bretagne and Provence-Alpes-Cotes D'Azur
Switzerland	1	698 mm at station Lugano (198% of the 1981-2010 average)	1764, for the southern part of the country
Portugal	17		1932
Austria	1	370 mm at station Klagenfurt (355% of the 1981-2010 average)	1813

Outstanding was the precipitation surplus on the Balkan Peninsula in **spring 2014**. The map of the absolute anomalies gives a more realistic characterization than the relative anomaly in this case. The map of the anomalies of the highest 5-day precipitation totals shows that the catastrophic flooding event in May 2014 mainly caused this surplus (For details see section 4.3 or the Seasonal Bulletin for Serbia, Spring 2014).

Summer 2014 was wetter than normal in southern and Central Europe with exception of the Iberian Peninsula. The highest positive anomalies occurred from the Balkan states to the north-western part of Turkey. In Croatia the precipitation surplus was more than 70mm and the relative anomalies range from 100% to 302% of the multi-annual average for this season.

The **autumn of 2014** was drier in the north and wetter in the south of the WMO region VI. The precipitation deficit reached values below -30 mm/month (100 mm/season) or below 40% in northern Poland, Belarus, European Russia, Estonia and northern Norway and northern Sweden. More than normal precipitation was observed in southern Europe, especially in western Iberia, southern France, northern and southern Italy, the Balkan and Turkey. The province of Genova (Italy) was hit by an intense thunderstorm on 9th-10th October with maxima cumulated rain over the two days of 569.6 mm at the station of Geirato. A low pressure system west of France brought warm and moist air masses from the Mediterranean. From mid-September to late November, 10 episodes of particularly violent rains hit the southeast of France. Accumulated records for the season were beaten with e.g. 722 mm at station Bormes-les-Mimosas (Var), 916 mm in Prades-le-Lez (Hérault) and 1826 mm in Barnas (Ardèche).

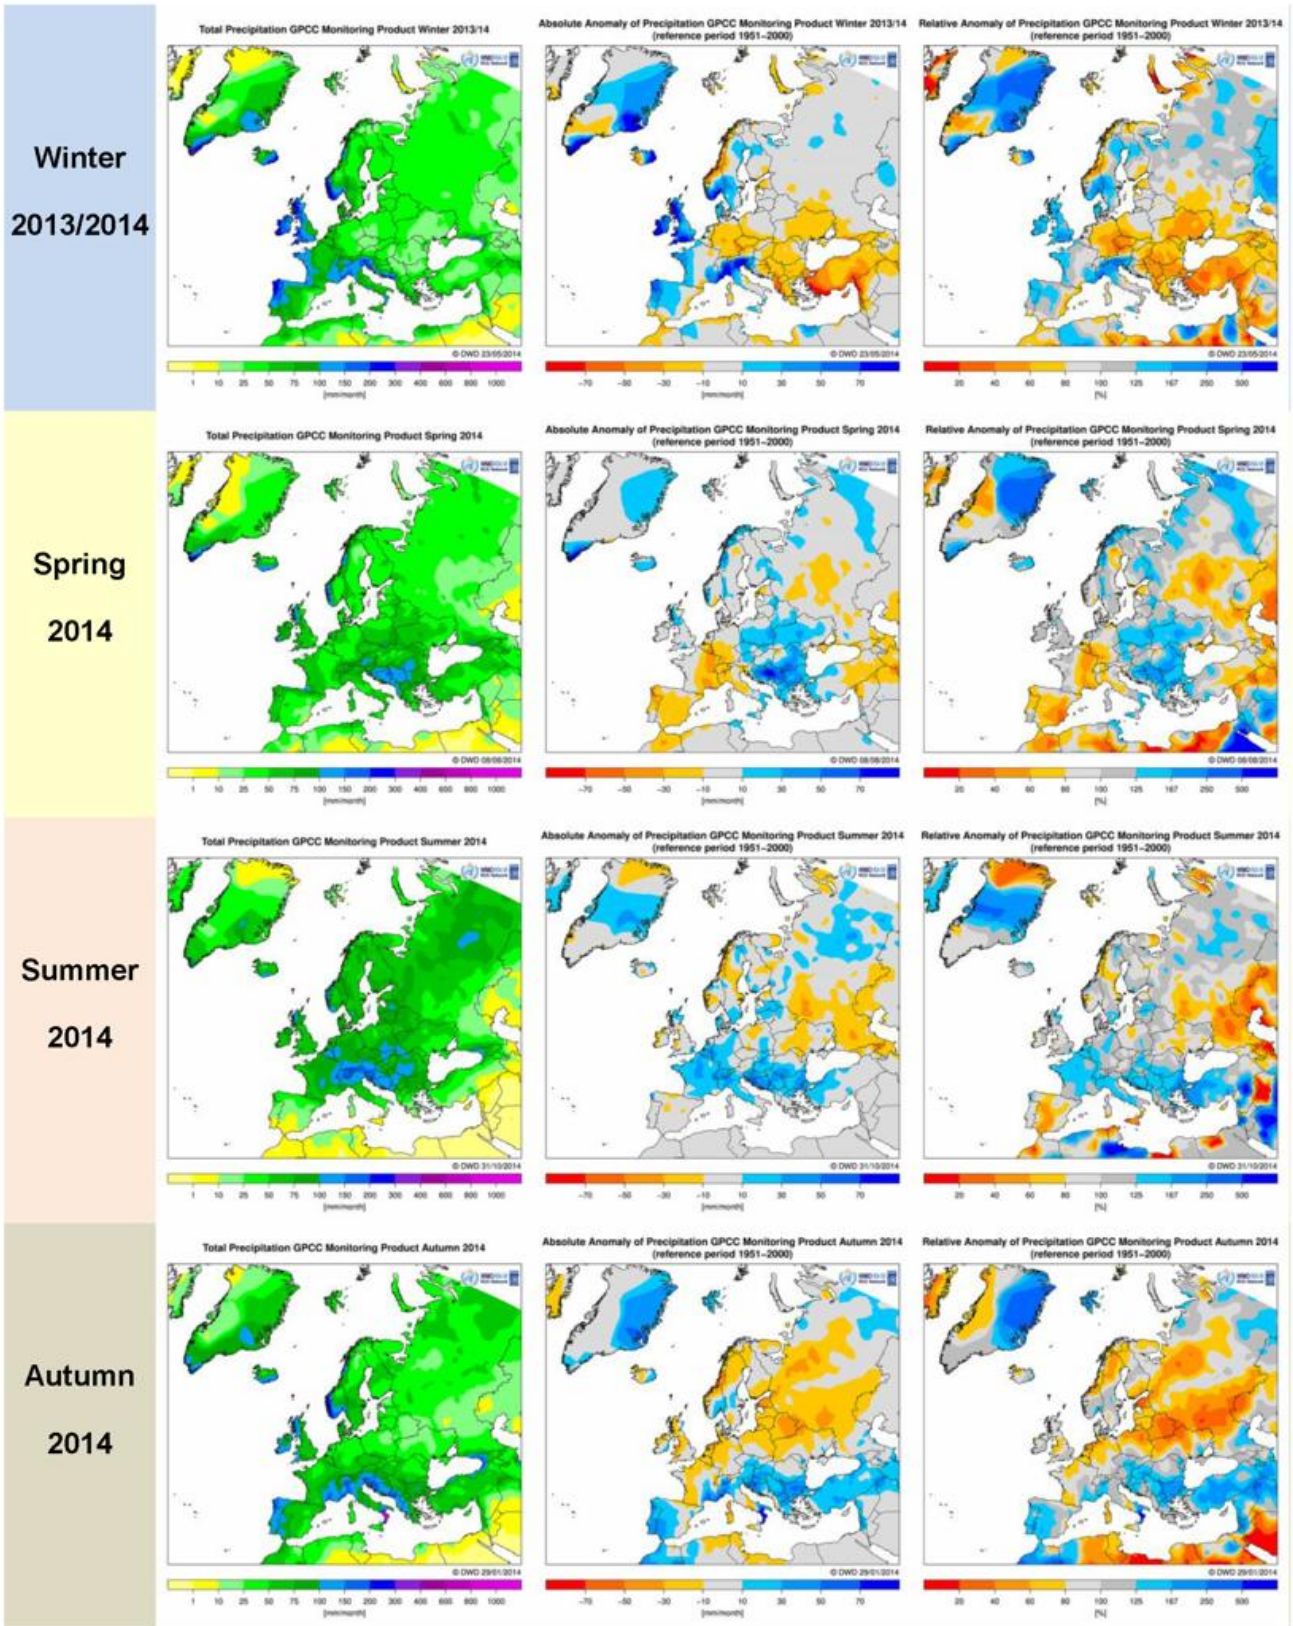

Figure 3.3: Seasonal total precipitation (left, in mm/mon), absolute anomalies (middle, in mm/mon) and relative anomalies (right, in %) in 2013/2014, reference period 1951-2000
(Source: http://www.dwd.de/rcc-cm)

3.1.4. Sunshine duration

Winter 2013/2014 was sunnier than normal in southern UK, western and central Europe, most of the Balkan Peninsula, Turkey and Middle East. It was less sunny than normal in most of northern and eastern Europe as well as the western Mediterranean region. In Germany winter 2013/2014 was on rank 11 of the sunny winters since 1951.

Parts of western and central Europe were 25% to 50% sunnier than normal in **spring 2014** while north-eastern Europe and the Middle East were dull with partly below 50% of the normal. In Belgium at station Ukkel sunshine duration in spring 2014 was 572 hours that is about 123% of the normal value of 463 hours. Especially March was very sunny with a total of 197 h, which is well above the normal value of 114 h. Therefore March was the second sunniest month of the year after June with 206 h. March also leaved behind July (194 h) and of August (150 h).

The **summer of 2014** was sunnier than normal in northern and central Europe as well as in Spain and southern Italy. The surplus reached more than 25% in Poland and more than 50% in Finland. Middle Europe and Lithuania had a sunshine deficit of up to 25%, Turkey even up to 50%.

In 2014 the **autumn** was sunnier than normal in northern and western Europe while the south-eastern part had a deficit. Values of more than 150% of the relative anomaly were dominated in Poland, Belarus, Ukraine and western Russia.

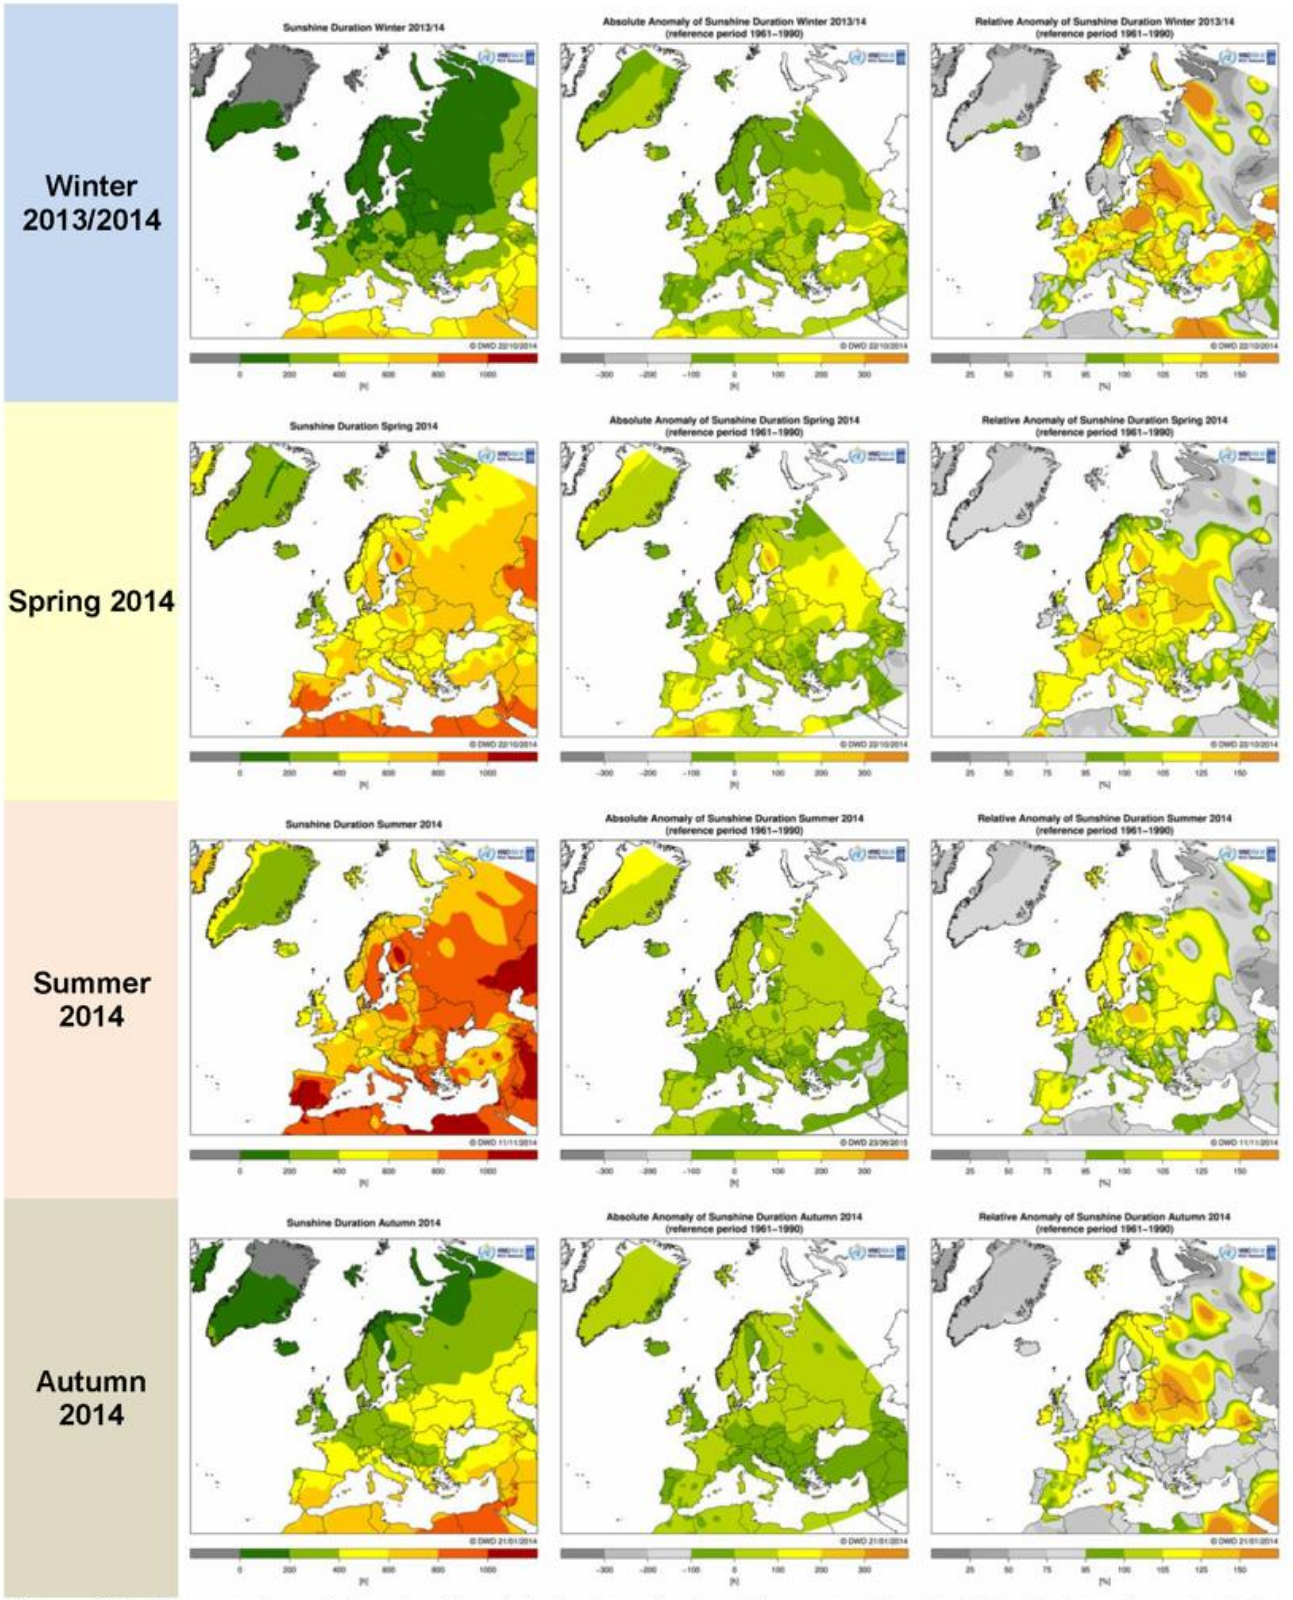

Figure 3.4: Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and relative anomalies (right, in %) in 2013/2014, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.5. Drought

The Winter 2013/14 was drier than normal (see below) in Turkey and Middle East while the British Iles, northern Spain, the Alps and southern Norway were wetter than normal. In spring the Balkan was very wet resulting in floods whereas Central Europe and Spain were dry. Turkey was partly very wet in summer and autumn. In autumn eastern Europe was drier than normal.

Reports on longer lasting dry periods
from the National Meteorological and Hydrological Services:

In **Israel** the main months of the rainy season are December, January and February. However, the two and a half months period from mid-December 2013 until the end of February 2014 provided very little precipitation, making it the driest since records began more than 70 years ago (Figure 3.5). In the first part of December three precipitations systems crossed the Eastern Mediterranean, including the extreme snow storm just before mid-December. Since then there were no significant systems in the region. The few systems that did cross the Eastern Mediterranean resulted in local and limited precipitation amounts.

Precipitation totals were less than 20% of normal in many parts of the country. The Galilee mountains (northern Israel) received 50-100 mm from mid-December 2013 until the end of February 2014 compared with an average of 350-450 mm for the period 1981-2010, and in other areas the amounts were even smaller. In the Judean Mountains precipitation totals were merely 10-30 mm, which is less than 10% of normal (1981-2010**,** Figure 3.6**).**

Comparison of the precipitation totals in the aforementioned two and a half month period to the same period totals in previous years reveals that in most stations the extremely small amounts of rainfall this season are record breaking. It is even more remarkable when compared to the previous records (Figure 3.6). There are differences of more than 50 mm between the present record and the previous one (which was set in most of the northern parts of the country in 1978/79 and in most of the southern parts, in 1959/60). The comparison was performed with stations that have precipitation records for more than 70 years, some of them even more than 100 years (rainfall reports in Jerusalem date back to the mid-19th century).

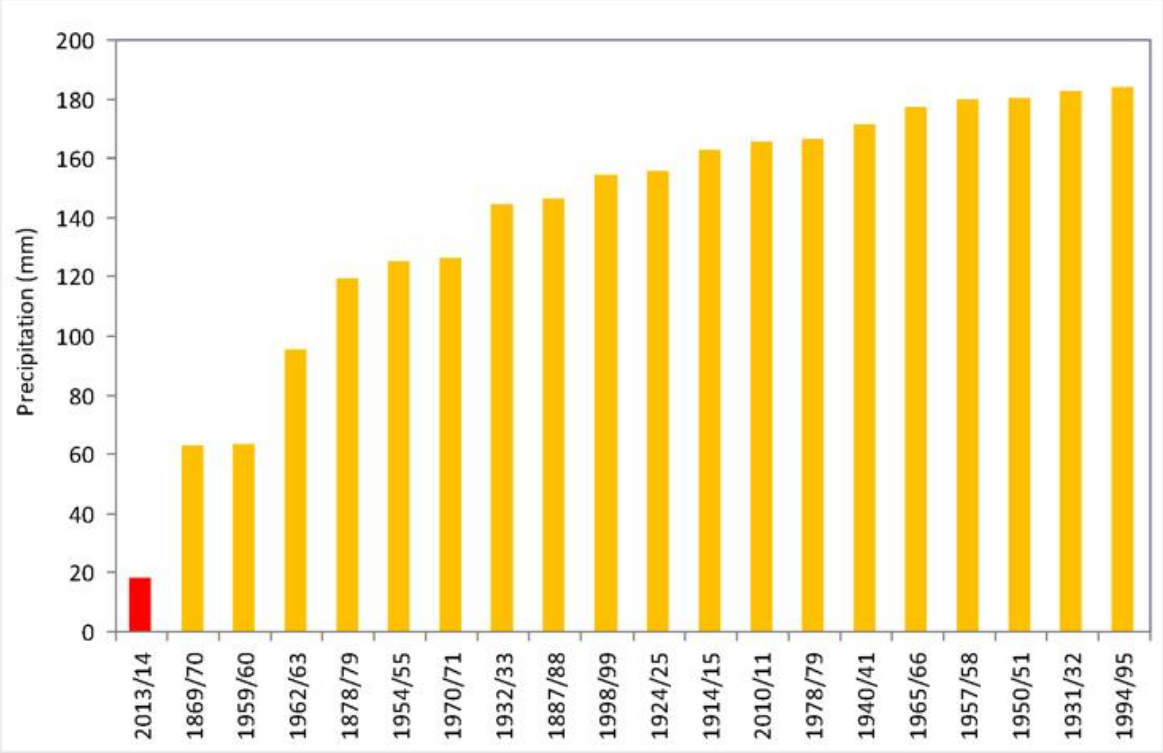

Figure 3.5: The 20 lowest accumulated precipitation totals (mm) in Jerusalem for the period December 15th until February 28/29th 1861/62-2013/14 (Source: Israel Meteorological Service)

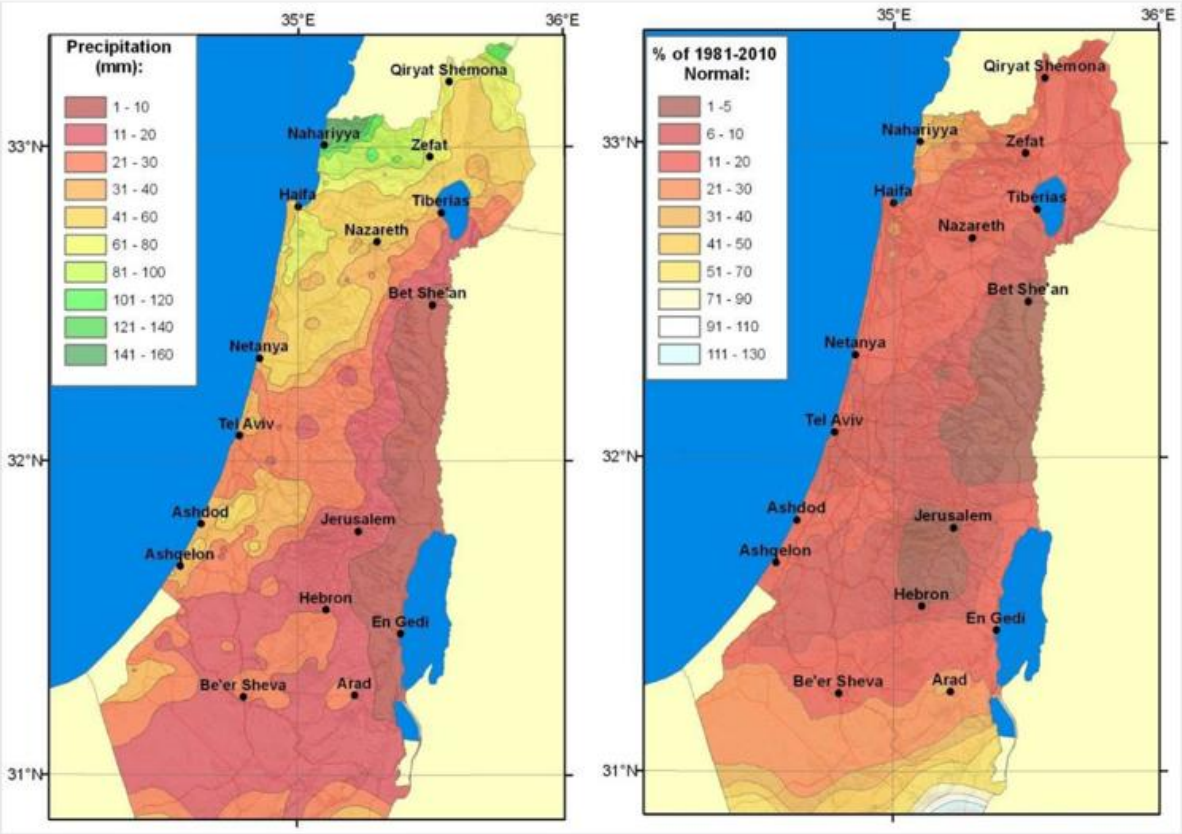

Figure 3.6: Accumulated precipitation (left; in mm) and percent of normal (right in %) for December 15th 2013 to February 28th 2014 (Source: Israel Meteorological Service)

A similar drought situation also occurred in the neighbouring country **Jordan**. The precipitation deficit in January and February in Jordan was about 30 mm of the long term mean for 1961-1990 (Figure 3.7, Figure 4.11)

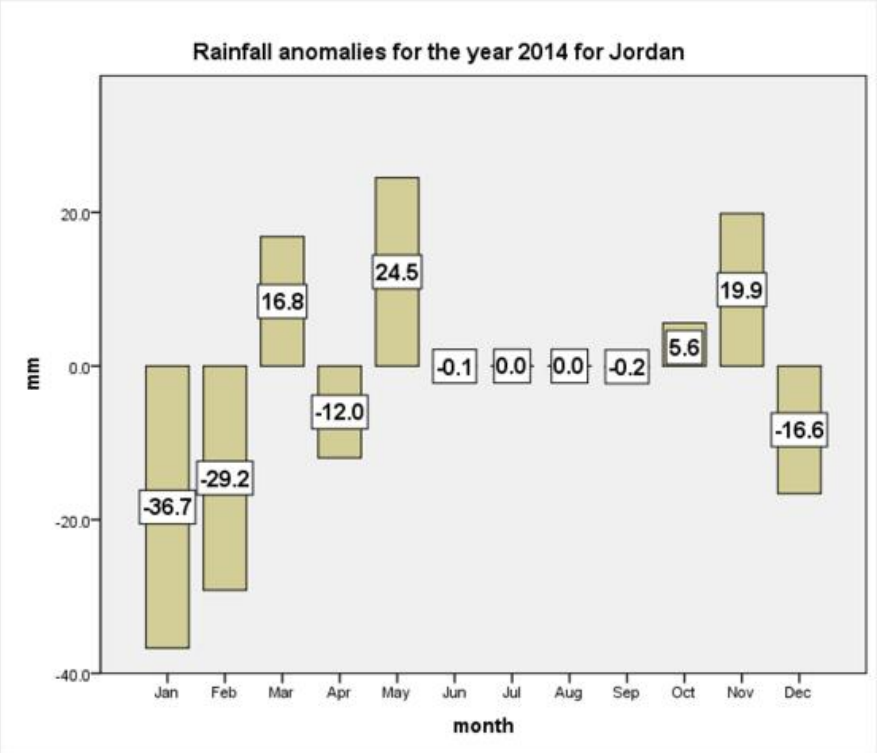

Figure 3.7: Monthly precipitation anomalies for Jordan for the year 2014 (in mm, source: Jordan Meteorological Department)

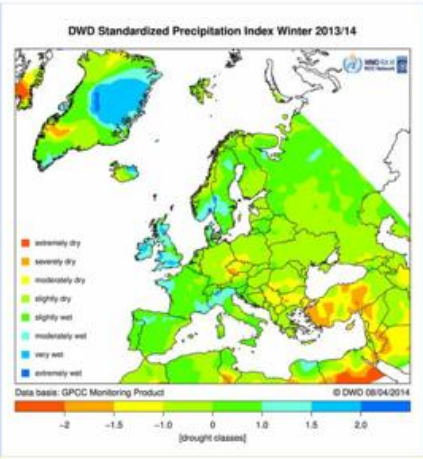
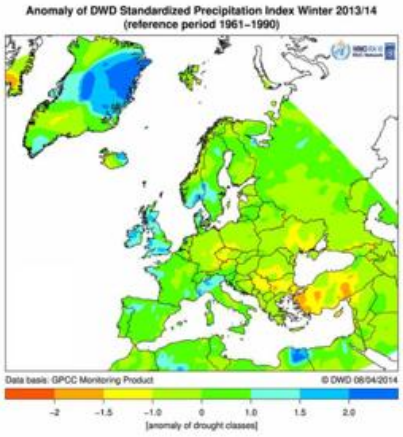
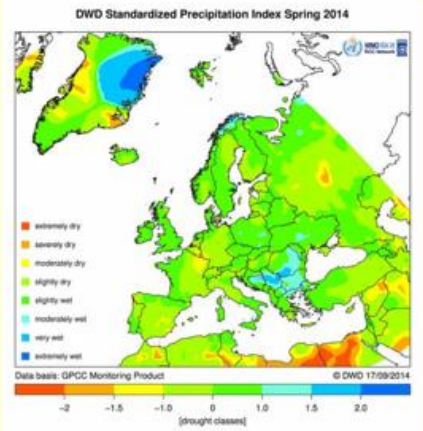
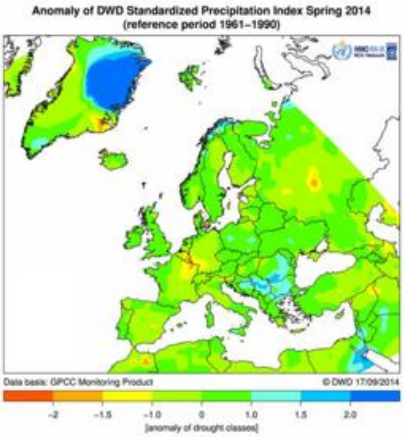
Winter 2013/2014



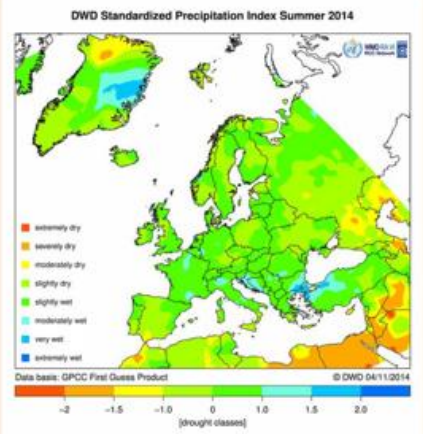


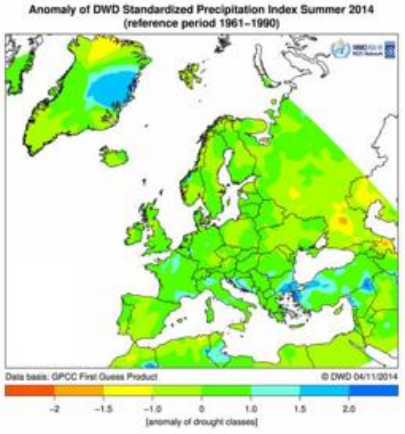
Spring 2014



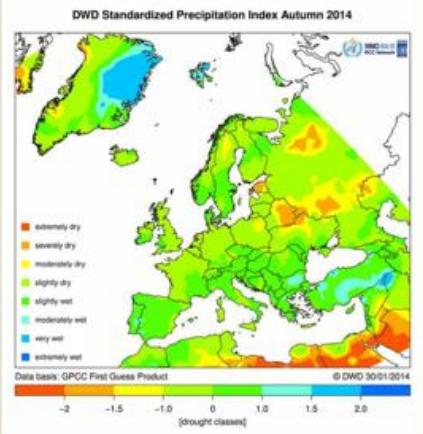


Summer 2014





Autumn 2014



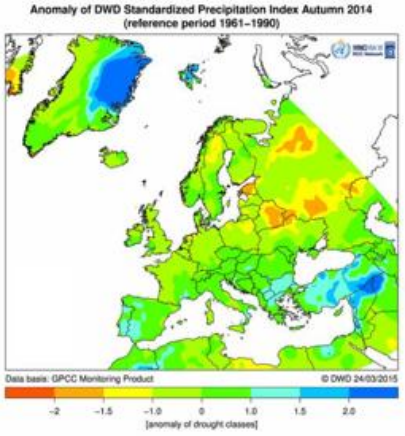


Figure 3.8: Seasonal standardized precipitation index (SPI, left, in drought classes) and anomalies (right) in 2013/2014, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2014 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation, sunshine duration for each months as well as monthly overviews of extremes and notable events.

4.1. Sea surface pressure and circulation indices

This chapter about the atmospheric circulation provides information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based upon the Monthly Bulletins on the climate in WMO RA VI and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4.1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the Arctic Oscillation, for January 2014 to December 2014

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2014	1	-0.17	1.37	-1.32	1.75	-0.79	-0.969
2014	2	1.07	2.23	-1.93	1.10	-1.86	0.044
2014	3	0.44	0.92	-0.11	-0.47	0.04	1.206
2014	4	0.19	0.52	1.23	-0.66	1.02	0.972

2014	11	0.58	0.43	1.28	1.77	1.75	-0.530
2014	12	1.63	-0.59	-0.44	-0.4	-0.93	0.413

Note that all values are standardized with reference to the period1981-2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In ***January 2014*** the Icelandic low was extended far southwards with a mean pressure below 995 hPa enclosing most of Ireland and Scotland. This means a negative anomaly of more than 14 hPa for the British Isles and northwest of them. Low pressure extended far onto the European continent with negative anomalies in the range of -2 to -6 hPa over most of central and southern Europe and -6 to -10 hPa for the west of the continent. Northern, eastern and south eastern Europe had higher mean pressure that causes an high Scandinavia Pattern index of 1.75. The positive anomalies were highest over northern Scandinavia and the Arctic Sea with 10 to 14 hPa. The strong gradients between the North Atlantic low and the Azores high allowed several cyclones to affect the British Isles and the west of the continent with high wind speeds, high sea waves and extreme precipitation that last until February.

February 2014 was characterized by low sea surface pressure below 995 hPa as monthly mean on the North Atlantic. Low pressure extended also over the western and northern European continent. The Azores high was weak and shifted southwards. The negative anomalies exceeded -14 hPa. High pressure was centred over the east with more than 1020 hPa as a mean over the eastern Ukraine, Russia and the Caucasus region and Middle East. The positive anomalies of more than 10 hPa were centred over northern Russia.

Storm on 12th February 2014 over Ireland (as provided by the Irish Meteorological Service)

The most severe windstorm occurred on the 12th February 2014 and was associated with an active depression off the south coast of Ireland that tracked steadily north-eastwards. Kinsale Energy Gas Platform recorded its highest maximum wave height of 25 m on the same day.

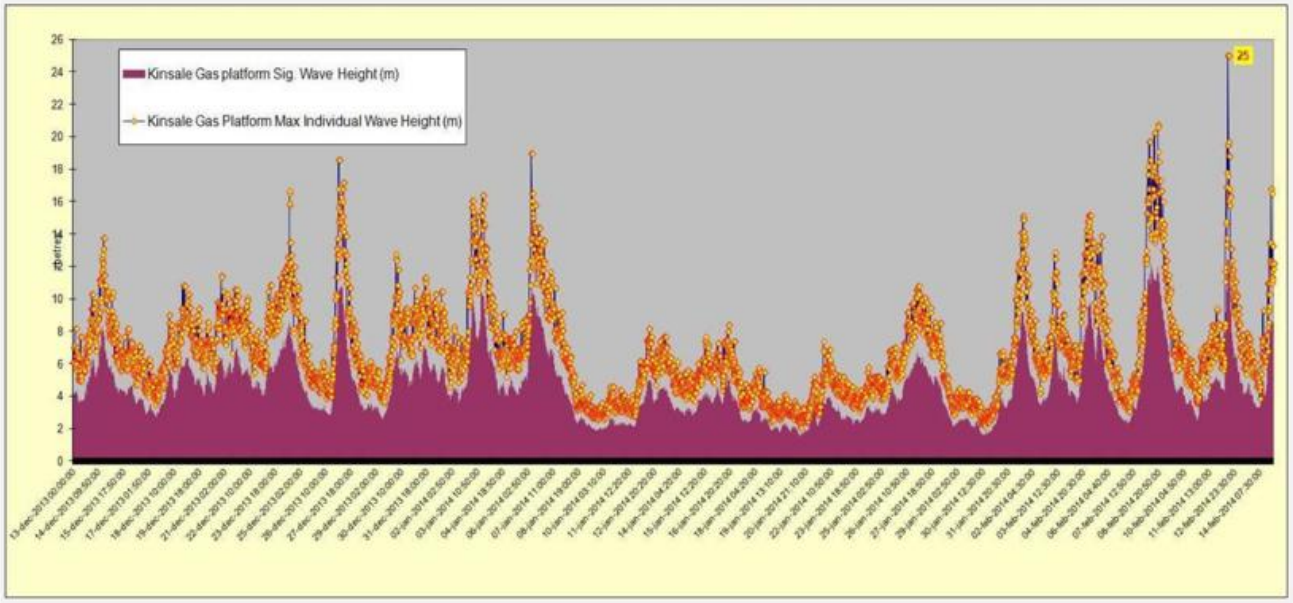

Figure 4.1: Significant and maximum wave height at Kinsale Energy Gas Platform as recorded from 13.12.2013 – 14.02.2014 (as provided by the Irish Meteorological Service).

Winds: Southeast to south gale to strong gale force 9 in the morning off the south coast, increasing to storm force 10 at midday and veered west in the evening. Increased to violent storm force 11 for a time in the south and west; backed west to southwest overnight and steadily decreased to force 5-7 by morning. Hurricane force 12 winds off the west coast

Weather: Moderate rain at first, showers merged to longer spells of rain, some wintry and thundery.

Significant Weather Event: Hurricane force winds were recorded at Mace Head, a mean 10-minute wind speed of 65 kts.

Maximum gust recorded was 86 kt, at Shannon Airport. Shannon also recorded a 10-minute mean wind speed of 61kts, its highest since records began in 1945.

Historical Context: The distinguishing feature of the weather this winter was the seemingly unending series of vigorous Atlantic storms that crossed the country. Nevertheless only one individual storm, on the 12th Feb 2014, was exceptional but not without parallel. We have had more violent storms in the past such as Hurricane Debbie in 1961, where the maximum gusts were between 70 and 85 knots generally with a maximum of 93 kt

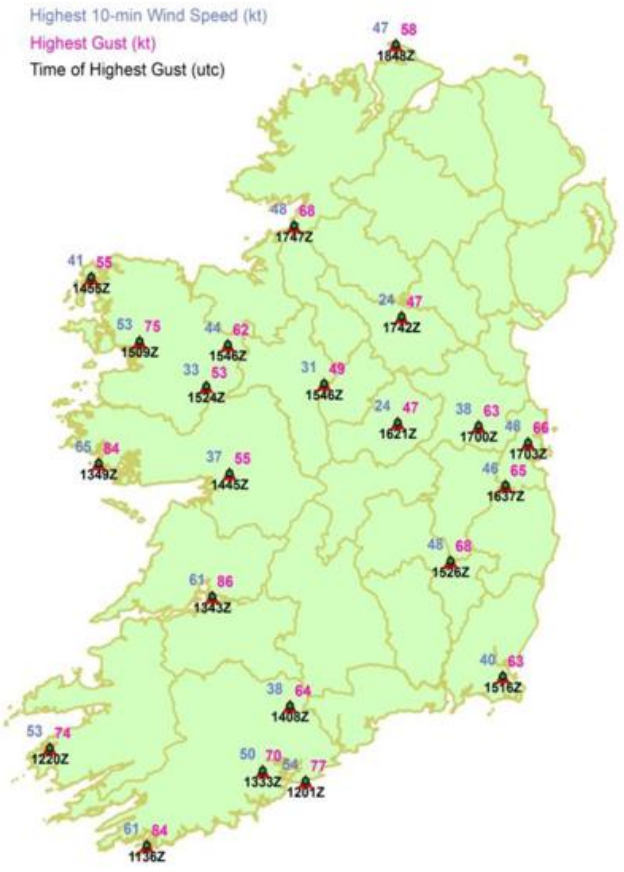

Figure 4.2: Highest 10-min wind speed (in kts), highest gust (in kts) and time of highest gust during 12th February 2014 over Ireland (as provided by the Irish Meteorological Service).

reported in the northwest. The more recent storms of 26th December 1998 and 24th December 1997 were also of greater intensity. In February 1990, an unusually long series of vigorous storms crossed the country producing record winds and rainfall amounts.

March 2014 was characterized by low pressure in the north with 2 centres, one south of Greenland below 995 hPa and another over Novaja Semlja below 1000 hPa and an Azores high above 1025 hPa shifted south-westwards. The anomalies were negative in the north and northeast with -14 hPa for the low pressure over Novaja Semlja, less than -6 hPa over Greenland and the northern North Atlantic as well as the Arctic Sea and Russia and less than -2 hPa over northern and eastern Europe. The positive anomaly of the Azores high was weak with 2 to 6 hPa.

In **April 2014** the Icelandic low was centred southeast of Greenland with 1000 to 1005 hPa and higher pressure (1015 to 1020 hPa) prevailed over the Azores and the southern North Atlantic, most of the Iberian Peninsula and parts of the western Mediterranean, western Europe, the North Sea, the Baltic region and southern Russia and the Caucasus region. The anomalies were negative over the north (down to -14 hPa) and the west. Referred to 1961-1990 nearly the whole European continent had no significant anomalies.

The anomalies of the sea level pressure in **May 2014** were positive in an area east of the Azores, over Greenland and the northern North Atlantic. They were negative in a region southeast of Greenland.

In ***June 2014*** positive anomalies above 2 hPa prevailed over the northern North Atlantic including Greenland, the British Isles and western Scandinavia. Northeast of Iceland and over parts of Greenland the positive anomalies exceeded 6 hPa. Slightly negative anomalies occurred in an area north of the Azores (-2 to -6 hPa). Except these anomalies the sea level pressure was normal.

July 2014 had higher than normal sea level pressure over northern Europe and Greenland with positive anomalies of +6 to +10 hPa over northern Russia. The anomalies over western, central and south-eastern Europe were negative as well as for Iceland.

August 2014 had lower than normal sea level pressure over the entire RA VI Region except Greenland where positive anomalies of +6 to +10 hPa occur. The lowest anomalies showed values below -6 hPa over South Norway. The NAO with an index value of -2.28 was significantly low.

In ***September 2014*** lower than normal sea level pressure were found over Southern Europe as well as the Arctic Region. Positive anomalies with values of more than +6 hPa appeared in a band from UK over Scandinavia to Estonia accompanied by positive temperature and sunshine anomalies as well as lower than normal precipitation.

October 2014 was characterized by a lower (below -6 hPa) than normal Icelandic low that was shifted to the south. In Southern Europe the pressure was normal. In north Scandinavia and Greenland the pressure anomalies reached values of more than 10 hPa. These high pressure anomalies induced positive anomalies of sunshine duration mainly above Scandinavia.

November 2014 the Icelandic Low and Azores High was more intense than normal (-14 hPa/+6 hPa) but both centres were shifted to the south-west, which resulted in a weaker influence on north-western and central Europe. Exceptional high pressure prevailed in Eastern Europe and Scandinavia with anomalies of more than 14 hPa. This pressure anomaly pattern was responsible for higher than normal temperature anomalies in western and Central Europe as well as wetter conditions in western and south-western Europe and positive sunshine duration anomalies especially in Russia.

The mean sea level pressure (slp) in **December 2014** showed an anomaly-pattern similar to the mean slp. This means that the centres of action, the Icelandic low and the Azores high were more intense than normal and shifted to the north-east. This was indicated also by the high NAO-index value of 1.63. This circulation pattern was accompanied by flow of warm air to Central Europe and heavy precipitation at the coast of the British Isles and Scandinavia. Due to the warm Mediterranean sea surface temperature more than 20 tornadoes have been observed in the Aegean Sea.

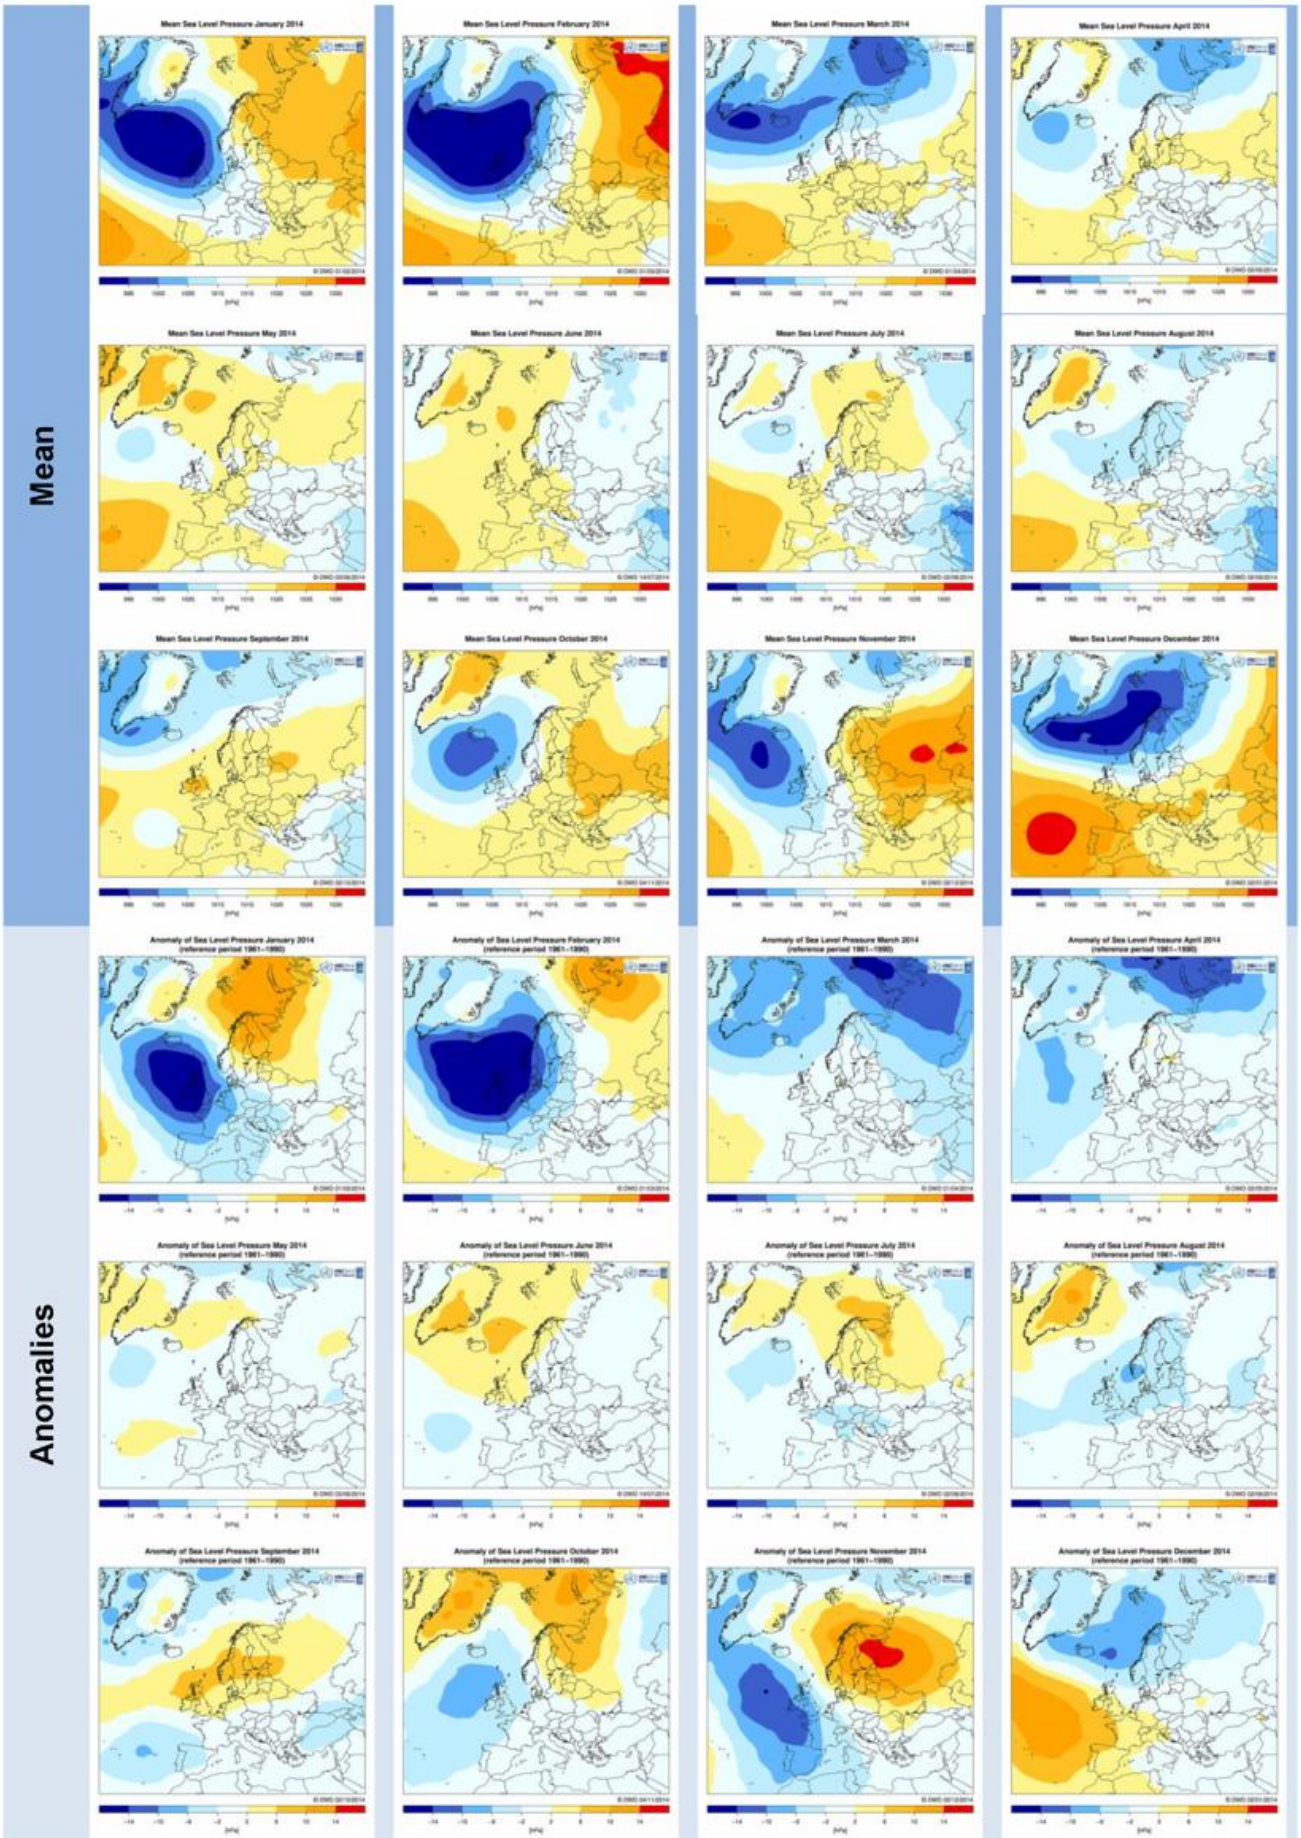

Figure 4.3: Mean and anomalies of sea level pressure in hPa for each month of the year 2014. (First column January, February, March, April)

4.2. Temperature

In most of the months and sub-regions 2014 was warmer than normal especially the winter month as can be seen from Table 4.2. In the Nordic und Baltic Countries, Iberia and the Mediterranean area each month of the year 2014 had positive anomalies.

Table 4.2: Monthly and annual area average of temperature anomalies in °C for each sub-region in the year 2014 (reference period: 1961-1990)

Region	year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.
Central and western Europe	1.85	2.54	3.06	3.01	2.76	0.53	1.25	1.73	-0.30	1.45	2.17	2.55	1.47

In **January 2014** it was warmer than normal nearly over the complete RA VI area with exception of the south-eastern Baltic Sea and parts of northern Scandinavia. Most remarkable is the positive anomaly over the Balkan Peninsula as well as over the Norwegian Sea and the Arctic Ocean with more than +4°C. On Iceland in the eastern part it was in places the 2nd warmest January since measurements started in 1873. In France it was the warmest January since 1900 together with 1988 and 1936. Also in the Netherlands January 2014 was one of the 10 warmest Januaries since 1901. In Portugal it was the 3rd warmest January since 1931 together with 1955 and 1966. It was also the 3rd warmest January since 1961 in Spain. In Austria it was the 5th warmest January since 1768. In Switzerland January 2014 ranked on place 9 of the warm Januaries since 1864. The lower level places of Switzerland north of the Alps did not register a single ice day (maximum temperature below 0°C) which is rather seldom. It was the 4th warmest January since 1961 on Malta.

In **February 2014** it was again warmer than normal in the whole WMO RA VI region. The positive anomalies were above 4°C from the Arctic Sea over Scandinavia to eastern Central Europe, eastern Europe and parts of the Balkan Peninsula as well as partly in eastern Turkey. Several Arctic stations registered new records of high February mean temperatures. The positive anomalies ranged from 4.9°C (Jan Mayen) to 14.5°C (Svalbard Lufthavn). For Jan Mayen February 2014 was the 3rd warmest on record and also the station Ekofisk in the Norwegian Sea. In Norway the positive anomalies were 6 K above normal for the whole country and it was the 2nd warmest February since 1900. In Belarus the mean temperature was 4-6°C above the normal February mean in the whole country. In Sweden several stations broke their warm February records since 1800. Latvia reports February 2014 as the 8th warmest on their record. The Netherlands report February 2014 on place 4 of the warm Februaries since 1901 (based on the station de Bilt). In Austria February 2014 was on rank 9 of the warm Februaries for 247 years.

March 2014 was much warmer than normal in Europe. In parts of Sweden it was the warmest March since 1859. Several stations registered new records of March maximum temperatures. It was the 3rd warmest March since 1900 in Norway, in Germany together with March 2002 since 1881 and in the Netherlands after 1990 and 1991 since 1901. At the station Ekofisk in the Norwegian Sea it was the 3rd warmest March since 1980. The water temperature observed here was the warmest (together with March 1990) since the start of measurements in 1980. It was the

4th warmest March since 1864 in Denmark. Also in France it was one of the 10 warmest March months for 50 years. In Austria it was the 2nd warmest March for 247 years. In Belarus it was the 2nd warmest March for more than 100 years. The mean monthly anomalies exceeded 4°C in the Arctic and the Norwegian Sea, in northern and eastern Europe except the Atlantic coastal region and southern Europe.

April 2014 was like March 2014 mostly warmer than normal. It was the 7th warmest April since 1900 in Norway (with the station Utvira fyr having the warmest April since 1868.) and 4th warmest April in Denmark (since 1883), the Netherlands since 1901, Germany (since 1881), and in Belgium (since 1960). In Austria it was the 10th warmest April in 247 years. In France it was the 5th warmest since 1900. In Portugal it was the 4th warmest April since 1961 (together with 1995).

May 2014 was warmer than normal mostly in the Arctic region and in the North Sea region including the British Isles and Denmark, in eastern Europe, in the southwest and in the southeast. In Central Europe, in the south and in Sweden it was around normal. The highest positive anomalies of more than +3°C were reached or exceeded in western European Russia. Though the monthly mean temperatures were close to normal in central and western Europe there were widely spread more warm days than normal.

June 2014 was warmer in most of the Europe except of Scandinavia and the Baltic countries with negative anomalies between -1 and -2°C. The highest positive anomalies occurred in southern France, north-western Spain, south-western Germany, Switzerland, north-eastern Italy and partly in the western Mediterranean Sea with 2 - 3°C. Similarly positive anomalies are as well recorded in the northern North Atlantic including Iceland.

June average temperature in **Israel** was close to normal, though two extreme Sharav events were recorded. On June 4th temperatures reached 42-43°C (11-12°C above the long term mean) in the coastal plain and the northwestern Negev. The Sharav continued to prevail at night, so at midnight (June 4-5th) 32-34°C were measured in the coastal plain and the northern valleys and in areas like Haifa region and the Lower Galilee, midnight temperatures reached 35-38°C. Such high temperatures at night are very unusual (Figure 4.4). The second Sharav event, on June 27-29th, was a prolonged one. The warmest areas during this event were the eastern Valleys, where 42-45°C were measured (5-7°C above average). In Elat, at the southern end of the eastern valleys, a new high record for June was set: 47.9°C. This value is also the second highest for the whole year.

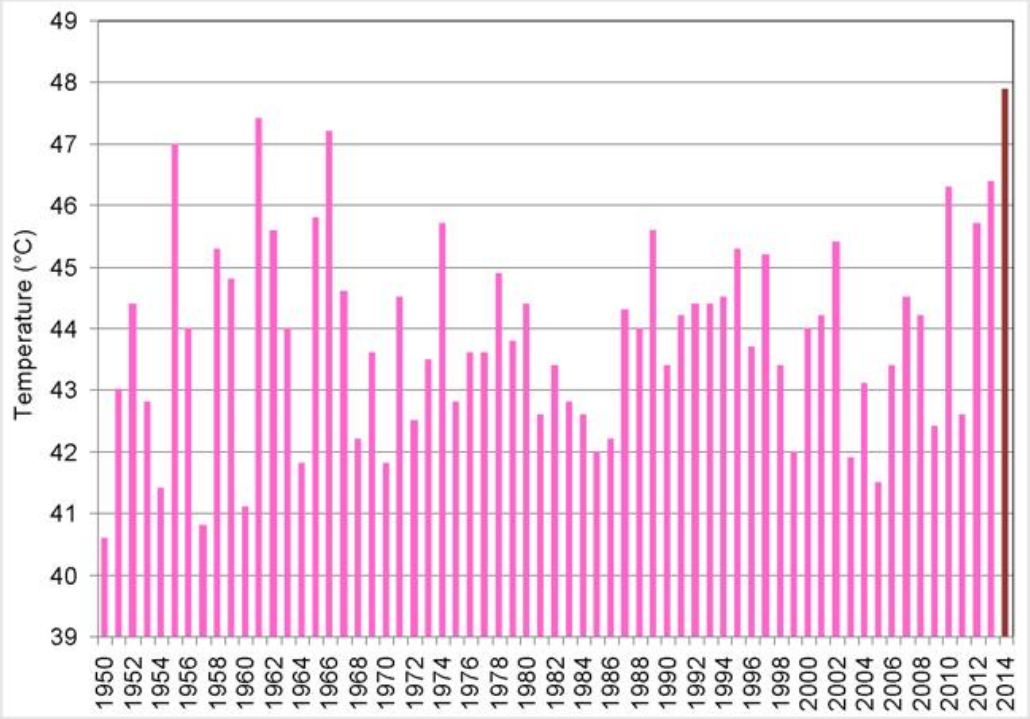

Figure 4.4: Highest maximum temperature (°C) in Elat (southern Israel) for each year in June 1950-2014 (Source: Israel Meteorological Service)

July 2014 was warmer than normal in northern, central and south-eastern Europe and colder than normal in north-eastern Europe. Slightly colder or close to normal was southern Europe. The highest positive anomalies of more than 4°C were registered in Scandinavia. On Iceland July was the 2nd warmest July since 1984 in the north and the 3rd warmest since 1972 in southern parts. In Norway it was the warmest July since 1900 with a positive anomaly of +4.3°C. In Denmark July 2014 was the 2nd warmest since 1874.

August 2014 was warmer than normal in northern, eastern and southern Europe, colder than normal or normal in central Europe. The highest positive anomalies of more than 4°C were registered around the Caspian Sea.

The temperature for **September 2014** showed for the whole WMO Region VI positive anomalies. The highest positive anomalies of more than 3°C were registered in Iceland and parts of Africa. In Ireland the Valentia Observatory and Cork Airport reported 1.7°C and 1.6°C above their average mean temperature, the warmest September for Valentia since 1991 (23 years) and since Cork Airport opened in 1962 (52 years).

The temperature for **October 2014** showed for western and southern Europe positive anomalies. The highest positive anomalies of more than 3°C were registered in Spain, Switzerland, Germany and Denmark. In Norway it was the warmest October since 10 years. The average monthly temperature in Denmark was 12.1°C therefore this was the second warmest October since measurements began (1874). This was only 0.1°C below the warmest October in the year 2006, which was 12.2°C. This October was also the third-warmest since measurements began in Germany with anomalies of 2.1°C.

The temperature in **November 2014** showed for most of the area positive anomalies. The highest anomalies of more than 4°C were registered in northern Italy, Austria and Iceland. Negative anomalies were found in East Europe with values below -4°C.

In Austria the November 2014 was 3.6°C warmer than the average for 1981-2010. This was the warmest November in the 248-year temperature measurement followed by the November of 1926 with 3.4°C.

Several stations in Switzerland also observed all-time records of temperature. Monthly mean temperature in Reykjavík, Iceland, was 5.5°C or 4.3°C warmer than the average for the period 1961-1990 and 3.2°C above the average of the last 10 years. Thus it was the second in the rank of the warmest Novembers since the beginning of measurements. In Akureyri the averaged monthly temperature was 3.4°C, that was 3.7°C above the 1961-1990 average.

The temperature in **December 2014** showed for most of the area positive anomalies. The highest anomalies of more than 4°C were registered in Finland, the arctic Russia and Turkey. Negative anomalies exist only in southwest Europe and Kazakhstan. The last days of December in many parts of Europe, except Northern Europe and Turkey were conditioned by a cold snap.

In December 2014 the central western part of Finland was more than 4.0°C warmer than the average for 1981-2010.

In Lugano (Switzerland) the December temperature reached 2.6°C above normal (1981-2010), the highest December mean since measurements began in 1864, and was 0.4°C above the last record from December 1953.

In Turkey at stations Florya and Edremit new all-time records of maximum temperature were observed.

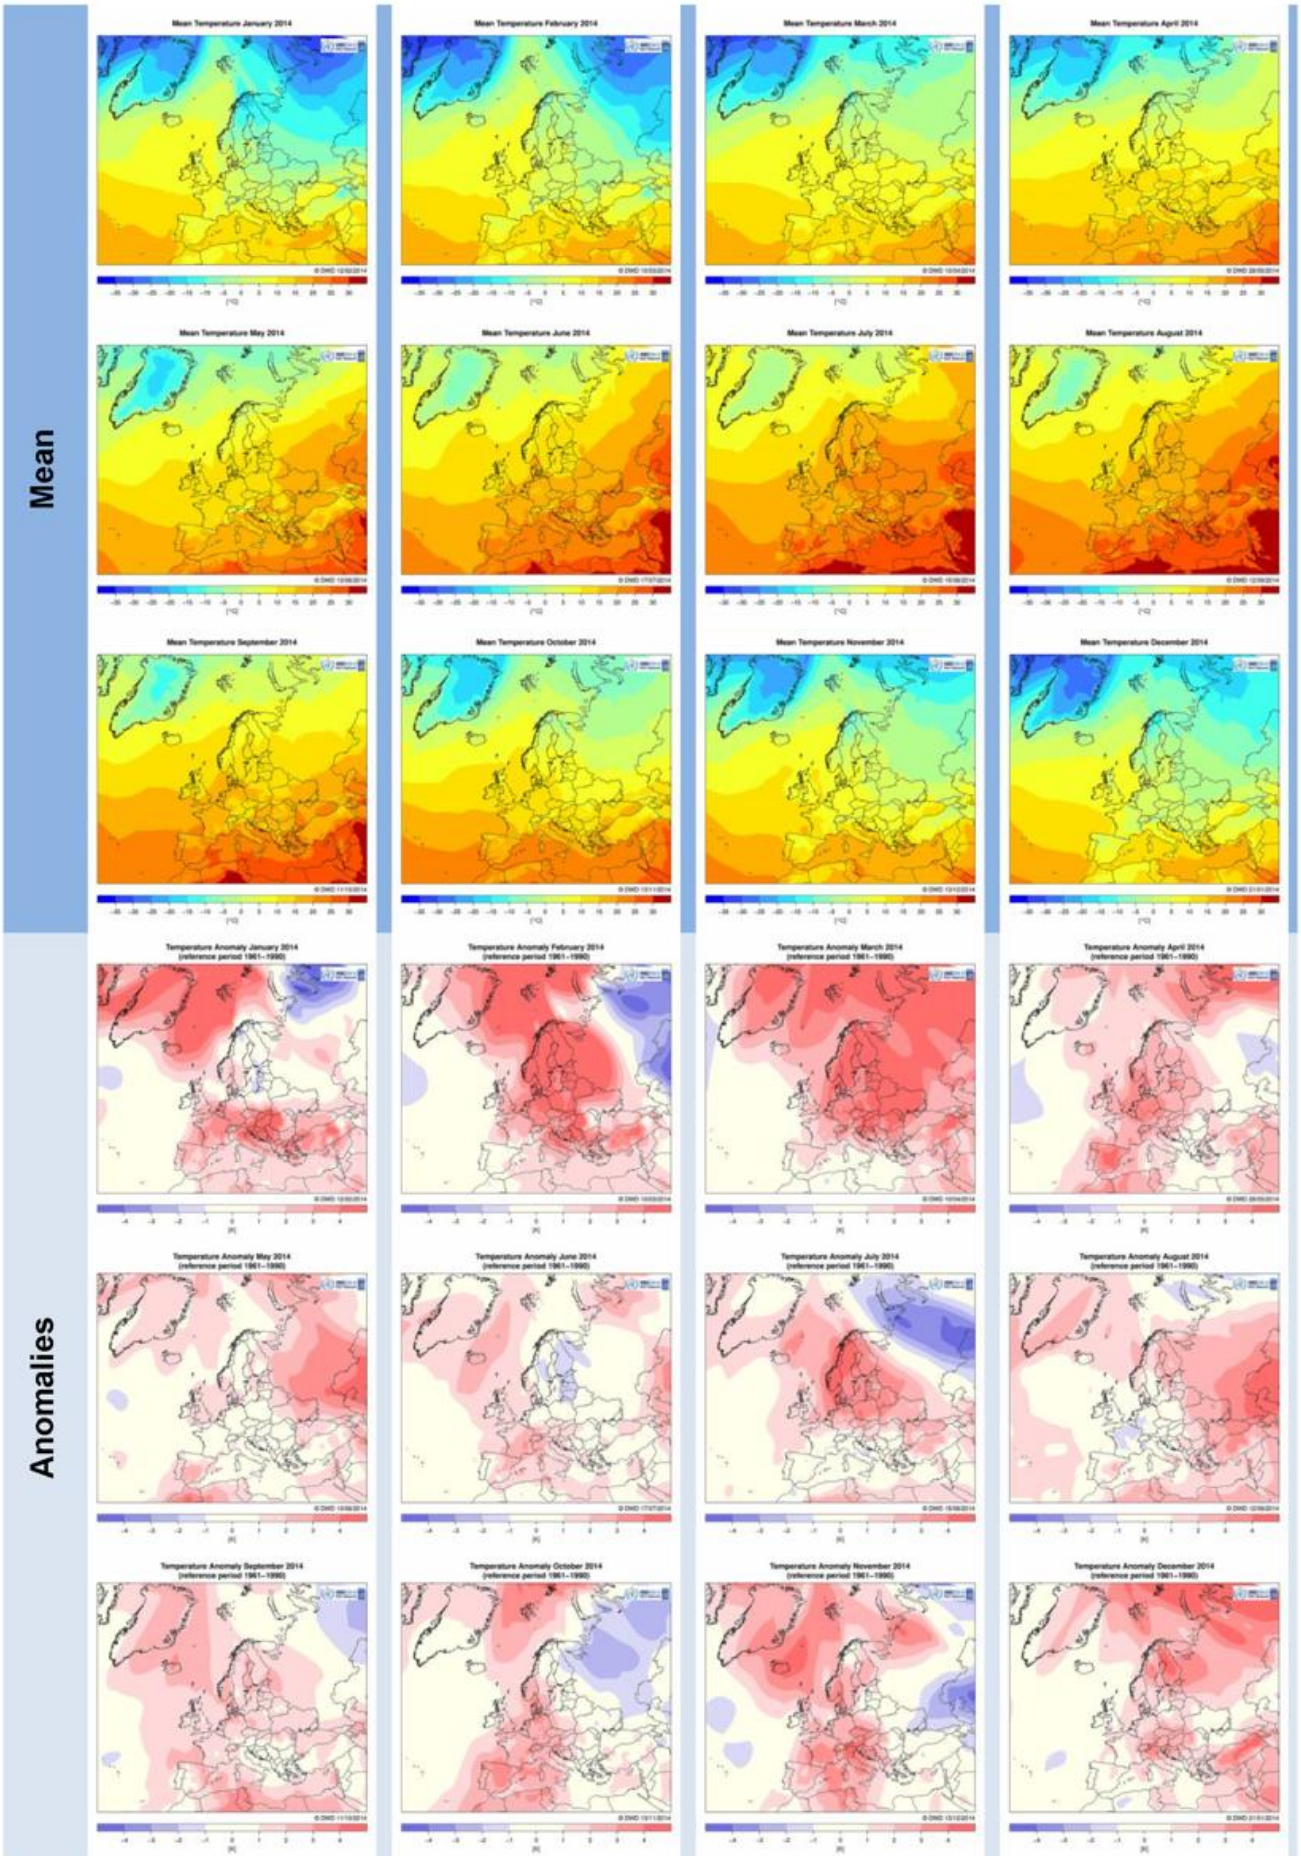

Figure 4.5: Mean and anomalies of temperature (in °C) for each month of the year 2014. (First column January, February, March, April)

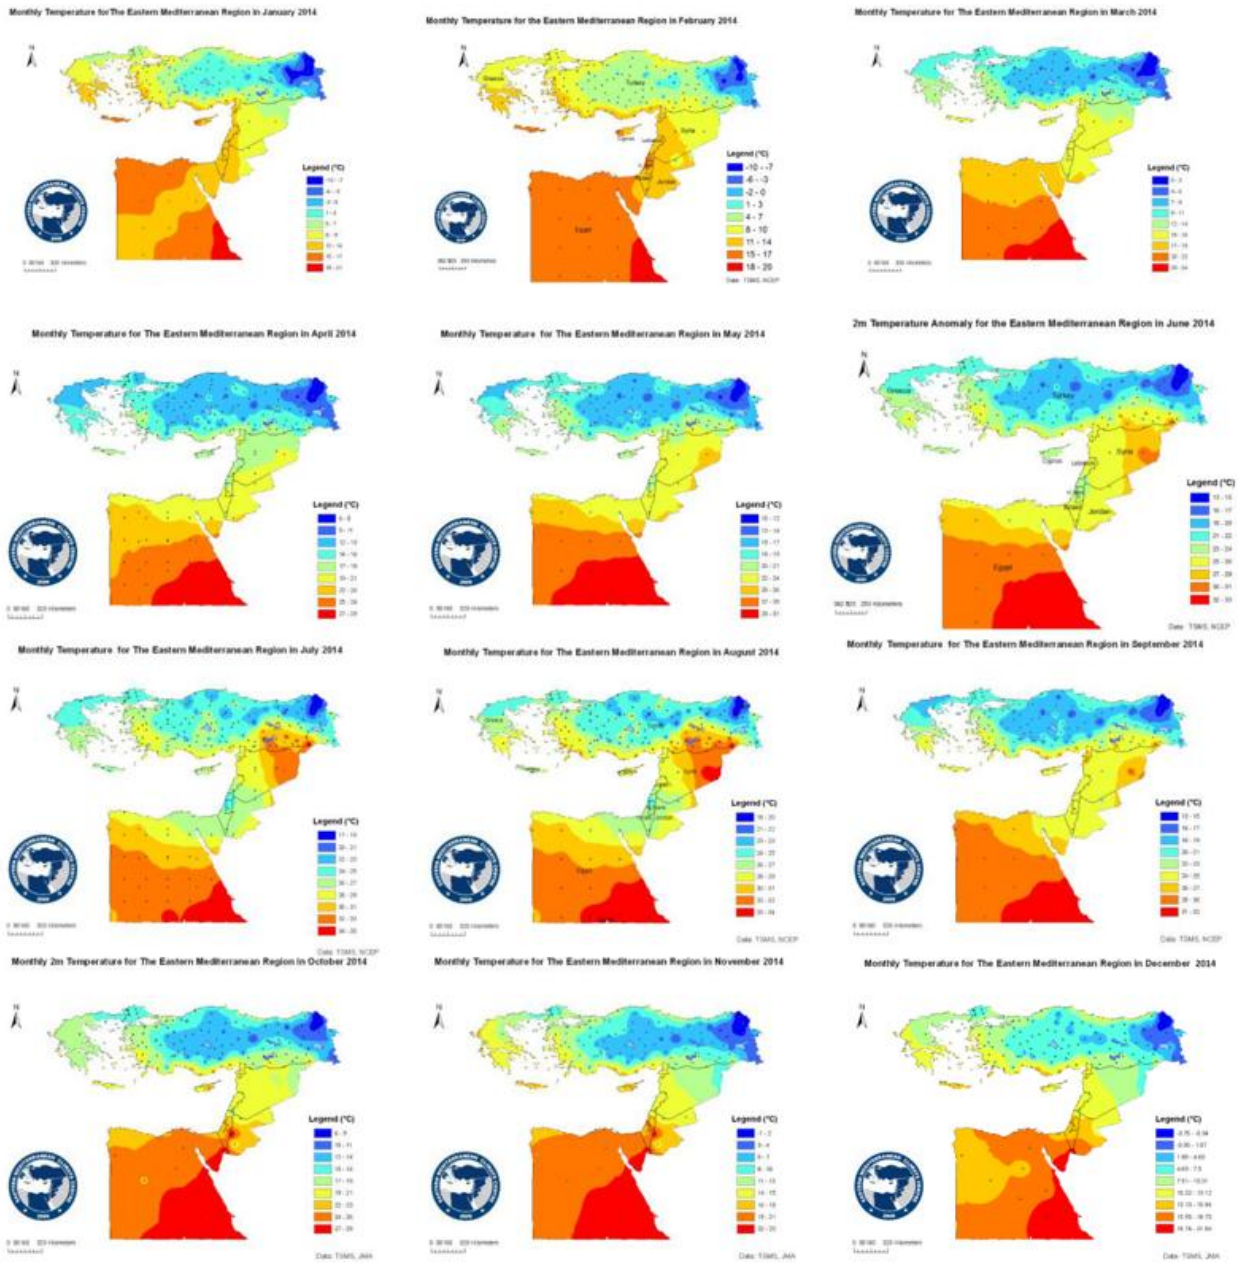

Figure 4.6: Monthly mean temperature (°C) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC)

4.3. Precipitation

In ***January 2014*** more precipitation than normal fell over the northern North Atlantic, the North Sea, in western and southwestern Europe including the Iberian Peninsula, the western Mediterranean Sea with the Adriatic Sea, in eastern Central Europe, the eastern Balkan Peninsula and southern Russia. It was drier than normal in most of northern Europe, in Central Europe and on the western northern Peninsula as well as in Turkey and the eastern Mediterranean Sea. The positive anomalies were remarkably high at the Atlantic coasts, in southern France and the southern Alpine region and the eastern Adriatic coast where heavy rainfall contributed much to flooding.

The UK overall received 151% of average rainfall making it the third wettest January in the series. A broad region from east Devon to Kent and up to the central midlands received 200 % and some locations 300%. Parts of eastern Scotland were also similarly wet, with in excess of twice the normal rainfall. It was also the wettest January in the England and Wales precipitation series that is based on a much smaller network of rain gauges, but extends back to 1766, with January 1948 being the closest comparable to January 2014. It was not wet everywhere parts of northern

Scotland were significantly drier than average. In France January 2014 was overall one of the 10 wettest Januaries since 1959. In parts of Austria (Osttirol, Oberkärnten) it was the wettest January since 1917 while easterly parts of the country were drier than normal. The last decade of January 2014 brought cold air from Russia and Scandinavia to Central Europe and precipitation fell as snow so that the covered area grew compared to December 2013 in northern, central and eastern Europe. Generally there was not much snow in January 2014 in the northern Alps but episodes of very intense snowfall led to higher totals of freshly fallen snow than the mean of 1981-2010 for instance in places in Austria or Switzerland in the southern Alps.

February 2014 was wetter than normal in western and southern Europe, in Sweden, southern Norway and Denmark as well as in eastern parts of the Baltic States and in northern Russia. It was also wetter than normal in the southern Alpine region and the north-western Adria, especially in Slovenia. Switzerland reported monthly totals close to new records for February at some stations. At Lugano the 2nd highest total was registered since 1864. The region Bretagne in northwestern France had its wettest February since 1959 with 200% to 300% of the long-term mean. For the whole country it was the 4th wettest February since 1959. It was as well the 4th wettest February in UK with 184% of the 1981-2010 long-term reference. Valentia Observatory in Ireland reported its wettest February since records began in 1866 (148 years) with 292.4mm and 236% of the long-term average. In southern Norway more than 300% of the normal February rainfall was recorded as well and in a smaller region even 400% were exceeded. In Slovenia at the beginning of February 2014 4-day totals between 130 mm and 400 mm occurred. It was drier than normal in eastern Central Europe as well as on the eastern Balkan Peninsula, southern Ukraine and southern Russia, the eastern Mediterranean and Middle East. In parts of eastern Central Europe, north of the Black Sea in Middle East (cf. Figure 4.7) and in parts of the Levante monthly totals were below 10 mm, partly even below 1 mm. Rather dry was as well most of Norway. Due to the warm temperatures southern Sweden, western, central and southern Europe, the Mediterranean, most of the Balkan Peninsula and most of Middle East had few snow. Exceptions were the Alps and eastern Romania.

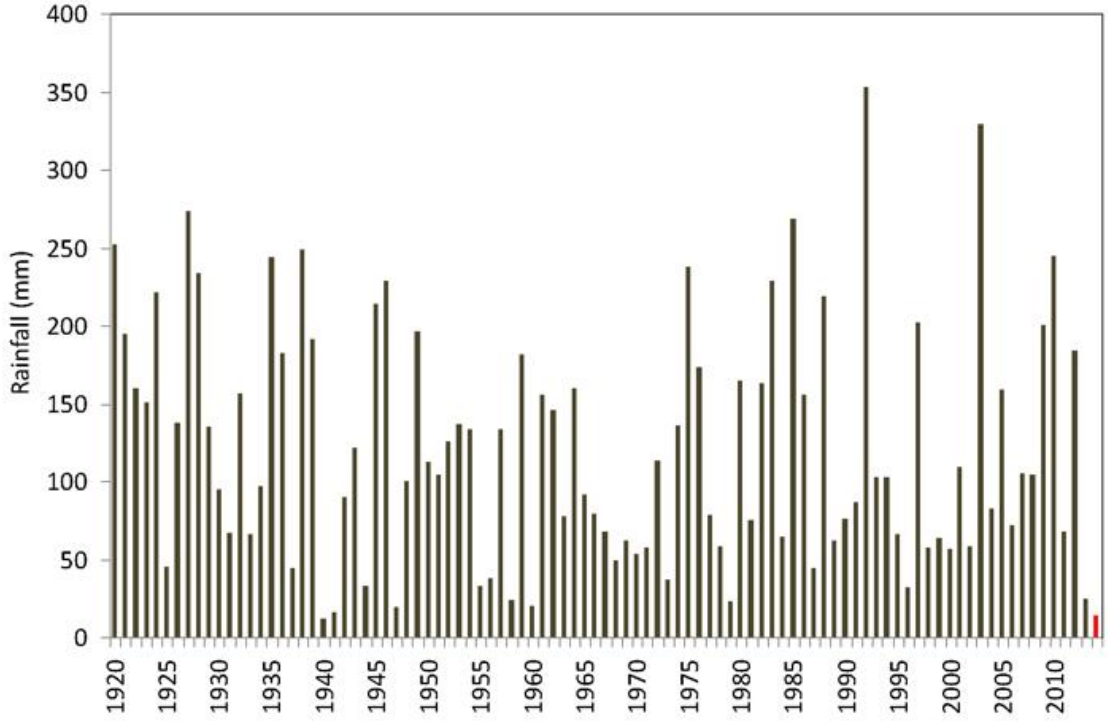

Figure 4.7: Monthly rainfall (mm) in Jerusalem in February 1920-2014 (Source: Israel Meteorological Service)

March 2014 was very dry in western and central Europe, the northern Balkan Peninsula, most of the Iberian Peninsula and eastern Europe and western Russia. In France, the Netherlands and Germany precipitation was below 40% of the normal, partly in Germany and France even below

20%. March 2014 was in France not as dry as in 2012 but in the region of the Alsace it was the driest March since 1959. March 2014 has been the 5th driest March in Germany since 1881. In northern Spain it was partly wetter but the whole country resulted close to normal. A daily total of 121 mm occurred in Puerto de Navacerrada on 1 March. The Norwegian coastal region, Poland and the eastern Balkan Peninsula, southern Russia and Middle East as well as the eastern Mediterranean were wetter than normal. For Norway 2014 was the 7th wettest March since 1900.

April 2014 was wetter than normal on the Balkan Peninsula and southern Italy as well as in Scandinavia at the Atlantic coasts and in eastern parts of European Russia. It was drier than normal mainly in central Europe, in the central parts of Sweden and in southern Finland and western European Russia as well as the Baltic states, in Belarus and in the eastern Mediterranean Sea and Middle East. Elsewhere it was close to normal. For instance in Austria the station Retz had the lowest precipitation total for the period October to April since 1895. In France it was the 14th driest April since 1959. In Germany it was the 41st driest April since 1901 and the 49th driest since 1881. April 2014 brought partly heavy thunderstorms with heavy to extremely heavy precipitation (partly as snow) in the Mediterranean region (inc. the Iberian Peninsula) and the Balkan Peninsula. The precipitation surplus on the Balkan Peninsula corresponds to totals above the 80th percentile (based on the 1981-2010 reference).

May 2014 was wetter than normal in western and central Europe, most of the northern European continent as well as on the Balkan Peninsula, western Turkey and the eastern Mediterranean Sea area. Drier than normal were Iceland, western Scandinavia, the Iberian Peninsula, southern France and northern Italy, Greece, most of western European Russia and Middle East. The precipitation surplus in the southeast as well as in the northwest exceeded the 80th percentiles (1981-2010 reference). They were due to very heavy to extremely heavy precipitation events.

Report from the Republic Hydrometeorological Service of Serbia

May 2014 in Serbia was marked by precipitation that was significantly above the average values. Record breaking daily precipitation sums were registered at Valjevo, Loznica and Belgrade principal meteorological stations. Total 3-day precipitation amount exceeded 1000-year return period sum, in parts of western and central Serbia.

The total May amount of precipitation compared to the normal for the 1961-1990 base period was in a range between 134% in Kursumlija and 394% in Belgrade.

The highest precipitation amount was recorded in the period 14 – 16 May 2014, when the sums ranged between 26.3 mm in Kursumlija and 213.2 mm in Loznica.

The highest 3-day precipitation sums were registered in western and parts of central Serbia (above 100 mm) which is above the average for May (Figure 4.8).

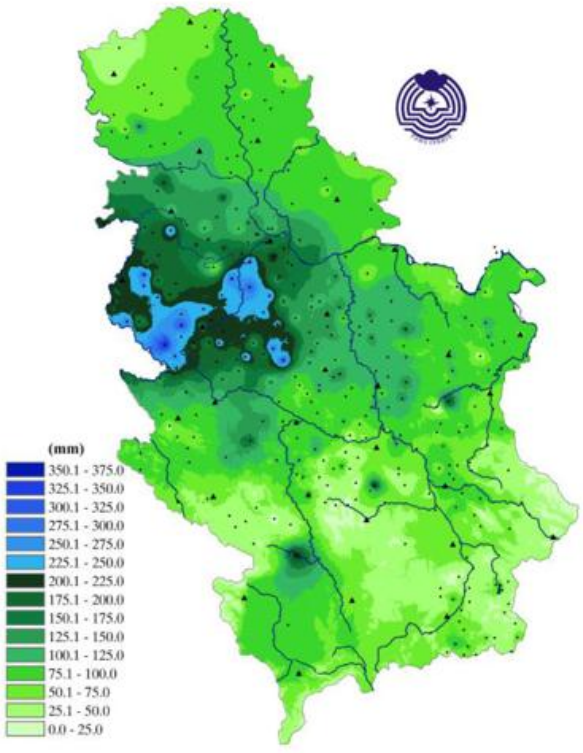

Figure 4.8: Spatial distribution of 3-day precipitation sums for the period 14 - 16 May 2014 in Serbia based on the data obtained from meteorological, climatological and precipitation stations (Source: Republic Hydrometeorological Service of Serbia)

June 2014 was drier than normal in central, western and south-western Europe. In Germany it was the 11th driest June since 1901 and the 14th driest since 1881. In the southern part of Germany

the drought conditions were classified as severely dry. More - partly much more - precipitation than normal fell in western Turkey and on the Balkan Peninsula, especially in Romania as well as in European Russia and the Baltic states.

In ***July 2014*** was wetter than normal in western and south-eastern continental Europe and most of central and southern Europe and parts of Middle East. Wetter than normal was also the eastern part of European Russia. Drier than normal were the British Isles, most of northern and eastern Europe and southern Iberia, Sicily and western Turkey. July 2014 was the 9th wettest July since 1901 and the 10th wettest since 1881 in Germany. July 2014 brought many heavy precipitation events in connection with convective activity which mostly contributed to the precipitation surplus.

August 2014 August 2014 was wetter than normal in most parts of Europe except southern Europe, and parts of Middle East, and the southern part of Russia and Ukraine. A precipitation affected the northwest quarter of France with an amount reaching one and a half to three times of the normal.

September 2014 was drier than normal in western, northern and eastern Europe. In the UK it was the second driest September in a series from 1910, and only 1959 was drier. In Portugal several stations reported more than 300% of relative precipitation, also the absolute values ranges between 100 and 160 mm. From central Europe over the Balkan Peninsula and Turkey a band of high monthly precipitation totals occurred with more than 300 mm in Italy even 479.3 mm at station Monte S. Angelo. The relative precipitation anomalies show also dramatic values of 400% above normal in this region. In Montenegro the monthly precipitation totals ranged from 137 to 503 mm or 168% to 455%.

The precipitable water anomalies show for the whole Mediterranean values of up to 8 mm or more than 3 standard deviations. Two peaks are remarkable one above Costa Brava/Gulf of Lions and the other western off the Spanish/French Atlantic coast.

October 2014 was drier than normal in eastern Spain, southern France and Italy. In northern Scandinavia and Russia as well as over an area extended from Poland, Belarus, Ukraine and Russia till Kazakhstan, lower precipitation amounts were observed.

Some of the Norwegian stations registered more than 250% of the normal precipitation resulting in many floods. The Balkan and Turkey received more than normal precipitation, locally more than 200%. In Italy were also heavy precipitation registered at some stations eg. at station Termoli, both the daily extreme increased from 65.1 to 91.6 mm, and the monthly extreme, increased from 130.8 to 168.8 mm.

9-10 October: the province of Genova was hit by an intense thunderstorm with maxima cumulated rain over the two days of 569.6 mm at the station of Geirato. During this event several rivers overflew and the event was followed by several other minor local intense event and floods which produced a substantial destabilization of the slopes, making the territory more vulnerable.

13 October: the province of Parma (Emilia-Romagna) was hit by an intense thunderstorm. Maximum intensities recorded during the event were 81.8 mm in 1 hour at Marra, but many station over the Apennines in this province recorded more than 30 mm in 1 hour for several consecutive hours. Maximum daily accumulated precipitation in that day reached a maximum of 302.4 mm at the station of Marra. (as provided by the Servizio Idro-Meteo-Clima ARPA EMILIA-ROMAGNA)

The anomalies in **November 2014** showed negative values in Central and Eastern Europe. In Portugal, Spain, southern France, Switzerland, southern Austria and northern Italy observed higher precipitation.

The surplus amounted in Austria of up to 254% at station Kötschach-Mauthen. The precipitation sum observed in Switzerland reached at station Lugano 587 mm or 462%. Many other stations reported heavy precipitation as a result floods occurred at Lago Maggiore and Lago di Lugano.

In southern France five episodes of heavy precipitation were observed with up to 500 mm. Many monthly records were broken eg. 318 mm in Oletta, 387 mm in Lanas, 563 mm in Nice and 575 mm in Bormes-les-Mimosas.

According to TSMS's Flash Flood Guidance System (FFGS), heavy precipitation was expected in Marmaris on 13 November 2014 at 18:00 UTC. This forecast was published as warning by TSMS. Marmaris's normal rainfall for November is 171mm. But on 13 November 244mm rainfall received in one day. Due to this heavy rainfall, Beldibi River overflowed; landslides occurred on some village roads, muddy water covered some of the shops and basements, urban traffic was disrupted temporarily. There were no casualties but some property damages.

Table 4.3 Rainfall intensity analysis of Marmaris on 13.11.2014 **(**as provided by the Turkish State Meteorological Service**,** TSMS**)**

Start Date	Start Time	End Date	End Time	Duration (min)	Amount (mm)	Intensty (mm/ha)

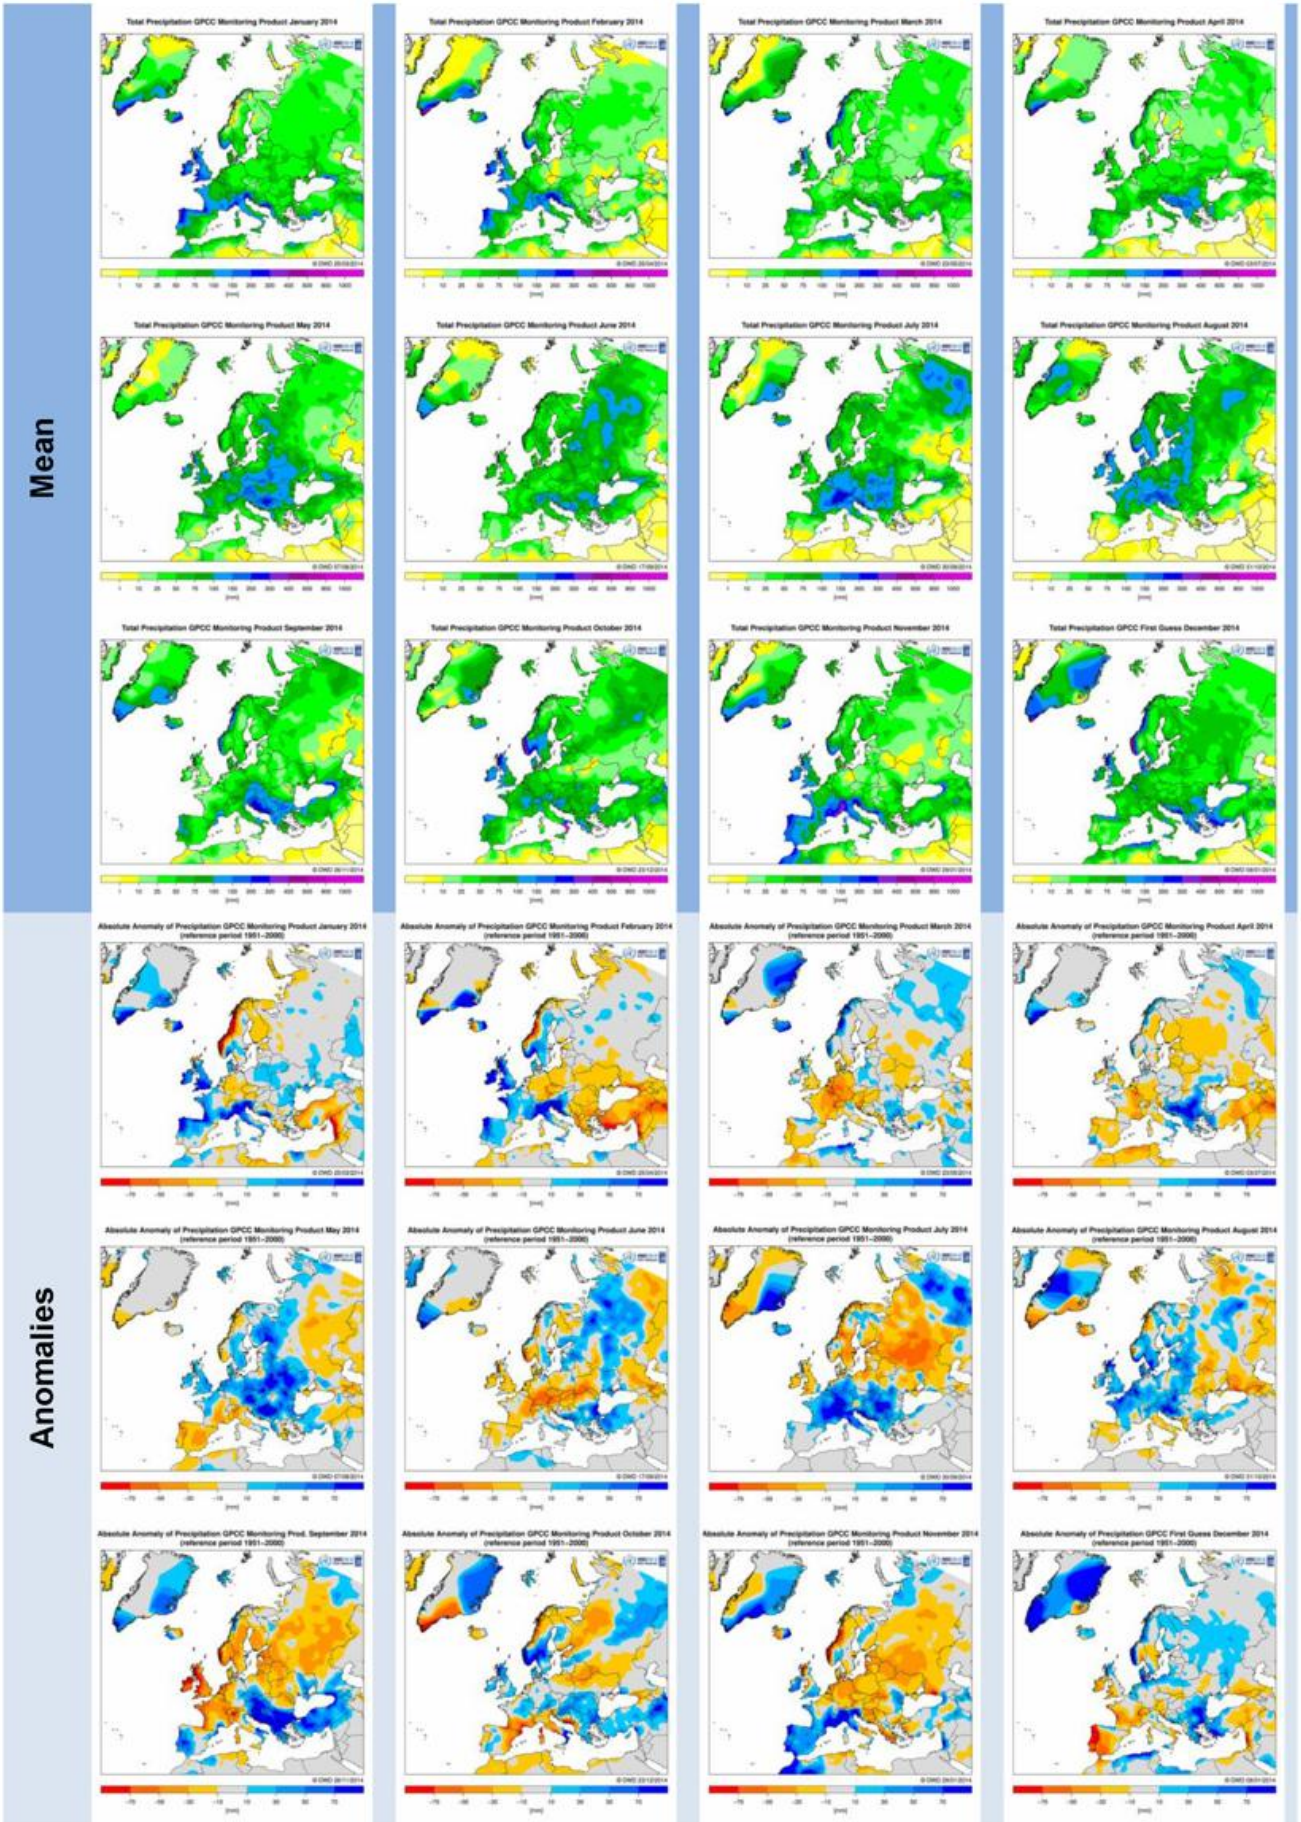

Figure 4.10: Mean and anomalies of precipitation (in mm/month) for each month of the year 2014. (First column January, February, March, April)

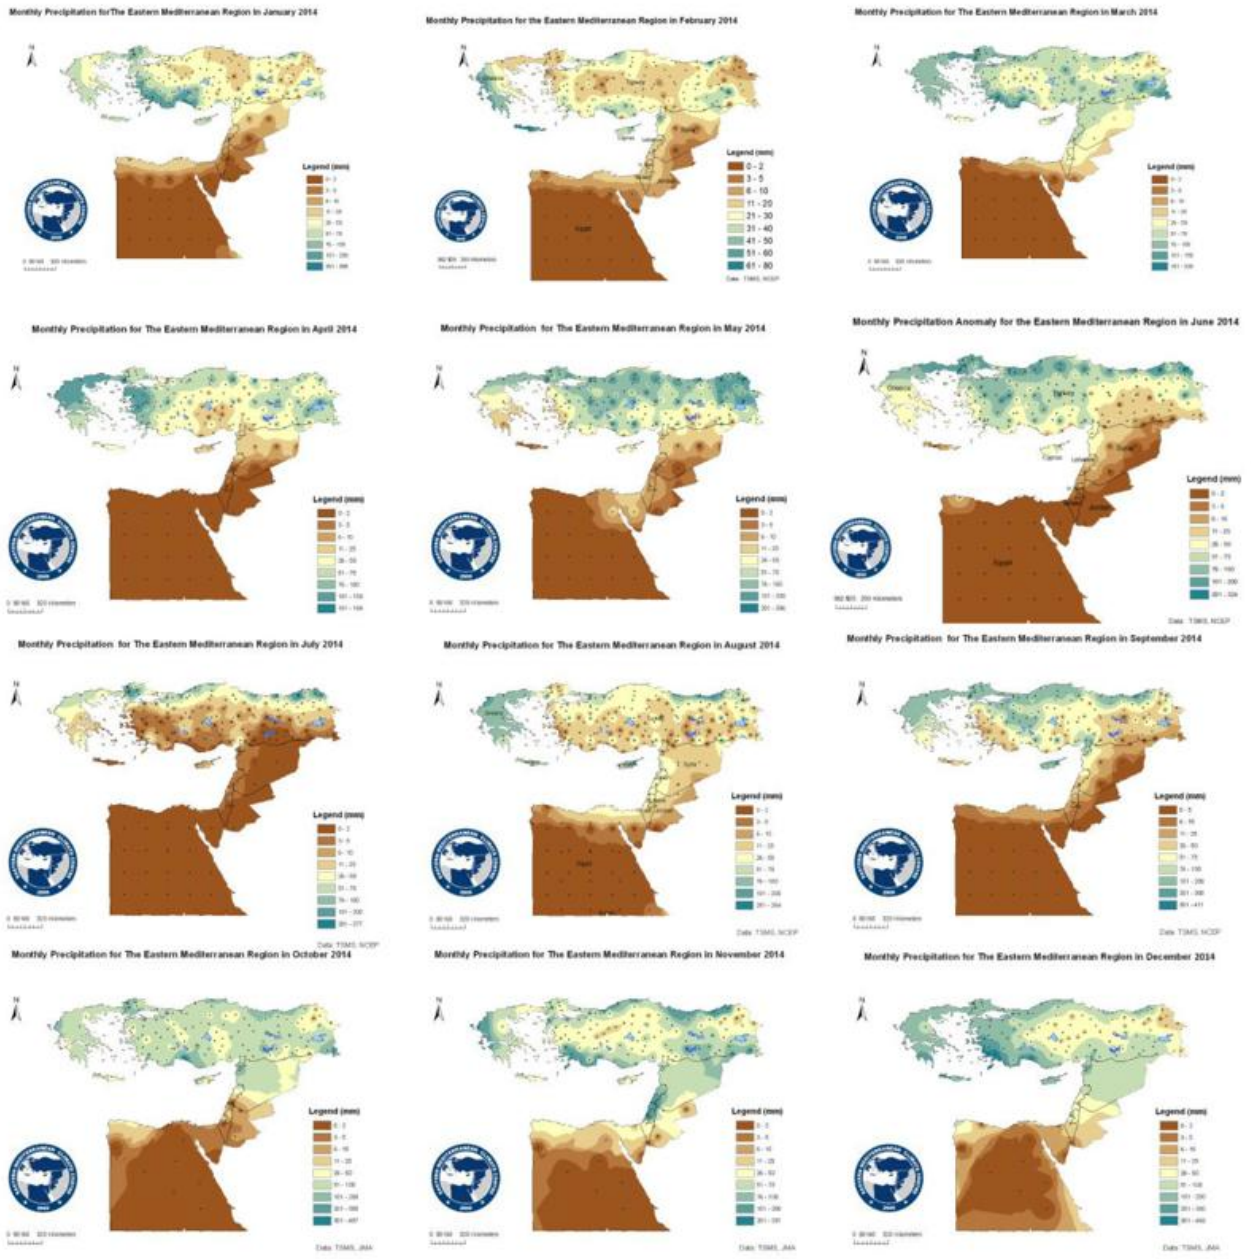

Figure 4.11: Monthly precipitation totals (mm) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC)

4.4. Sunshine duration

January 2014 was sunnier than normal mainly over European Russia and the eastern parts of the Baltic Sea area. In western Central Europe, the south of the British Isles, parts of the Balkan Peninsula, on Sicily and eastern Turkey it was partly sunnier than normal as well but the pattern was very variable. Less sunshine than normal prevailed in the northwest, in the west, in the south and in the southeast of the region.

February 2014 was mostly sunnier than normal from western Europe to the Middle East, while it was dull in Scandinavia and most of eastern Europe as well as in the southwest and south. France received less sunshine than normal except the north-western part of the country. In Poland and eastern Germany the sunshine surplus exceeded 150% as well as in parts of Turkey and Middle East. Below 25% of sunshine were recorded in Finland and adjacent parts of Russia. The cloudy conditions reduced the outgoing longwave radiation and Finland observed the second warmest February on record with temperature anomalies of up to +8.2°C

Most of the European continent was sunnier than normal in **March 2014**. In south-eastern UK, central, northern and eastern France, the Netherlands, most of Germany, eastern Austria and central Poland and parts of the Czech Republic, Slovakia and Hungary as well as in eastern Ukraine and southwestern Russia the anomalies were above 50%. March 2014 has been the sunniest March in the Netherlands since 1901 and in France the sunniest since 1950. It was the 3rd richest March in sunshine since 1951 in Germany.

April 2014 was sunnier than normal in large parts of the European continent with exception of the far north, the east, the Balkan Peninsula and mostly the Atlantic west coast. It was sunniest around the Baltic Sea. The monthly sunshine duration in Lithuania amounted to 240–290 hours or 60–98 h longer than normal.

May 2014 was sunnier than normal on the Iberian Peninsula and the western Mediterranean, in northern Scandinavia, in eastern central Europe and on the northern Balkan Peninsula as well as in most of European Russia except the north. It was dull in Ireland and on the British Isles, in central Europe, the Baltic States, around the Black Sea and in Middle East. In Ireland sunshine totals were all below average with percentage of LTA values and total sunshine hours ranging from 56% and 98.7 hours.

June 2014 was sunnier than normal in most of western, central and eastern central Europe as well as in most of central Finland. More than 125% of the normal sunshine duration was registered in western England, eastern France, southern Germany, in Poland, Austria, Slovakia and parts of Hungary as well as in central Finland. It was less sunny than normal around the North Sea, in the North, in Eastern Europe, the Balkan Peninsula and Middle East. June 2014 in Austria was the sunniest since the year 2003. The sunshine duration was 28 % above the average 1961-1990.

July 2014 was sunnier than normal in northern and eastern central Europe as well as northern Europe. In Sweden, Norway, Finland and Poland the surplus partly exceeded 50%. Denmark recorded the 7th sunniest July since 1920. Sweden registered more sunshine than normal at all stations. Most sunshine had station Luleå with 407 hours. Eastern Europe and also parts of France, Switzerland and Italy received less than 75% of the normal sunshine duration.

August 2014 was sunnier than normal in northern, and Eastern Europe. In parts of Siberia the surplus partly exceeded 25%. Remarkably less than normal sunshine was recorded in central Europe and also parts of France. Turkey received less than 25% of the normal sunshine duration.

September 2014 was sunnier than normal in northern, and Eastern Europe. In Sweden a new record of sunshine duration in Stockholm (the series started 1908) and other stations were registered. In Finland and Poland the surplus partly exceeded 50%. Remarkably less than normal sunshine was recorded in central and southeastern Europe. Parts of Kazakhstan received less than 50% of the normal sunshine duration. New record for sunshine was recorded in Sweden with 243 hours.

In ***October*** higher than normal sunshine duration was measured in eastern Spain, southern France, Italy, northern Scandinavia, Baltic countries, Poland, Belarus, Ukraine and western Russia.

In a band from UK across Central Europe, the Balkan to Turkey the sunshine duration was below normal.

Higher than normal sunshine occurred in ***November*** in a band from the Netherland and Belgium through northern Germany, Poland, Belarus, Ukraine to western Russia. In southern Europe the sunshine duration was below normal and accompanied by rainy clouds.

The UK received 152% of the average sunshine hours, and it was the second sunniest **December** in a series from 1929 whereas Northern Europe showed a lack of sunshine receiving only 25% of the long term mean. In southern Scandinavia, Iberia, the Balkan, Ukraine and Belarus the anomalies of the sunshine duration showed values of more than 150%.

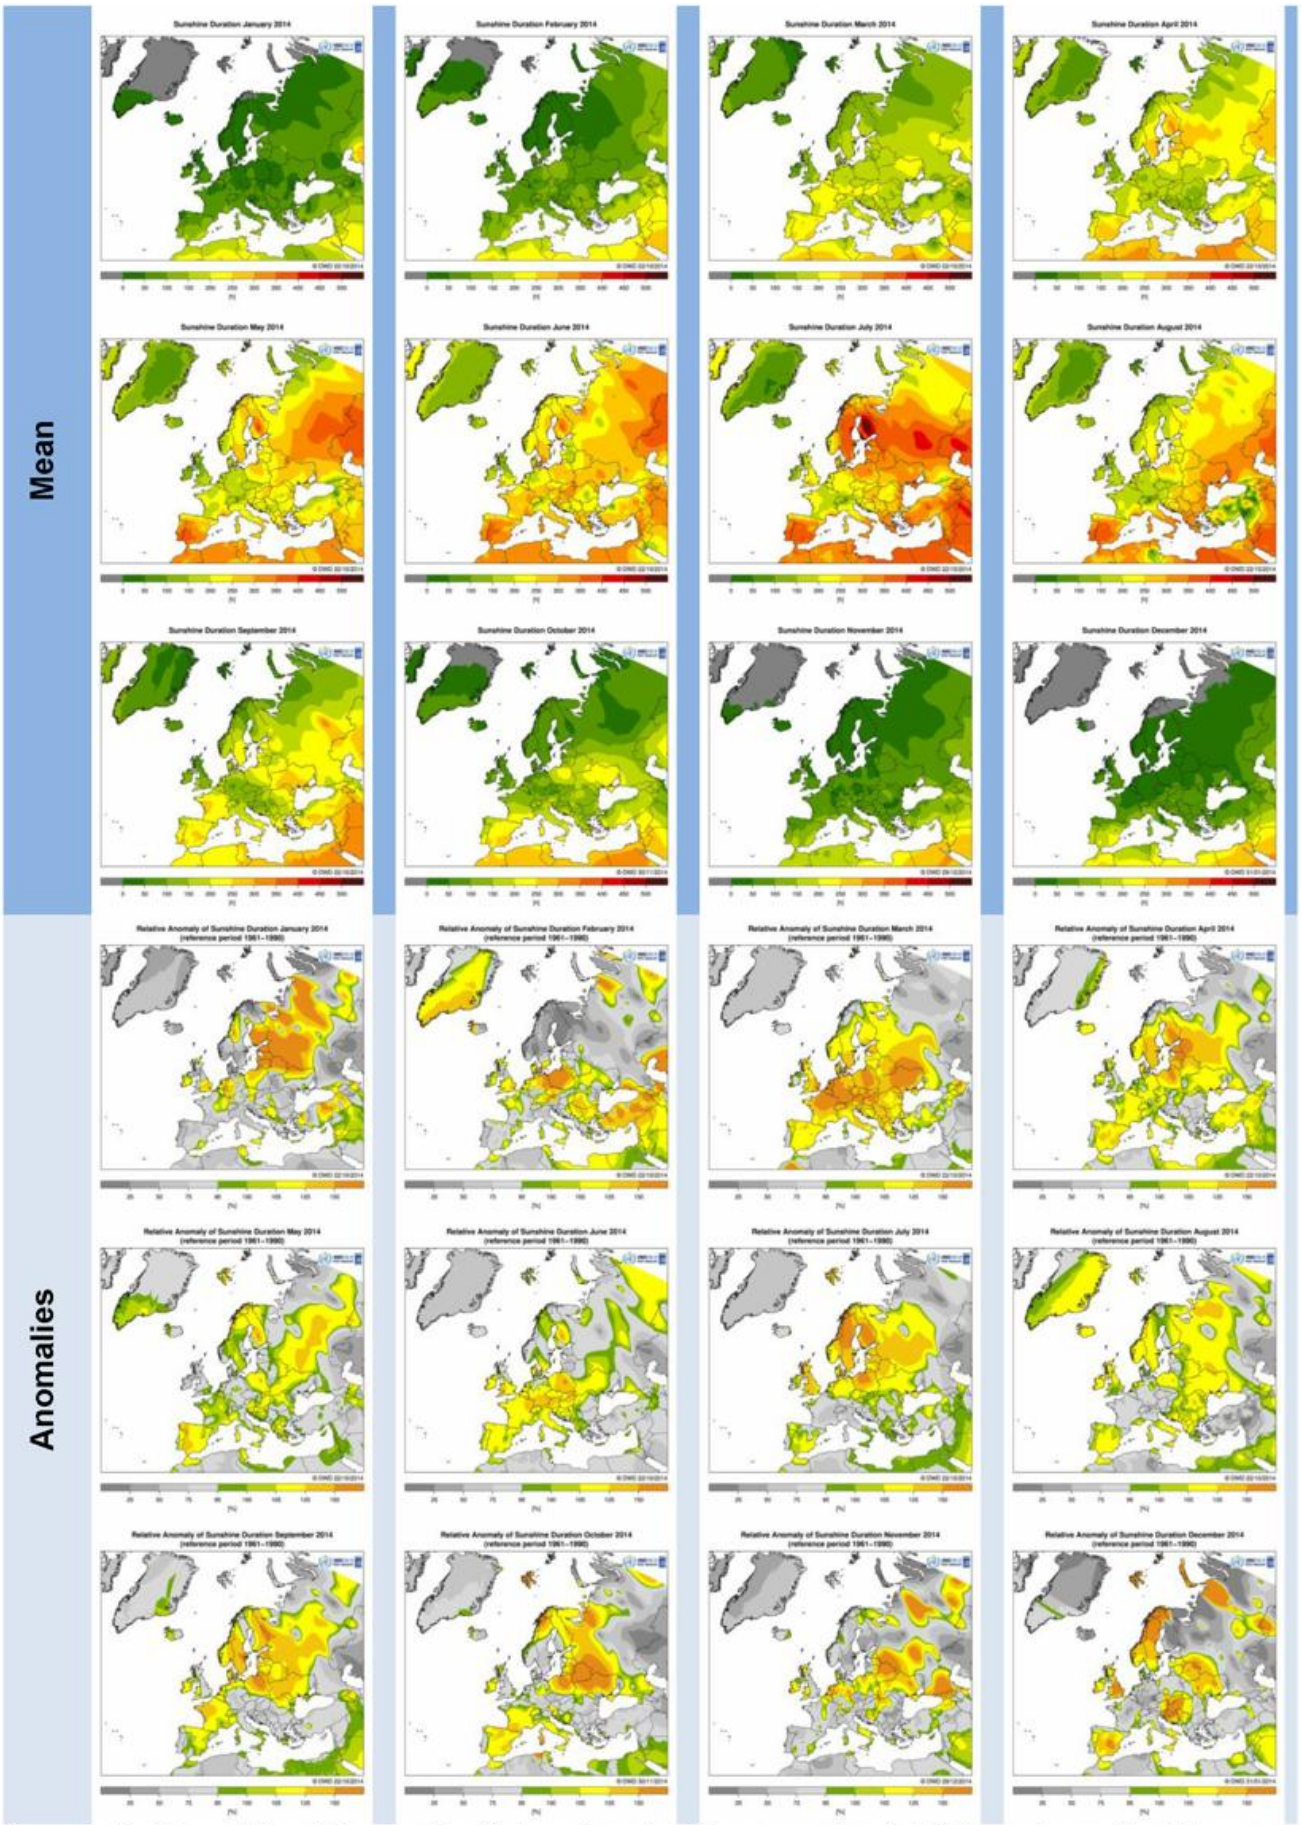

Figure 4.12: Mean of Sunshine duration (in hours) and relative anomalies (in %) for each month of the year 2014. (First column January, February, March, April)

4.5. Monthly climate extremes and events

The following maps are based on different data (as noted in parentheses) and should summarize the weather conditions in each month of the year 2014.

From January to March 2014 in Northern and Central Europe the monthly temperature anomalies were 4°C warmer than the normal and the number of warm days (exceeding the 90th percentile) were above normal. The areas at the Atlantic costs and the British Isles were affected by strong wind gusts.

In April and May in the Balkan the number of wet days (exceeding the 95th percentile) was higher than normal and caused flooding.

In June in many parts of Scandinavia the number of cold days (below the 10th percentile) was above the long term mean while the remaining parts of Europe showed more number of warm days.

Eastern Russia and the western Mediterranean showed in July cold anomalies and more number of cold days than usual. Most of Europe showed also a higher number of wet days.

In August Western Europe was affected by more cold days while Central and Northern Europe showed again higher number of wet days.

Greenland and Norway was affected in September by strong wind gusts. Central and Northern Europe showed again higher number of warm and wet days that continued in October.

During November and December most parts of Europe showed a higher number of warm and wet days. Norway, the Baltic States and in the Gulf of Lions were affected by strong wind gusts in November and December.

The Monthly Event Map contains information about the extreme anomalies of temperature, precipitation and wind gusts. Point are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (>=32 m/s) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

Legend of Figure 4:13:

- Anomaly of very wet days > 0 (ECAD)
- Wind gusts (>=32 m/s) (SYNOP)
- Anomaly of warm days > 0 (ECAD)
- Anomaly of cold days > 0 (ECAD)
- Anomaly of TG ≤ -4K (CLIMAT and ship obs.)
- Anomaly of TG ≥ 4K (CLIMAT and ship obs.)
- Aridity index < -1.5 modified SPI (GPCC)
- RR ≥ 150% of climatology (GPCC)

Based on climatology 1961-1990 (GPCC climatology: 1951-2000)

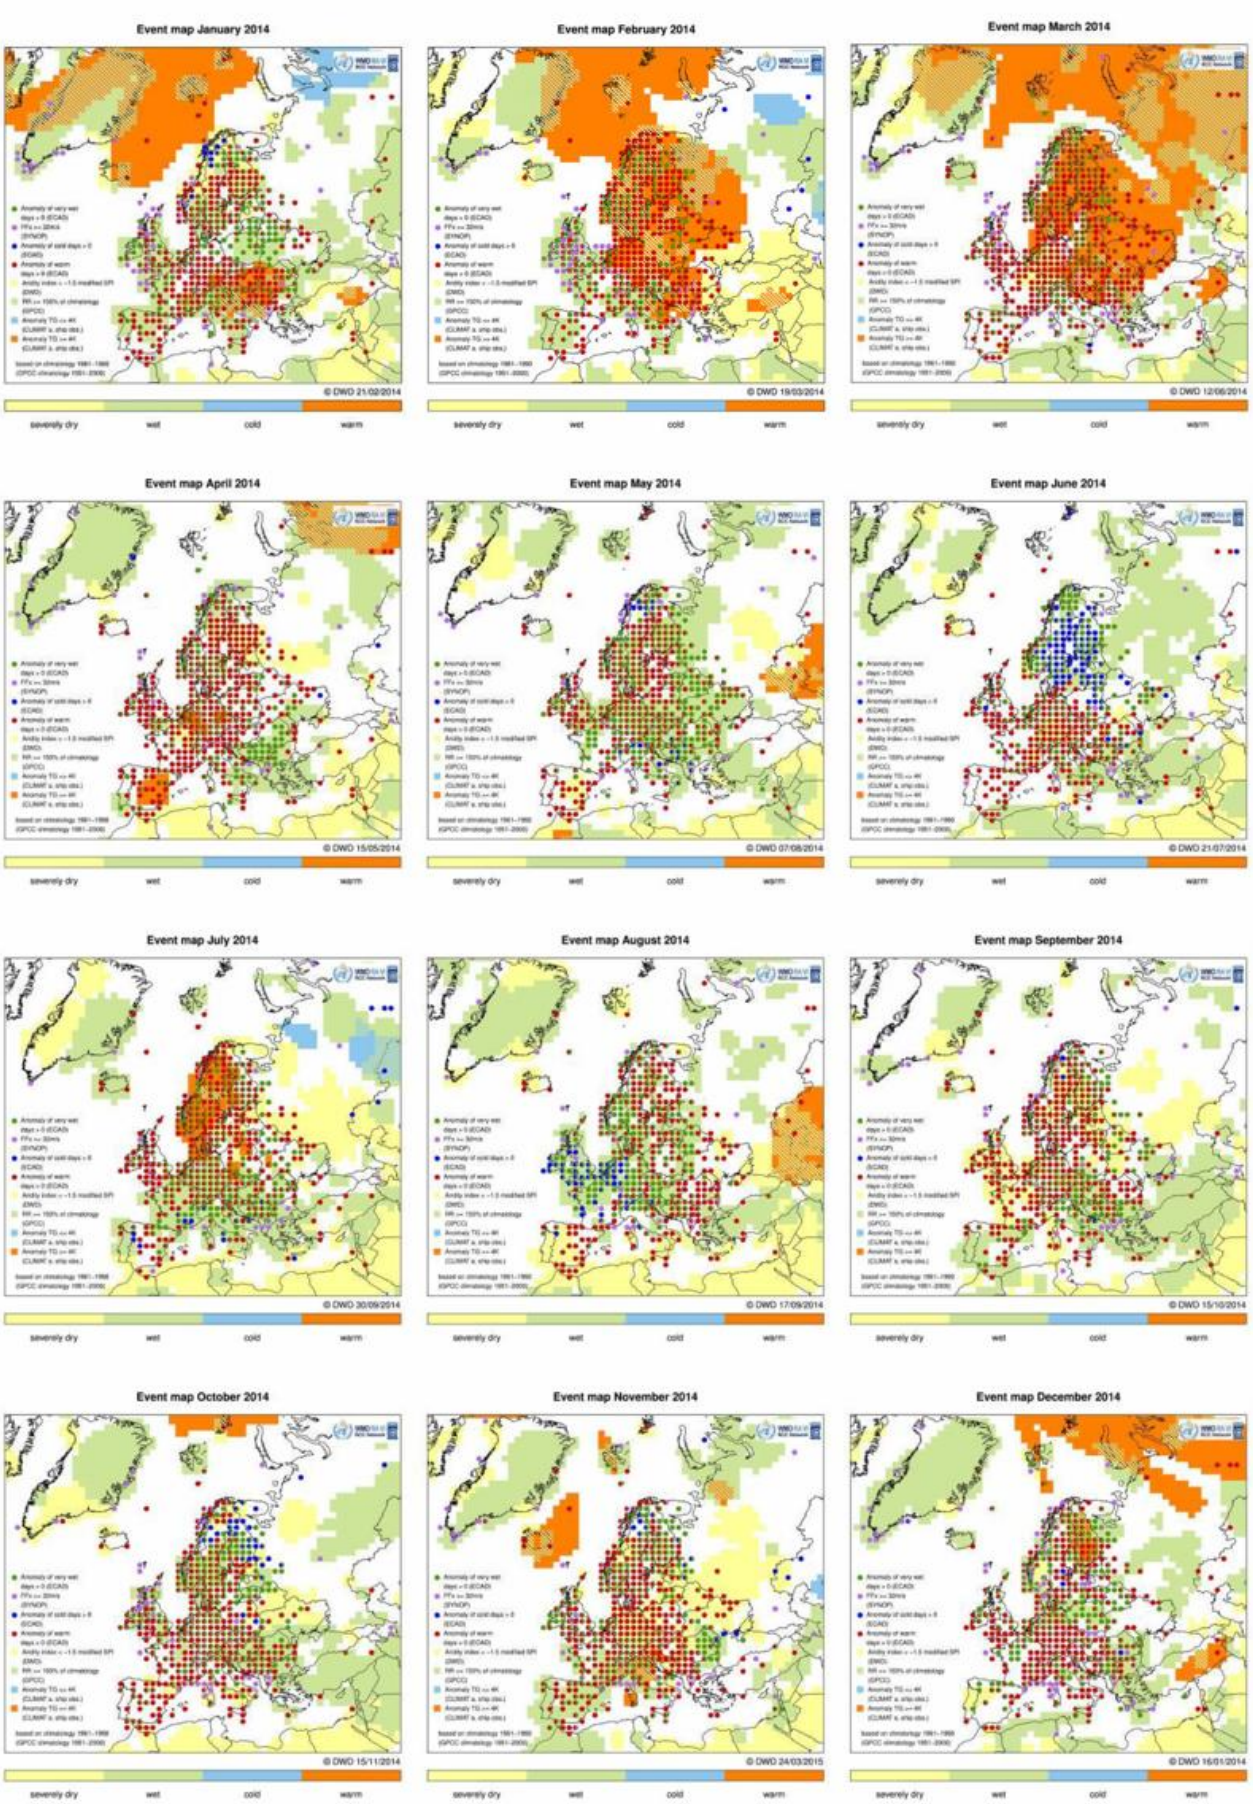

Figure 4.13: Map of Climate Extremes for each month of the year 2014.

5. Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the national meteorological services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 sub-regions defined above (Figure 1.1). An overview about the contributed countries, the time series lengths and the area representativeness can be found in Table 5.1. Most are temperature time series. Each sub-region is at least represented by one country. Time series of precipitation totals are fewer but each sub-region is represented with at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries and they belong to different sub-regions.

After this, we present examples of the temporal development of other temperature related phenomena, such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Władysławowo.

Table 5.1: Availability of the long-term records of temperature, precipitation and sunshine duration from some participant countries.

		Temperature		Precipitation		Sunshine Duration	
Sub-region	**Country**	**Spatial Mean1**	**Single Station**	**Spatial Mean**	**Single Station**	**Spatial Mean**	**Single Station**
Central and Western Europe	Austria	1768					
	Belgium		1833

5.1. Temperature

Central and Western Europe – annual temperature series

Austria, Belgium, France, Hungary, Germany, Luxembourg, Poland, Switzerland

Austria

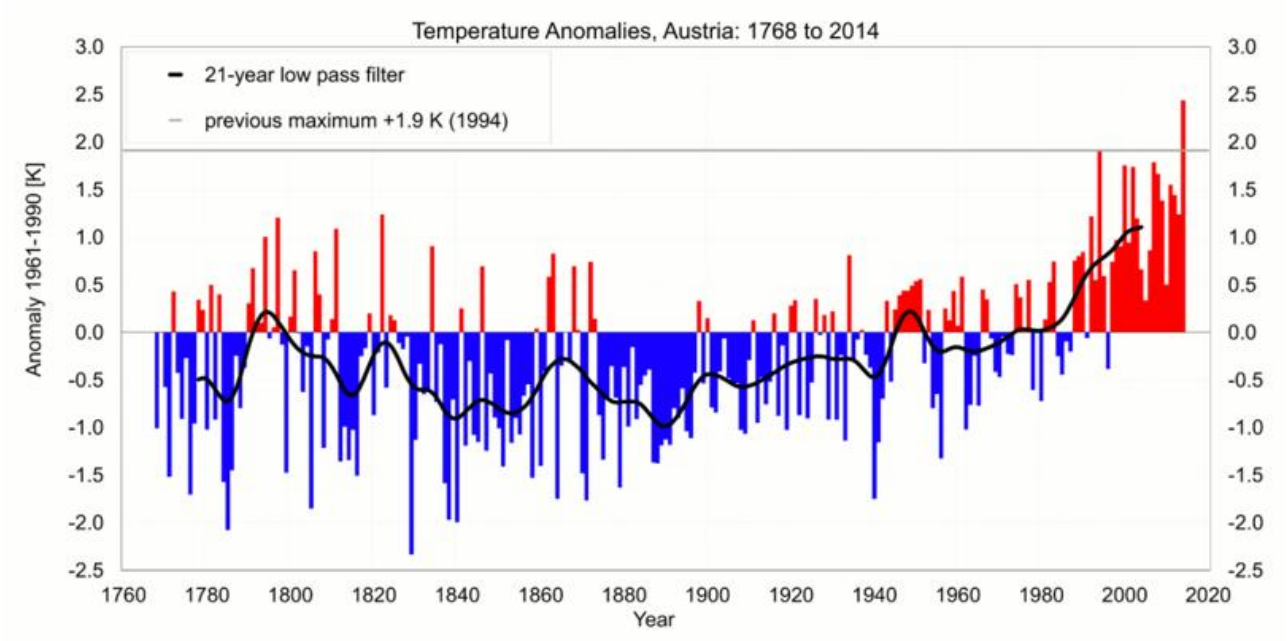

Figure 5.1: Time series of annual mean temperature for Austria (Diagram as provided by the NHMS)

Belgium

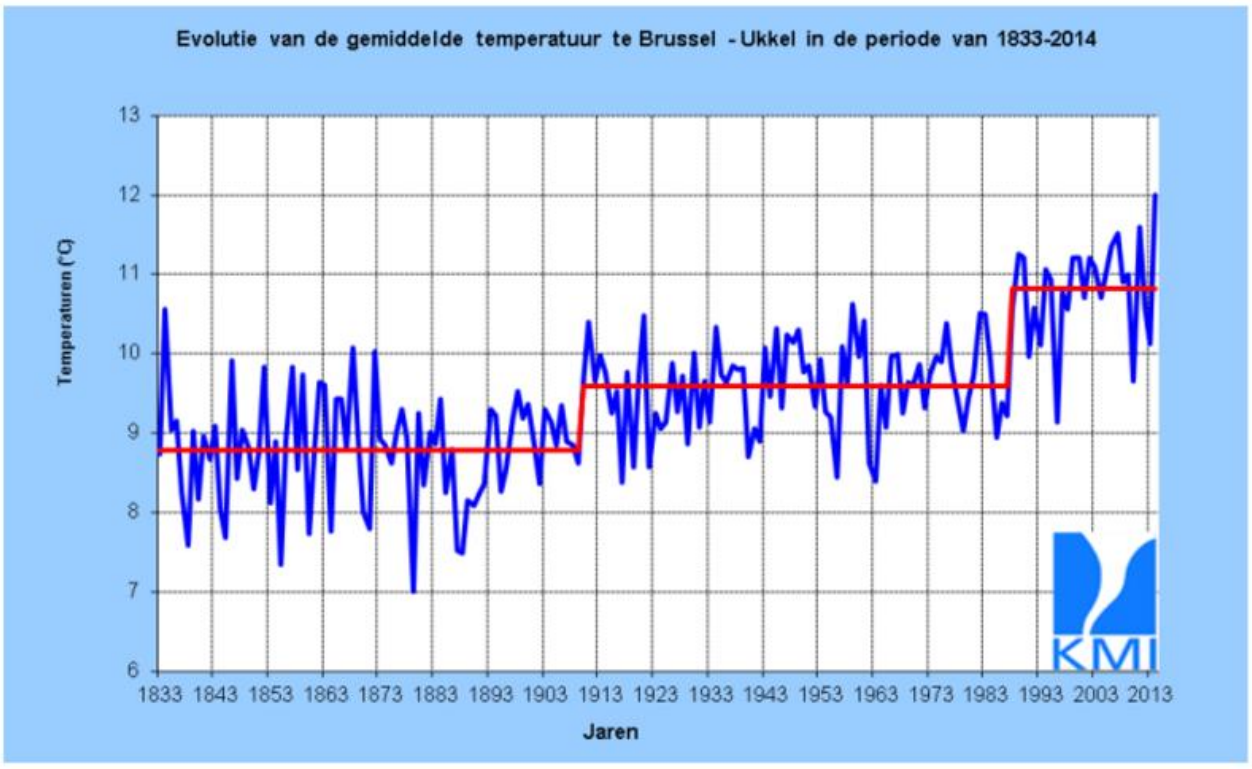

Figure 5.2: Time series of annual mean temperature for Belgium (Diagram as provided by the NHMS)

Central and Western Europe – annual temperature series

France

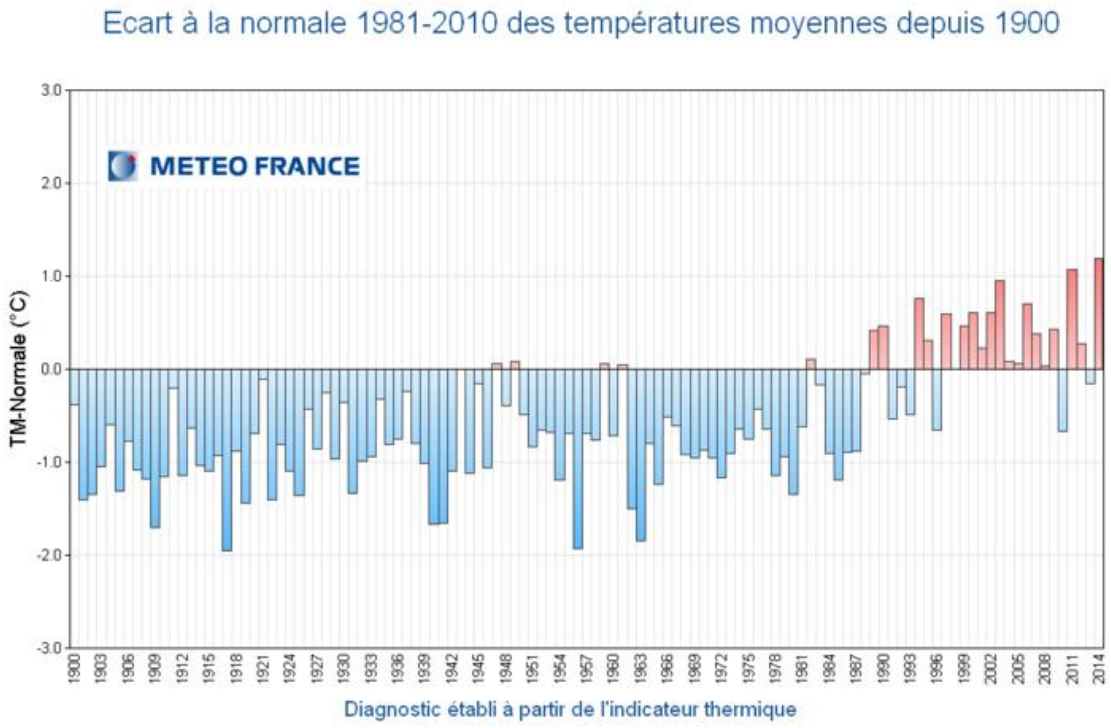

Figure 5.3: Time series of annual temperature anomalies for France (reference period 1981-2010; diagram as provided by the NHMS)

Germany

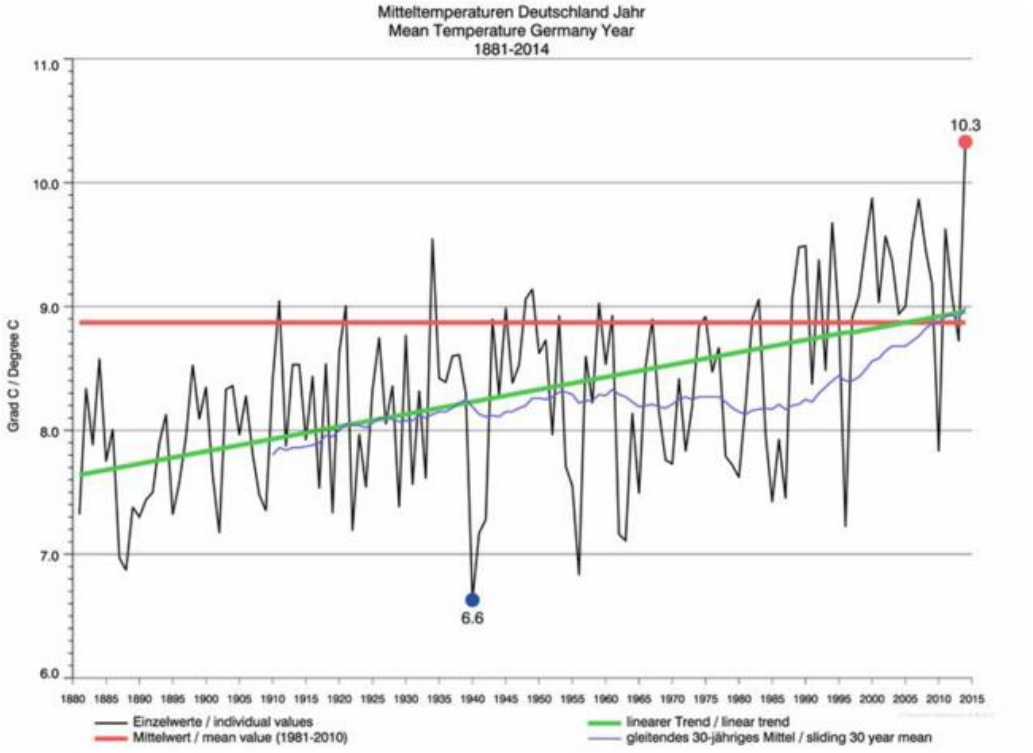

Figure 5.4: Time series of annual mean temperature for Germany (Diagram as provided by the NHMS)

Central and Western Europe – annual temperature series

Hungary

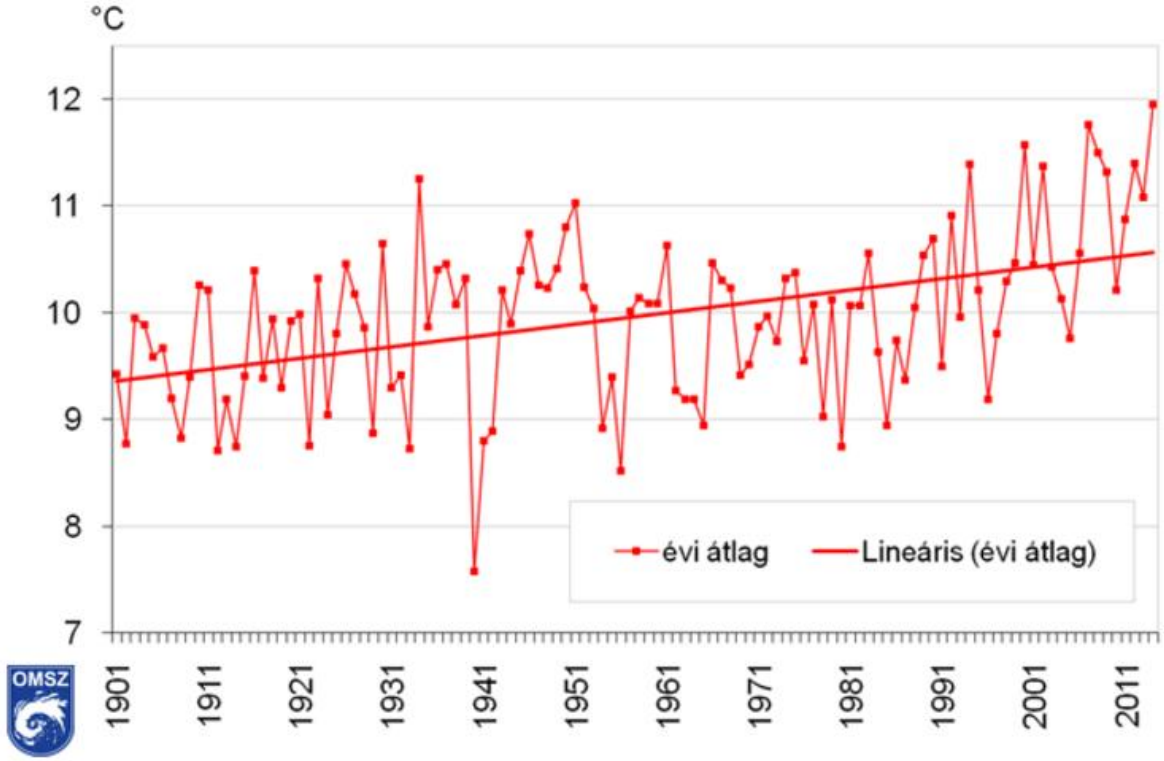

Figure 5.5: Time series of annual average temperature for the period 1901-2014 for Hungary (58 station based on data from homogenized, interpolated; Diagram as provided by the NHMS)

Luxembourg

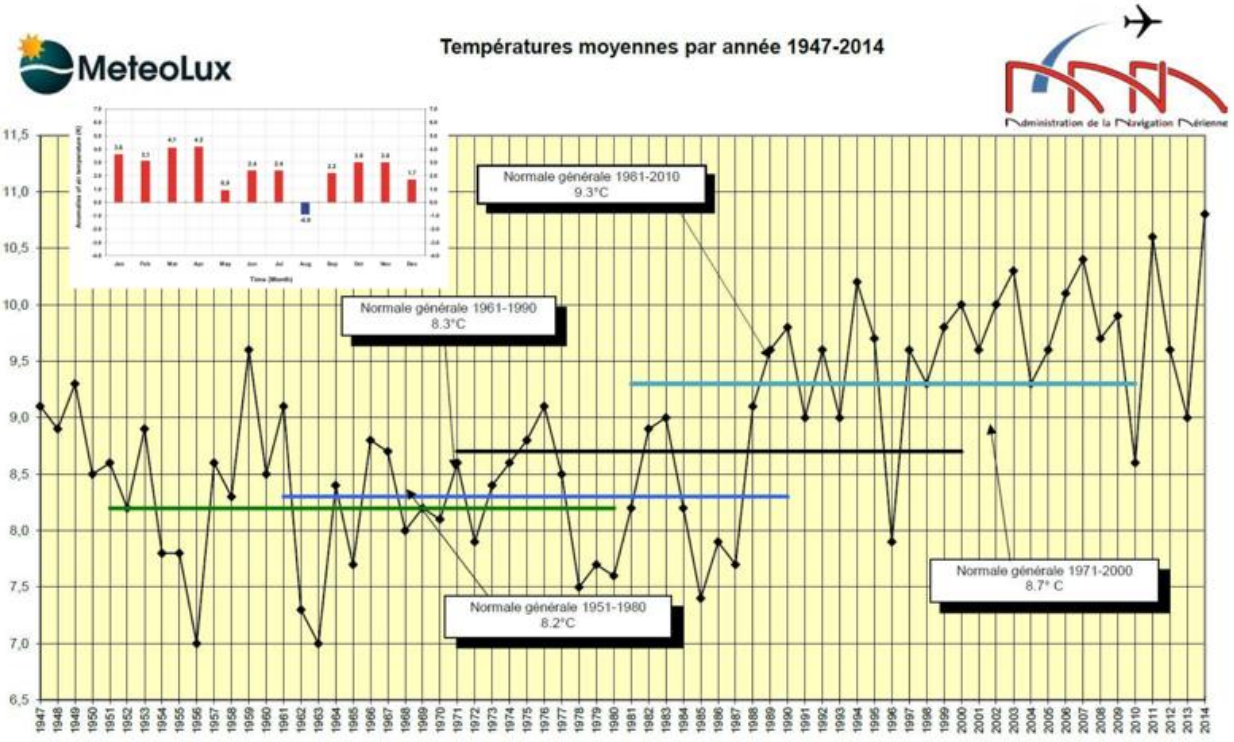

Figure 5.6: Time series of annual average temperature for the period 1947-2014 for Luxembourg (Diagram as provided by the NHMS)

Central and Western Europe – annual temperature series

Poland

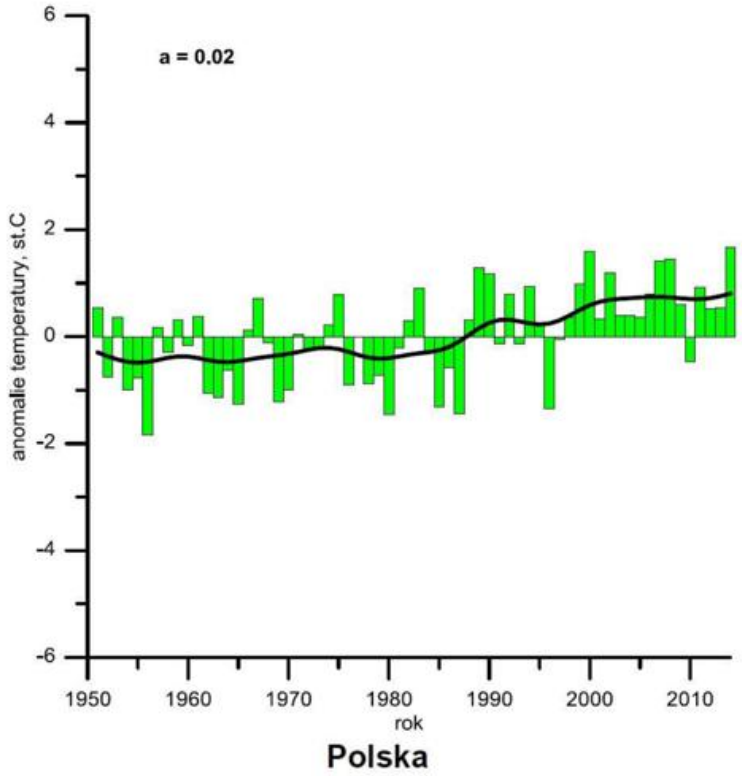

Figure 5.7: Time series of annual temperature anomalies for the period 1951-2014 for Poland (base period: 1971-2000; smoothed by 10-years Gaussian filter (black line) and the values of linear trend (°C/year); diagram as provided by the NHMS)

Switzerland

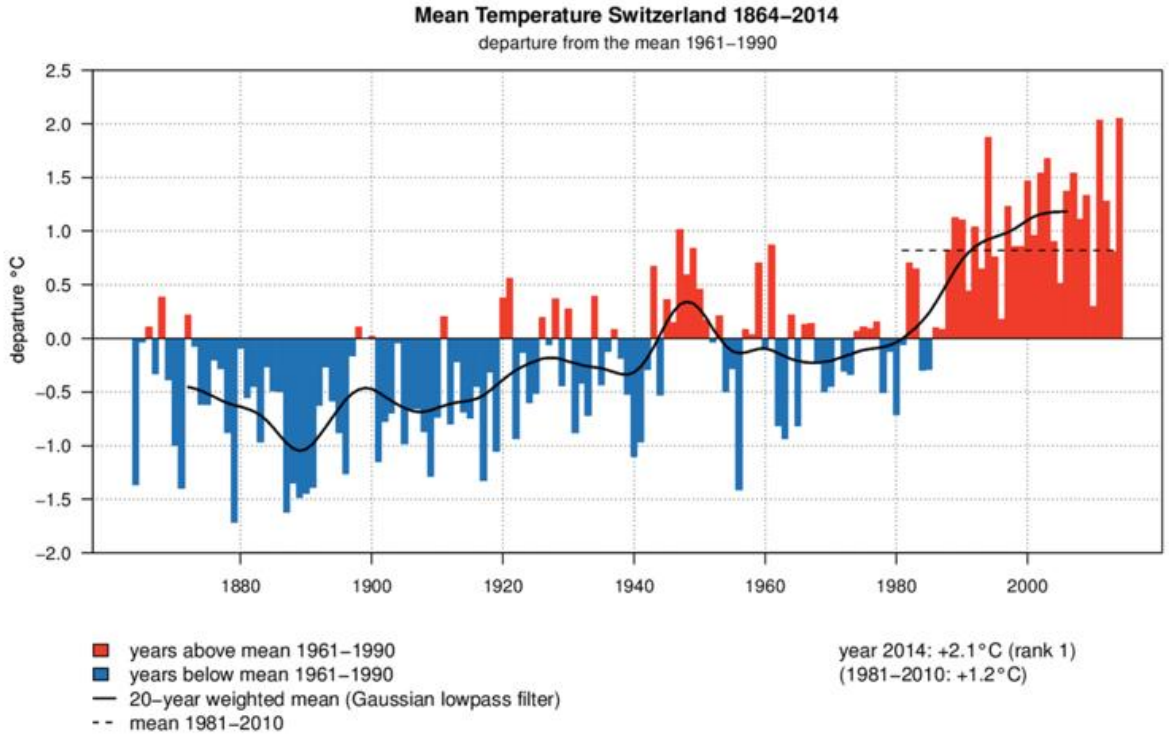

Figure 5.8: Time series of annual temperature anomalies for the period 1864-2014 for Switzerland (base period: 1961-1990; diagram as provided by the NHMS)

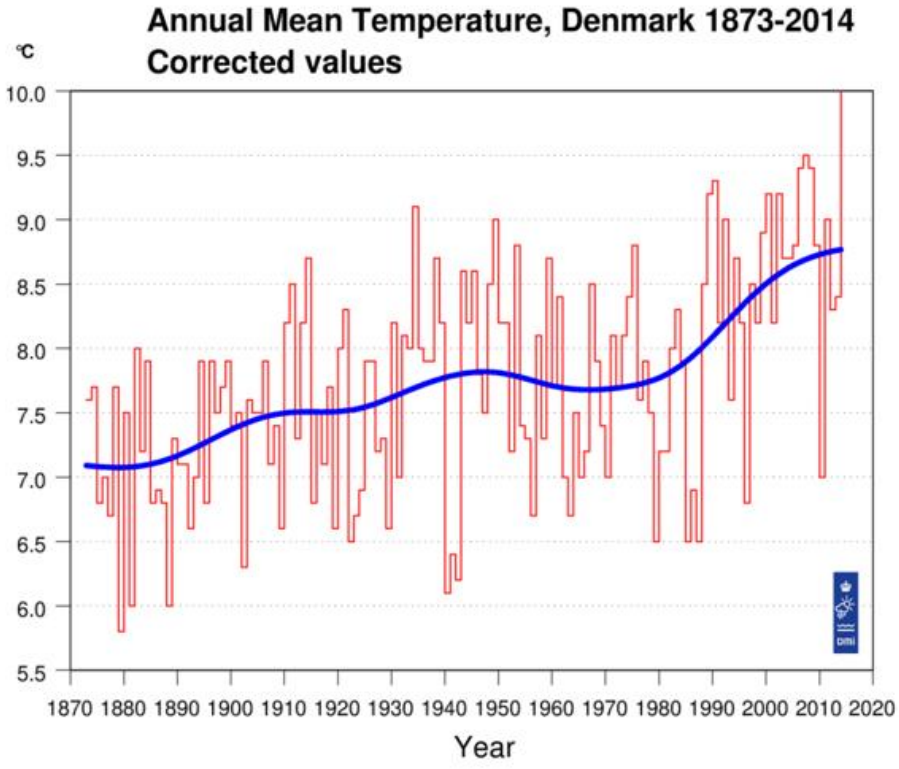
Nordic and Baltic Countries – annual temperature series

Denmark, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden

Denmark, Greenland



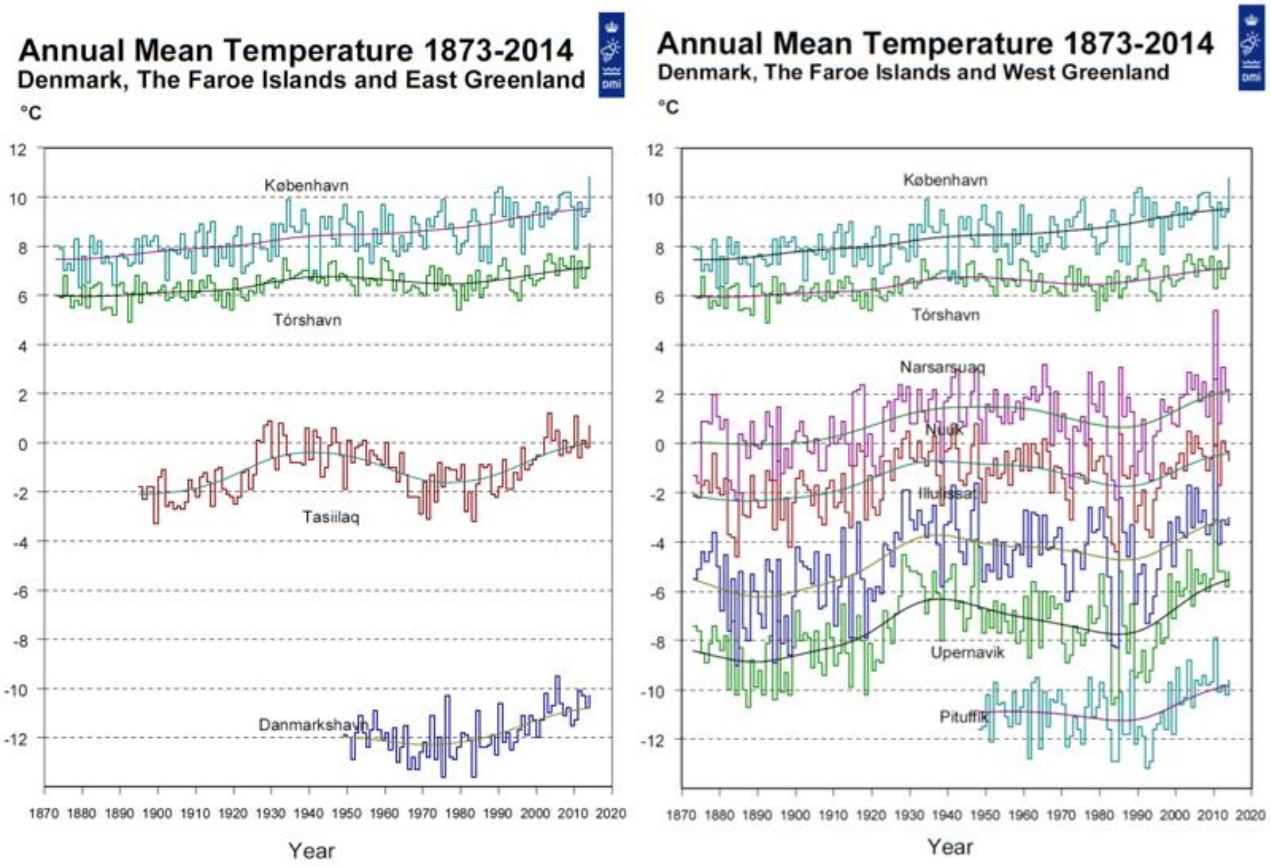


Figure 5.9: Time series of annual temperature for the period 1873-2014 for Denmark (top) and Faroe Islands and Greenland (bottom, diagram as provided by the NHMS)

Nordic and Baltic Countries – annual temperature series

Finland

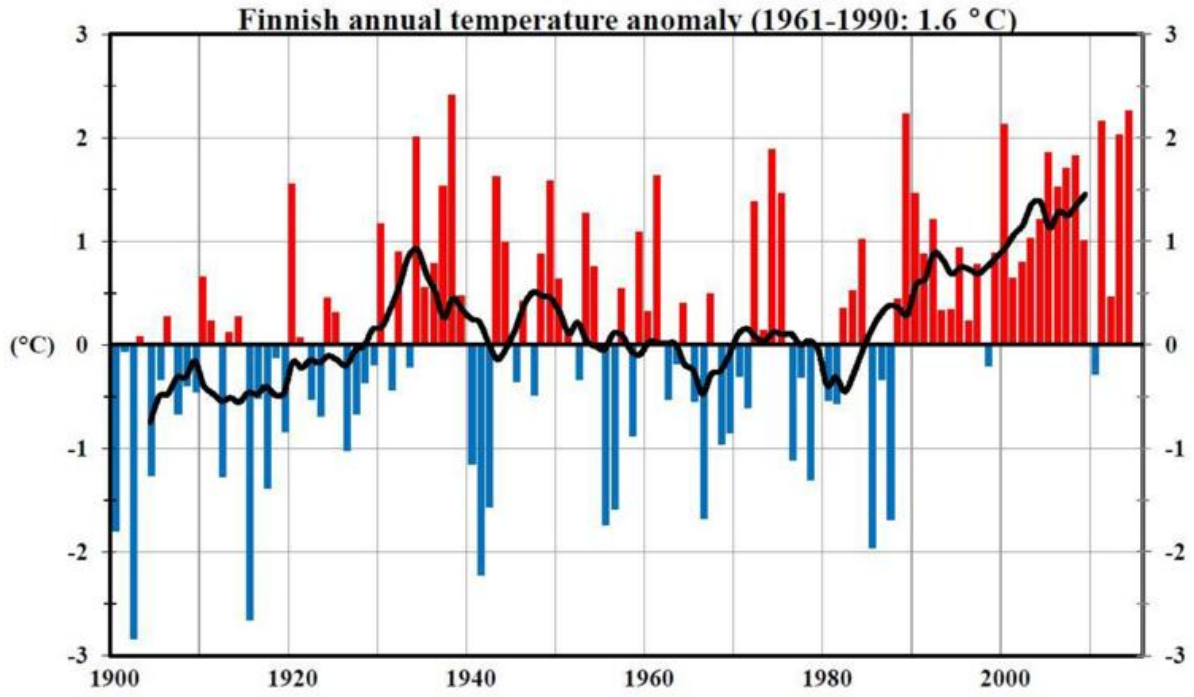

Figure 5.10: Time series of annual temperature anomalies for the period 1900-2014 for Finland (base period: 1961-1990; diagram as provided by the NHMS)

Iceland

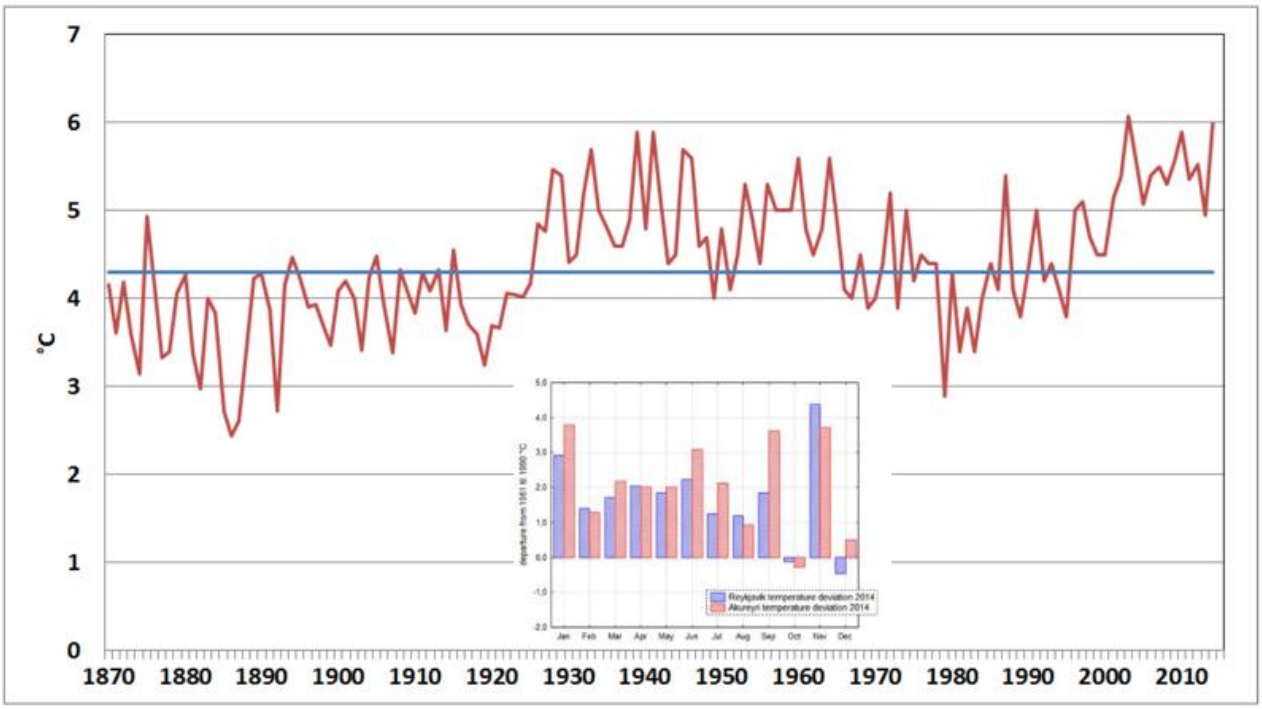

Figure 5.11: Time series of annual average temperature for the period 1870-2014 for Reykjavík (blue line: reference period 1961-1990; diagram as provided by the NHMS)

Nordic and Baltic Countries – annual temperature series

Latvia

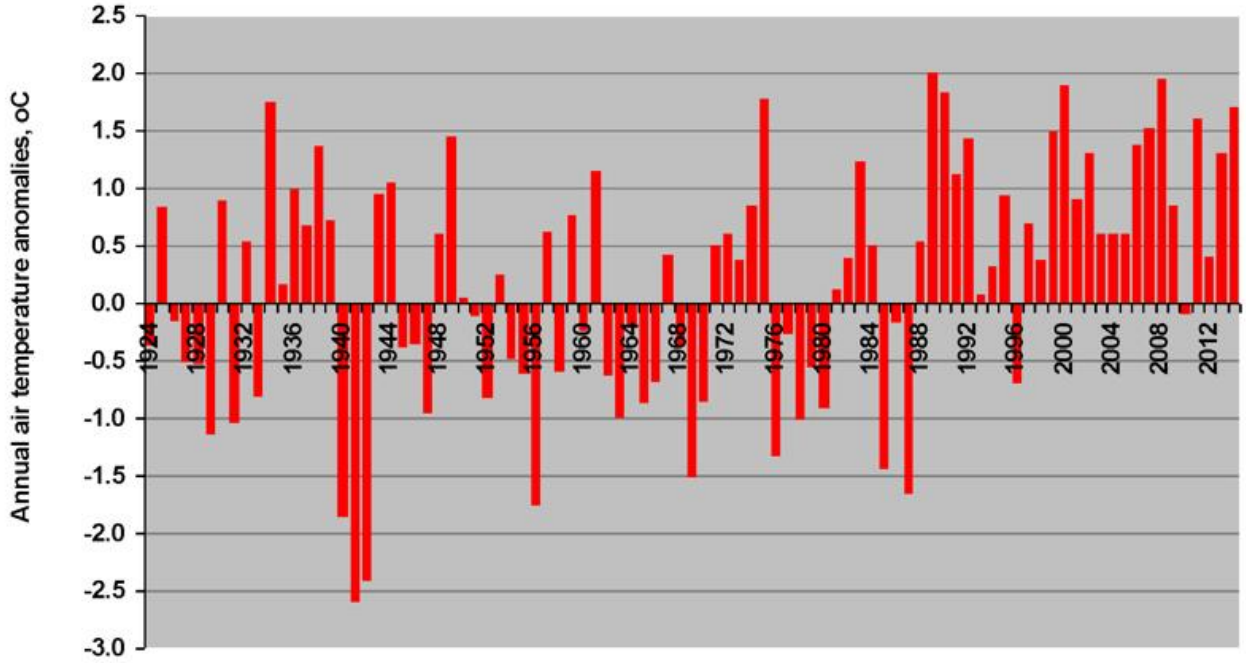

Figure 5.12: Time series of annual temperature anomalies for the period 1924-2014 for Latvia (reference period 1961-1990; diagram as provided by the NHMS)

Lithuania

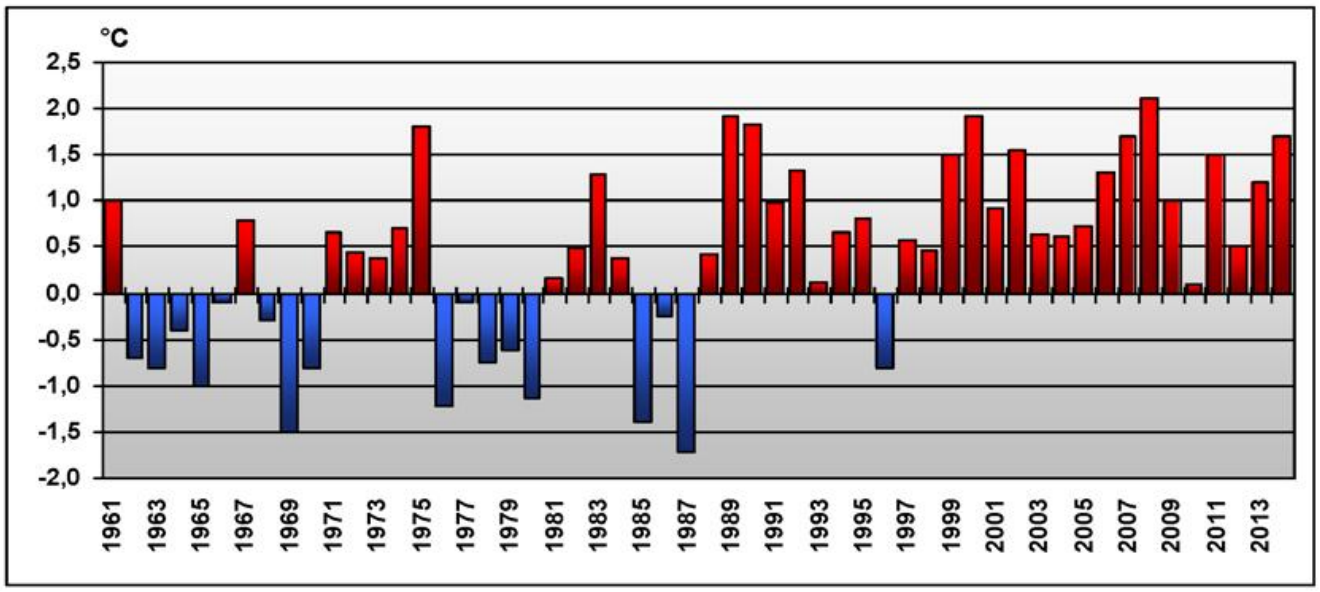

Figure 5.13: Time series of annual temperature anomalies for the period 1961-2014 for Lithuania (reference period 1961-1990; diagram as provided by the NHMS)

Nordic and Baltic Countries – annual temperature series

Norway

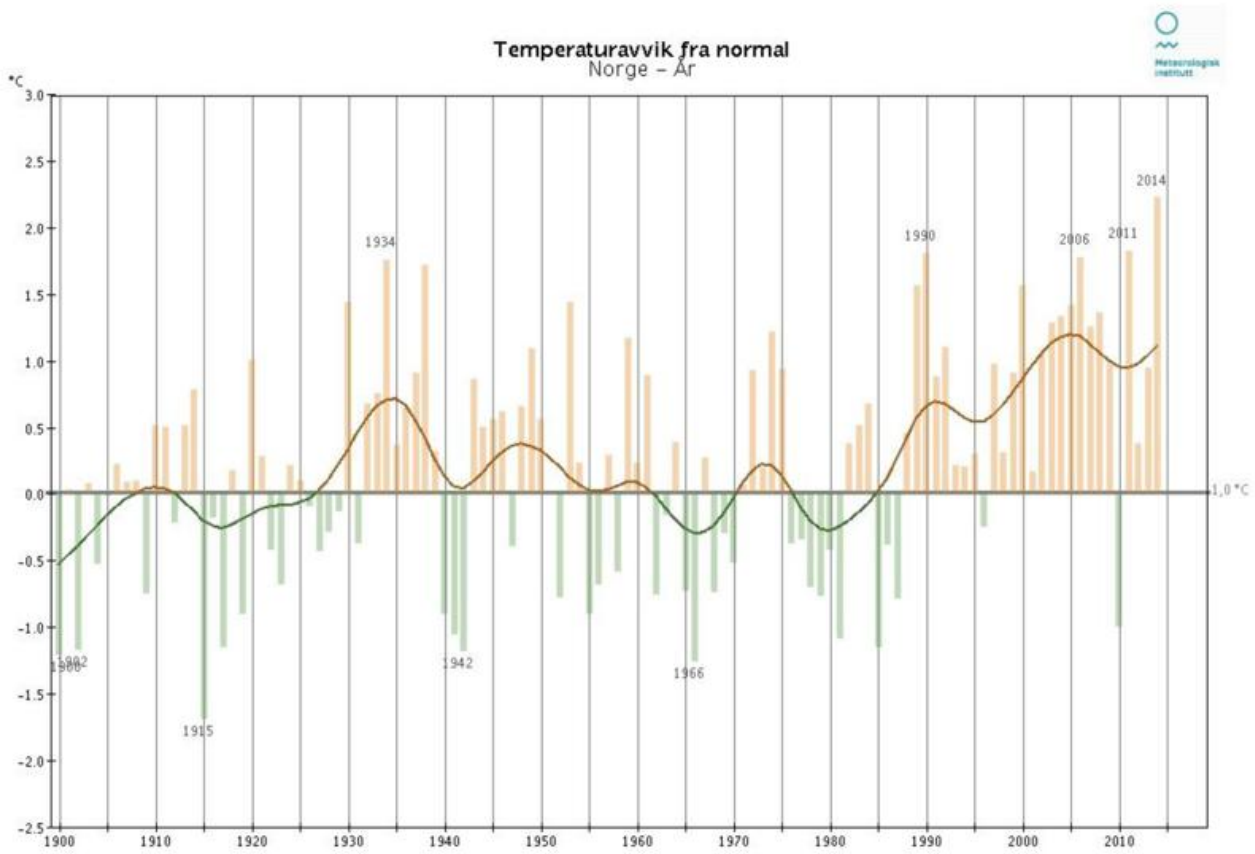

Figure 5.14: Time series of annual temperature anomalies for the period 1900-2014 for Norway (reference period 1961-1990; diagram as provided by the NHMS)

Sweden

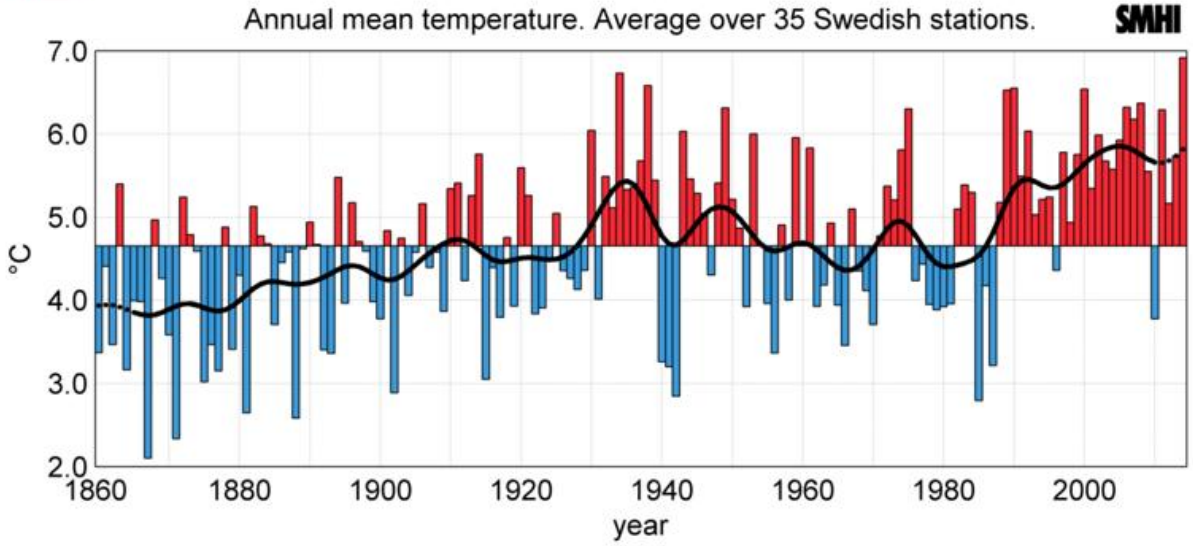

Figure 5.15: Time series of annual average temperature for the period 1900-2014 for Sweden (diagram as provided by the NHMS)

Iberia – annual temperature series

Portugal, Spain

Portugal

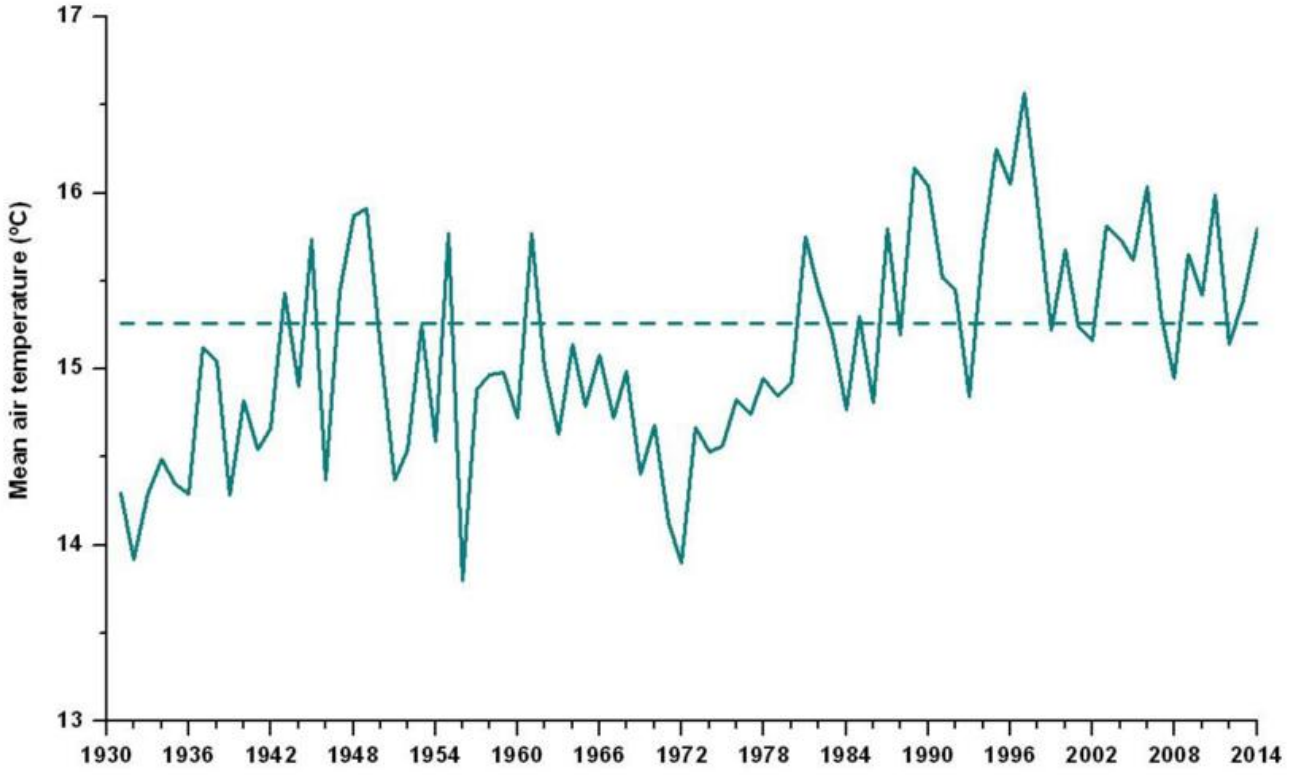

Figure 5.16: Time series of annual average temperature for the period 1931-2014 for Portugal (diagram as provided by the NHMS)

Spain

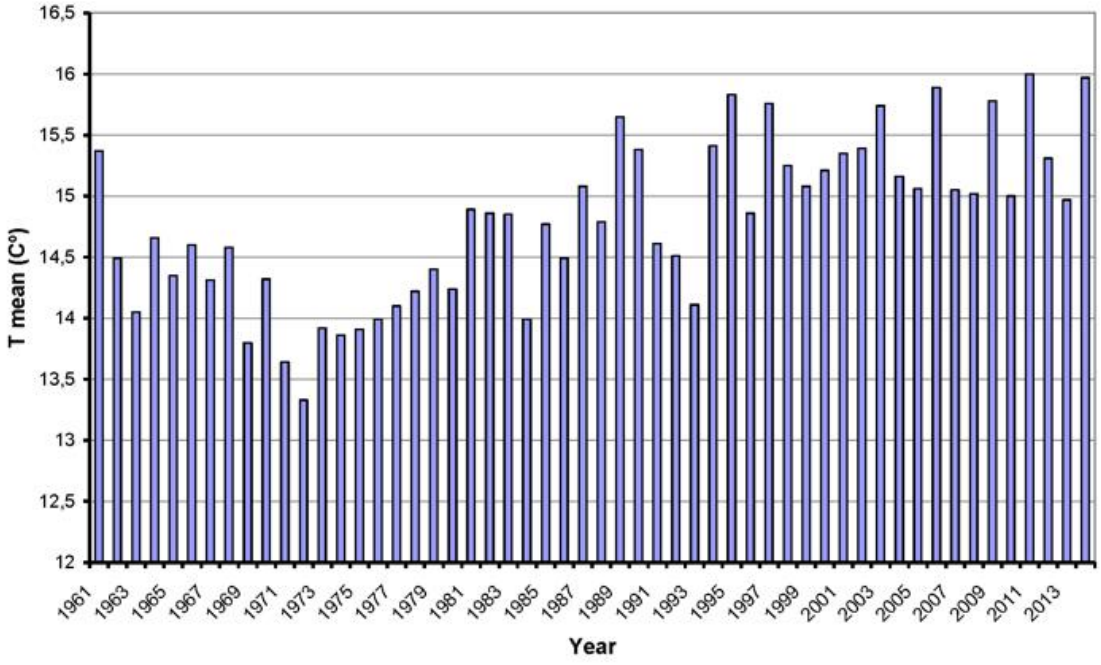

Figure 5.17: Time series of annual average temperature for the period 1961-2014 for Spain (diagram as provided by the NHMS)

Mediterranean, Italian and Balkan Peninsula – annual temperature series

Croatia, Italy,Slovenia, Turkey

Croatia

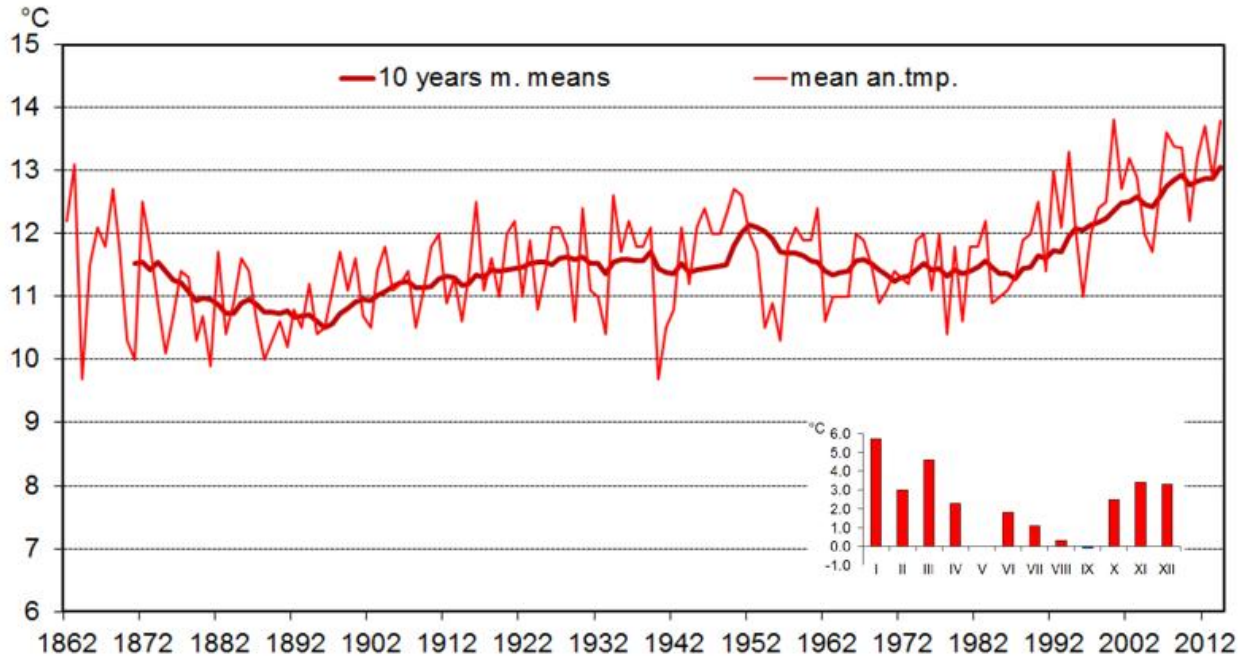

Figure 5.18: Time series of annual average temperature for Zagreb Grič (Croatia) for the period 1862-2014 with 10-year running mean and monthly anomalies for the year 2014 (diagram as provided by the NHMS)

Italy

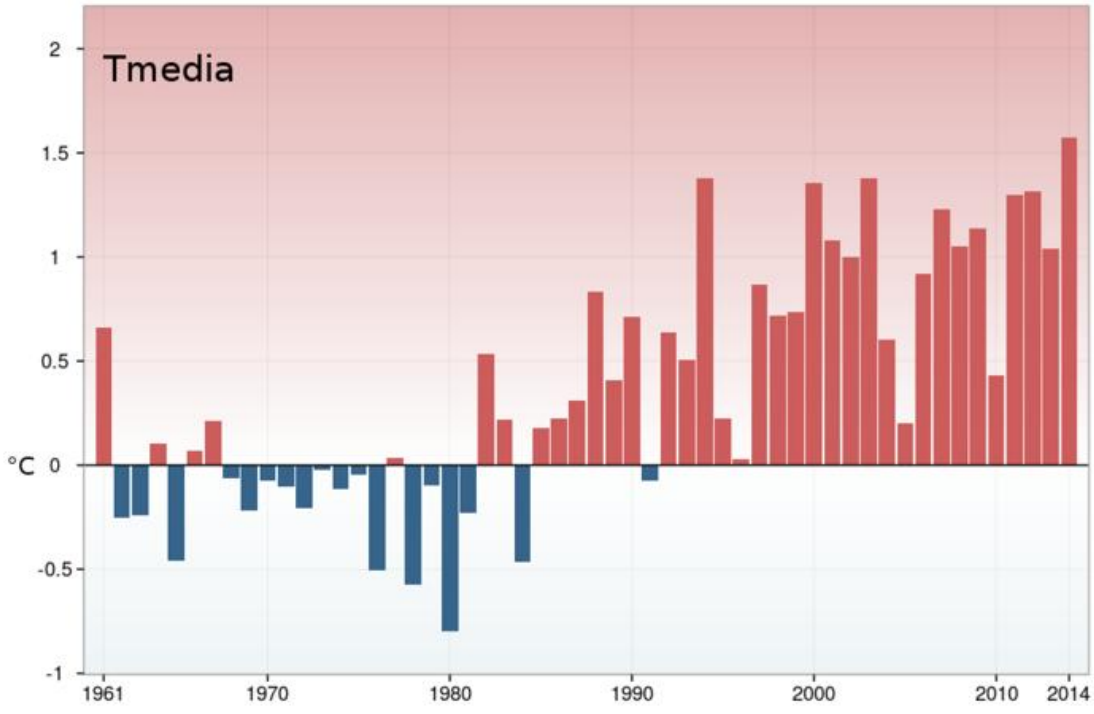

Figure 5.19: Time series of annual temperature anomalies for Italy for the period 1961-2014 (reference period 1961-1990; diagram as provided by ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

Mediterranean, Italian and Balkan Peninsula – annual temperature series

Slovenia

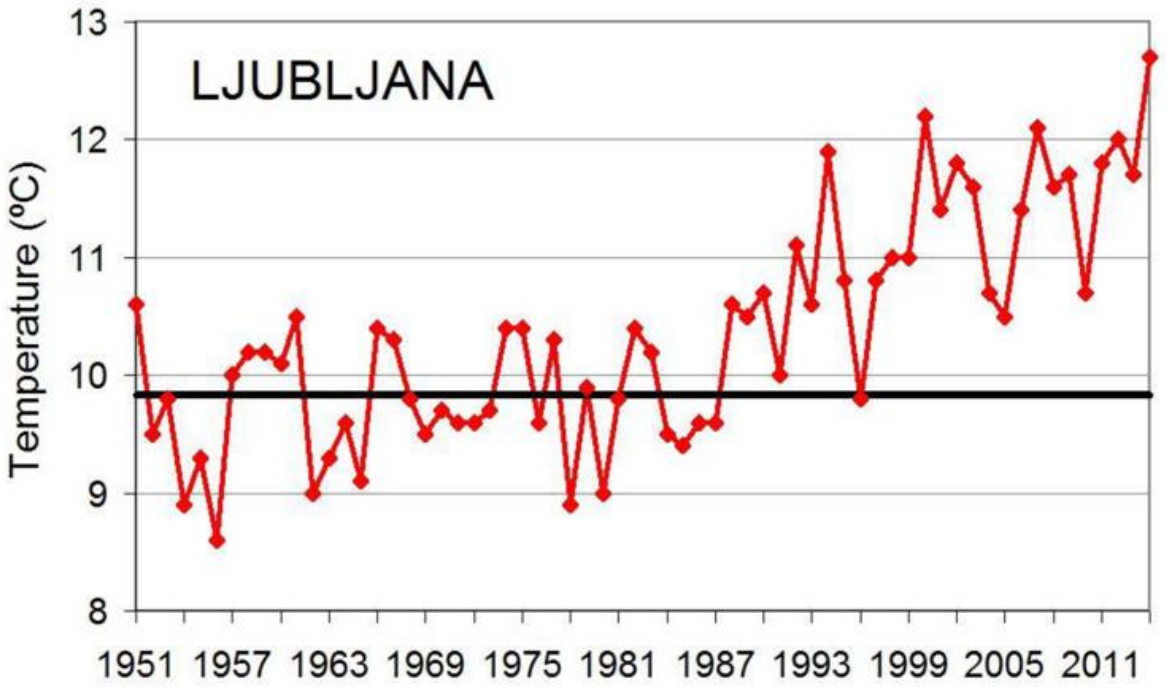

Figure 5.20: Time series of annual average temperature for Lublijana (Slovenia) for the period 1951-2014 (diagram as provided by the NHMS)

Turkey

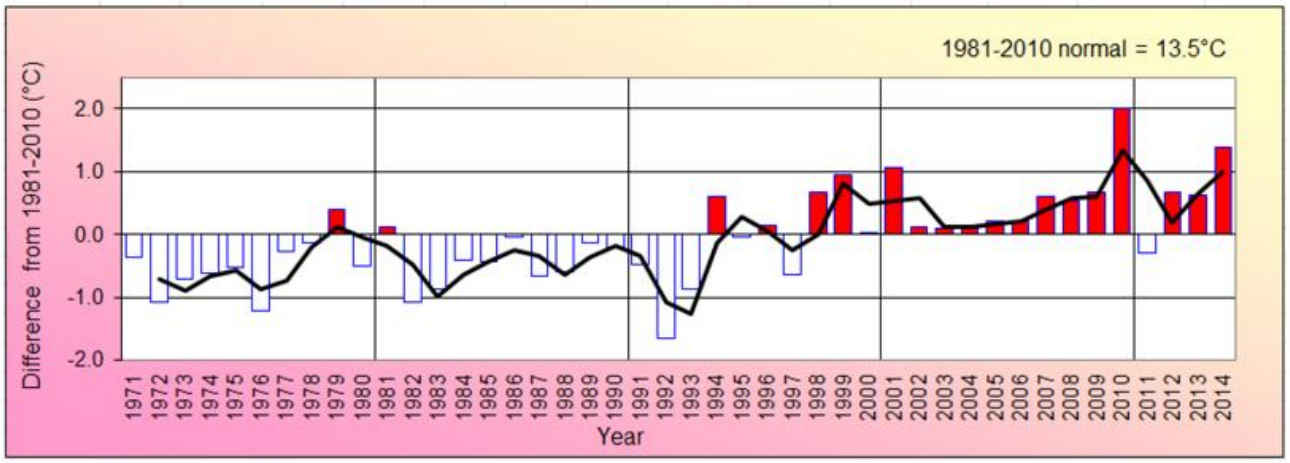

Figure 5.21: Time series of annual temperature anomalies for Turkey for the period 1971-2014 (reference period 1981-2010; diagram as provided by the NHMS)

Eastern Europe – annual temperature series

Belarus, Russia

Belarus

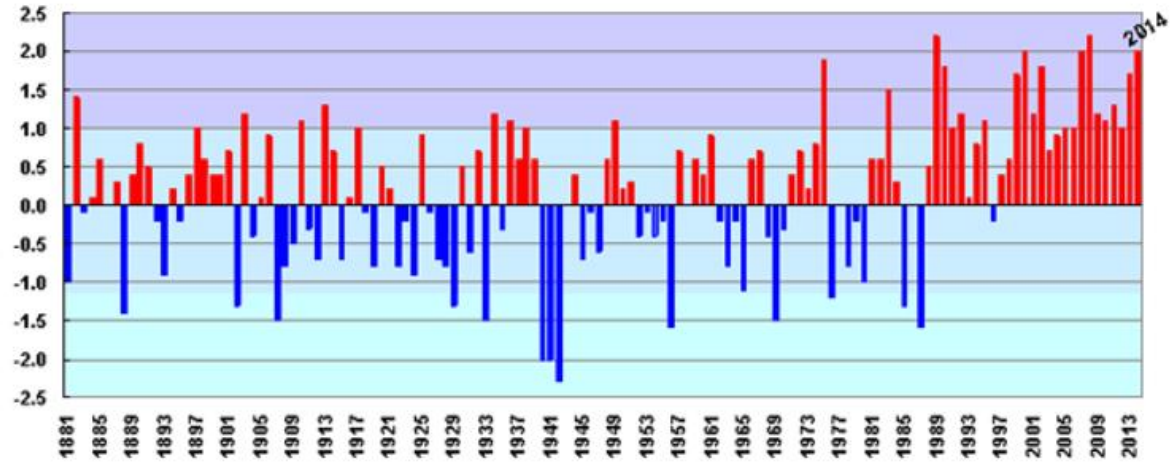

Figure 5.22: Time series of annual temperature anomalies for Belarus for the period 1881-2014 (reference period 1961-1990; diagram as provided by the NHMS)

Russia

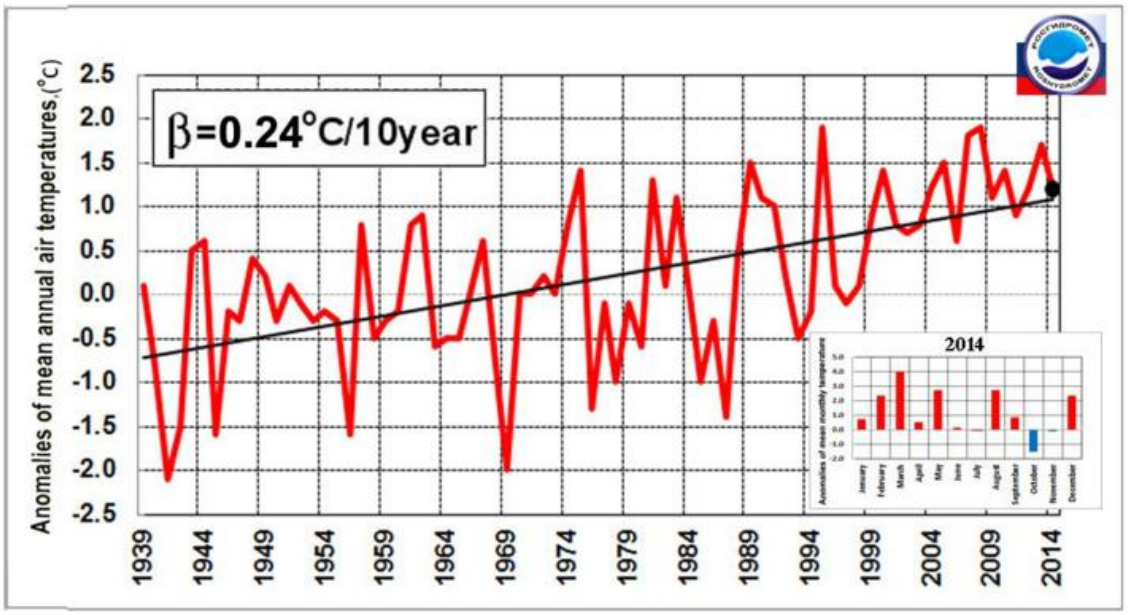

Figure 5.23: Time series of annual temperature anomalies for European Russia for the period 1939-2014 (reference period 1961-1990; diagram as provided by the NHMS)

Middle East – annual temperature series

Georgia, Israel

Georgia

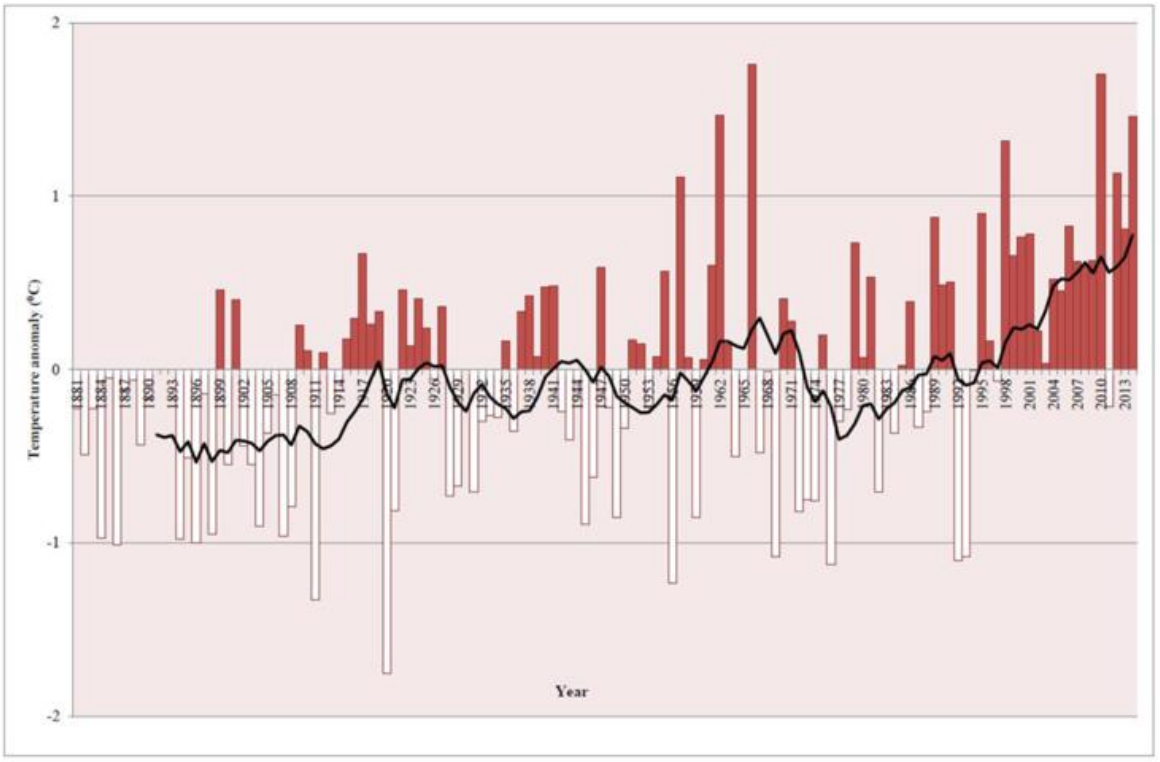

Figure 5.24: Time series of annual temperature anomalies and 11-yr moving averages for Tbilisi (Georgia) for the period 1881-2014 (reference period 1961-1990; diagram as provided by the NHMS)

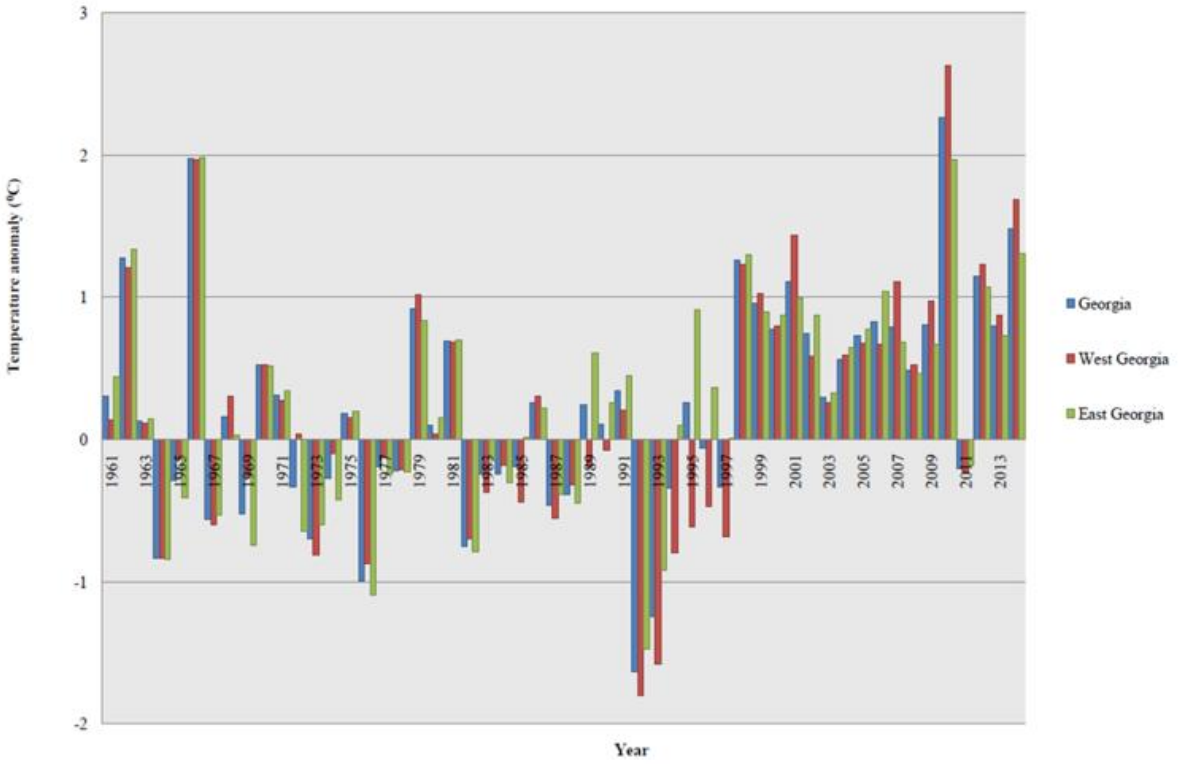

Figure 5.25: Time series of annual temperature anomalies for Georgia for the period 1961-2014 (reference period 1961-1990; diagram as provided by the NHMS)

Middle East – annual temperature series

Israel

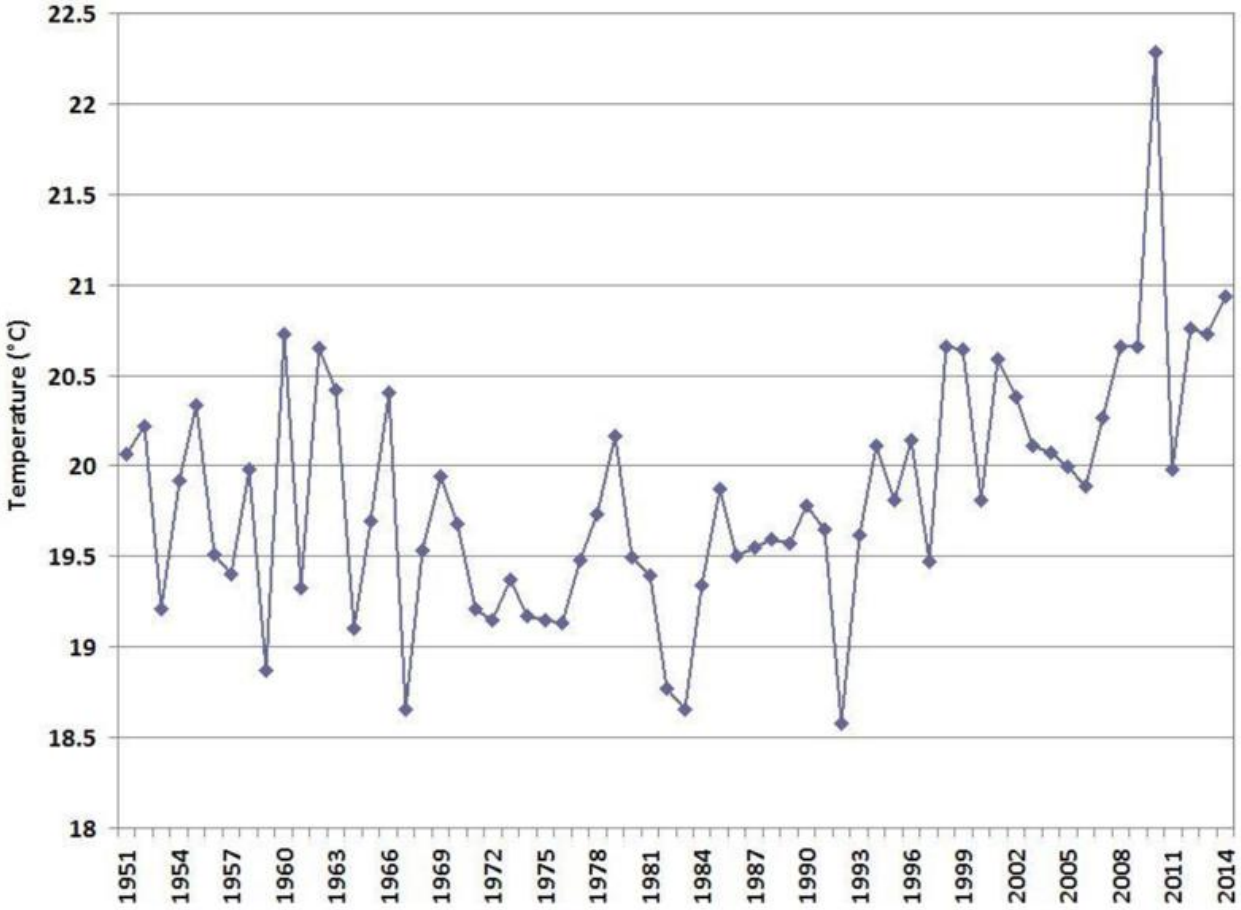

Figure 5.26: Time series of annual temperature for Israel (based on five stations) for the period 1951-2014 (diagram as provided by the NHMS)

5.2. Precipitation

Central and Western Europe - precipitation totals and anomalies

Germany, Hungary, Switzerland

Germany

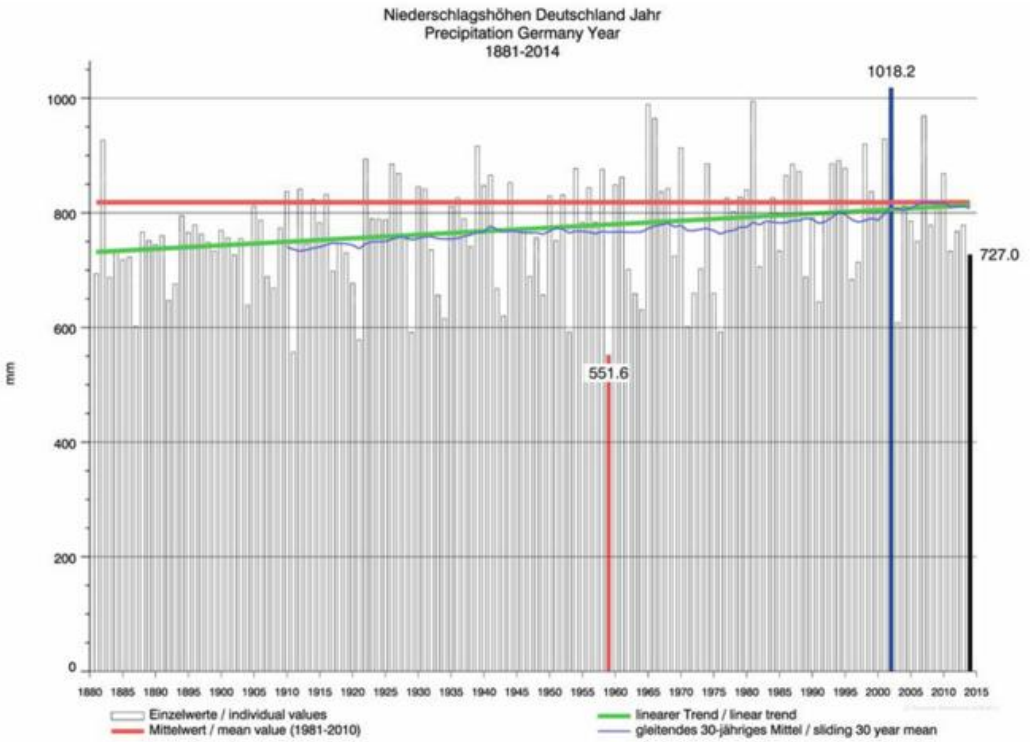

Figure 5.27: Time series of annual precipitation totals in mm/year for Germany (Diagram as provided by the NHMS)

Hungary

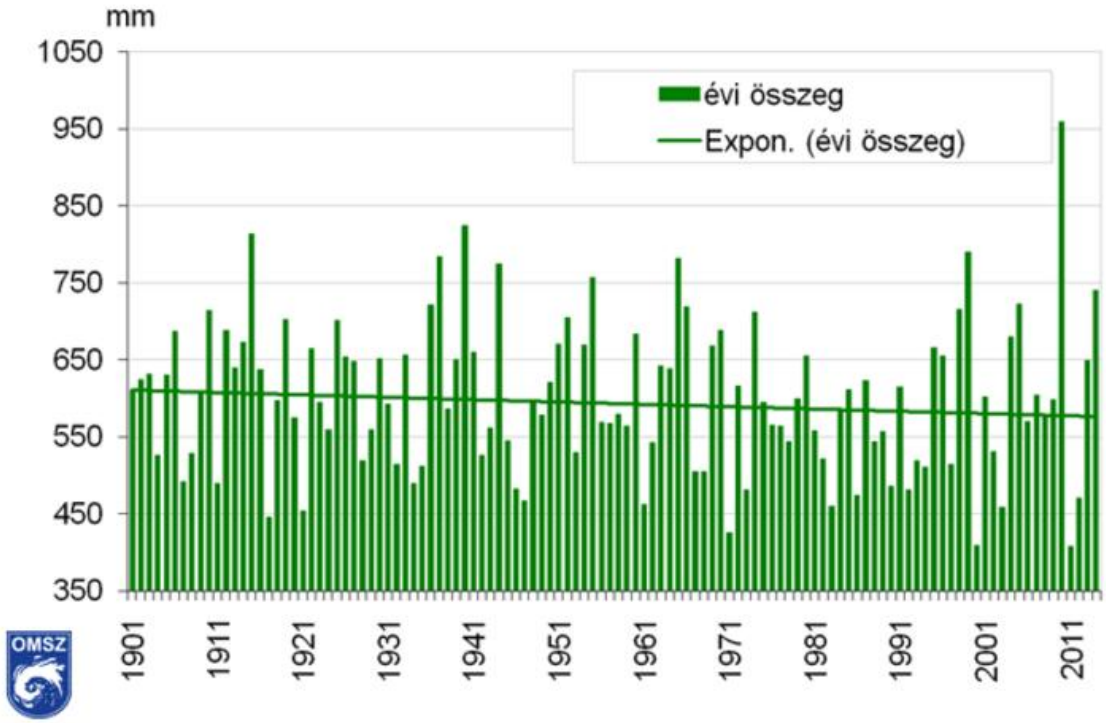

Figure 5.28: Time series of annual precipitation totals in mm/year for Hungary (Diagram as provided by the NHMS)

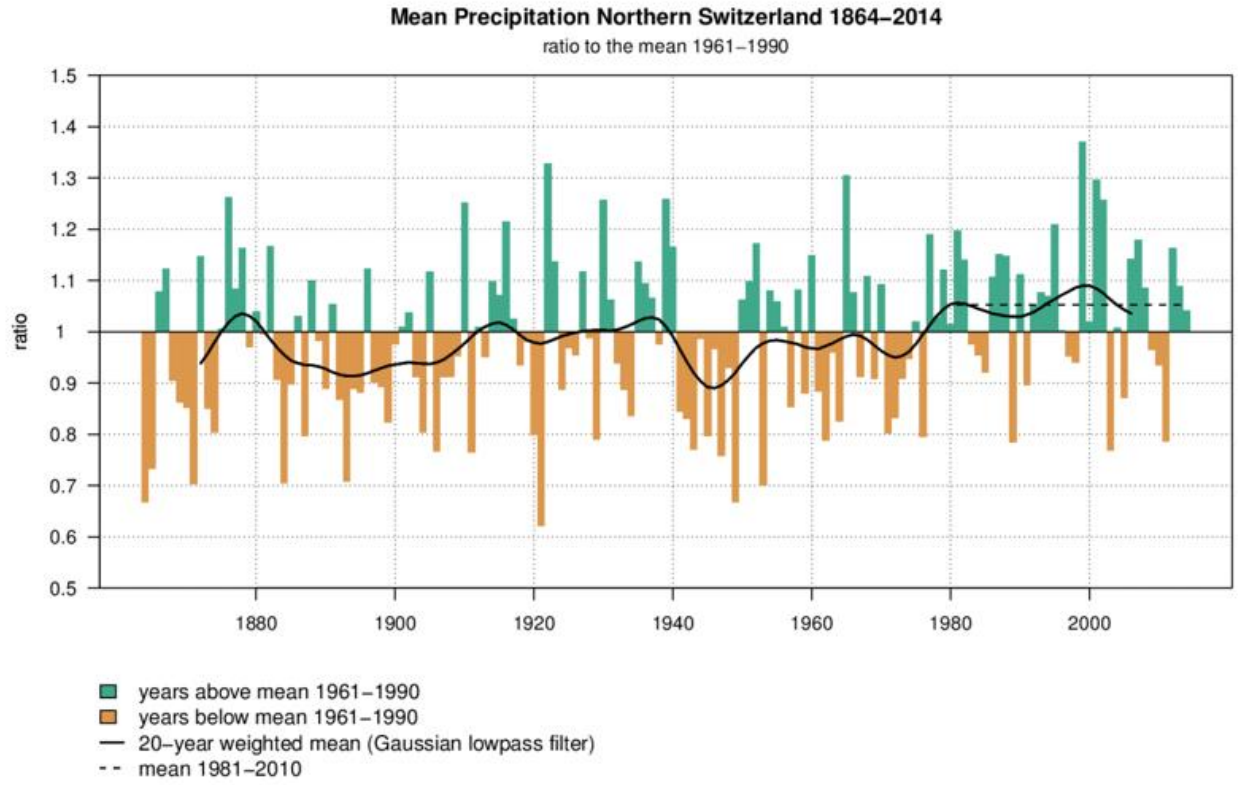
Central and Western Europe - precipitation totals and anomalies

Switzerland



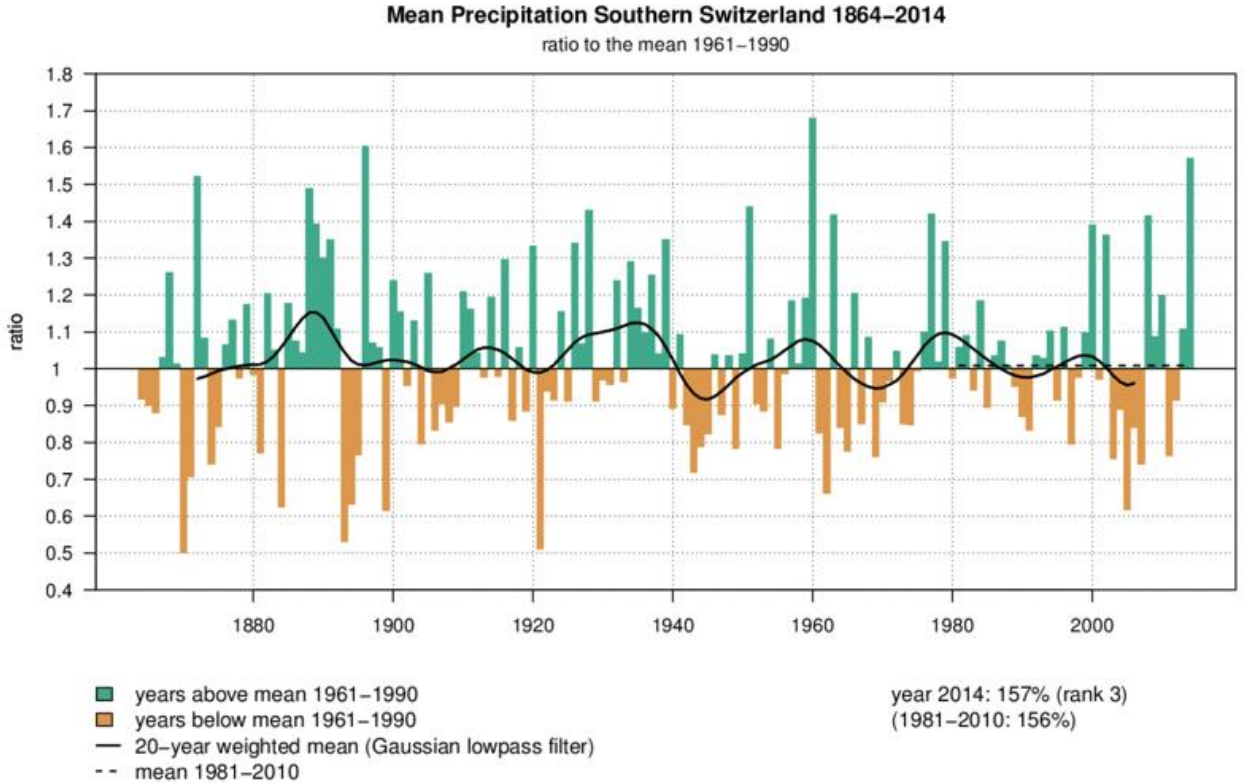


Figure 5.29: Time series of annual precipitation anomalies in relation to the mean of 1961-90 for northern (top) and southern (bottom) Switzerland (diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Denmark, Latvia, Norway, Sweden

Denmark

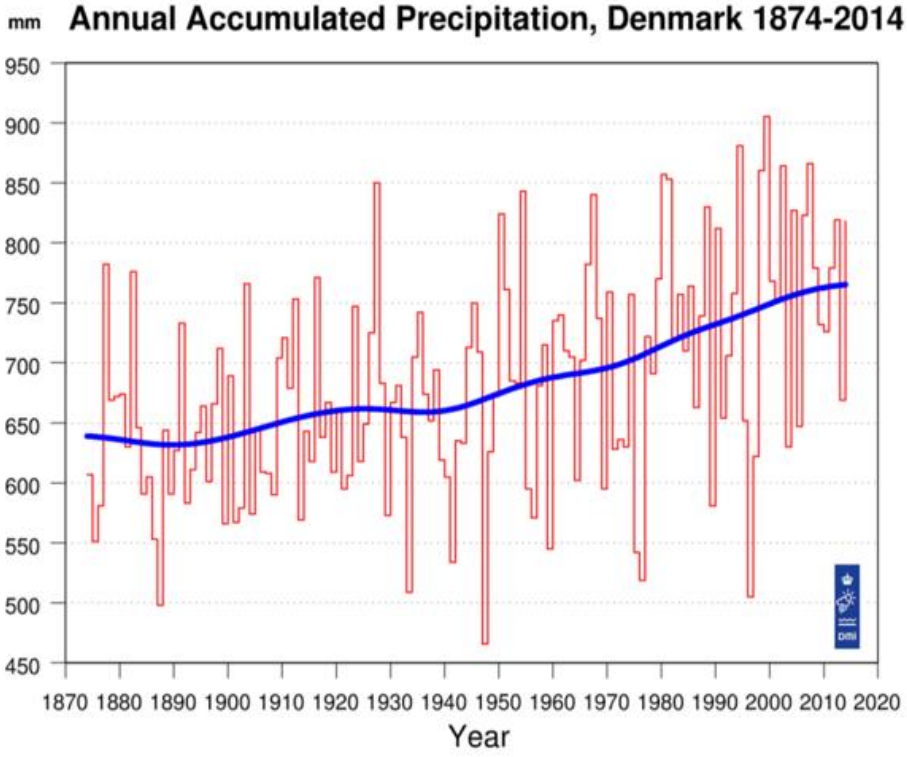

Figure 5.30: Time series of annual precipitation totals in mm/year for Denmark (Diagram as provided by the NHMS)

Latvia

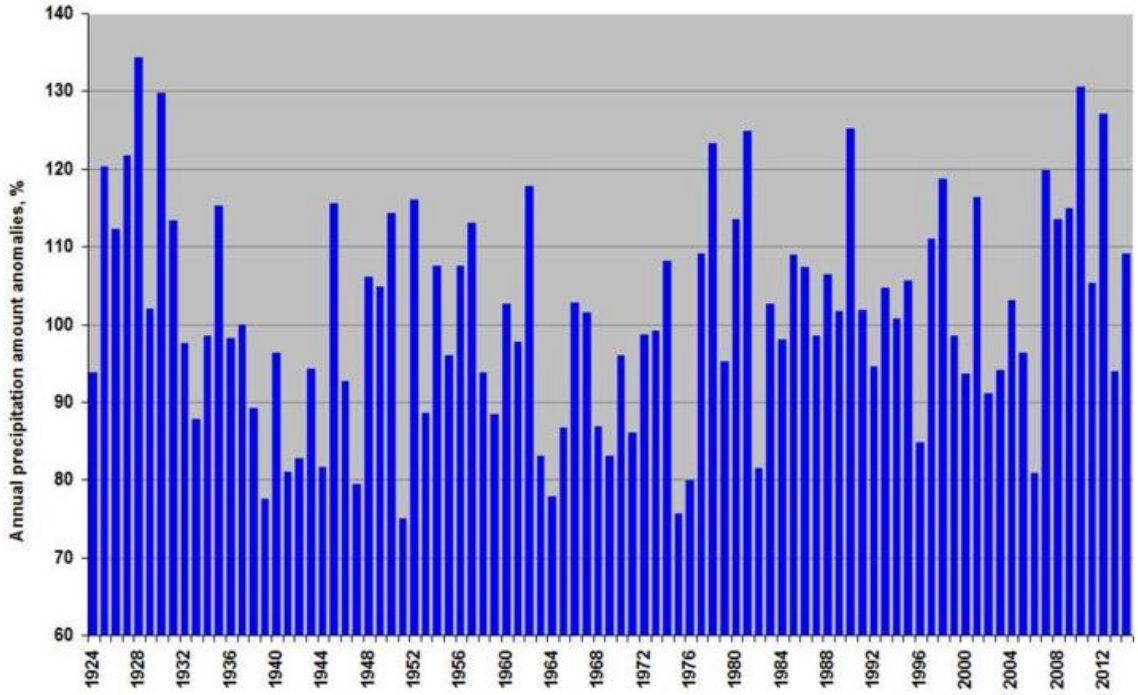

Figure 5.31: Time series of annual precipitation totals in relation to the mean of 1961-90 for Latvia (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Norway

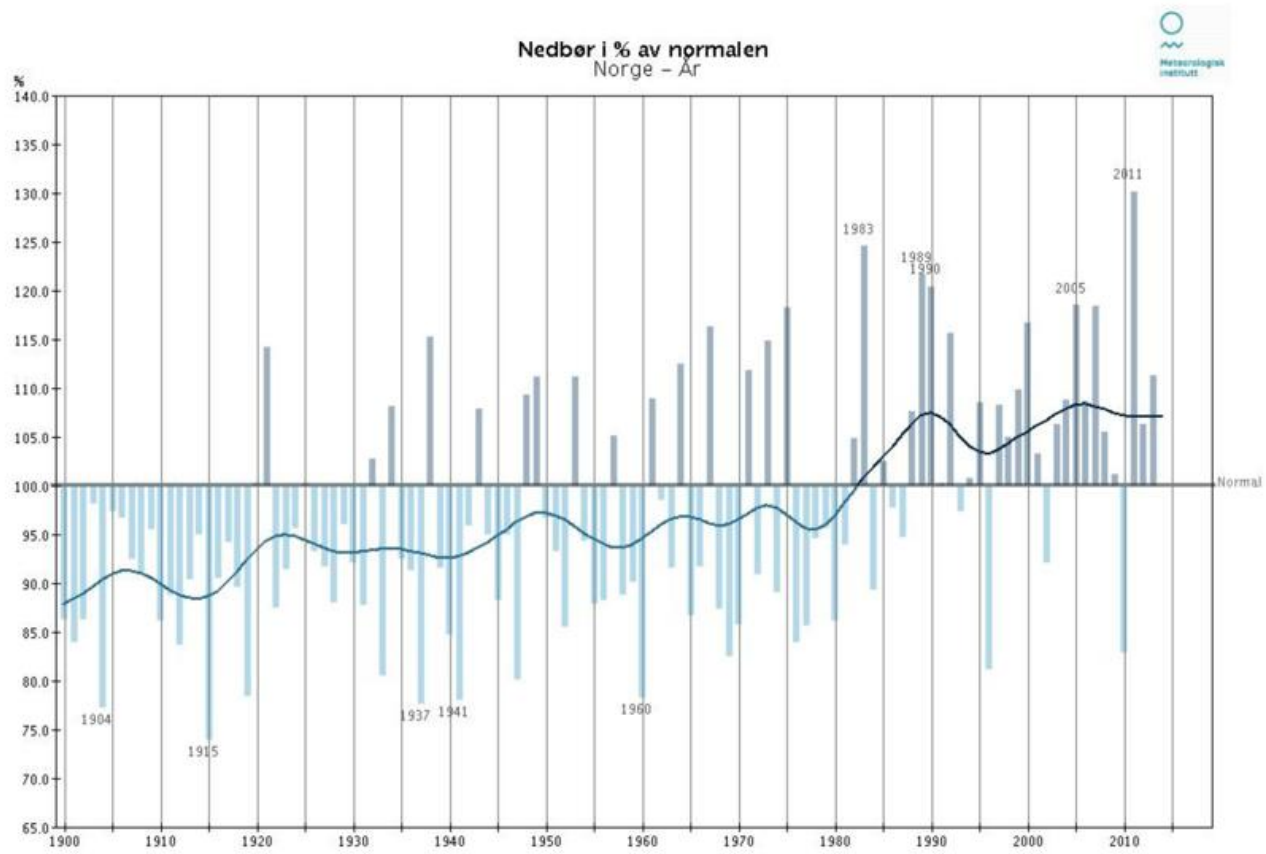

Figure 5.32: Time series of annual precipitation totals in relation to the mean of 1961-90 for Norway (Diagram as provided by the NHMS)

Sweden

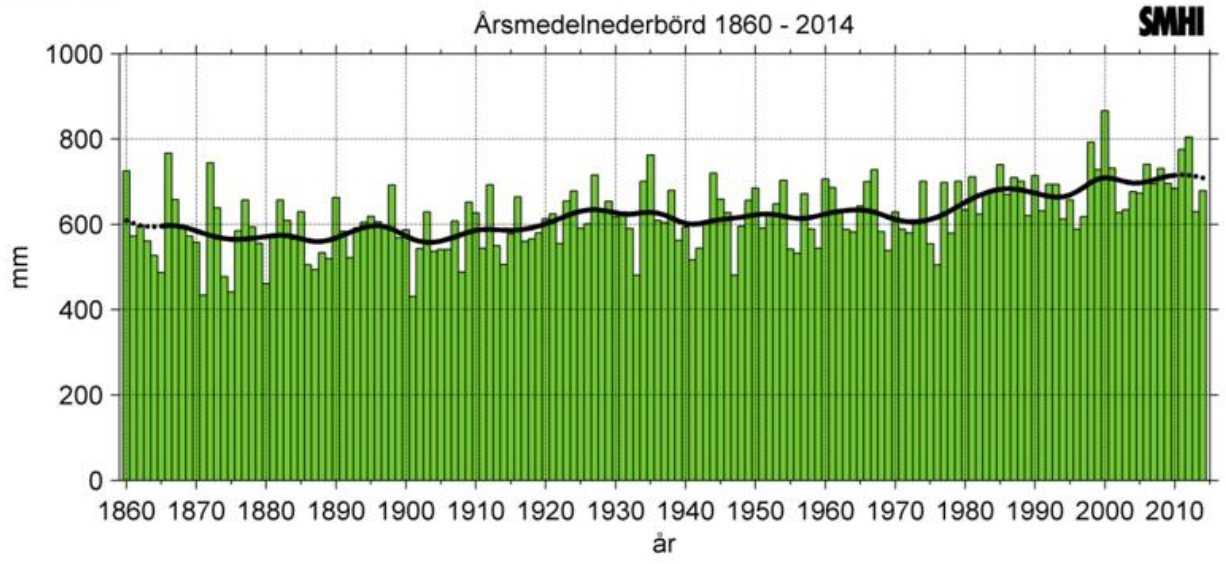

Figure 5.33: Time series of annual precipitation totals in mm/year for Sweden (Diagram as provided by the NHMS)

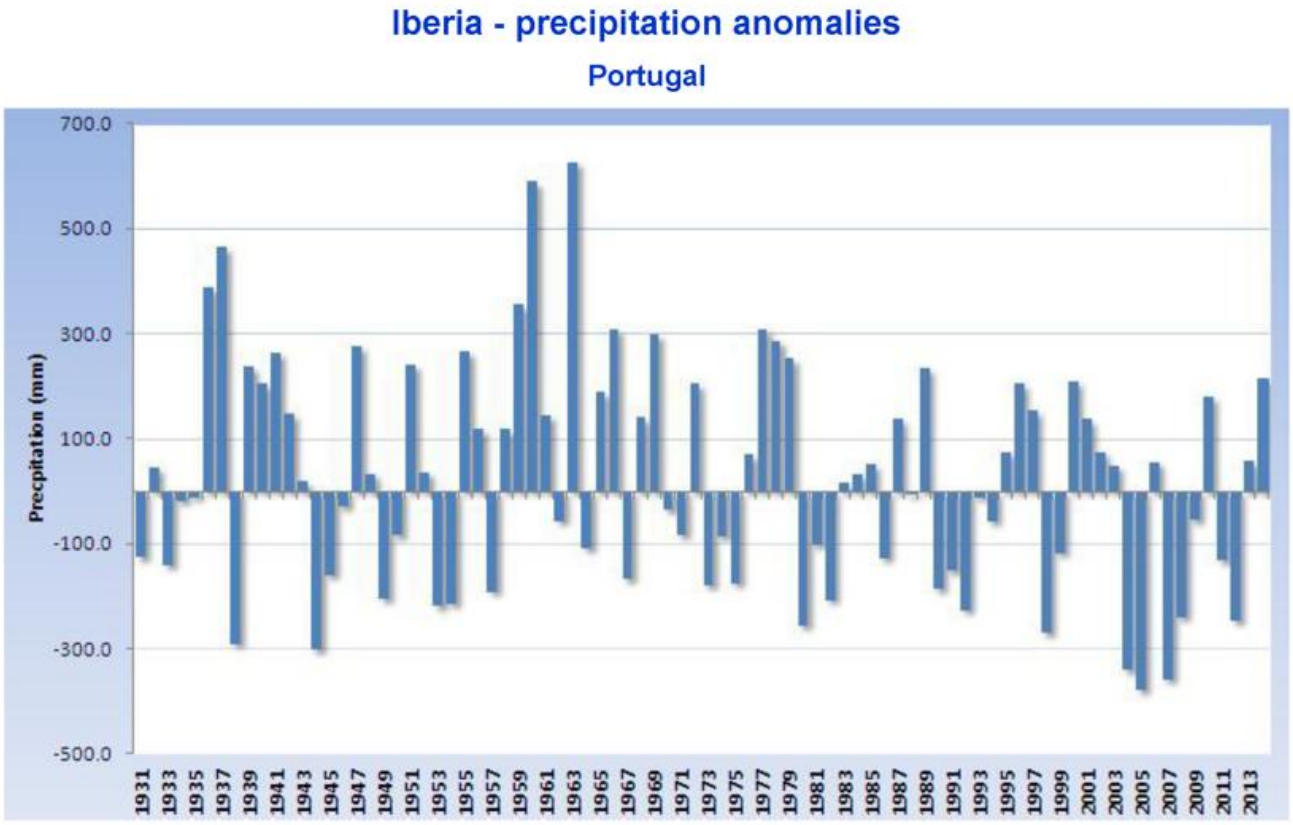

Figure 5.34: Time series of annual precipitation totals in mm/year (deviations from the mean of 1971-2000) for Portugal (Diagram as provided by the NHMS)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Italy, Slovenia, Turkey

Italy

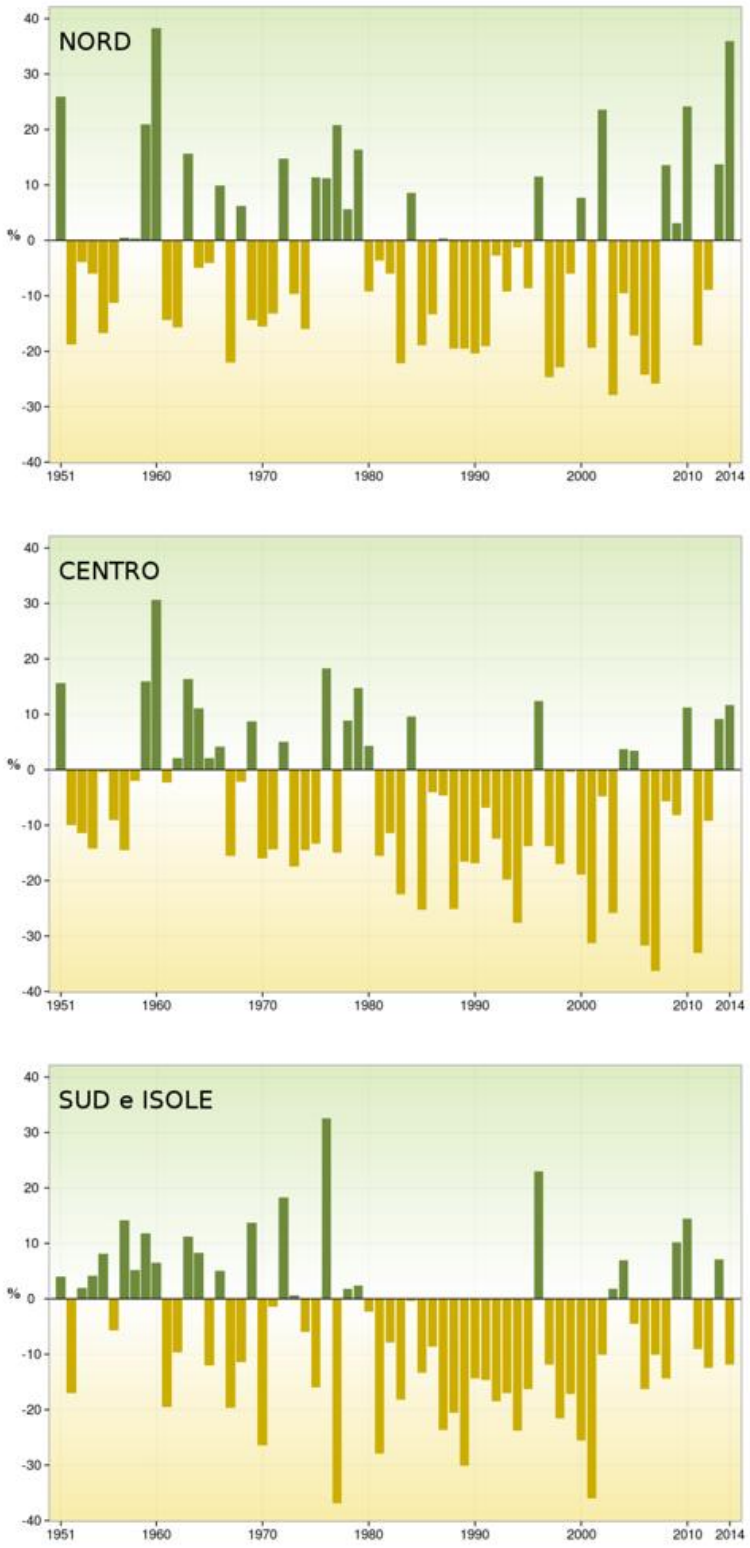

Figure 5.35: Time series of annual precipitation totals in relation to the mean of 1951-80 for northern (top), middle and southern (bottom) Italy for the period 1951-2014 (diagrams as provided by ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Slovenia

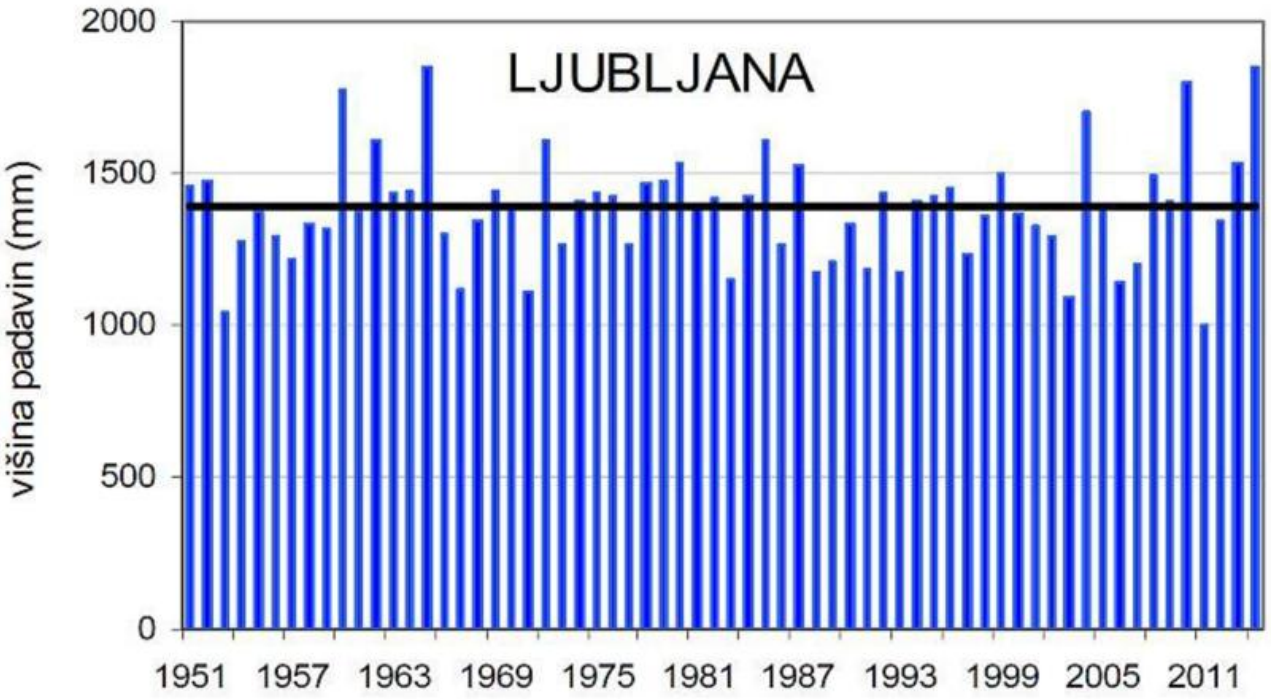

Figure 5.36: Time series of annual precipitation totals in mm/year for station Ljubljana (Slovenia, diagram as provided by the NHMS)

Turkey

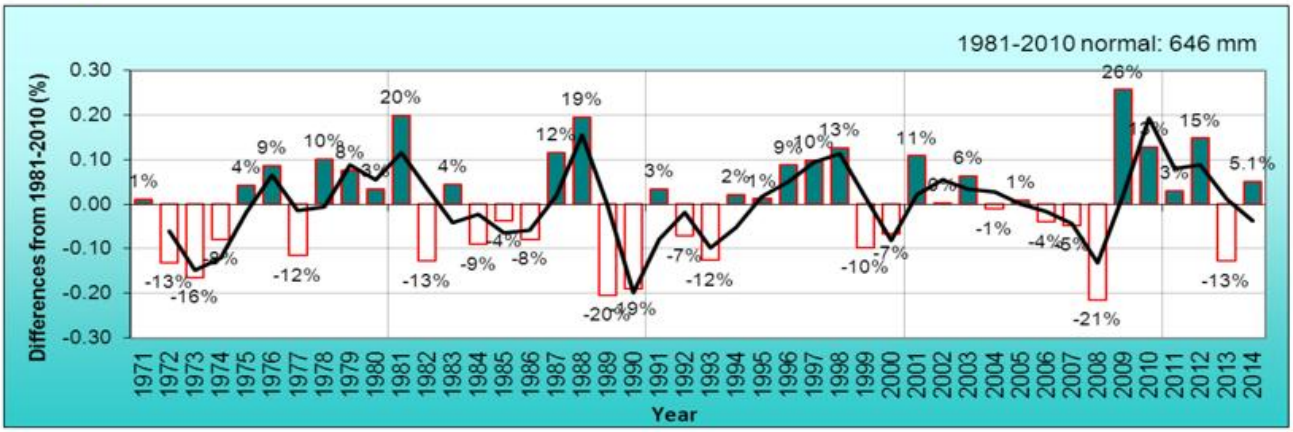

Figure 5.37: Time series of annual precipitation totals in relation to the mean of 1981-2010 for Turkey (Diagram as provided by the NHMS)

Eastern Europe - precipitation anomalies

Belarus, European Russia

Belarus

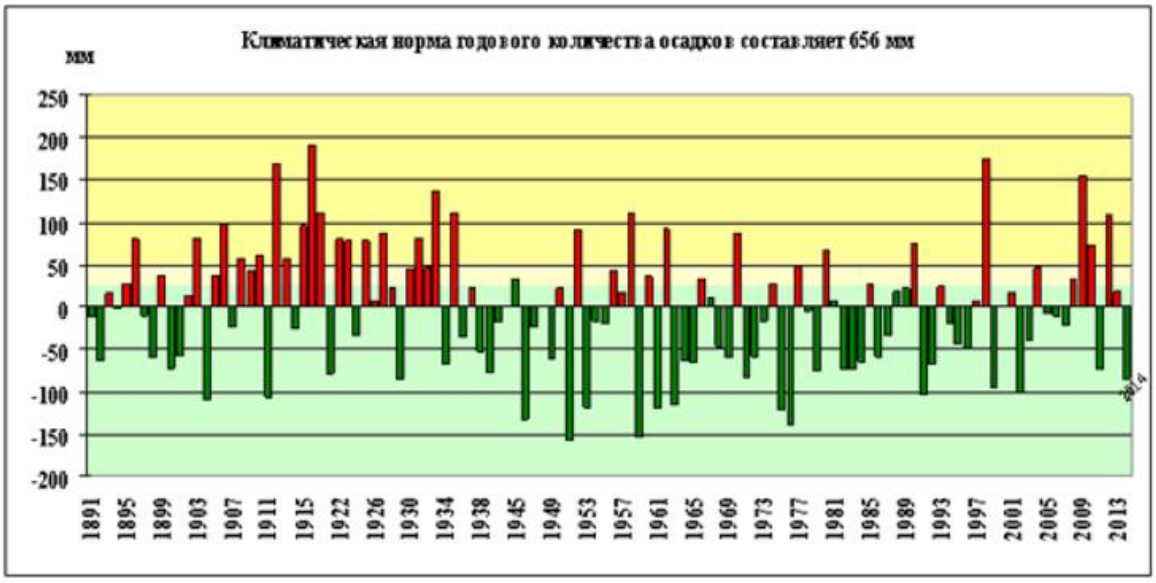

Figure 5.38: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Belarus (Diagram as provided by the NHMS)

European Russia

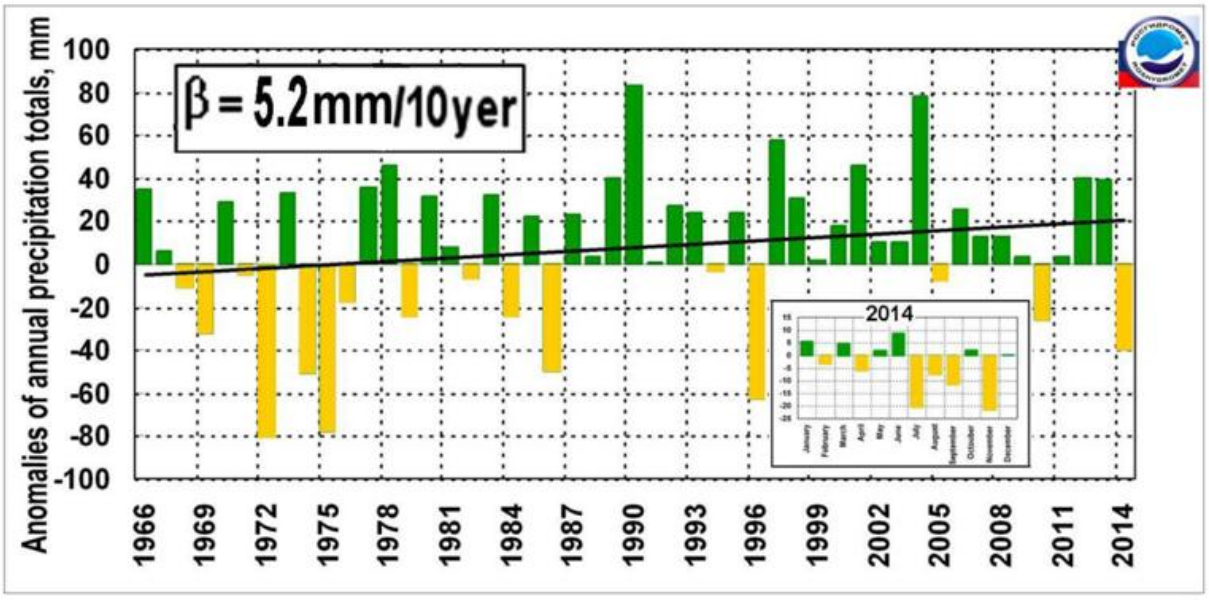

Figure 5.39: Time series of annual precipitation totals in relation to the mean of 1961-1990 for European Russia (Diagram as provided by the NHMS)

Middle East - precipitation anomalies

Georgia

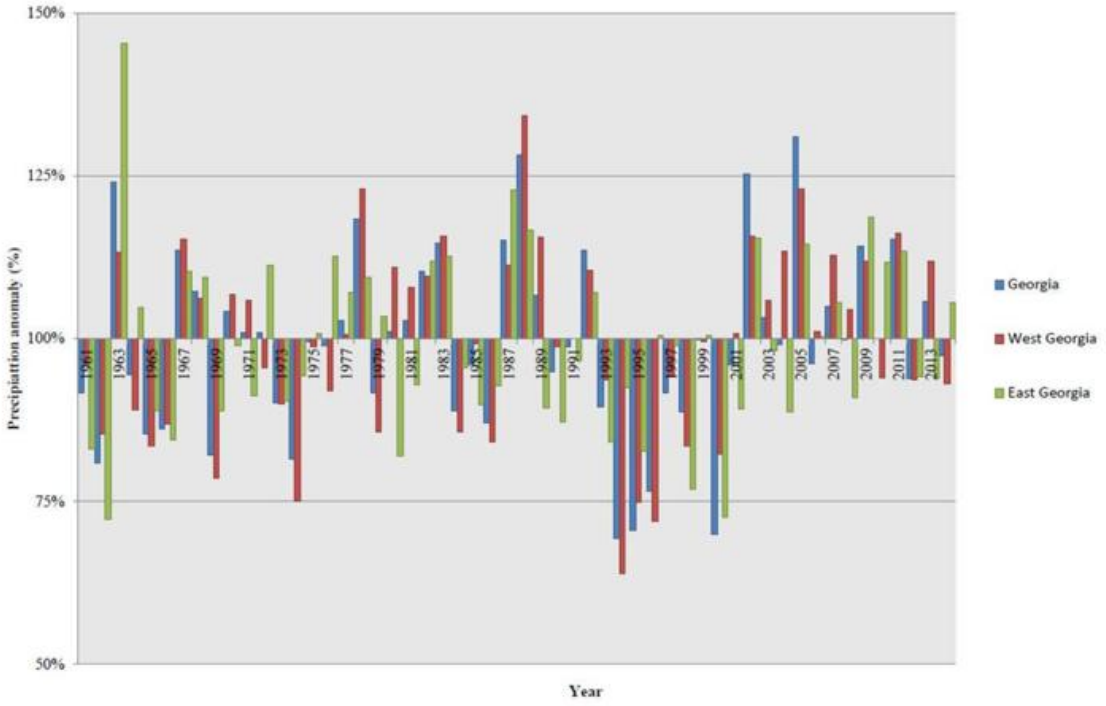

Figure 5.40: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Georgia (Diagram as provided by the NHMS)

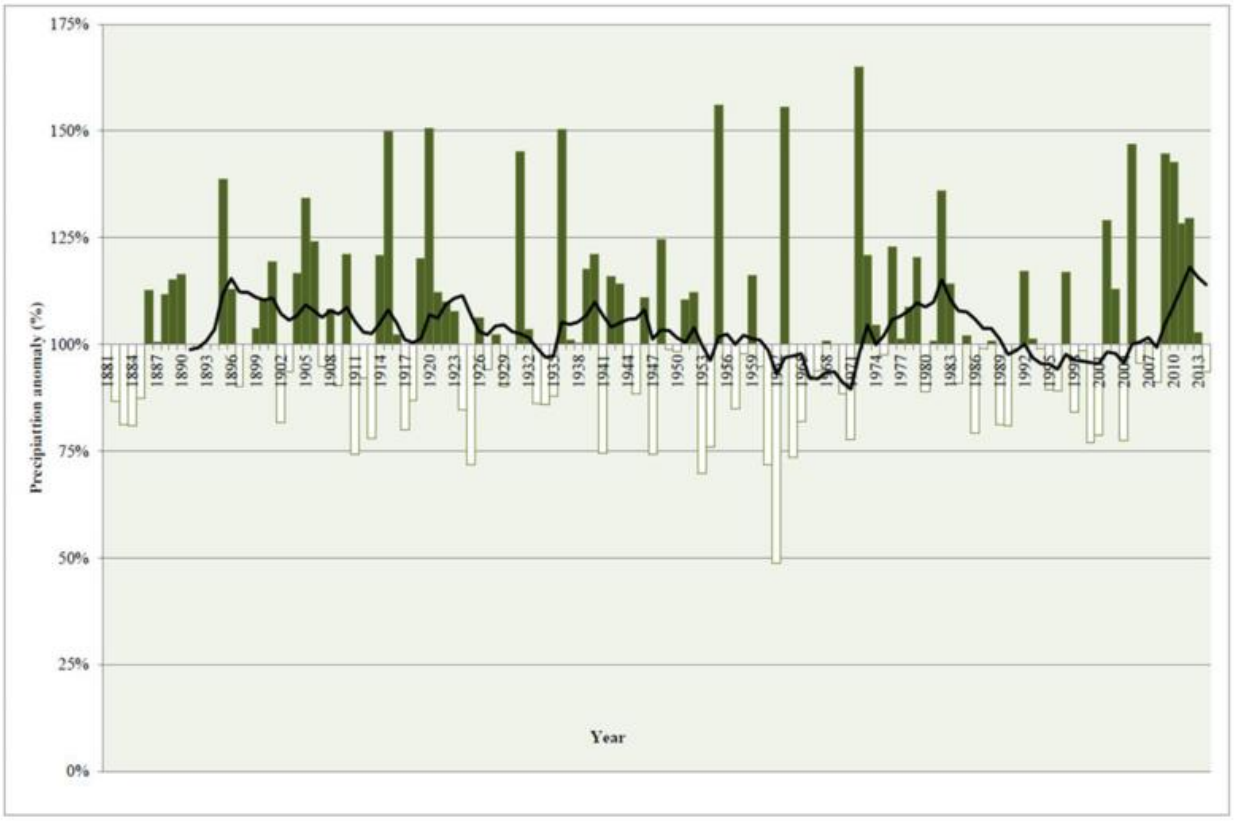

Figure 5.41: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Tbilisi, Georgia (Diagram as provided by the NHMS)

5.3. Sunshine duration

Central and Western Europe - sunshine duration anomalies

Germany, Switzerland

Germany

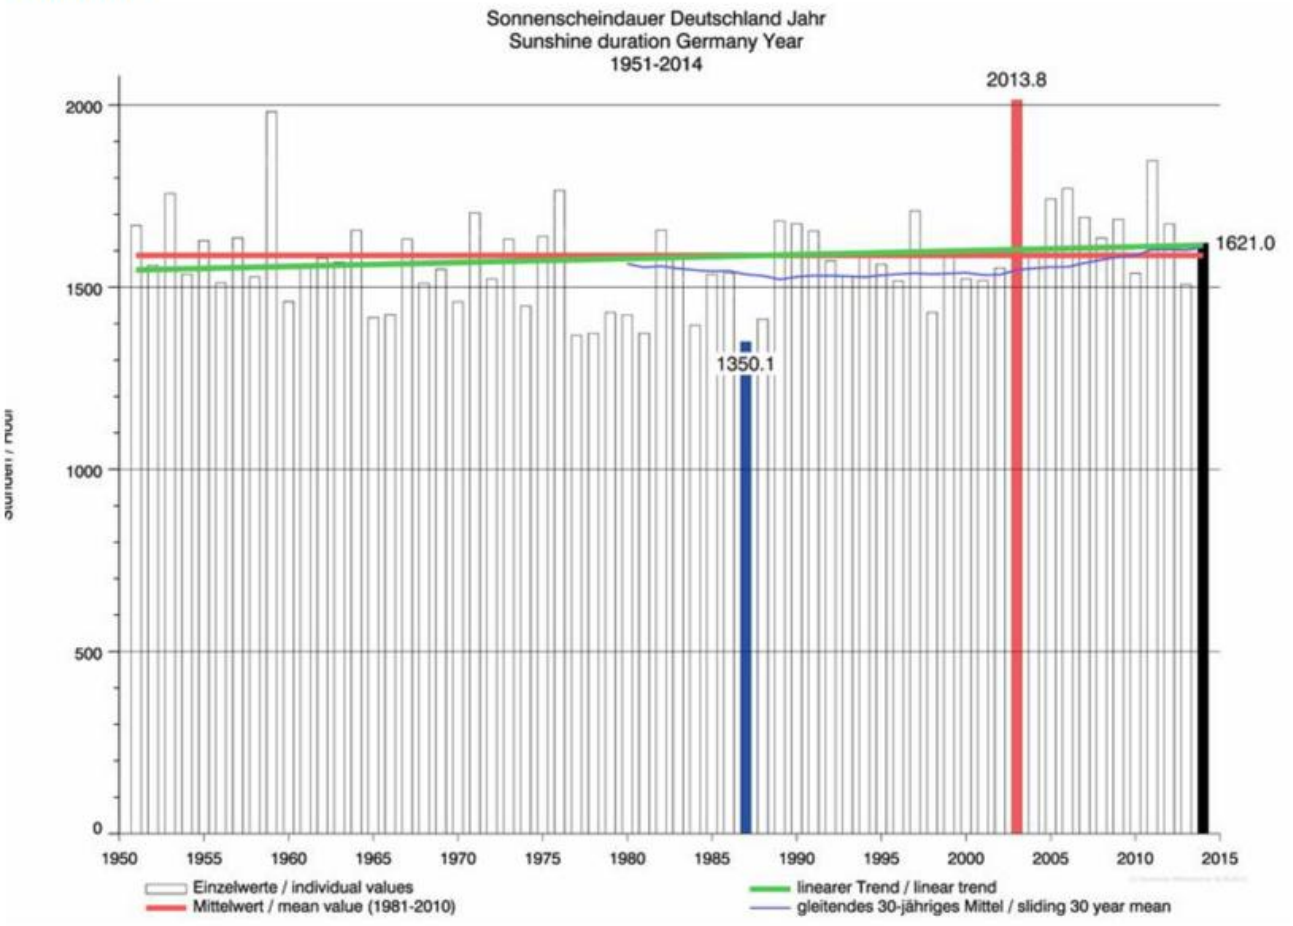

Figure 5.42: Time series of annual sum of the sunshine duration in hours for Germany (Diagram as provided by the NHMS)

Northern and Southern Switzerland

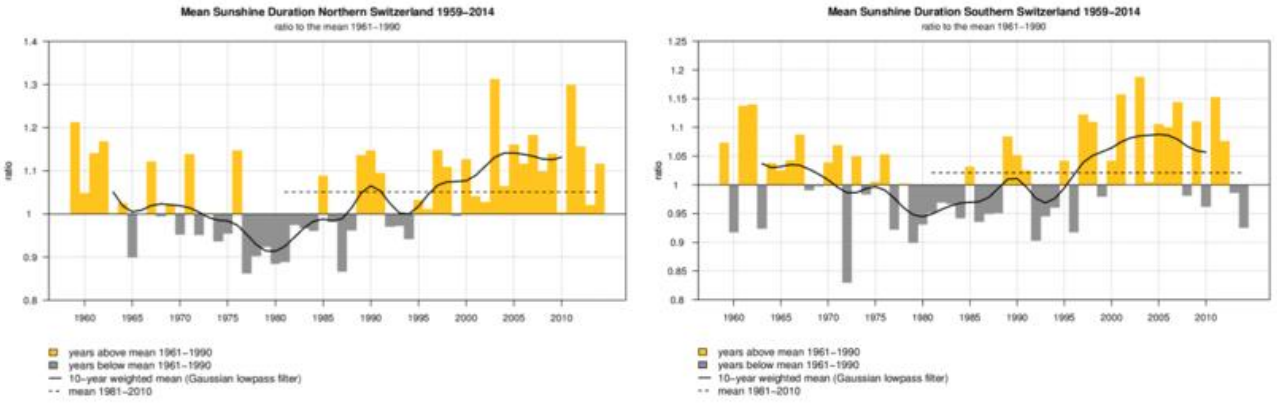

Figure 5.43: Time series of annual sunshine duration anomalies as ratio of the mean 1961-1990 for Northern (left) and Southern (right) Switzerland (reference period: 1961-1990; diagram as provided by the NHMS)

Nordic and Baltic Countries - sunshine duration

Denmark

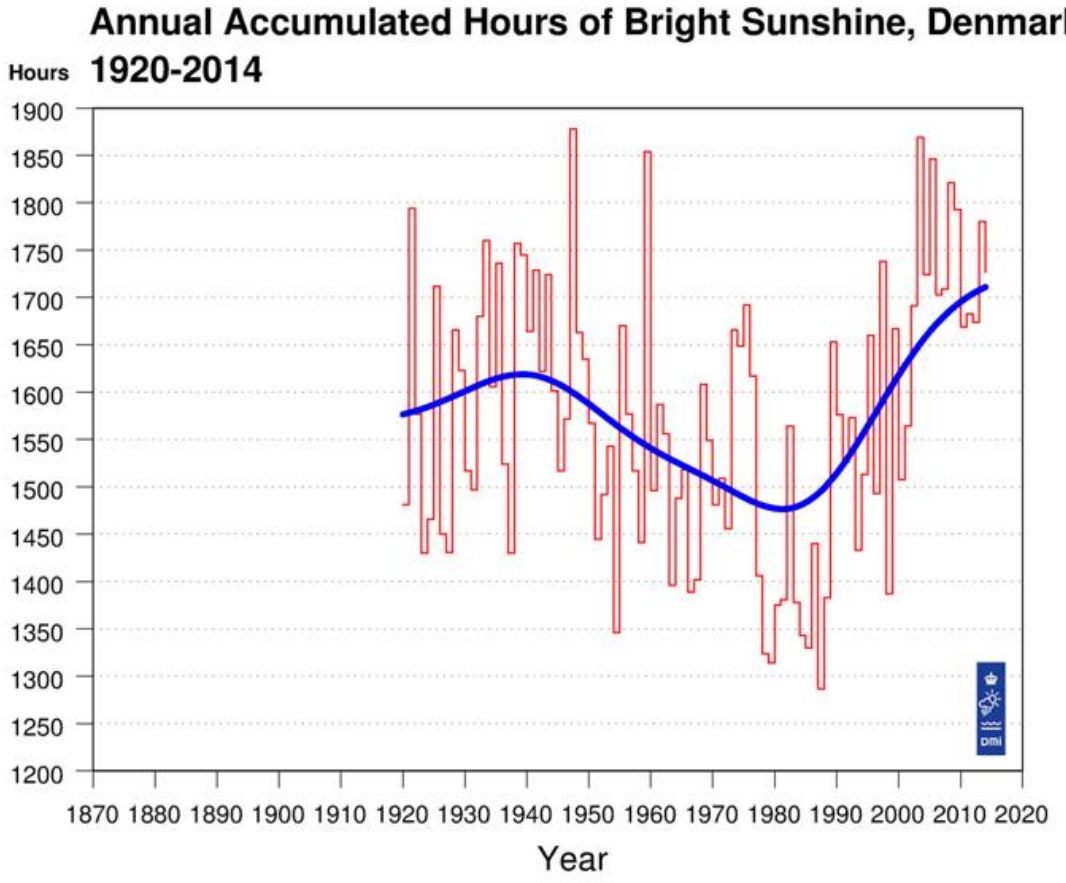

Figure 5.44: Time series of annual sunshine duration in hours for Denmark (Diagram as provided by the NHMS)

Note: DMI observed since 2002 the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. It should also be noted that all values before 2002 are adjusted in the best way possible ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990. http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf

5.4. Other climate related variables

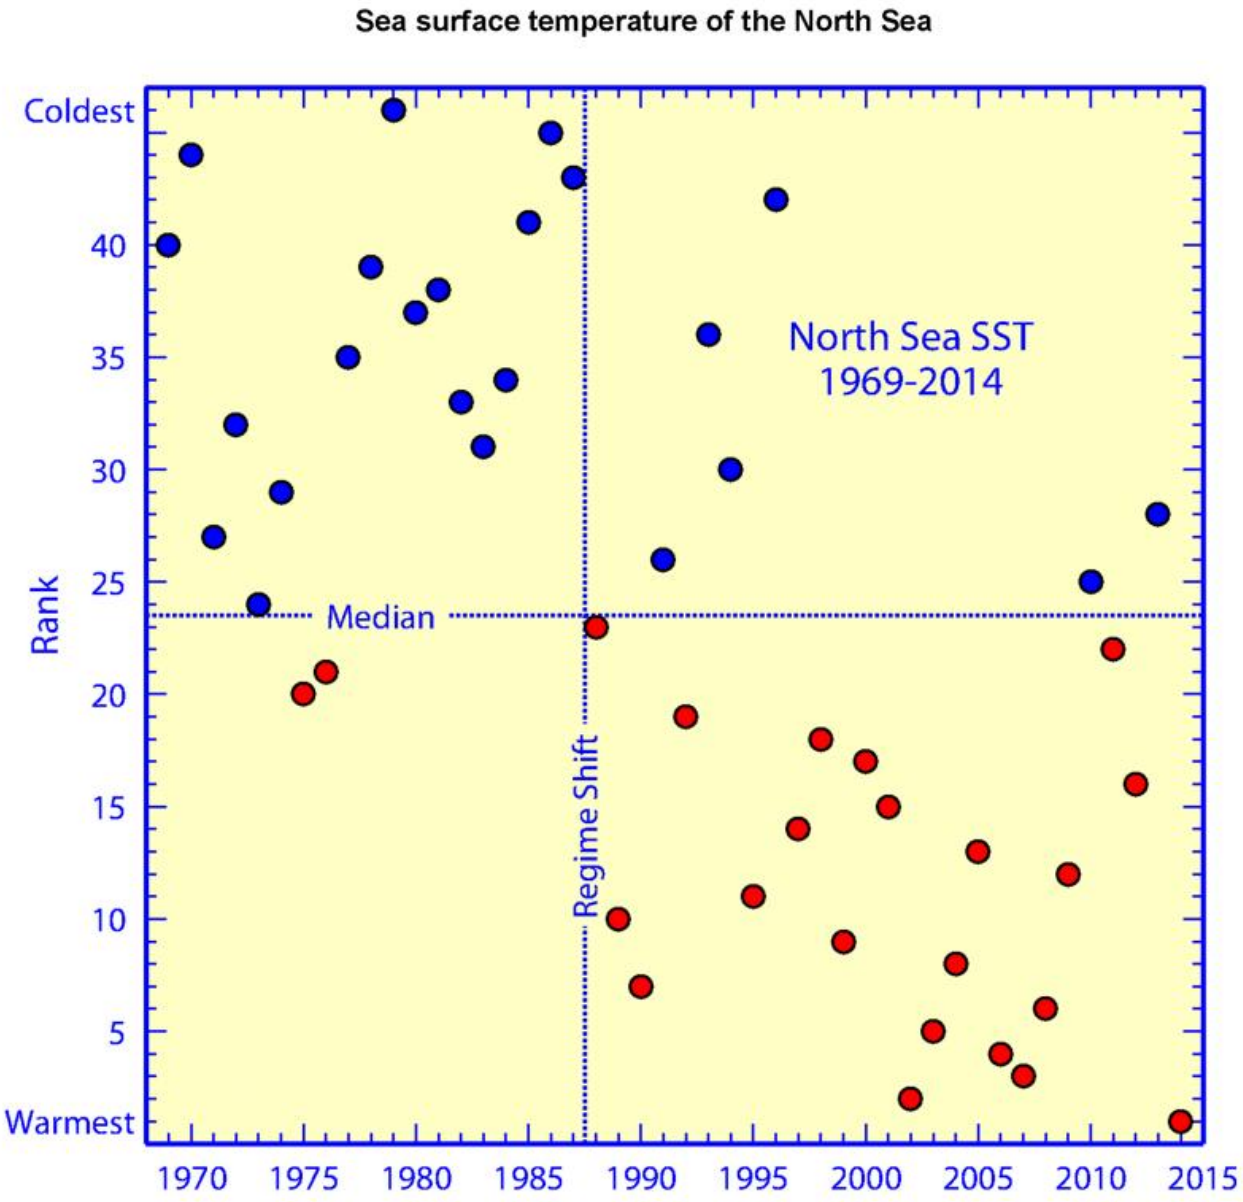

Figure 5.45: Rank statistics of the North Sea SST form 1969 to 2014 (Source: Bundesamt für Seeschifffahrt und Hydrographie BSH; year2014 means December 2013 to November 2014)

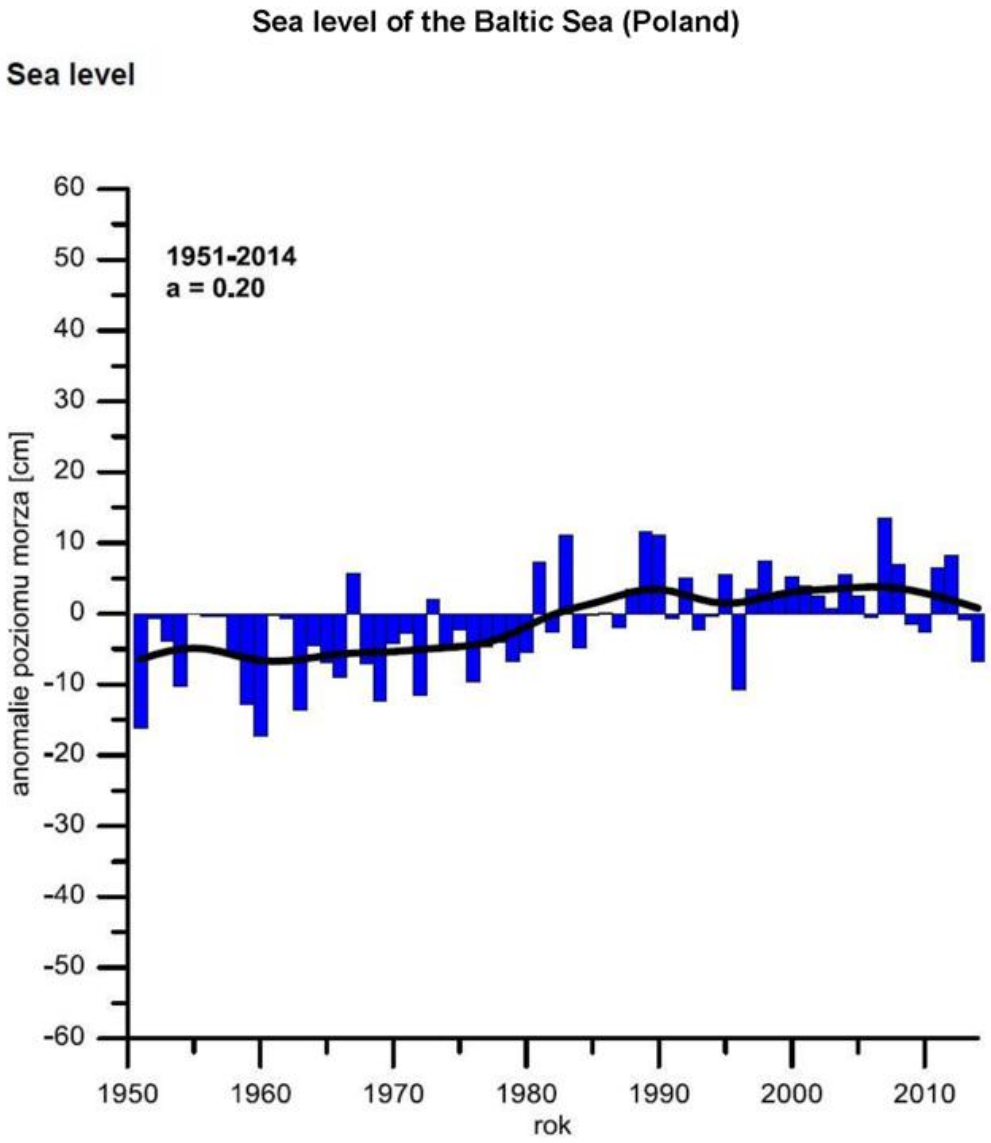

Figure 5.46: Mean annual sea level anomalies of the Baltic Sea in Władysławowo (1951-2014) in relation to the reference 1971-2000, smoothed by 10-years Gaussian filter (black line) and the value of the linear trend (cm/year, diagram as provided by the NHMS).

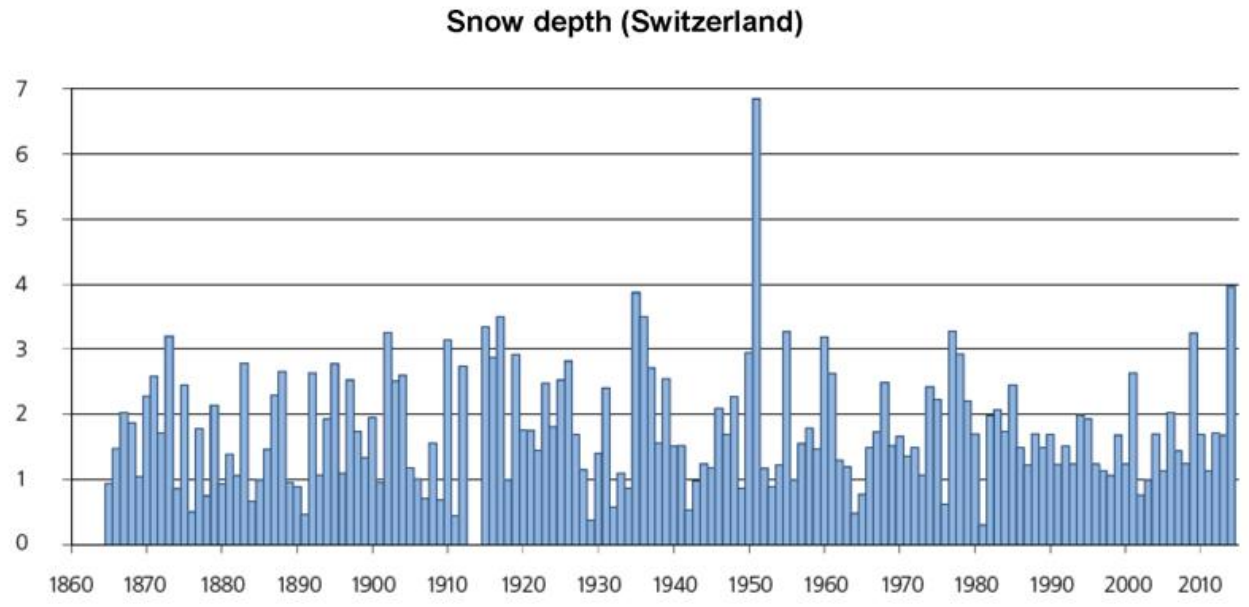

Figure 5.47: Fresh fallen snow during the snow-period (December – February in meters) at Segl-Maria (Switzerland, 1804 m NN) for the period 1864/65 until 2013/14 (Diagram as provided by the NHMS).

6. Annex: Monthly and annual tables

Table 6.1: Statistical values of **annual** mean temperature and total precipitation and their deviations from the long term mean (1961 – 1990, CLIMAT Data) for several stations of the RA VI region.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 52 individual countries) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Climate and the State of the Climate published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ amongst the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes 4 parts: the annual, seasonal and monthly survey of the climate state in 2015 as well as contributions of the NMHSs to the long-term variability of selected parameters up to 2015 (section 5).

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collection Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), operated by the Deutscher Wetterdienst
- Sunshine: CLIMAT data.
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

Sub-regional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC).

The following sub-regions are used in this Bulletin:

Central and western Europe (14 countries): *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, United Kingdom*

Nordic and Baltic Countries (9 countries): *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, Sweden*

Iberia (2 countries): *Portugal, Spain*

Mediterranean, Italian and Balkan Peninsula (12 countries): *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia, Turkey*

Eastern Europe (5 countries): *Belarus, European Russia, Moldova, Romania, Ukraine*

Middle East (9 countries): *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, western Kazakhstan*

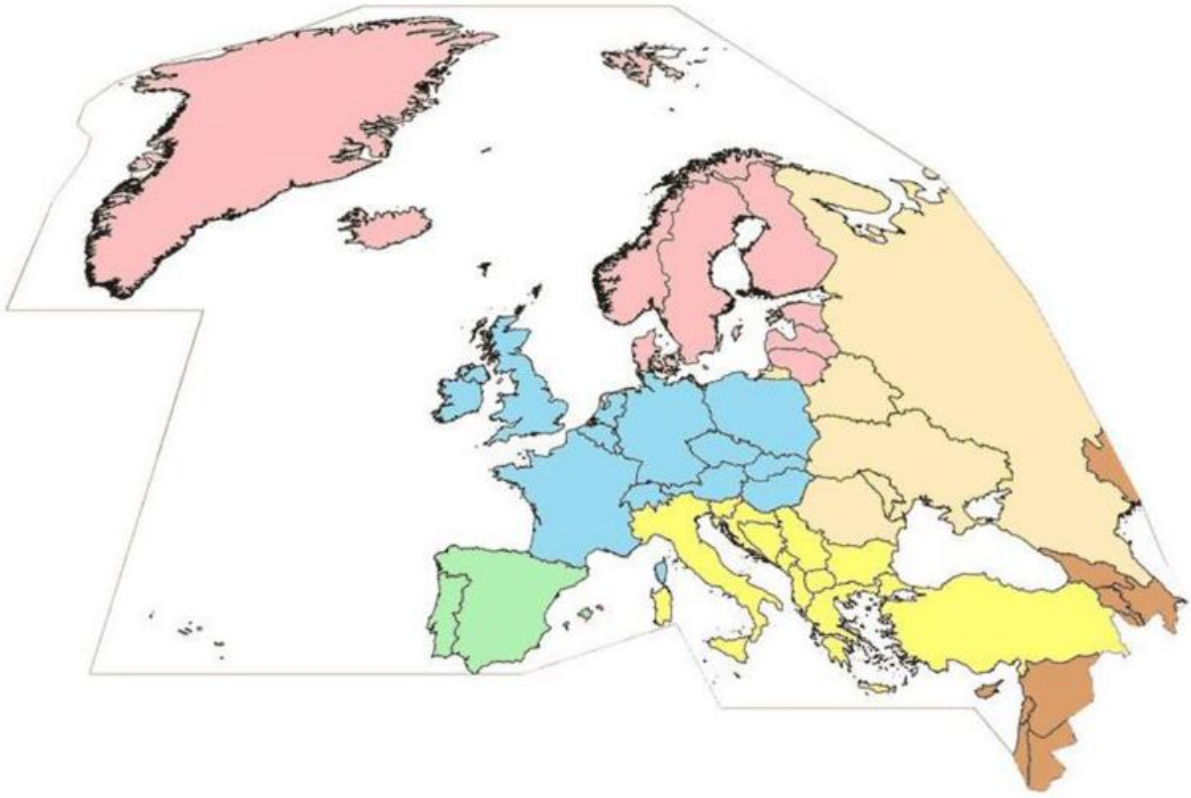

Figure 1.1: Definition of the 6 sub-regions used in this bulletin.

Box 1

Notable anomalies and events 2015

Anomalies

Temperature

- Record breaking year in many European countries (see **Table 2.1)**.
- 2015, followed by the year 2014 was globally the warmest year on record, according to several surface temperature observational analyses.
- Unusually temperatures in Israel in April.
- Heat wave over central and southern Europe from June to September.

Precipitation

- In January 2015 extreme monthly precipitation totals in Scandinavia with up to 400% of the normal at some stations; at Eikemo (Norway) 782.3 mm (279 % of the normal).
- Second wettest May since 1900 in Scandinavia.
- Several extremely intense rain-storm episodes of in the southeast of France in August, September and October.
- Long lasting drought and heat in summer extended over an area from southwestern and central Europe up to southwestern Russia.

Sunshine Duration

- Austria experienced its sunniest December on record with 190 % of normal.

Other Anomalies

- Lowest Arctic sea ice extent for March 2015 according to satellite records
- High pressure over Scandinavia in August 2015 accompanied by higher than normal temperatures.

Events:

- Several storm series passed Europe in March 2015
- Extreme precipitation and floods recorded in northern UK during December 2015 (Honister Pass (Cumbria) 341.4 mm/24 hours on the 5th).

2. Annual survey

The climate of 2015 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2.5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2015 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea surface pressure, surface temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for each participant country. Long-term trends in temperature and precipitation indices offers section 2.2.

More detailed insight into the long-term variability of the temperature and precipitation and also some other parameters from the individual participant countries are presented in section 5.

2.1. Annual averages and anomalies of selected essential climate variables

2.1.1. Sea level pressure

Generally, long-term mean annual sea level pressure distribution in 2015 over the WMO Region VI is dominated by a low pressure trough in the polar area with the Icelandic low that extend from southern Greenland over Iceland to northern Scandinavia. The second pressure system the subtropical high pressure belt extended from the centre over Azores (Azores high) across southern, western and central Europe to European Russia.

2015 the mean sea surface pressure differs to some extent from the long-term mean with a reduced pressure especially in a region west and northeast of Iceland with anomalies of -4 to -6 hPa. Higher pressure anomalies of +2 to +4 hPa occurred above southern and central Europe as can be seen from Figure 2.1 (right; normal period 1961-1990) which indicated in mean a stronger than normal NAO.

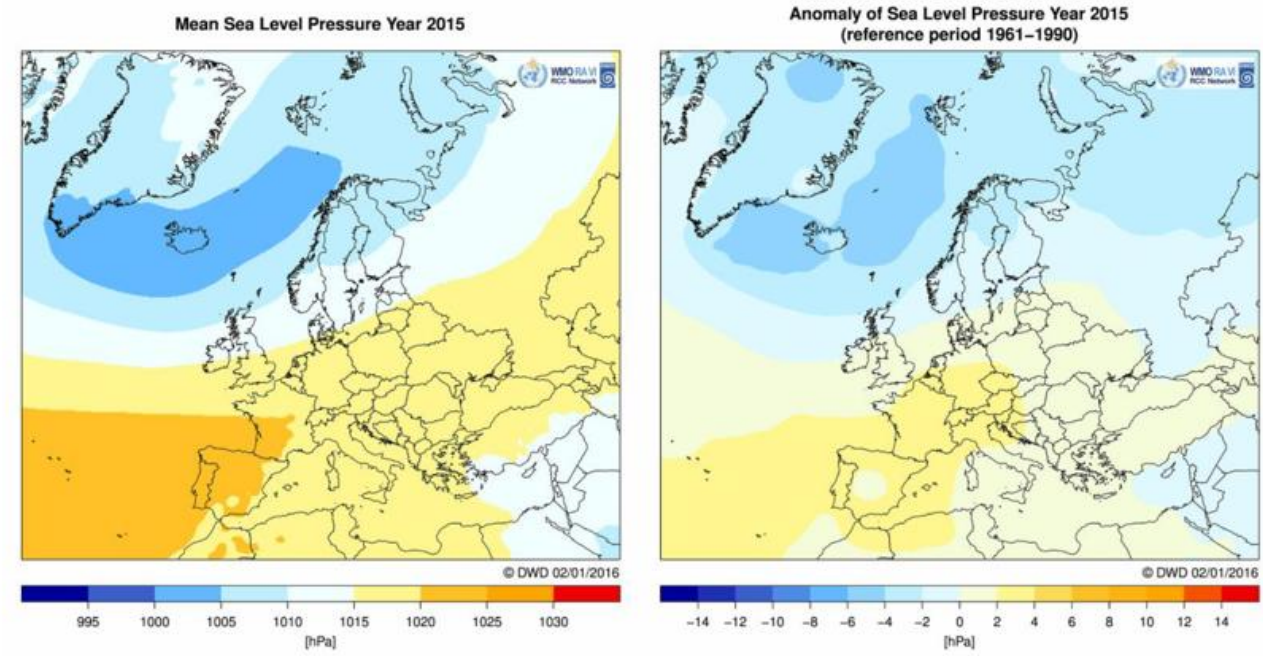

Figure 2.1: Annual mean of sea level pressure (left) and anomalies (right) for the year 2015 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.2. Temperature

In the entire European region (35°–75°N, 25°W–45°E) the year 2015 was the warmest since 1950 (slightly warmer than 2014) with an anomaly of 0.9°C above the reference period 1981–2010 or of 1.46°C related to 1961-1990. Many of the European countries reported new records (Table 2.1).

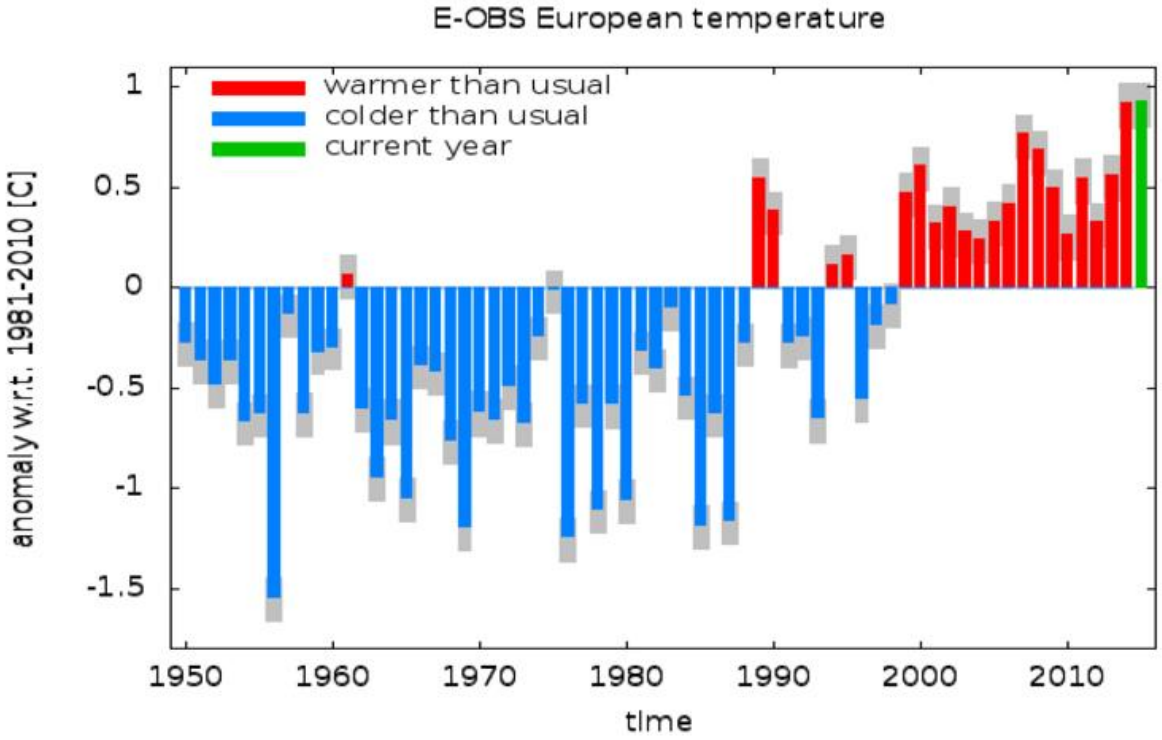

Figure 2.2: Annual temperature anomalies 1950-2015 for Europe (land area; 35°N - 75°N and 25°W - 45°E, reference period 1981–2010; source: www.ecad.eu, van der Schrier et al. 2013)

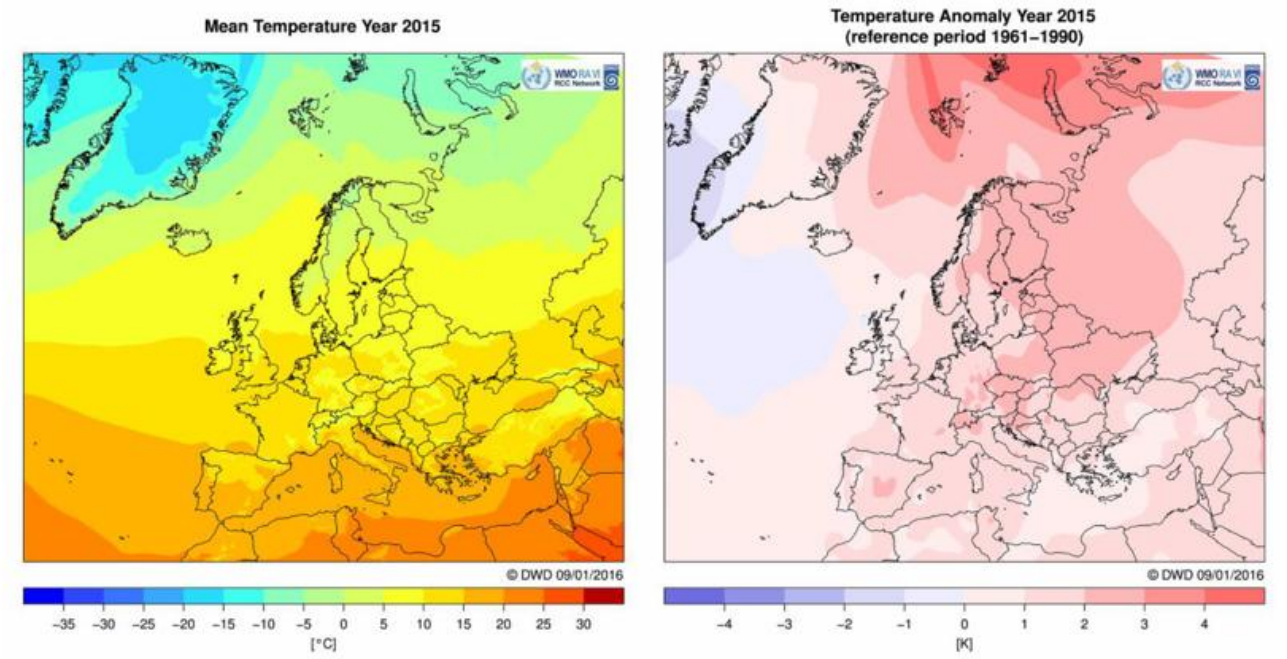

Figure 2.3: Mean annual temperature in °C (left) and anomalies (right) for 2015 (reference period 1961-1990. source: http://www.dwd.de/rcc-cm)

The highest annual anomaly of 2.29°C referred to 1961-1990 was observed in the sub-region Eastern Europe followed by Central and Western Europe (1.59°C), the Middle East (1.51), Mediterranean, Italian and Balkan Peninsula (1.48°C) and Iberia (1.41). The sub-region Nordic and

Baltic countries showed the lowest anomalies of 1.26°C (Table 3.2). Most of the months in 2015 were warmer than normal (1961-1990) with remarkably consistent deviations of +2 to +3°C especially from winter to summer across Iberia as well as the Mediterranean, Italian and Balkan Peninsula in winter and summer (cf. section 3.1.2 and 4.2).

The global annual temperature average for 2015 increased also to a record high 0.76 ± 0.09°C above the 1961–1990 average (WMO 2016, Blunden und Arndt 2016)

A summary of the annual temperature time series and the historical rating can be drawn from section 5. The rank statistics are listed together with the start of the time series and the anomaly of the year 2015 as provided by the NHMS are outlined in the following table.

Table 2.1: Rank statistics and anomalies of annual temperature in 2015 from some participant countries as reported by the National Meteorological and Hydrological Services (NMHSs).

Country	Rank of annual temperature in 2015	start of time series	Anomaly in °C	Reference period
Europe (35°–75°N, 10°W–30°E, E-OBS)	**1**	**1951**	**1.46**	**1961-1990**
Armenia	3	1961	1.8	1961-1990

Israel	3	1951		1961-1990
Italy	1	1961	1.6	1961-1990
Jordan			1.2	1961-1990
Kazakhstan	3	1936		1961-1990
Latvia	1	1924	2.1	1961-1990
Lithuania	1	1961	2.1	1961–1990
Luxembourg	3 (with 2007)	1947	2.1	1961–1990
Moldova	1-2		2.1-2.7	1961-1990
Montenegro	1-5		1.5-3.1	1961-1990
Netherlands	5	1901(de Bilt)	0.8	1981-2010
Norway	3	1900	1.8	1961-1990
Poland	1	1950	1.8	1971-2000
Portugal	7	1931	0.75	1971-2000
Romania	1	1901	1.96	1961-1990
Russia, European	1	1939	2.07	1961-1990
Serbia	3	1951	1.6	1961-1990
Slovakia	2	1951	2.0	1961-1990
Slovenia	2-3	1951	2-3	1961-1990
Spain	1 (with 2011)	1961	0.9	1981-2010
Sweden	3	1860		1961-1990
Switzerland	1	1864	1.29	1981-2010
Turkey	5	1971	0.8	1981-2010
Ukraine	1	1951	2.4	1961-1990
United Kingdom	16 (near average)	1910	0.4	1981-2010

2.1.3. Precipitation

The annual precipitation amount was close to normal over many parts of continental Europe except for Ireland, northern UK, Denmark, most parts of Scandinavia and south-eastern Europe, where positive anomalies above 10 mm/month were recorded. Parts of Iberia, France, the region around the Alps and parts of eastern Europe showed drier conditions with anomalies below -10 mm/month and also values below the 0.1 percentile indicating a drought situation. The annual figures of the year 2015 give only rough hints of the regions with outstanding precipitation events. Detailed descriptions can be found in the seasonal (3.1.3) and monthly survey (4.3).

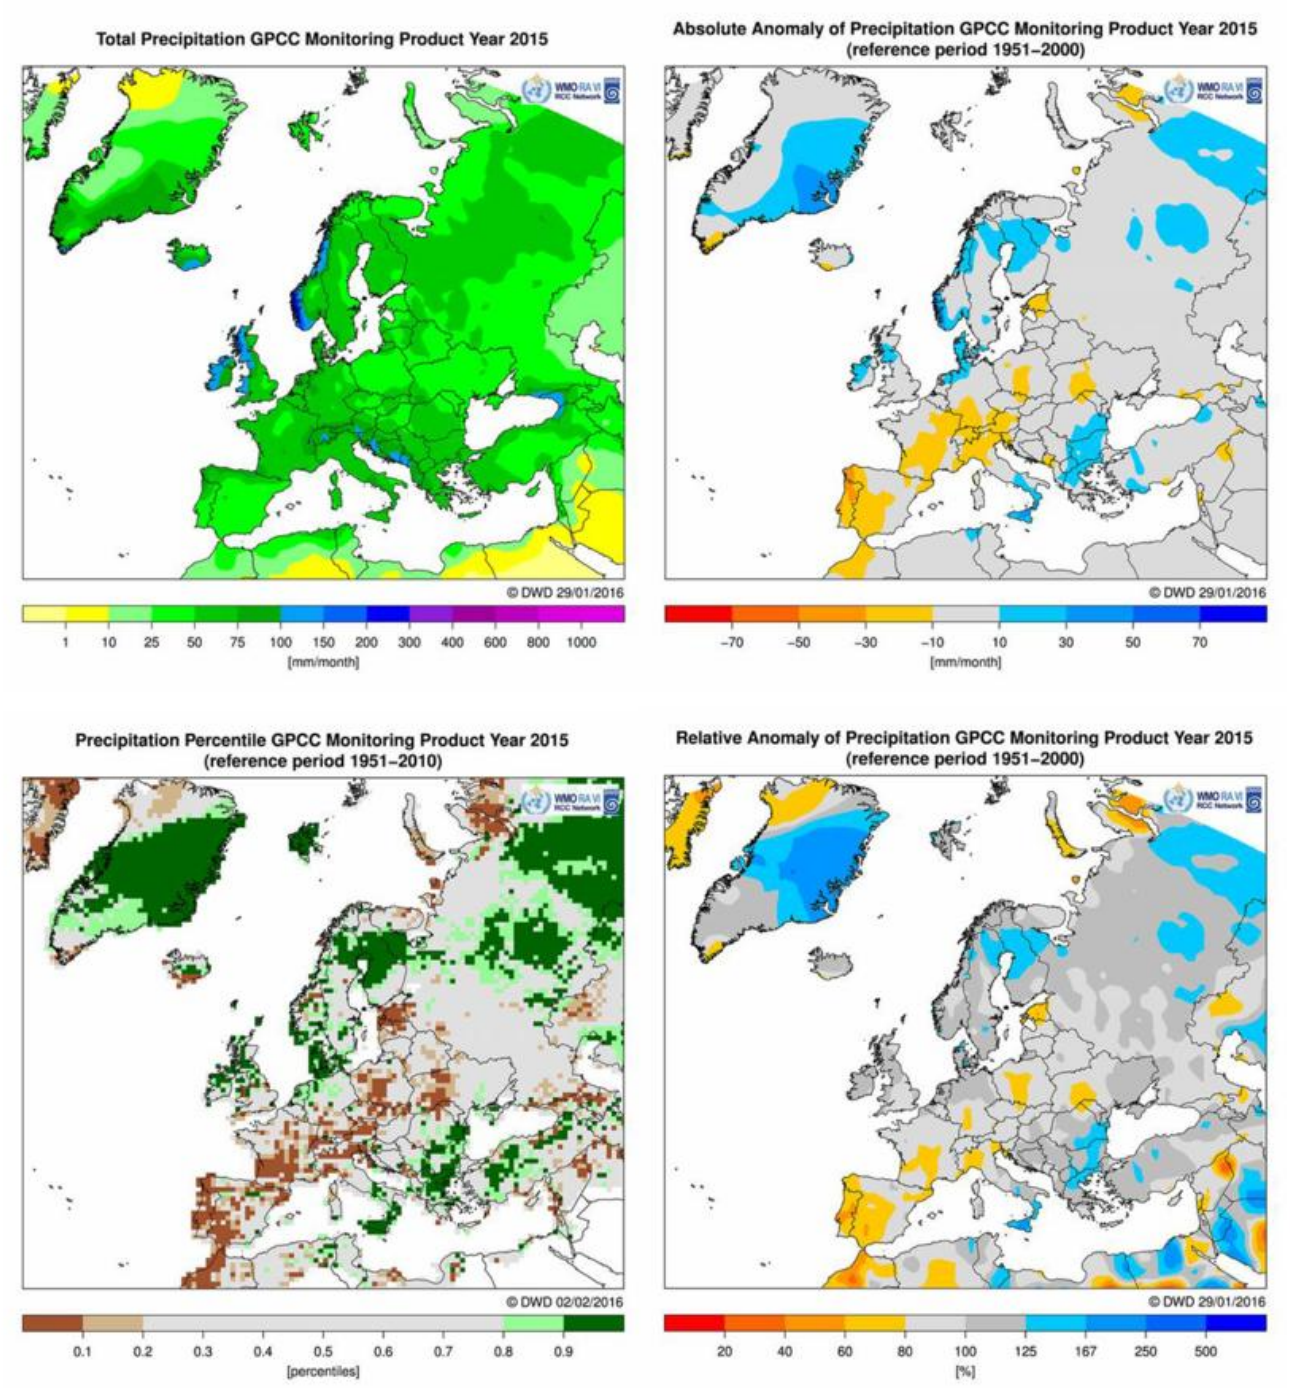

Figure 2.4: Total precipitation (left, top), absolute anomalies (right, top) in mm/month, percentiles (left, bottom) and relative anomalies in % (right, bottom) for 2015 (reference period 1951-2000; source: http://www.dwd.de/rcc-cm)

2.1.4. Annual extreme values of temperature and precipitation

In this section an overview is given for the temperature spread and the extreme precipitation for each country. Absolute annual extreme values for 2015 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5 consecutive days with precipitation for each country in the WMO Region VI are given in Figure 2.5.

The spatial pattern of extreme temperature corresponds roughly to those of the temperature anomalies of 2015. The highest maximum temperatures (above 40°C) occurred primarily in sub-regions Middle East, Mediterranean, Italian, Balkan, some countries of Central Europe and Iberian Peninsula. Maximum temperatures higher than 35°C were reported from most of the countries in central and eastern Europe, but also from some of Nordic and Baltic Countries. The one-day precipitation totals (RX1) of more than 150 mm for individual countries are documented in several sub-regions; the highest values occurred in Italy (481 mm/day, at a local station) and Great Britain (341 mm/day). Highest total precipitation from 5 consecutive days (RX5) (above 300 mm) was measured in Great Britain (381 mm), Greece (358.6 mm), Italy (358 mm, only synoptic stations), Austria (350 mm) followed by Slovenia (323 mm).

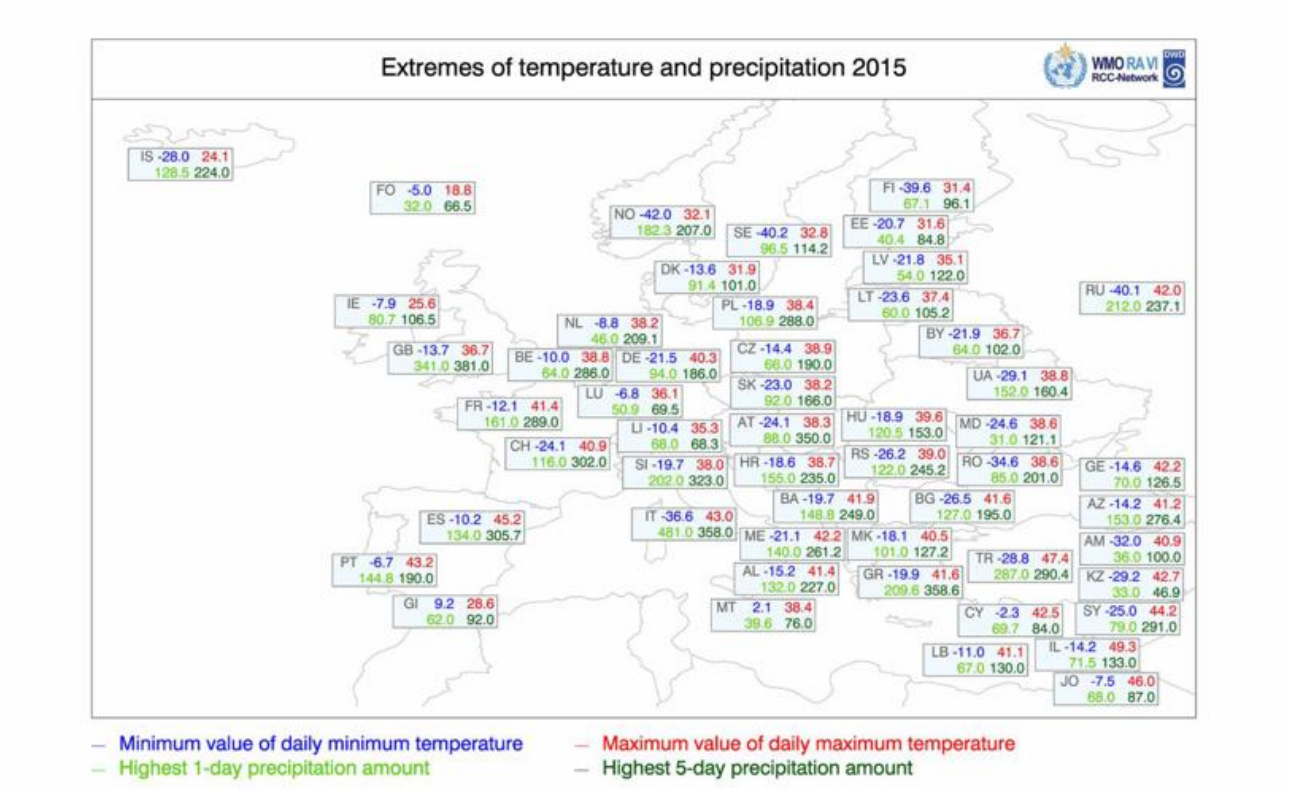

Figure 2.5: Annual extreme values for each country in 2015: first row: Internet country code, lowest daily minimum temperature (in °C, blue) and highest daily maximum temperature (in °C, red); second row: maximum daily precipitation totals (in mm, light green) and maximum 5-daily consecutive precipitation totals (in mm, dark green).

Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their Internet country codes. (Source: http://www.dwd.de/rcc-cm)

2.1.5. Sunshine duration

As expected, the annual sum of sunshine duration 2015 showed from the south to the north generally gradual decreasing values. More than normal sunshine hours have been primarily noted in most parts of Europe except in Portugal, southern Italy as well as in Turkey and north-eastern Europe. Svalbard, Poland and southern Russia showed in almost every season above normal sunshine (>125 %). Positive anomalies of the same range were also noted in Svalbard.

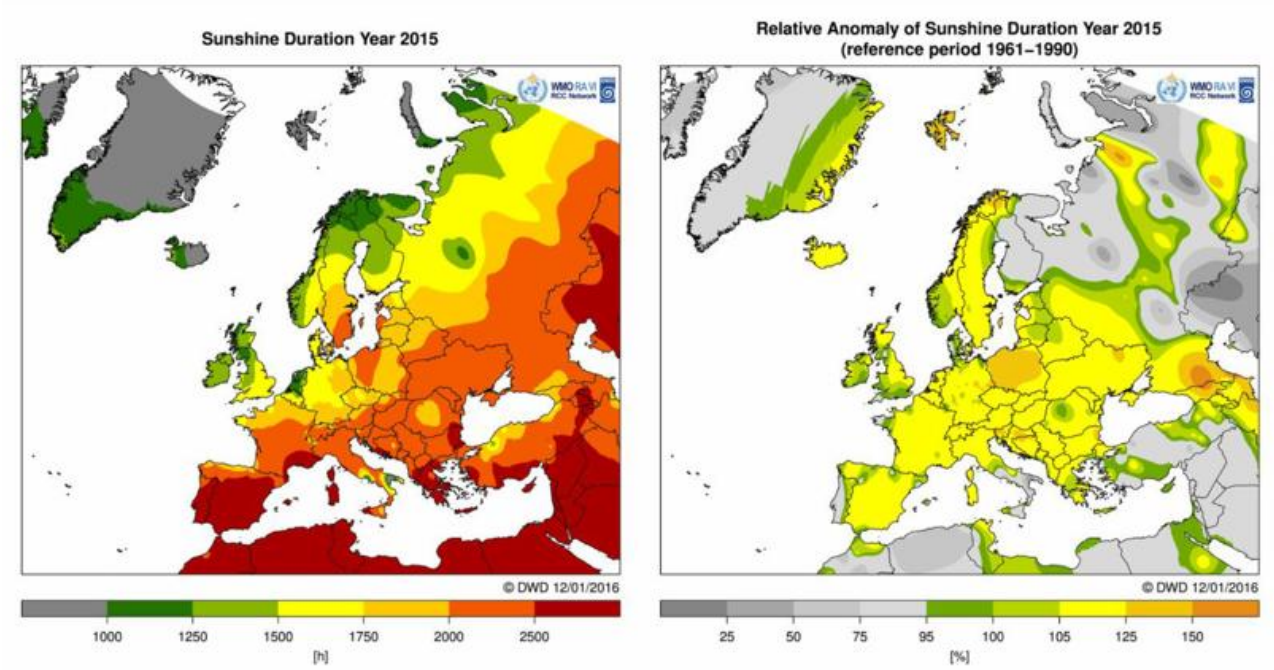

Figure 2.6: Annual sum of sunshine duration (left) and relative anomalies (right) for the year 2015 in hours with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.6. Drought situation

The drought index (SPI) in 2015 differed only slightly from its normal values. The anomalies from Spain over central Europe to Russia were slightly below normal while northern Europe and south-eastern Europe were slightly wetter. In these areas annual precipitation was above normal linked with floods.

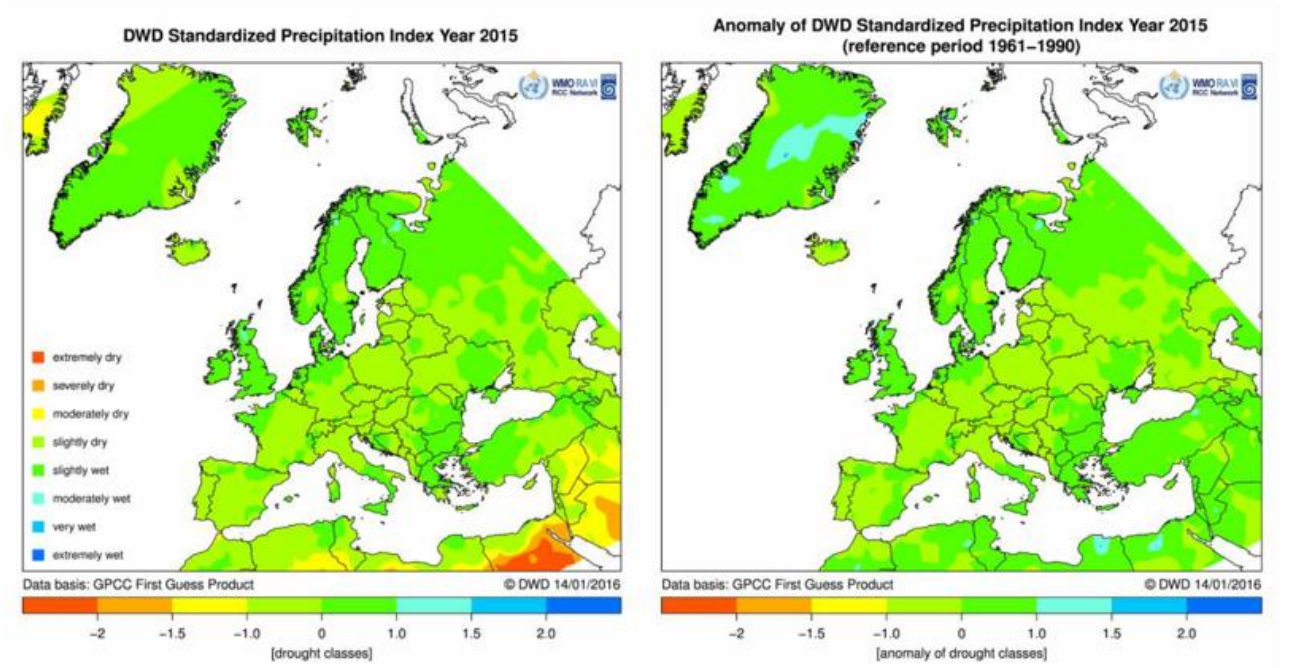

Figure 2.7: Annual modified Standardized Precipitation Index (DWD-SPI) for the year 2015 (left) and its anomalies (right) with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm)

2.1.7. Snow cover

The snow-season 2014/2015 (September 2014–August 2015) was warmer than normal and consequently in many low land areas in west and south Europe no snow occurred at all. Apart from mountain areas, in the central Europe the partly occasional snow fall events occurred in December. As expected, towards the northern and eastern Europe the snow cover duration was longer and ended in April and May.

However, late snow prevailed in Austria and Switzerland.

In the second half of January 2015 north-westerly and northerly currents brought the winter to **Switzerland**. Even at low altitudes snow fell on both sides of the Alps. In February there was also snowfall down to low altitudes in many parts on both sides of the Alps with colder than normal temperatures. Especially south of the Alps, snowfall was substantial. In mid-February 16 cm of fresh snow fell in Locarno-Monti within two days. In Airolo (1100 m a.s.l.) and San Bernardino (1640 m a.s.l.) snowfall amounted to 63 cm, in Bosco-Gurin (1500 m a.s.l.) as much as 96 cm. One week later a cold air front from northwest covered almost the whole of Switzerland in fresh snow. In low altitude areas north of the Alps amounts remained under 10 cm. South of the Alps 10 to 20 cm of fresh snow were recorded even at low altitudes while at higher altitudes over half a meter was measured.

In winter the absence of snow in **Austria** was remarkable. In the lower parts of the country the days with snow cover was 40 % below the average, because it was the 8th warmest winter on record. Due to the high temperature the larger parts of the precipitation fell in form of rain.

In 2015 the number of days with snow cover in Poland was significantly below the normal and ranged from several days in North and West, through 10-45 days in central part of Poland to above 100 days in the mountains. Snow cover at Kasprowy Wierch (1991 m a. s. l.) in Tatra Mountains was observed on 209 days. The maximum snow depth across the country did not exceeded 20 cm. In the mountains it was higher, reaching 217 cm at Kasprowy Wierch in Tatra Mountains.

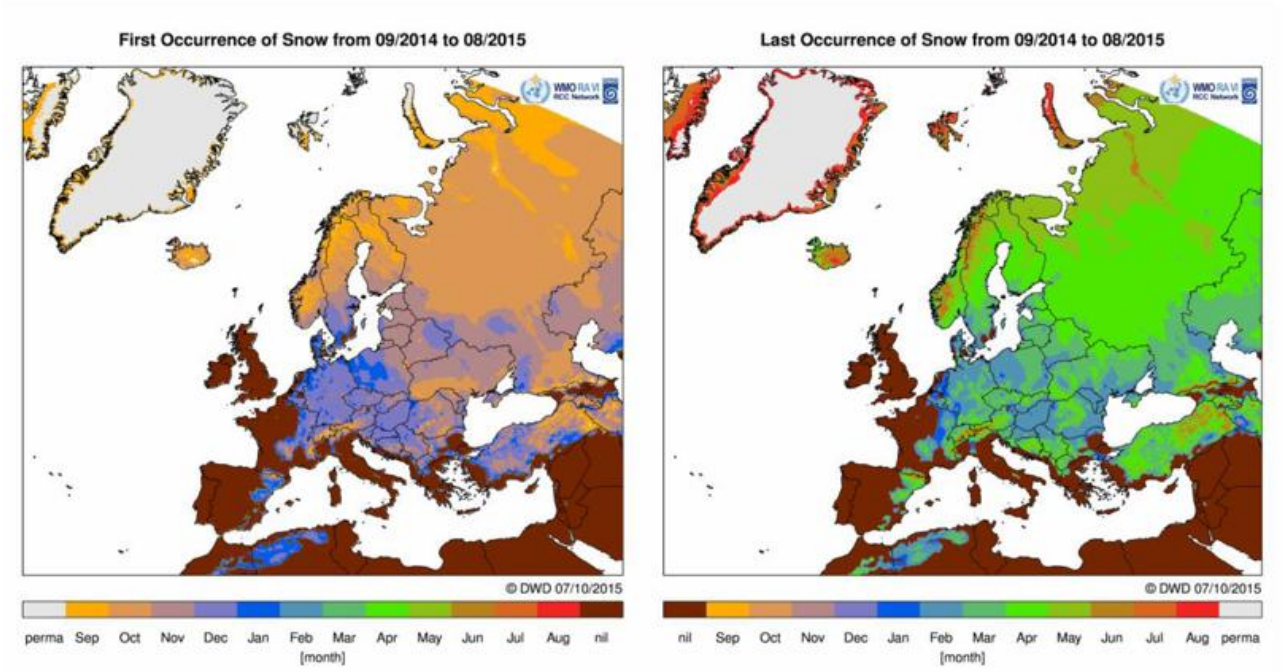

Figure 2.8: First occurrence of snow (left) and last occurrence of snow (right) during the snow-season 2014/2015. (Source: http://www.dwd.de/rcc-cm)

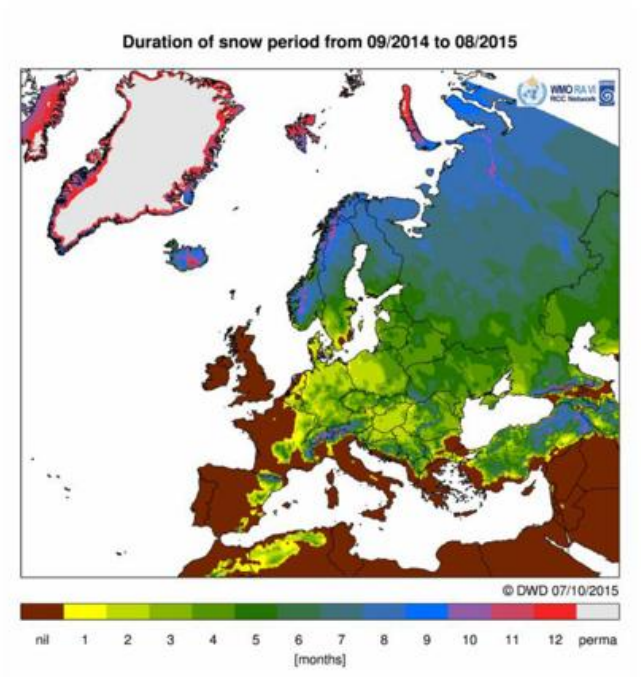

Figure 2.9: Duration of snow cover in the snow-season 2014/2015. (Source: http://www.dwd.de/rcc-cm)

2.2. Trends of temperature and precipitation indices 1951-2015

This section presents trends for selected temperature and precipitation indices for the period 1951-2015.

In the northern, north-western and eastern Europe most stations showed an increase in the annual number of wet days (RR1) for the last 65 years while in southern Europe a decreasing trend prevailed. The decreasing and increasing trend at neighbouring stations, however, indicate inhomogeneities in the time series. The number of warm and wet days (WW) increased over whole Europe with exception of Greece. The annual number of summer days (SU) increased in Central and southern Europe while in the north-western and northern Europe no significant changes were observed. The annual numbers of tropical nights (TR) showed increasing tendencies in the south-east part of Region VI while the north-west part noted no significant changes.

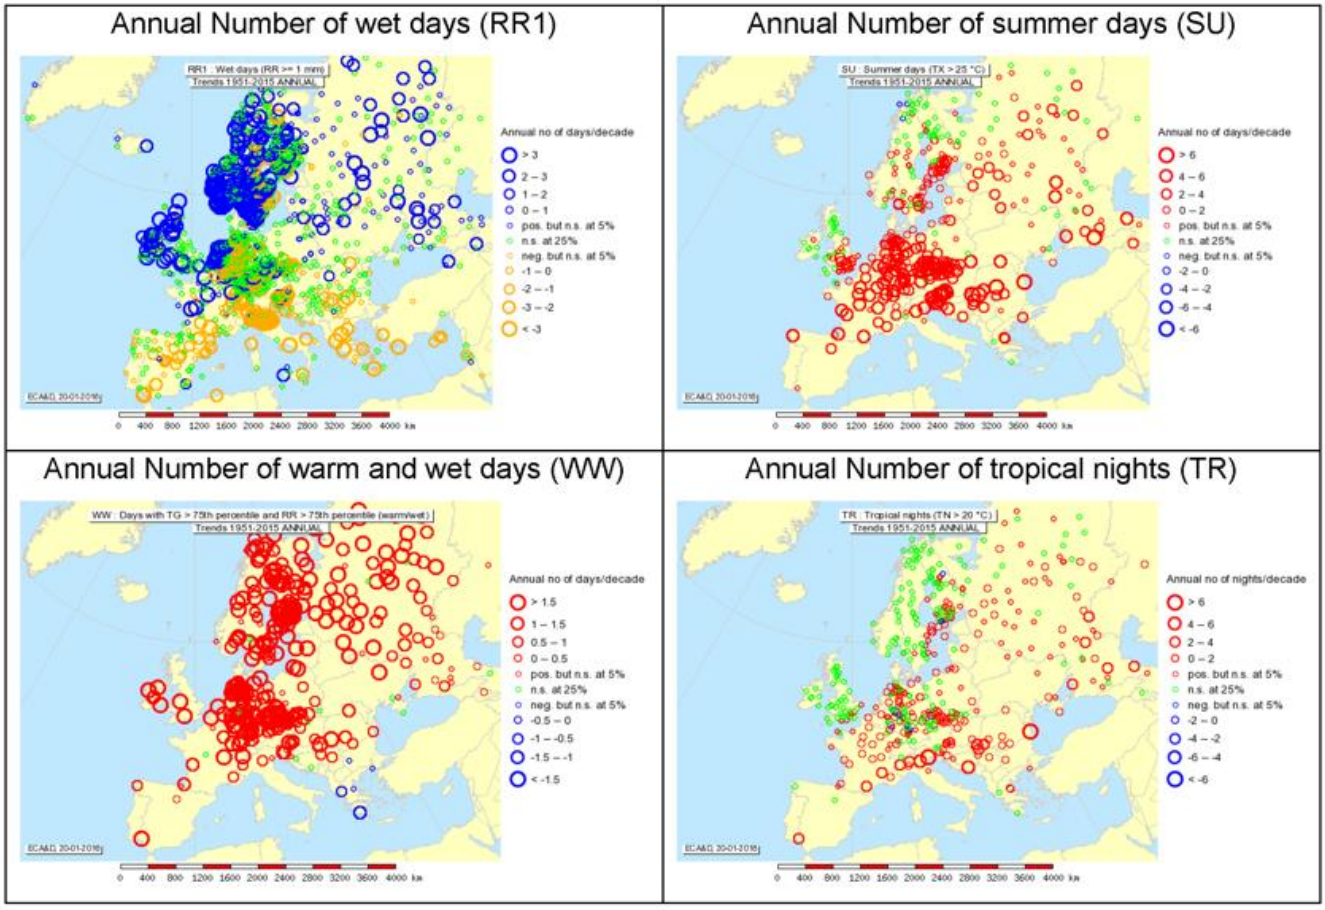

Figure 2.10: Trends of Selected Climate Indices 1951 to 2015 (Source: ECA&D, http://www.ecad.eu)

Legend of Figure 2.10:

1. **RR1, Number of wet days**: count of days where RR (precipitation > 1 mm)
   Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally effected.
2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) > 25°C
3. **WW, Number of warm and wet days:** days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile
4. **TR, Number of tropical nights**: count of days where TN > 20°C

2.3. Socio-economic impacts of extreme climate or weather events

Several countries reported socioeconomic impacts of climate extremes or weather events. This was done partly given in a standardized structure (WMO guiding table for country submission of information on extreme climate events) or the information was part of the regular monthly reports on the internet or it was separately submitted. However, this information is heterogeneous and does by far not give a complete overview. Not only due to the different administrative structures the information cannot easily be gathered but also many kinds of impact are difficult to estimate. In the following only a short extract will be given.

The following figure (Figure 2.11) shows the number of observed extreme weather or climate event as reported by the NMHSs in 2015. Conclusions should be drawn only with caution because some of the events were reported simultaneously by several countries. The total number of cases for this figure was 316. No diagrams were shown for the injured persons and fatalities as well as the economic losses because the number of reports were too few (about 6, 11 resp. 5). In some cases the reported numbers were not fix but like 'hundreds' or 'few'. The economic damage was estimated as well by some countries but the information is not sufficient to be presented with any reliability of representativeness. The reported economic damages will be summarized individually below.

The most frequent events in 2015 were 'Extreme Precipitation' with 87 events or 25% that also happened in most of the countries with reported 75 fatalities and 56 injured. The second one with 20% or 62 events were 'Heat Waves' that mainly occurred in Central, southern and eastern Europe (Serbia and Portugal reported 7 heat waves, Slovenia 5). Rank three were 'Wind Storms' with an occurrence of 17% or 53 events mostly in winter in the western part of Europe together with extreme precipitation. The next extreme events were 'Floods' (10%, 27 persons injured, 15 fatalities) and 'Droughts' (7%).

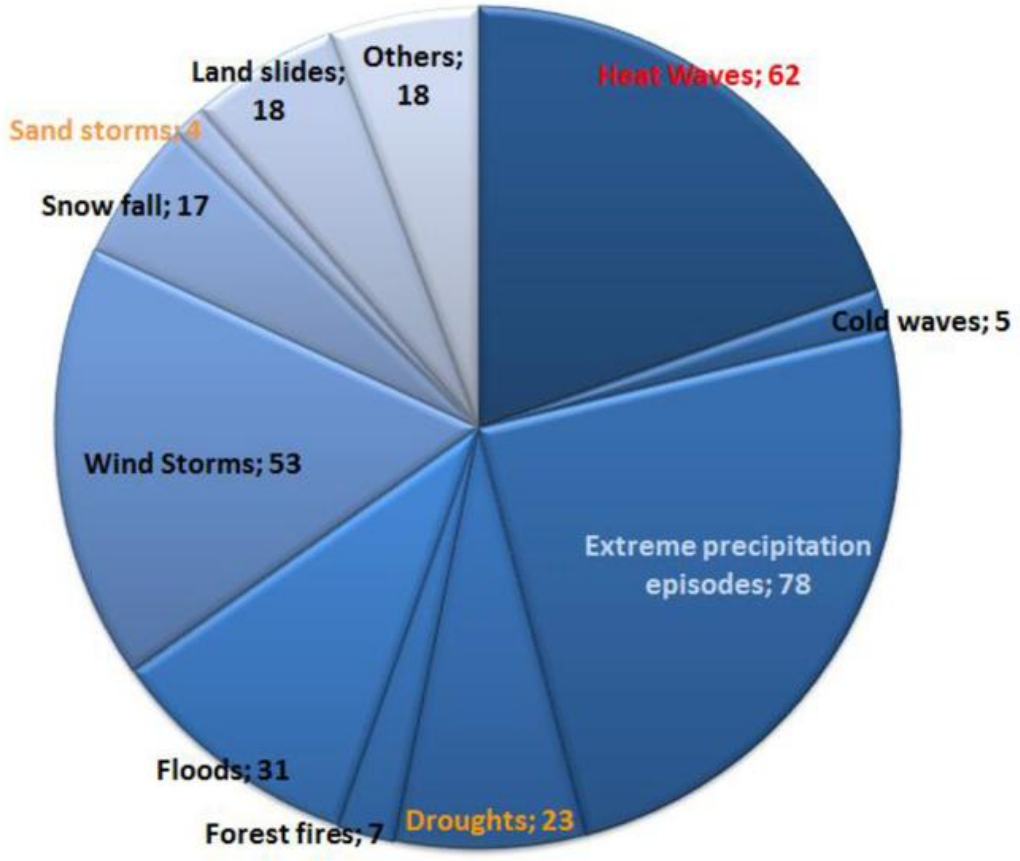

Figure 2.11: Relation of observed extreme weather or climate events in 2015 based on 35 reports from NMHSs (total events reported for 2015: 316)

High economic damage is usually connected with floods, storm, cold spells (all kinds of frost, snow or ice), hail, drought or extreme heat. There are some figures which are summarized in the following but much of this kind of damage cannot be estimated (by meteorologists).

From 8th to 11th January the winter storms Elon and Felix hit mainly Germany, Scandinavia and the UK with high wind speeds, thunderstorms, hail, heavy rain and snowfall. Thousands of buildings, schools, houses were damaged. Many weather–related accidents occurred, air and rail traffic were also affected. The overall loss amounted to 500 Million €.

South-central and eastern Bulgaria as well as northwest Greece was hit by an extreme precipitation episode from 1st to 3rd February 2015. The geographical extent in Bulgaria was 23,300 km^2 (5 districts). On February 1st the highest daily precipitation amount was 210 mm, recorded in Kirkovo (Bulgaria) corresponding to the double of the monthly normal mean. In Greece a 3 day precipitation of 359 mm was observed at station Derviziana during 30, 31st January and 1st February 2015. Greece also reported wind gusts of 46 m/s. This heavy rain caused flooding especially in the eastern Rhodopes area (Bulgaria) accompanied by landslides. More than 2,300 houses were damaged, roads and farmland flooded. 14 people lost their lives and the loss summed up to 660 Million Euro.

Snowfall affected southern Bulgaria from 5th to 7th March 2015 on a geographical extent of 23000 km^2 (6 districts). During these three days maximum wind gusts of 24 m/s in Burgas or 34 m/s in Sliven, torrential rain and snowfall in Momchilgrad with 238 mm in 48 h, Krumovgrad with 148 mm in 48 h and Haskovo with 125 mm in 48 h were measured. The total snowfall for two days varied from 200% (Krumovgrad) to 420% (Momchilgrad, Kardjali region) of snowfall average. The snow reached heights up to 1.5-2 m. Landslides were activated especially in south-central and southwestern Bulgaria. Above 1120 towns and villages were left without electric supply in south-central Bulgaria and 30 electrical towers were broken. The estimated damages were about 16 Mio. € and 4 people died.

On 8th July 2015 extremely severe thunderstorms and hailstorms broke out in the western, central and southern parts of Austria. Most damages were registered in Carinthia. According to the regional insurance company, it was the worst natural disaster according to economic losses in Carinthia in their 150 year history. Due to the extreme storms 11 were injured and damages around 150 Mio. € were caused.

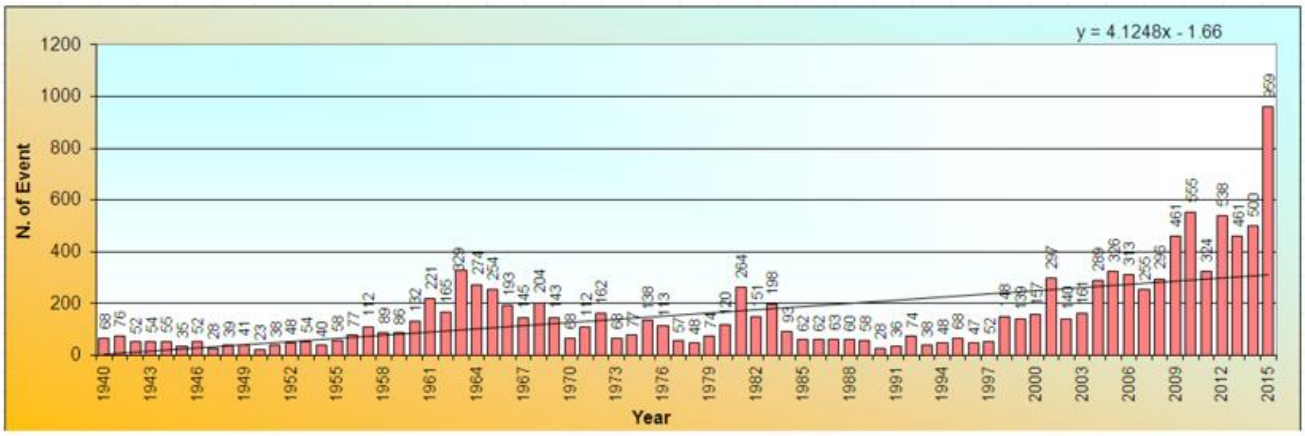

Figure 2.12: Annual count of extreme events occurred in Turkey from 1940-2015 (Diagram as provided by the NHMS).

The number of extreme events in Turkey in 2015 reached 959. (Figure 2.12). There is an increasing trend in extreme events (41 events/decade).

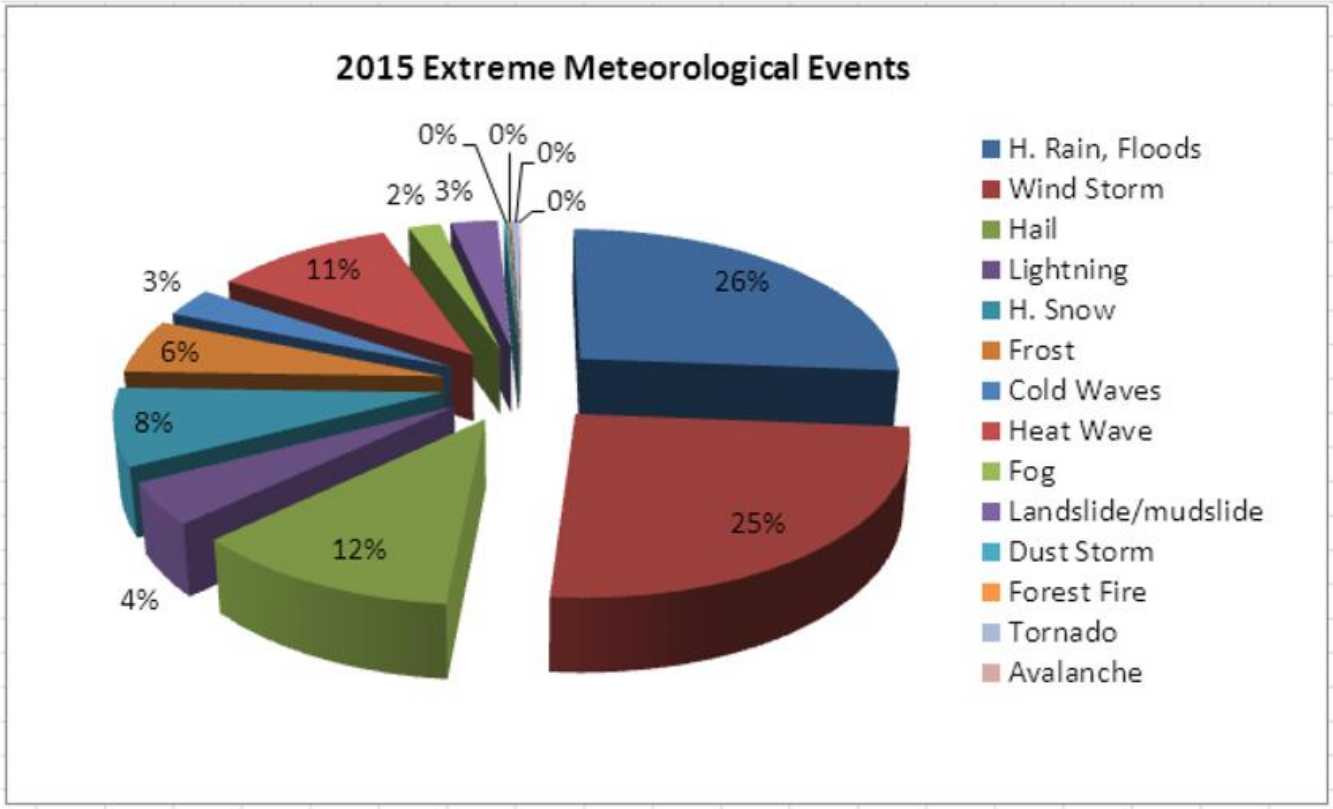

Figure 2.13: Distribution of extreme events occurred in Turkey in 2015 (Diagram as provided by the NHMS).

During 2015 most hazardous extreme events were heavy rain/floods (26%), wind storm (25%), hail (12%), heat wave (11%), heavy snow (8%), frost (6%), lightning (4%), cold wave (3%), landslide/mudslide (3%) and fog (2%) respectively (Fig. 14). Although rare, 1 forest fire, 2 dust storm, 1 avalanche and 4 tornados also occurred in 2015.

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2015 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. Seasonal averages and anomalies of selected climate variables

3.1.1. Sea level pressure and circulation indices

The pressure distribution in **winter 2014/2015** showed similar patterns for the mean and the anomalies. In seasonal average the Icelandic low possessed a core pressure below 995 hPa and the Azores high a core pressure above 1030 hPa. This indicates that the two pressure centres were intensified in relation to the reference period. This can also be seen in the North Atlantic Oscillation index (NAO) with values above 1.0 in all three winter months (Table 4.1) associated with several storms in northern Europe. In Eastern Europe and the eastern Mediterranean the negative pressure anomalies were associated with several low pressure systems.

In **spring 2015** both circulation centres, the Icelandic low and Azores high were well distinct. The Icelandic low with a centre pressure below 1000 hPa (or anomalies of -8 hPa related to 1961-1990) was located west of Iceland. The Azores high was situated southwest of the Azores. The positive anomaly above 4 hPa was located above France.

In spring the NAO index was only moderate but positive. The EA/WR index changed between April and May from positive to negative values. In May the situation changed. The negative SCA is characterized by higher temperatures than normal in western Europe, below normal precipitation in southern Europe and wet conditions over Scandinavia. All the indices fit together and confirm the maps below.

Table 3.1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2014/2015	1.42	0.16	-0.53	0.32	0.38	0.85
Spring 2015	0,65	0.93	-0.04	-1.08	0.10	1.27
Summer 2015	-1.33	0.79	0.29	-0.59	0.11	-0.46
Autumn 2015	0.73	0.64	-0.17	0.44	-0.42	0.51

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In **summer 2015** both circulation centres were shifted southwards. Therefore high pressure over Greenland could establish with anomalies of more than 8 hPa. Most of Europe showed above normal pressure anomalies coincided with above normal sunshine duration and below normal cloud cover leading to several heat waves. Highest anomalies of more than 2 hPa dominated above the Baltic States and Belarus reflecting the situation of August. Only northern and western Europe as well as the eastern Mediterranean Sea showed below normal anomalies.

The calculated CPC-NAO index with -3.14 for July 2015 was very extreme. Only once in the 66 years an identical index value was calculated in 1993. This must be seen in combination with the East Atlantic/West Russia Pattern (EA/WR) indicated below normal pressure in northern Russia.

The circulation pattern in **autumn 2015** was marked by a well-developed Iceland low with the core west of Iceland (below 1000 hPa). The anomalies around Greenland reached values below -4 hPa. Below normal pressure occurred also in a band from south Italy to southern Russia. The Azores-high was also well developed together with a second high over Kazakhstan with core pressure above 1020 hPa. One centre of above normal pressure anomalies was located over Scandinavia and the other over northern Russia with values above 4 hPa.

The circulation indices in **autumn 2015** with values below ±1 were not representative because the monthly values showed different signs.

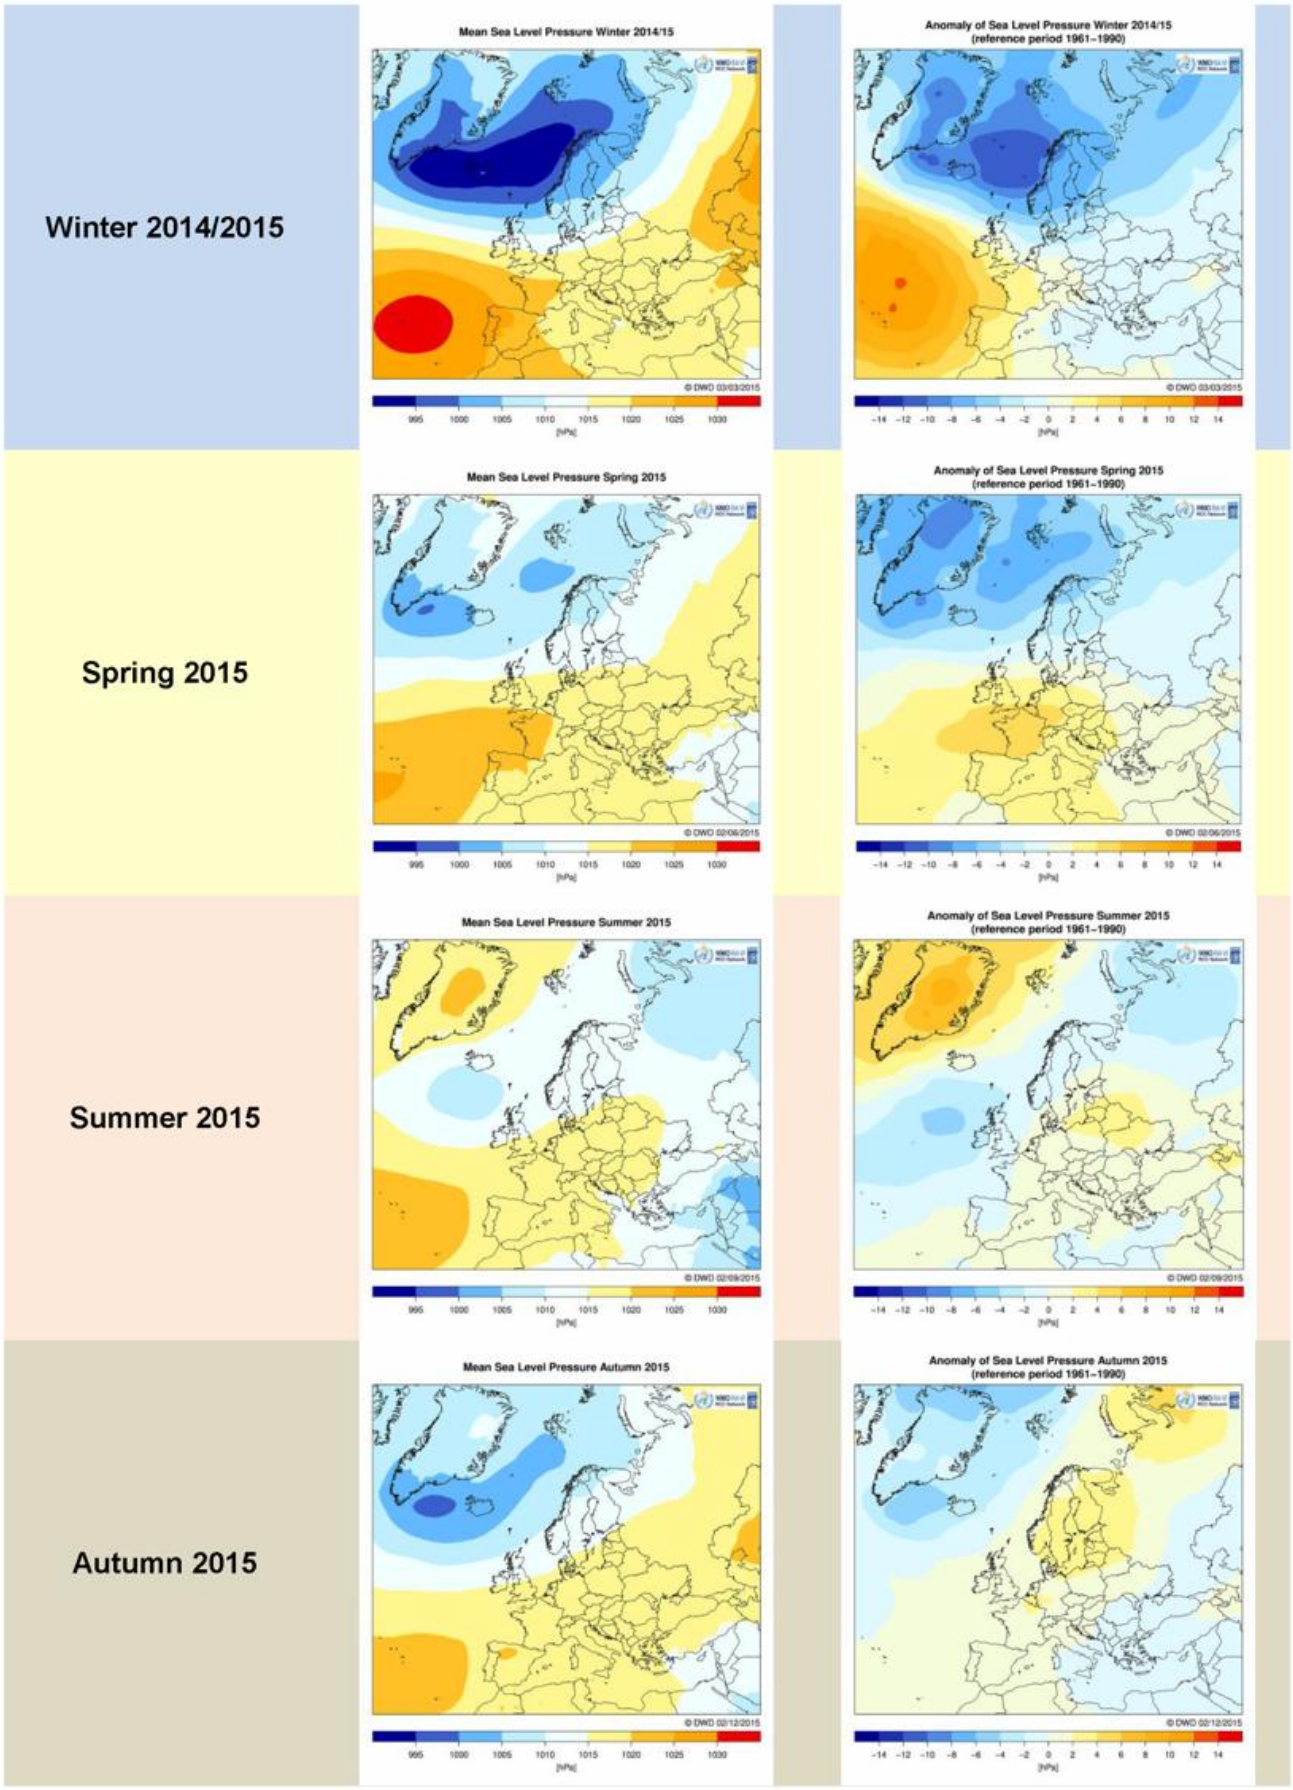

Figure 3.1: Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2014/2015, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.2. Temperature

On average for the whole WMO Region VI and sub-regions the temperature in all seasons in 2014/2015 (except Iberia in winter) was warmer than the normal period 1961-1990. In regional view, however, some differences existed (Tab. 3.2).

Table 3.2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2015 (reference period: 1961-1990)

Sub-Region	Winter 2014/2015	Spring 2015	Summer 2015	Autumn 2015	Year 2015
Central and western Europe	1.37	1.18	2.03	0.80	1.59
Nordic and Baltic countries	2.13	0.58	0.62	1.74	1.26
Iberia	-0.29	2.24	2.33	0.67	1.41
Mediterranean, Italian and Balkan Peninsula	1.36	1.04	2.35	1.39	1.48
Eastern Europe	3.21	2.18	1.01	0.80	2.29
Middle East	1.70	0.81	1.80	1,97	1.51

The temperature anomalies for **winter 2014/15** showed values lower than normal only in southwest Europe and values higher than normal in northern, central and eastern Europe. The positive anomalies reached values of more than 4°C in Scandinavia, northern Russia and in the area between Turkey and Armenia.

Some ranks of warm winters based on web-available bulletins by NMHSs are given below:

Table 3.3: Seasonal rank statistics for winter mean temperature (2014/2015) as provided by the NMHSs.

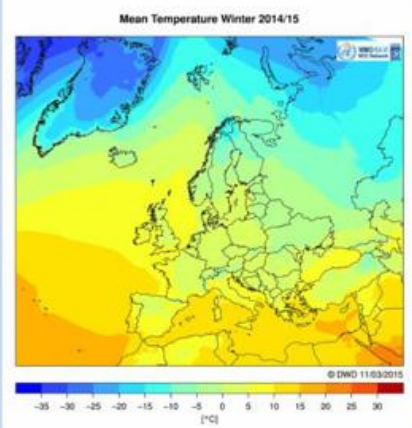
Country	Rank	Time series available since
Europe (35°–75°N, 10°W–30°E, E-OBS)	1	1950
Global	1	1880/1881
Austria	8	1767
Belarus	5	1945
Denmark	13	1874
Estonia	4	1961/62
Switzerland	2	1864

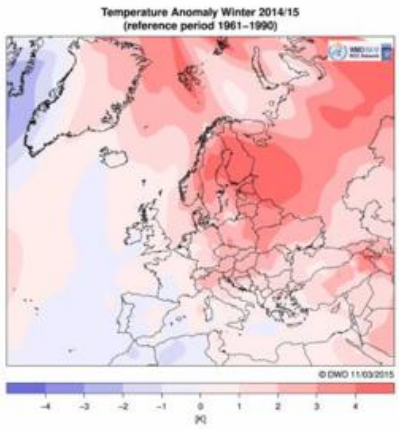
Spring 2015 was in most parts of Europe more than 1°C warmer than the reference period 1961-1990. Especially Spain and southern France showed anomalies of more than 2°C, northern Scandinavia more than 3°C and northern Russia more than 4°C. Only central Turkey, Ireland, Greenland and western Iceland noted normal or below-normal temperatures.

Summer 2015 was characterized by a long lasting heat wave from end of May to end of August. The temperature anomalies pattern for summer revealed a belt of positive values of more than 3°C from Spain to Ukraine while northern Europe and the British Isles noted normal or below normal temperature.

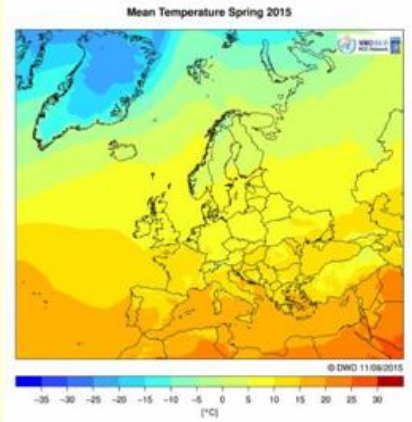
Autumn 2015 was characterized by warmer conditions than normal in nearly whole Europe. Especially the region north of Spitzbergen and Russia was partly more than 4°C warmer. Turkey and Scandinavia, especially Finland, had also higher temperatures with anomalies of more than 3°C above the reference period 1961-1990.

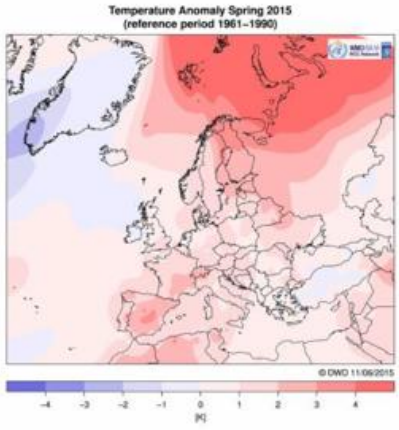
Winter 2014/2015



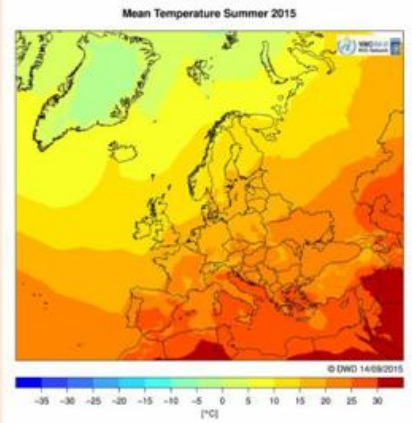


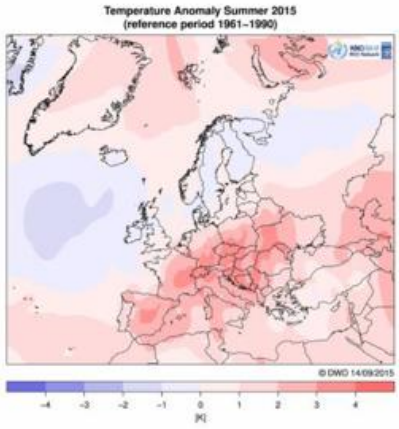
Spring 2015



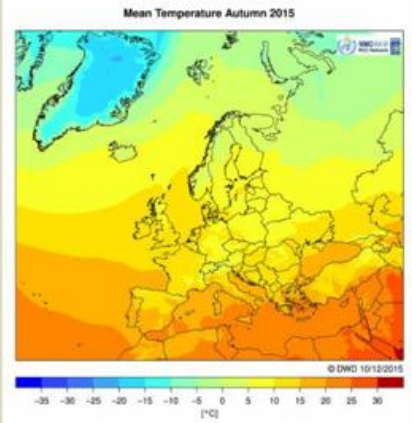


Summer 2015





Autumn 2015



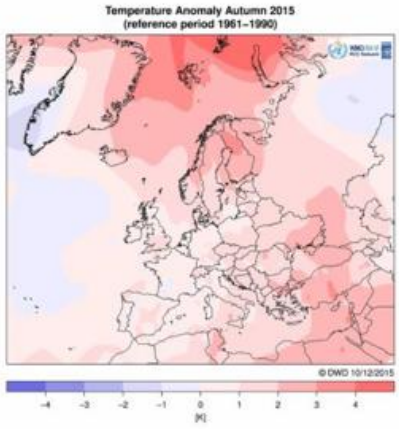


Figure 3.2: Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2014/2015, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.3. Precipitation

In **winter 2014/15** most regions of Europe received normal or above normal precipitation. Some regions like northern Spain (partly more than 300%), Scotland, southern Norway, the Balkan and eastern Mediterranean area received up to 250% of their seasonal precipitation amount. Ireland reported the highest seasonal total of 702.0 mm (148 % of the long term mean) at Newport, the lowest seasonal total with 150.0 mm (68% of the long term mean) at station Carlow (Oak Park). In Croatia the precipitation amount for winter 2014/2015 was within the range from 71% to 225% of the multi-annual average. In Montenegro the total amount of precipitation ranged from 196 mm in Rozaje to 1522 mm in Cetinje. In Norway precipitation was very variable this winter and ranged from more than 300% (in the west) down to 25% in the east (lee side). The highest daily and seasonal precipitation sum with 147.5 mm (19th February 2015) resp. 1846 mm was recorded at station Hovlandsdal. The predominance of northerly and north-westerly winds in the Biscay resulted in heavy precipitation along the Pyrenees with up to 300 % of the normal. Precipitation in the winter months was higher than usual in Finland with more than 200 mm in western and central areas.

A precipitation deficit noted Portugal, southern Spain, southern France and Georgia.

Precipitation anomalies for **spring 2015** showed more than normal precipitation in northern and western Europe. Scandinavia and Ukraine recorded partly more than 150%. In some parts in western Norway the precipitation was 2-2.5 times higher than normal. The wettest station was Hovlandsdal with 1150 mm (209% of normal). At this station also the highest daily precipitation was measured on 8th March with 123.8 mm. In the UK existed a high contrast between western Scotland (with totals of more than 130% or 900 mm) and southern England (less than 70% or around 90 mm). For Scotland it was the second wettest spring since 1910.
In north-western Spain and northern Portugal less than 60% precipitation occurred. In Portugal 3 heat waves brought only 45% of normal precipitation. Precipitation deficit exhibited (<60%) also southern France, central Germany and the Middle East. France registered nearly 20% less precipitation than normal.

Precipitation anomalies for **summer 2015** showed above normal precipitation in western and northern Europe and in Russia of partly more than 150%. The surplus in Turkey was even more than 250%. Western and southern France as well as north-eastern Spain received due to some extreme precipitation events above normal precipitation. In France new records were set in August at station Gonneville (Brittany) with 178.4 mm (more than three times the normal amount) and Montpellier with 234.2 mm (nearly seven times the normal amount). Due to the higher than normal pressure combined with a long lasting heat wave below normal precipitation was observed especially in central Europe. Western and southern Iberia had a precipitation deficit that lasted since the beginning of the year. The affected area of Portugal by drought on August 31 was for severe and extreme drought categories 74% that is the 2nd worst in 70 years (100% in 2005 and 73% in 2012). Since 1st June, Warsaw received less than half of the normal precipitation (172 mm). A total of 47 mm of rain has fallen in Belgrade during the same time, which is less than 30% of normal. In the Ukraine the precipitation deficit caused low river levels. In Germany this summer was the driest of the last 50 years.

Precipitation anomalies for **autumn 2015** showed higher precipitation than normal in the Balkan, parts of southern Italy, northern Germany, Denmark and parts of Finland. In nearly entire Serbia the sums of autumn precipitation exceeded the mean of the 1961-1990 period; station Negotin recorded 358.5 mm or 234%, for example. In Greece precipitation amount for autumn was higher than normal due to some heavy precipitation events accompanied by floods and tornadoes which caused a lot of damage. Northern Germany was also wetter than normal. With 101 mm mean precipitation in November 2015 it was 34.6 mm or 52.1% above the reference period 1961-1990.
In contrast, most parts of western Europe, Iceland, northern Italy, the Baltic States and parts of Scandinavia were drier than normal. Spain obtained in autumn 165 mm precipitation that is 18% less than normal. France was also drier, the rainfalls were about 15% less than normal. In UK September and October were very mild, precipitation anomalies for September were 56% and for October 57% only November with 145% was wetter than normal.

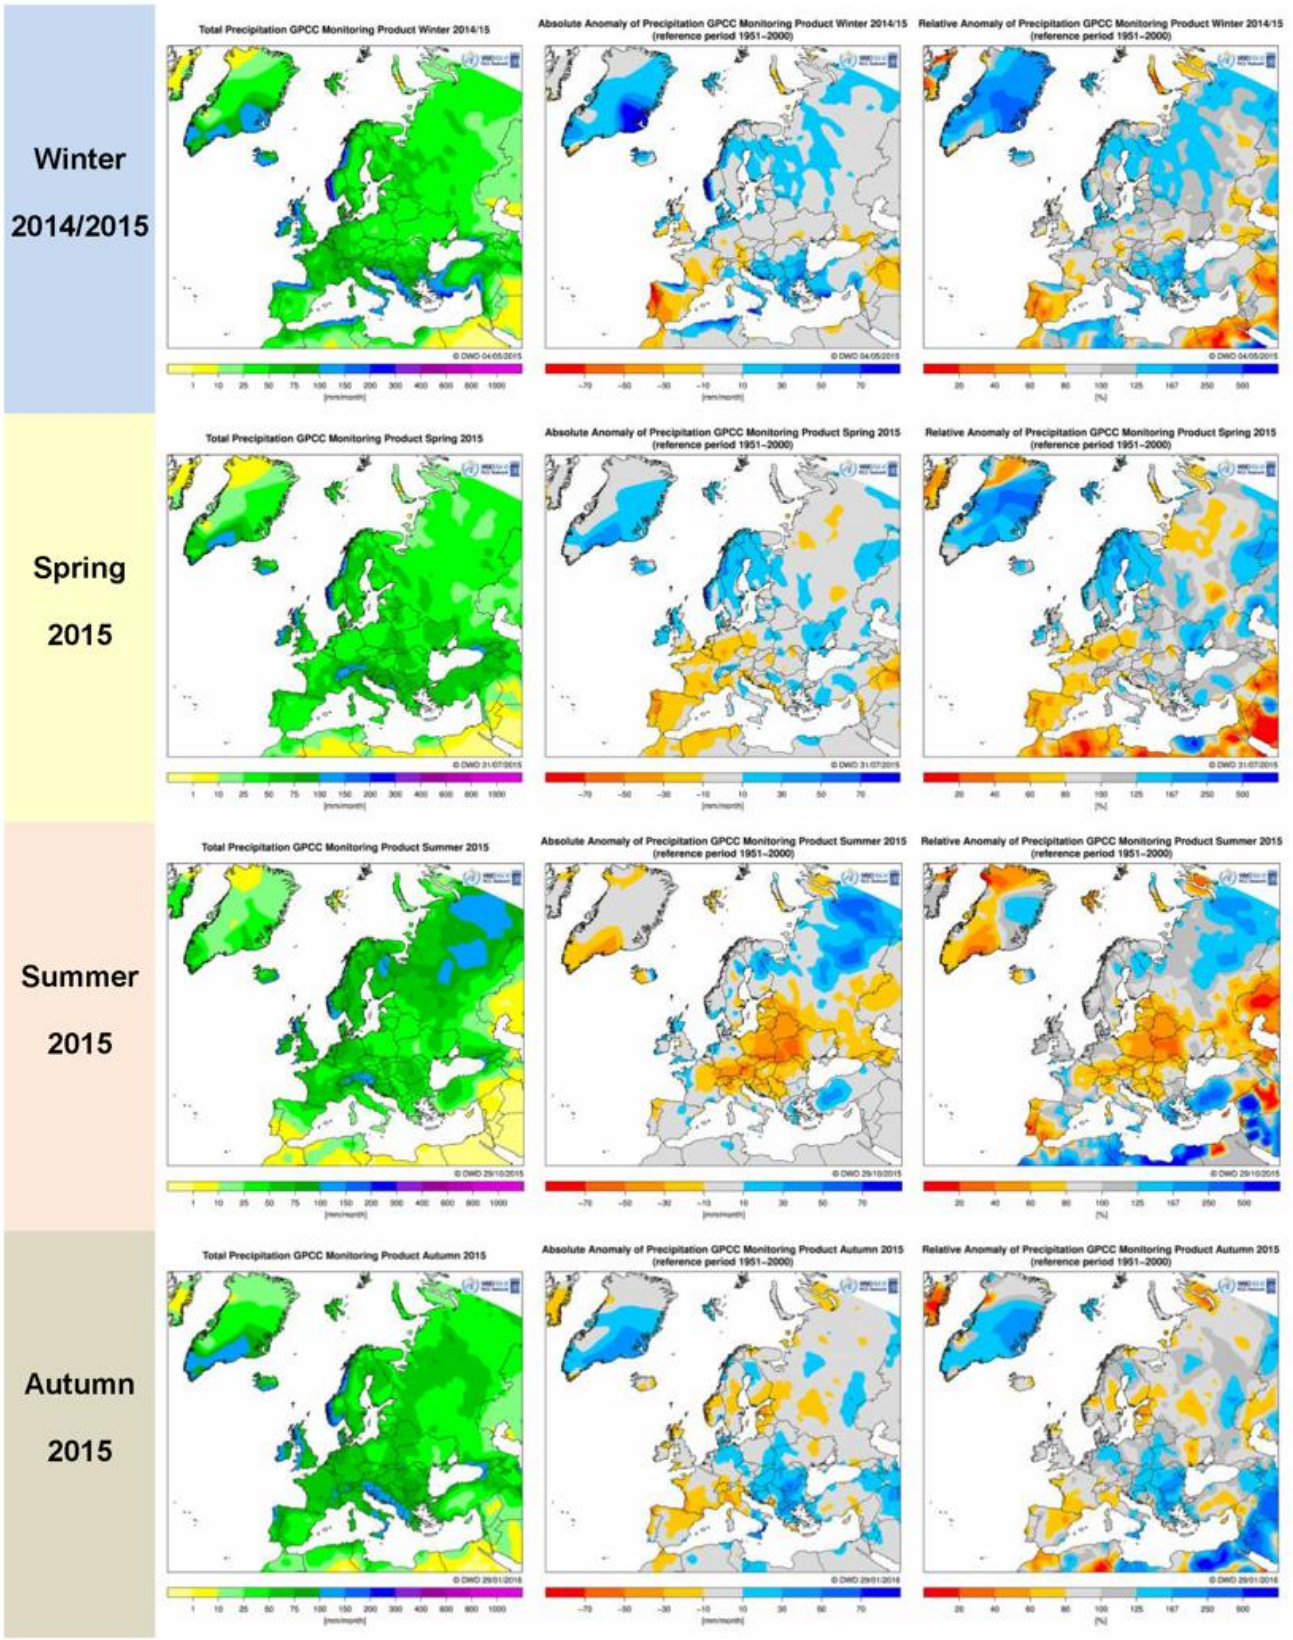

Figure 3.3: Seasonal total precipitation (left, in mm/mon), absolute anomalies (middle, in mm/mon) and relative anomalies (right, in %) in 2014/2015, reference period 1951-2000
(Source: http://www.dwd.de/rcc-cm)

3.1.4. Sunshine duration

In **winter 2014/2015** the sunshine duration in many parts of Europe dropped below 100 %. Only Spain, southern Italy, the Balkan States, western Poland and northern Scandinavia were sunnier than normal. It is very remarkable that Svalbard and northern Scandinavia had a sunshine duration above 150 %. The cloud cover in winter was nearly everywhere below normal.

In **spring 2015** most of Europe registered above normal sunshine duration. Sunshine deficit revealed Finland, northern Sweden, south Italy, parts of Turkey and parts of Russia. The cloud cover in spring was also below normal.

Most of Europe reported in **summer 2015** above normal sunshine duration, except Russia, northern Finland and eastern Mediterranean. Only some parts of Great Britain received the normal amount of sunshine. The cloud cover was also below normal.

In **autumn 2015** most of Europe registered above normal sunshine duration, except Russia, Romania, parts of Turkey, south Italy, Portugal, southern Great Britain, Ireland, northern France and western Germany. The cloud cover was from Germany to the Black Sea normal and in the other parts of Europe below normal.

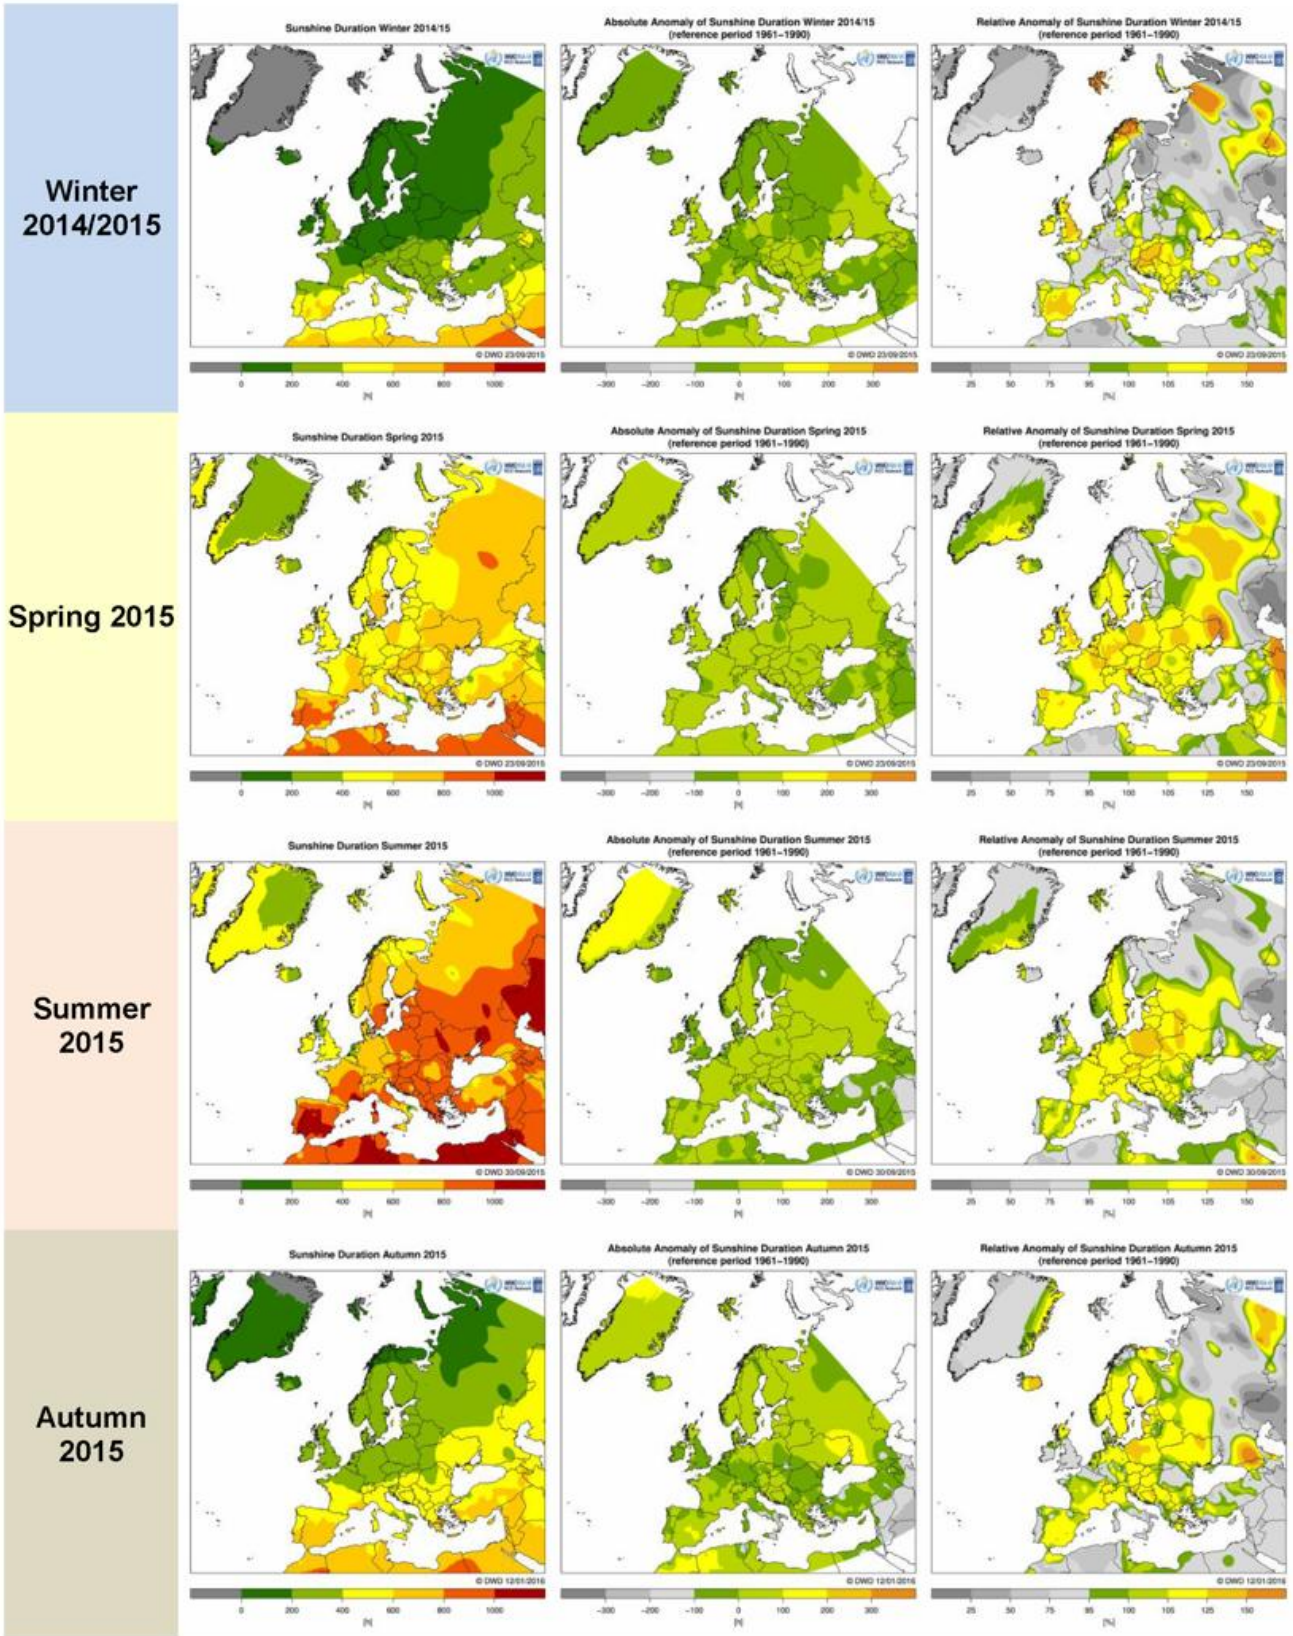

Figure 3.4: Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and relative anomalies (right, in %) in 2014/2015, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

3.1.5. Drought

The **Winter 2014/15** was in most parts of Europe normal. Only Greenland, northern Spain, northern UK and some regions in Scandinavia and Balkan were wetter than normal.

In **Spring 2015** Scandinavia, Ukraine, northern UK and Greenland were very wet whereas Central and south-western Europe was dry.

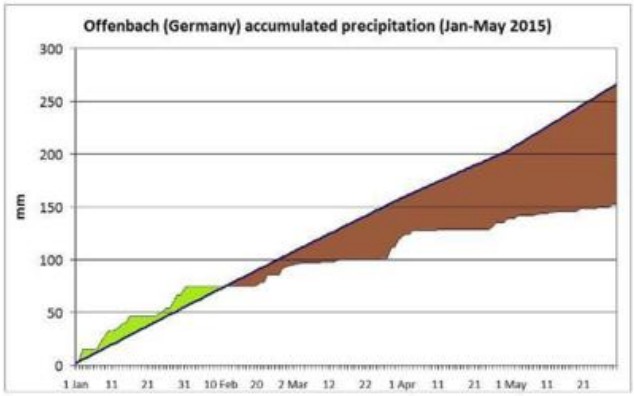
The Baltic countries, Belarus, the Ukraine, southern Spain and Portugal were severely dry in summer. In autumn the Balkan was wetter than normal.

From April to August a severe drought covered an area from the Baltic States across Poland, Belarus and Ukraine to Romania. The loss calculated by MunichRe sums up to 1,500 Million Euro. The dry conditions with lack of rain affected the water supply, fisheries, tourism and about 16,600 km^2 of farmland. August was extremely dry in Belarus (the driest ever measured), only 11 mm or 16% of the normal was measured. The monthly precipitation for August in Ukraine was 24 % of the normal (15 mm). It was the driest month in the series going back to 1891 in Ukraine.

Drought over southwestern and central Europe

In **May** the area with precipitation deficit extended from western Poland across Germany, France, Spain and Portugal. The relative precipitation anomaly for May showed values below 40% and in central Spain values below 20%. In Offenbach (Germany) a deficit existed since mid of February 2015. During February and May only 80 mm instead of 194 mm was registered or 41 % of the normal value.

In Spring the situation in north-western Spain was very dry and the weather service of Portugal published following overview.

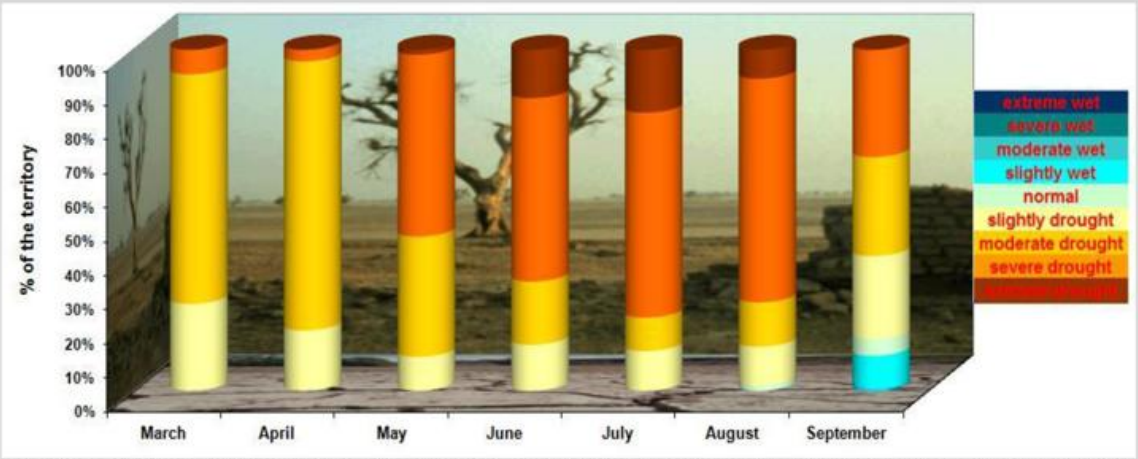


Accumulated precipitation from January to May 2015 in Offenbach (Germany, source: DWD)

Drought Situation in Portugal:

The drought began in March, in the whole territory, intensifying until the end of July, maintaining in August in almost the entire territory and starts to decreasing in September.

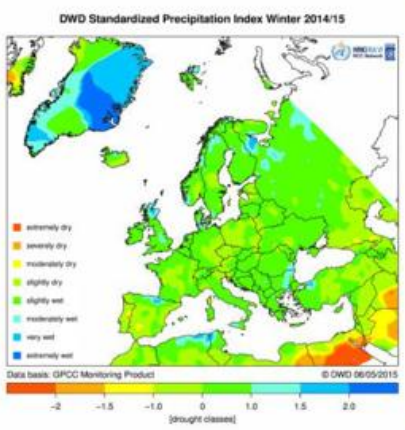
The months with higher severity were from May to July, with almost the entire territory in the classes of moderate to extreme drought, according to PDSI index.

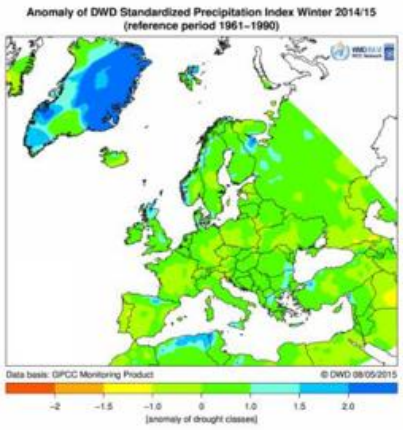


Percentage of territory (area) in the different classes of meteorological drought index PDSI between March and September 2015

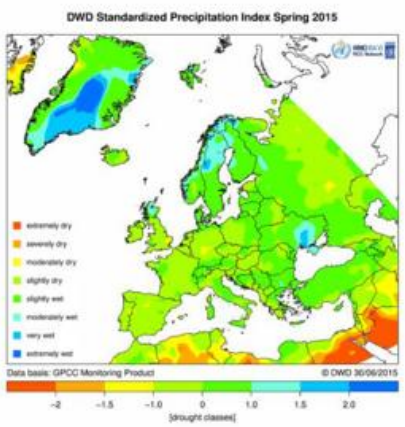
PDSI - Palmer Drought Severity Index - meteorological drought index, it responds to weather conditions that have been abnormally dry or abnormally wet. It is based on the supply-and-demand concept of the water balance equation, taking into account more than just the precipitation deficit at specific locations.

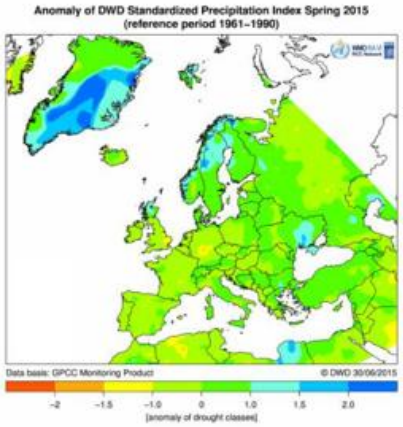
Winter 2014/2015



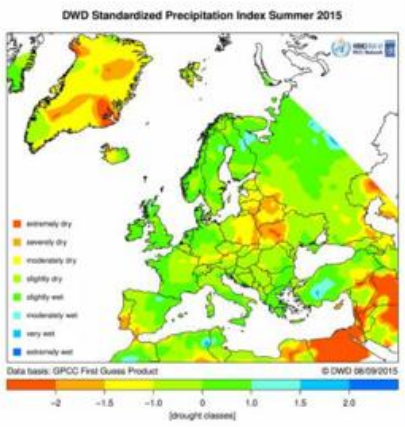


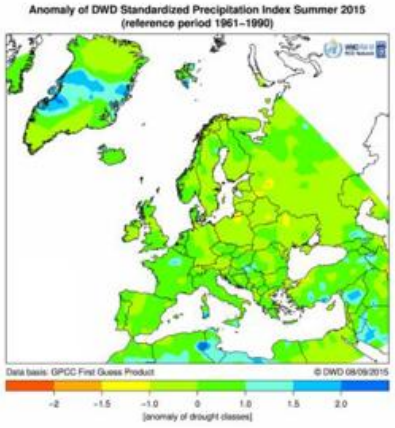
Spring 2015



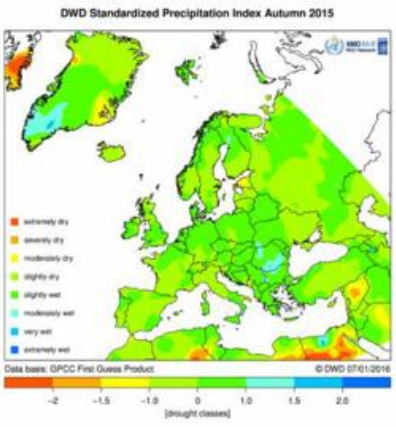


Summer 2015





Autumn 2015



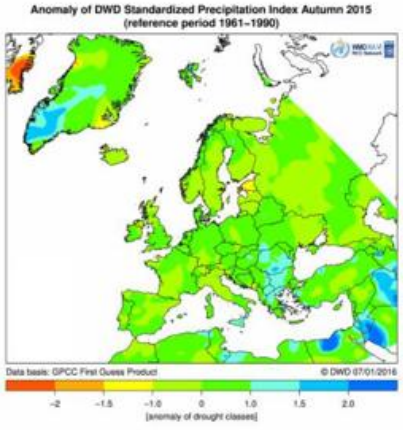


Figure 3.5: Seasonal standardized precipitation index (SPI, left, in drought classes) and anomalies (right) in 2014/2015, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm)

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2015 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each months as well as monthly overviews of extremes and notable events.

4.1. Sea surface pressure and circulation indices

This chapter about the atmospheric circulation provides information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based upon the Monthly Bulletins on the climate in WMO RA VI and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4.1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the Arctic Oscillation, for January to December 2015

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2015	1	1.57	1.11	-0.24	-0.18	-0.03	1.092
2015	2	1.05	-0.04	-0.92	-0.37	2.09	1.043
2015	3	1.12	1.20	0.27	0.39	0.68	1.837
2015	4	0.64	0.88	1.12	-1.49	-0.88	1.216
2015	5	0.19	0.71	-1.50	-2.15	0.50	0.763
2015	6	0.24	1.06	-0.78	-1.52	-0.20	0.427
2015	7	-3.14	0.22	2.01	-1.11	0.39	-1.108
2015	8	-1.10	1.08	-0.37	0.87	0.13	-0.689
2015	9	-0.49	0.15	-1.67	1.09	-0.13	-0.165
2015	10	0.99	0.22	0.59	0.62	-0.47	-0.250
2015	11	1.70	1.55	0.56	-0.40	-0.66	1.945
2015	12	1.99	3.14	1.28	0.08	0.58	1.444

Note that all values are standardized with reference to the period1981-2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

January 2015 started with a high North Atlantic Index (NAO) where both, the Azores high and the Icelandic low were more intensive than normal. Both were also shifted to north-east. This leads to more westerly winds and higher temperature anomalies (see section on temperature). Two storms passed **Scandinavia** Svea (2nd January 2015) and Egon (10th January 2015) with wind gusts of nearly 40 m/s. Two low pressure systems (Elon, Felix) with high wind speeds, thunderstorms, hail, heavy rain and snowfall crossed UK, Germany and Scandinavia. Thousands of buildings, schools, houses were damaged. Weather–related accidents occurred; air and rail traffic was affected. The airport of Helgoland, Germany was also damaged. After MunichRe the loss of this two winter storms was estimated to about 500 Million Euro and caused 3 fatalities.

From 30th January – 03rd February 2015, a severe weather event caused extending floods over the west (mainly northwest) part of **Greece**, **Albania** and **Bulgaria**. As a result of the heavy rain flooding occurred; in Bulgaria an area of about 23300 km^2 and in Greece about 70 km^2 of farmland was flooded. The 3 day precipitation at station Zlatograd, Bulgaria, summed up to 123 mm while at station Derviziana, Greece 358.6 mm/72h was measured and a wind speed of 46 m/s at station

Paximada, Greece on 31st January. In Greece more than 2300 houses were damaged with 14 fatalities. The loss was estimated to about 660 Million Euro after MunichRe.

In **February 2015** the Azores high was more intense than normal with sea level pressure anomalies of more than +10 hPa. The Icelandic low was also more intense with anomalies below -14 hPa and shifted to the north. In eastern and southern Europe negative pressure anomalies prevailed. Both, the North Atlantic Oscillation (NAO) and Arctic Oscillation (AO) index showed values of more than 1. In Lithuania strong winds of up to 29 m/s were observed at the 8th of February in Ventspils. A deep low pressure, which was renamed to Ole of the Norwegian weather service, drew in the northernmost part of Scandinavia on 7th and was accompanied by strong winds. In Katterjåkk in Lapland (Sweden) 20 cm of snow was observed, the strongest wind was reported from Stekenjokk (Sweden) with 38 m/s in average and 43 m/s in the wind gusts.

In **March 2015** the two pressure centres were more intensive. The Icelandic low had anomalies of -14 hPa and the Azores high of more than +8 hPa. The second high pressure centre over Russia was about 8 hPa higher than the long term mean. Therefore the North Atlantic Oscillation index (NAO) with 1.12 and the East Atlantic Pattern (EA) with 1.20 showed above normal values. The Arctic Oscillation (AO) with an index value of 1.837 was very high.

Several storm series passed Europe

The storm Anton affected between 4th and 7th March 2015 **UK**, **France**, **Corsica**, **Italy** and **Croatia** in combination with the Bora and caused damages by storm gusts. In western parts of Scotland the storm was combined with flooding, exacerbated by snowmelt. Three other storms between 22th and 31st March 2015 (Isegrim, Mike and Niklas) crossed **UK**, **Netherlands**, **Denmark**, **Germany**, **France**, **Spain**, **Italy**, **Slovenia**, **The Former Yugoslav Rep. of Macedonia**, **Greece**, **Turkey, Romania** up to the **Ukraine** with locally damages, flooding and hail. In France from 29th to 31st March 2015 several monthly records were broken with wind speed above 35 m/s. Storm Niklas from 30st March and 1st April 2015 caused 11 fatalities and a loss of more than 1,400 Million Euro (after MunichRe). Due to the high wind speed of more than 30 m/s trains and cars were damaged, rail traffic disrupted and the air traffic were also affected.

April 2015 was characterized by a secondary high pressure centre over Western Europe (in addition to the Azores high) on monthly average. At the **Swiss** station Zürich-Fluntern a new record for April since 55 years was measured with a station pressure of 968.2 hPa (1036.5 hPa reduced to mean sea level). High pressure influence dominated over the whole Mediterranean region except eastern parts (Middle East, eastern Turkey and South Caucasus). In contrast, low pressure extended from northern to eastern Europe.

In **May 2015** sea level pressure anomalies were highest between the Azores high and Iberia with values of +2 to +4 hPa. The Icelandic low was more intense and shifted to the east with anomalies below -10 hPa above Scandinavia. In Eastern Europe negative pressure anomalies prevailed. Both, the North Atlantic Oscillation (NAO) and Arctic Oscillation (AO) index showed nearly normal values. But the Scandinavia Pattern (SCA) with a value of -2.15 explains much of the circulation. The negative SCA is linked with drier and warmer weather in Iberia and colder and wetter conditions in Scandinavia.

In **June 2015** sea level pressure anomalies were positive in the area between Iceland and Greenland and over central Europe indicating a north-eastward shift of the Azores high. The Icelandic low was also shifted north-eastward. For June the dominant circulation pattern for Europe was the Scandinavia Pattern (SCA) with an index value of -1.52.

In **July 2015** the two Atlantic pressure centres were more intensive. The Iceland low had anomalies of below -6 hPa and was shifted to the south. The Azores high had anomalies of up to +2 hPa. The second high pressure centre over Greenland was more than 12 hPa higher than the long term mean. A second low pressure system over north-eastern Europe with a central pressure below 1000 hPa and anomalies below -10 hPa resulted in a negative North Atlantic Oscillation index (NAO) of -3.14 the lowest value in the time series of CPC since 1950 (together with July 1993). The Arctic Oscillation (AO) with an index value of -1.108 was also negative.

In **August 2015** the Icelandic low was more intensive with a core pressure below 1005 hPa and was shifted to the south. The pressure anomalies were lowest between Iceland and the British Isles with values below -6 hPa. The high pressure over Scandinavia is striking with values of more than 1020 hPa and anomalies of more than +6 hPa. This high pressure was responsible for the highest temperatures in Scandinavia during this summer.

During **September 2015** the Iceland low was shifted to the west located at the southern edge of Greenland with anomalies below -2 hPa. The pressure anomalies of the Azores high ranged from below -2 hPa up to +2 hPa. The second high pressure centre located over Kazakhstan had a similar core pressure like the Azores high (above 1020 hPa). The positive anomalies were centred over north Scandinavia with more than 6 hPa above than the long term mean and ranged from the British Isles to European Russia. The North Atlantic Oscillation index (NAO) of -0.49 and the Arctic Oscillation (AO) of -0.165 were not very remarkable but the East Atlantic/West Russia Pattern (EA/WR) with a value of -1.67 and the Scandinavia Pattern (SCA) with 1.09.

In **October 2015** the Iceland low had a core pressure below 1000 hPa that was below his long term average. The high pressure centre was located over Scandinavia and East-Europe. The positive pressure anomalies were centred above Scandinavia with values of more than 6 hPa. This pressure distribution caused more sunshine and little precipitation. The NAO-Index of about 1.0 was above normal although the Azores high was not well developed. In southern Europe the pressure anomalies were below normal with values of -4 hPa west of Portugal.

In **November 2015** the Iceland low was shifted to the north-east located between Iceland and Scandinavia with anomalies below -12 hPa. The pressure anomalies of the Azores high ranged from below -2 hPa up to +6 hPa. The second high pressure centre located over eastern Russia had a similar core pressure like the Azores high (above 1025 hPa). The anomalies were centred over north Siberia with more than 6 hPa above the long term mean. The pressure anomalies in Scandinavia, east Europe and Middle East were below normal. The North Atlantic Oscillation index (NAO) of 1.7 and the Arctic Oscillation (AO) of 1.9 were remarkable high.

In **December 2015** the Icelandic low was very strong with a core pressure below 995 hPa. Its core was located west of Iceland and the Azores high was shifted to the Mediterranean area. The high had a strong core pressure above 1030 hPa. The positive anomalies over the Mediterranean area were above 14 hPa and the negative anomalies over Iceland below -14 hPa. This high pressure caused less precipitation over southern Europe. The NAO-Index with 1.1 was above normal which reflected this strong low and high pressure system.

The low pressure over the North Atlantic was accompanied by winter storms. Those named Desmond and Eva brought high wind speeds, heavy rain, coastal and river flooding, channels burst their banks and more than 7000 houses were damaged. Bridges were damaged, roads blocked and tens of thousands of houses were without electricity. 5 people died and a loss of about 2600 Million Euro in UK, Ireland was estimated by MunichRe.

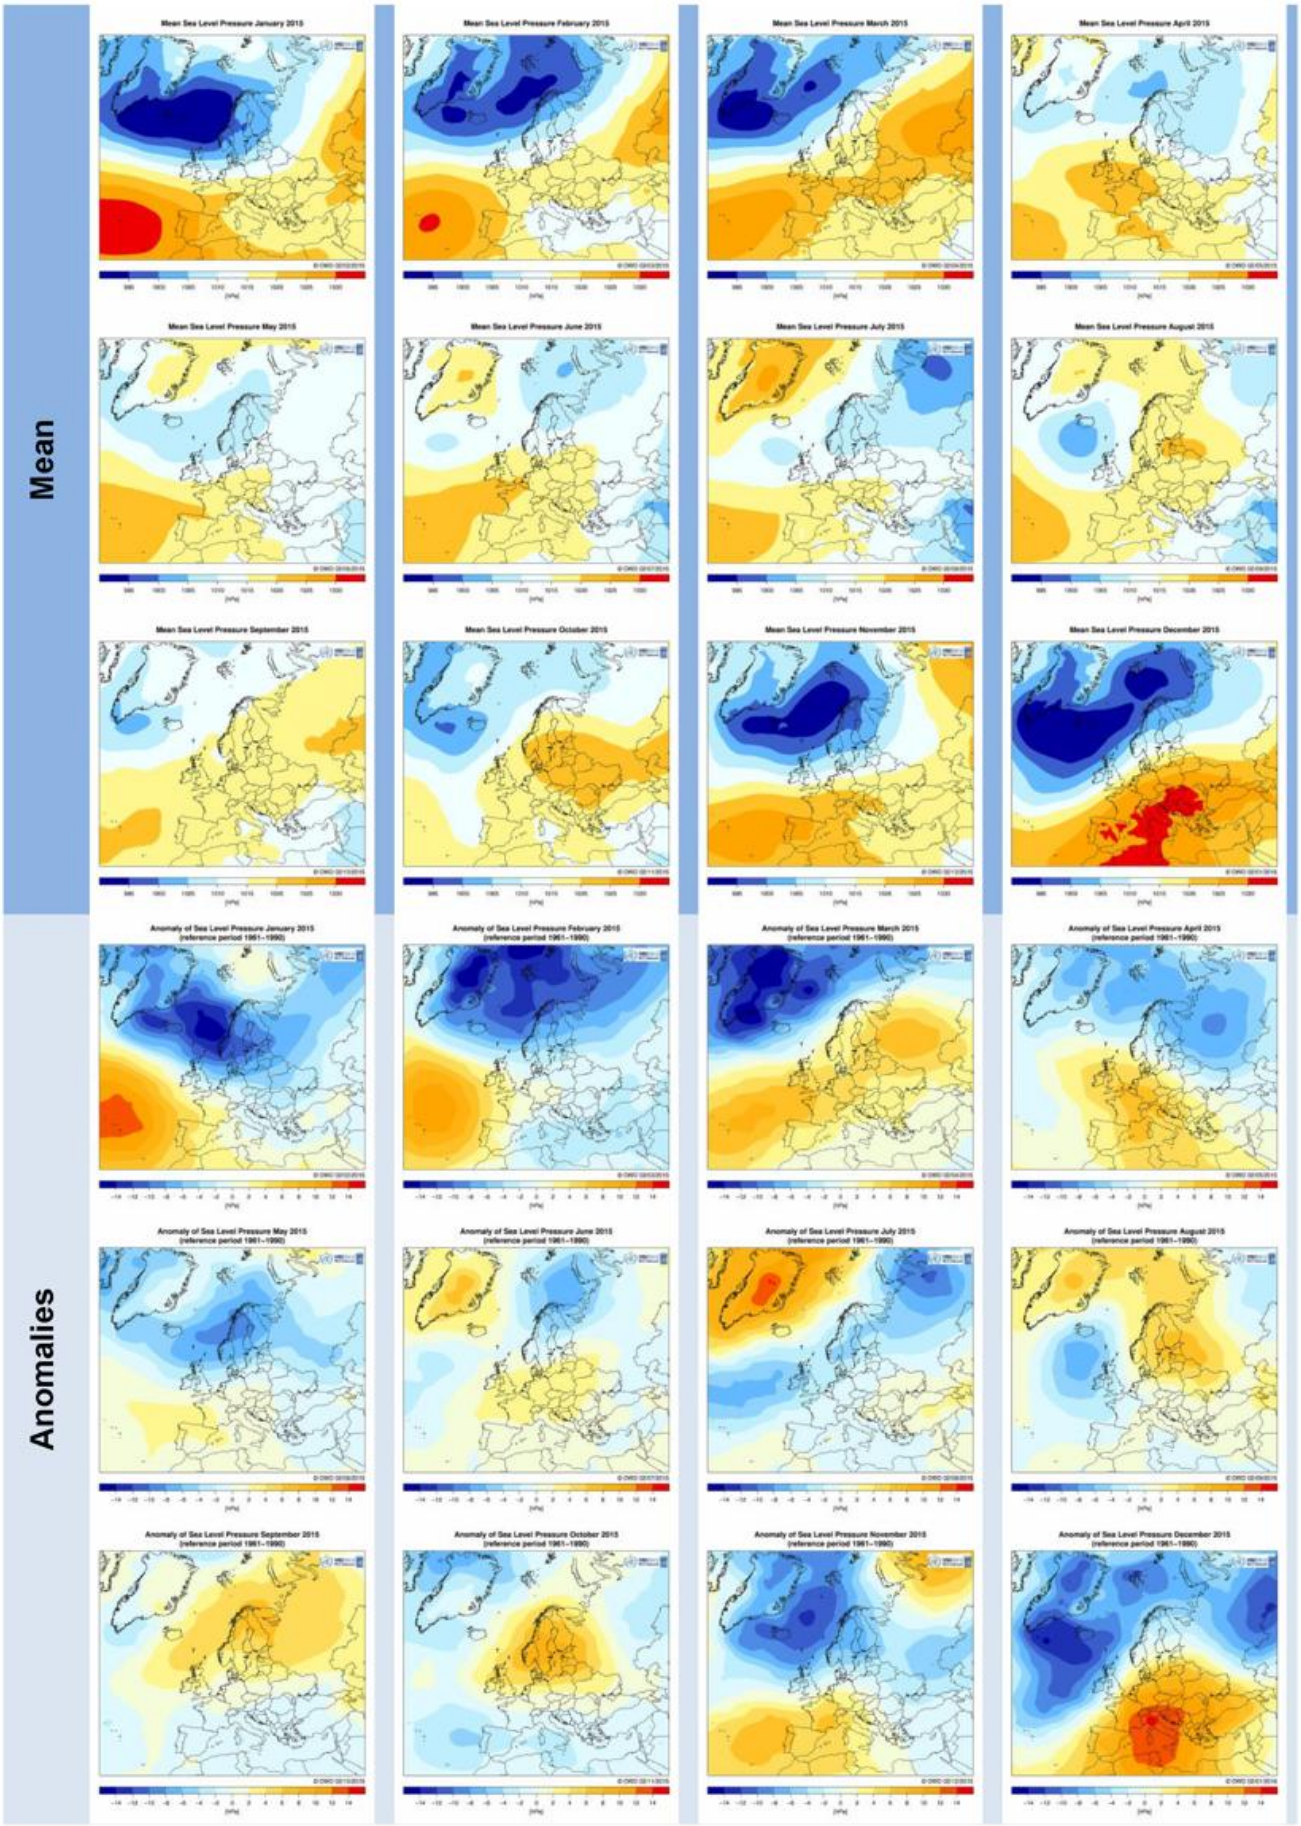

Figure 4.1: Mean and anomalies of sea level pressure in hPa for each month of the year 2015. (First row January, February, March, April)

4.2. Temperature

In most of the months and sub-regions it was warmer than normal as can be seen from Table 4.2. The Mediterranean area had positive anomalies throughout the whole year 2015 and in Eastern Europe anomalies above 3°C occurred in four month.

Table 4.2: Monthly and annual area average temperature anomalies in °C for each sub-region in the year 2015 (reference period: 1961-1990)

Region	Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.
Central and western Europe	1,59	2,19	0,44	1,56	1,41	0,58	1,18	2,25	2,68	-0,07	-0,39	2,86	4,44
Nordic und Baltic Countries	1,26	2,87	1,63	1,62	1,34	-1,22	0,24	0,60	1,02	1,86	1,35	2,00	1,84
Iberia	1,41	-0,14	-0,91	1,32	2,33	3,07	2,66	3,07	1,27	-0,64	0,76	1,91	2,26
Mediterranean	1,48	1,76	0,52	0,80	0,48	1,86	1,26	3,36	2,42	1,70	0,58	1,88	1,15
Eastern Europe	2,29	2,99	4,61	3,96	0,65	1,94	1,84	-0,17	1,36	3,40	-0,21	2,20	4,85
Middle East	1,51	1,24	2,00	1,58	-0,33	1,18	1,89	1,46	2,07	3,39	1,38	1,13	1,12

In **January 2015** Eastern Europe showed anomalies above 3°C up to above 4°C. Only western Spain and Portugal had negative anomalies. In Norway some stations reported 5 to 7°C higher temperature than normal, for the whole country it was 2.6°C above normal. Latvia reported monthly mean air temperature between -1.7°C and +1.0°C that is 4°C – 5°C above normal. The temperature anomaly in Austria was 2.7°C which is rank 17 in the 248 year long time series. At station Graz-Strassgang (Austria) a new record for January maximum temperature was set with 21.7°C. In Lucerne (Switzerland), the daily mean temperature reached 15.1°C (daily maximum 19.3°C), which has never been registered in the available measurement series since 1871 in winter months (December to February). For the first time maximum temperatures above 20°C in January were registered in Germany.

Monthly temperature for **February 2015** showed very high positive anomalies in the North-East with more than 4°C and negative anomalies in the South-West down to about -2°C to -3°C. The average air temperature in Latvia was -0.2°C in February which was 4.6°C warmer than normal and the thirteenth warmest February in observational history. February was abnormally warm over most of European Russia, with mean monthly air temperature anomalies of 6°C -8°C.

The monthly temperature for **March 2015** showed positive anomalies for most of Europe. Highest anomalies occurred in the North-East with more than 4°C. With an average temperature of 3.4°C in Latvia, this month was 4.7°C warmer than normal. This was the third warmest March in Latvia ever recorded. Estonian average temperature was 2.5°C and consequently 3.6°C higher than normal. The anomalies in Finland reached partly more than 4°C above the long term mean and 3.3°C to 4.9°C in Lithuania. For whole Norway the anomalies were 3.8°C above normal but in the northern part they reached values of 5°C - 7°C. In Sweden several stations observed new records and topped those from last year. Some Arctic stations recorded monthly temperature anomalies for March 2015 of more than +8°C above their long term mean (Svalbard Airport, Barentsburg).

March 2015 globally the warmest March since 1891

The Tokyo Climate Center estimated the monthly anomaly of the global average surface temperature for March 2015 (i.e. the average of the near-surface air temperature over land and the

SST) to +0.31°C related to the 1981-2010 average (+0.76°C above the 20th century average), and therefore the warmest March since 1891.

NOAA also declared March 2015 as the warmest in the 136-year period of record (12.7°C, mean global land and ocean surface temperatures), surpassing the previous record of 2010 by 0.05°C. The Northern Hemisphere had its second highest March temperature on record, behind only 2008, while the Southern hemisphere tied with 2002 for third highest.

Lowest Arctic sea ice extent for March 2015 in the satellite record

Arctic sea ice extent for March 2015 averaged 14.39 million square kilometres. This is the lowest March ice extent in the satellite record. It is 1.13 million square kilometres below the 1981 to 2010 long-term average of 15.52 million square kilometres. It is also 60,000 square kilometres below the previous record low for the month observed in 2006.

USA (NOAA): http://www.ncdc.noaa.gov/sotc/global#temp

Monthly mean temperature anomalies in **April 2015** were positive in the west and negative in the east part of Region VI and ranged from -4°C in eastern Turkey up to more than +4°C in Algeria. Norway's Finnmark recorded values of up to +4°C, Svalbard Airport even 6.9°C above normal. At the 20th of April at several stations new record breaking temperature were registered with up to 24.2°C. In southern Finland the anomalies were about 1°C and 2°C to 3°C in Lapland.

Unusually temperatures in Israel in April

An unseasonably late winter weather system occurred on April 10th-12th. Northern Israel received 50-100 mm and central Israel 30-70 mm precipitation. Snow piled up on Mount Hermon in the North (at an altitude of ~2000 meters) accumulating to around 20 centimetres and snow was also reported on Mount Meron (1200 meters). Some areas in northern Israel experienced heavy hail storms on April 12th in the afternoon and the hail remained on ground overnight. The event was outstanding for mid-April, with only 3-4 such winter-like weather events in the last 60 years. Temperatures were exceptionally low – a maximum daily temperature of 15-16°C in the coastal plain and less than 10°C in the mountain regions - more than 12°C below average. These low temperatures are unusual, the last time they occurred in 1997 (Figure 4.2 left). The cold spell was preceded by a Sharav on April 8th with daily temperatures of 37-38°C in the coastal plain and 30°C at midnight. It was followed by a rapid cooling of 17-18°C on the next day (Figure 4.2 right).

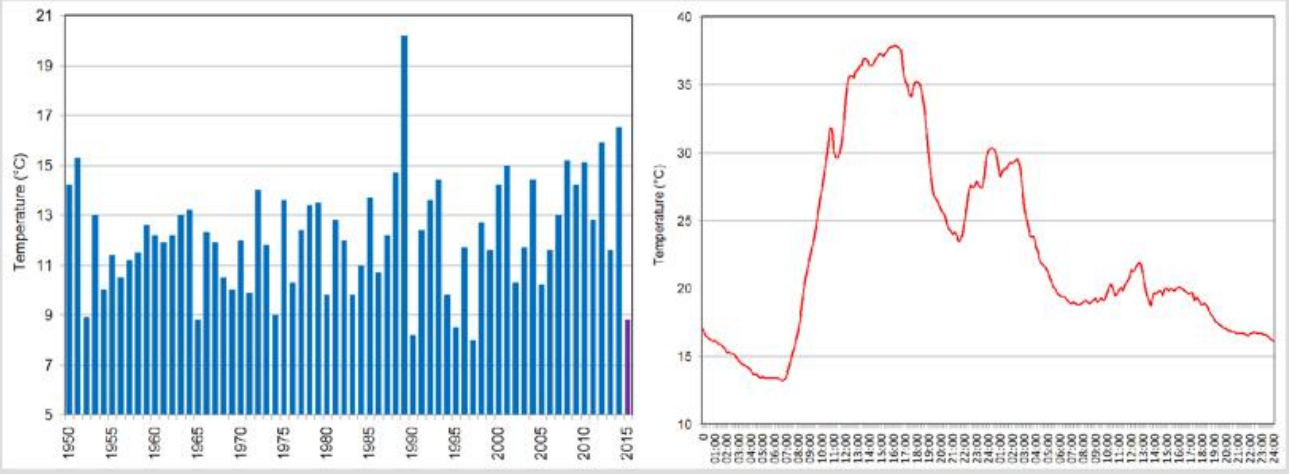

Figure 4.2: Lowest daily maximum temperature (°C) in Jerusalem for each year in April 1950-2015 (left) and Temperature (°C) in Bet Dagan (central coastal plain) on April 8-9th 2015 (left, Source: Israel Meteorological Service)

Another late and cool event occurred on April 21st-23rd. Precipitation amounts were small, yet snow fell over Mount Hermon, accumulating to several centimeters. Light snowfall was reported from

Mount Meron. This snowfall is very unusual for late April. The daily minimum temperature in Zefat (Upper Galilee) on April 24th was 3°C, the lowest ever recorded during this period (**Figure 4.3**, left).

A short time after this cold spell, a Sharav event occurred on April 27th-29th. In the Jordan Valley and the Arava temperatures were above 40°C. Elat had a maximum temperature of 43.3°C, very close to the April absolute maximum of 43.4°C from 2008 (**Figure 4.3**, right).

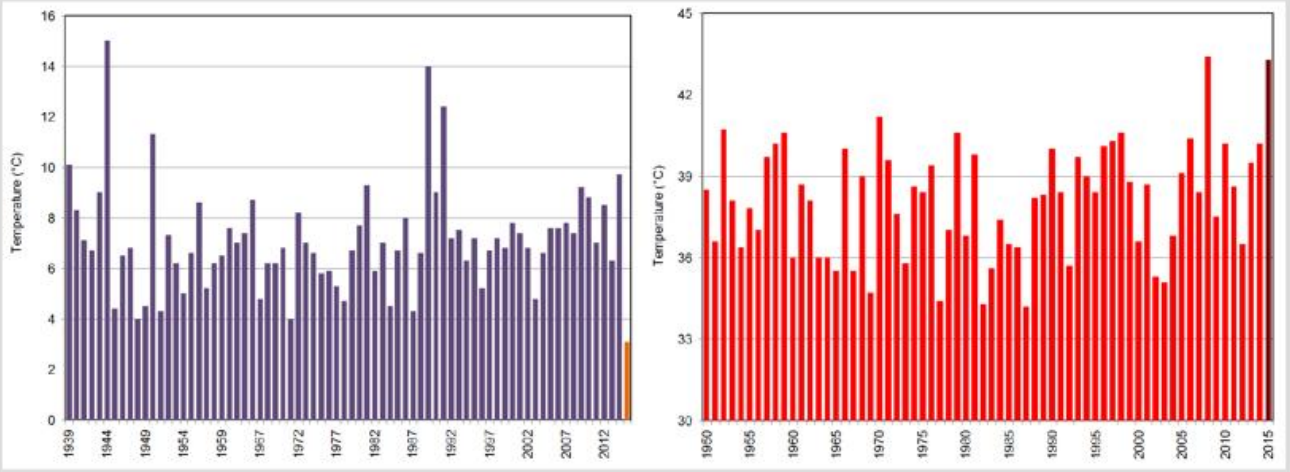

Figure 4.3: Lowest minimum temperature in April's third decade (21st - 30th) for each year in Zefat (Upper Galilee) 1939-2015 (right) and absolute maximum temperature in Elat in April 1950-2015 (left, Source: Israel Meteorological Service)

Monthly temperature for **May 2015** showed very high positive anomalies in the northern Russia and Spain with more than 4°C and negative anomalies in the north-west (from Ireland across Scandinavia, the Baltic States and Belarus) down to about -2°C to -1°C. At single days the temperature in Iberia reached more than 40°C, in Spain up to 42.6°C.

Monthly temperature for **June 2015** showed very high positive anomalies of more than 4°C in northern and southern Russia. The other area of high positive anomalies concentrated on south-western Europe with values of up to 4°C. Negative anomalies prevail from Ireland in the north-west across Scandinavia and northern Central Europe to the Baltic States with a minimum of -3°C in Sweden. At several days the temperature in Spain reached up to 43.7°C and in Portugal up to 41.6°C.

The monthly temperature for **July 2015** was dominated by very high positive anomalies of more than 4°C in south-western and central Europe. Negative anomalies occurred from Ireland in the north-west across Scandinavia, northern-central Europe to the Baltic States and northern Russia with a minimum of -3°C in northern Russia. In contrast during several days the temperature in southern Europe reached more than 40°C. In July several heat waves propagated from Iberia across central to Eastern Europe. Therefore July 2015 became the warmest July in many European countries.

Monthly temperature for **August 2015** showed very high positive anomalies especially in central Europe of more than 4°C. Negative anomalies occurred in Ireland, over the east Atlantic and north-eastern Russia. At single days the maximum temperature reached values of 40.3°C in Germany, 38.4°C in Poland or 41.5°C in Portugal. In Austria the monthly mean temperature ranked on the fourth place of the warmest August since measurements started in 1767 with 2.7°C above the mean. Only the August of the years 1807, 1992 and 2003 were warmer. From 1st to 4th August, Jordan saw temperatures nearly 8°C above normal, reaching 47.0°C at Wadi Elrayyan (WMO statement on the status of the global climate in 2015).

Heat waves over south-western and central Europe

At the beginning of **May** warm air came from Africa to Europe. Station Decimomannu in Sardinia (Italy) registered 38.4°C, the highest temperature in Europe on the 05th. During the second week, on the 14th May, remarkable temperature conditions were observed in Spain and Portugal with temperatures of 40°C to 44°C. In Portugal station Beja reported on the 14th May 40°C and on the consecutive 19 days maximum temperatures above 30°C, 14 days more than normal. The mean daily maximum temperature in Portugal of 25.46°C was +4.5°C higher than normal, being the highest value for May since measurements begun in 1931. At station Sevilla San Pablo (Spain) the maximum temperature in May reached every day above 25°C (summer days) and at 24 days values above 30°C (hot days) which are a new record. Even Lanzarote airport (Canary Islands, 13th of May) outperformed its May record with 42.6°C by +6°C. Agadir-Al Massira (Morocco) registered a maximum temperature of 45.6°C.

During **June**, temperature in Iberia, France and Italy were above normal, especially in the first decade and the last days of the month when extremely high temperature were recorded in both the daily maximum and night minimum. In these episodes record breaking heat waves reached the Iberian Peninsula and propagated to central Europe and Italy and further eastwards.

In **Portugal** June 2015 was the hottest of the last 10 years and the 5th warmest since 1931. The monthly average temperature was 21.8°C and +2.4°C higher than the normal value. The monthly mean of the maximum temperature with 29.0°C was +3.6°C higher than the long term mean, being the 3rd highest value for June since 1931. The absolute maximum temperature in Portugal was registered with 43.2°C at station Beja on the 29th June 2015.

June in **Spain** was also very warm, with an average temperature of 22.5°C or 1.4 K above the long term mean of this month (period: 1981-2010). Therefore it was the sixth warmest June since 1961 below the average temperature for the years 2003, 2004, 2005, 2009 and 2012.

In **Italy** the first ten-day period was the warmest of the month, especially in the central and northern regions, where the average anomalies of the maximum temperature exceeded the long term mean by 5°C, and at some places even by 7°C. Apart from Sicily, during this first ten-day period minimum temperature was higher in the central and northern part of Italy where the average deviation was about +3°C and even exceeded +6°C in some stations.

In **France** temperature in June remained with 1.5°C above normal during almost all the month. From 28th June onwards the maximum temperatures were 4°C -8°C warmer than normal over most of the country. On June 30th, they exceeded seasonal values by +12°C in the western part where records were broken with local peaks in the south-western France with 40.7°C in Arcachon (Gironde).

In **Austria** temperature anomalies were +1.4°C above normal. This was the 10th warmest June since 1767 for Austria. The absolute maximum temperature was 34.5°C at station Gars am Kamp (267 m a.s.l.)

In **Switzerland** it was the 4th warmest June with 33.2°C since beginning of measurements in 1864. The whole country was 1.8°C warmer than in mean of 1981–2010.

In **Germany** the maximum temperature of 35.0°C was recorded on the 5th June. However, the monthly mean temperature of 16.0°C was only 0.6°C or 0.3°C higher than the mean of the reference period (1961-1990 or 1981-2010).

The heat also reached **United Kingdom** with a record breaking maximum temperature of 32.5°C on the 30th at Heathrow-Airport (Greater London).

Hot air from Africa induced several heat waves in **July** with very high maximum temperatures as shown in the table below. The first heat wave reached on the 1st July the **United Kingdom** with the highest temperature since August 2003. The maximum temperature of 36.7°C at Heathrow (Greater London) was a new UK record for July. The heat wave reached also **Scandinavia** for some days and the mercury climbed to more than 30°C. In **Germany** the heat wave reached on the 5th July its peak with a new record breaking value of 40.3°C (at station Kitzingen). During the next days **Switzerland** registered its maximum value of 39.7°C on the 7th July and **Hungary**

39.3°C on the 8th. This first heat wave ended with severe thunderstorms and winds gusts, heavy rain and hail (of 3-4 cm diameter) in central Europe.

After a break of 2 days the next heat wave reached France on the 10th July but still remains in southern Europe.

On the 16th July the heat intensified again and culminated in new record breaking values in **Portugal** (42.1°C at station Mirandela) and **France** (41.4°C at station Brive) and propagated to the north and east. On the 18th July the heat reached the Black Sea. This third heat wave persisted in western Europe until the 24th and 25th in eastern Europe. In south Europe the heat wave lasted until the end of the month.

In **Austria** the highest temperature of 38.3°C was recorded on 19th July at 2 stations: Krems (203 m) and Langenlebarn (175 m). This was the first time in Austrian history that the morning temperature at 8 o'clock (06 UTC) was above 30°C (at stations Seibersdorf, Pottschach and Wiener Neustadt). Station Ljubljana (**Slovenia**) registered 21 hot days (T >30.0°C) that is a new record. Several other Slovenian stations documented also all-time records of hot days.

The implications of these high temperatures have not only caused strong thunderstorms with heavy rain, hail and flooding or damages at houses by lightning and forest fires. The long duration of this heat caused a precipitation deficit leading to shrinking water reservoirs and also low river levels (as reported from Poland, Russia and Germany). The agriculture had crop losses due to early harvesting as reported from Moldova and Germany.

Table 4.3: Selected countries and their statistics for July 2015 (as reported by the NMHSs)

Country	Rank	time series	Anomaly (°C)	Reference period	Absolute maximum in °C	Day of occurrence
Austria	1	1767	+3.1	1981-2010	38.3	19
France	3.	1900	+2.0	1981-2010	41.4	16
Germany	7.	1881	+1.4	1981-2010	40.3	5
Hungary	-	-	-	-	39.3	8
Italy	-	-	-	-	42.8	31
Norway	-	1900	-0.7	1961-1990	31.4	2
Poland	-	-	-	-	36.4	4
Portugal	13.	1931	+1.0	1971-2000	42.1	16
Romania	-	-	-	-	38.6	30
Serbia	2.	1950	+3 to +5	1961-1990	38.4	19
Spain	1.	1961	+2.5	1981-2010	45.2	6
Sweden	-	-	-	-	32.8	2
Switzerland	1	1864	+3.6	1981-2010	39.7	7
United Kingdom	-	-	-0.7	1981-2010	36.7	1

Notes: ranking of the country mean temperature and the start of this time series, as well as the anomalies with respect to the reference period as available by the national meteorological services

The average global land surface temperature for **August** 2015 was +1.14°C above the 20th century average (NOAA National Centers for Environmental Information, State of the Climate: Regional Analysis for August 2015, published online September 2015, retrieved on September 25, 2015 from http://www.ncdc.noaa.gov/sotc/global-regions/201508). It was the highest August value in the 1880-2015 record, exceeding the previous record set in 1998 by +0.13°C. For Europe the land surface temperature in August 2015 exceeded by +2.25°C the reference mean of 1910-2000 and was the warmest August since 1910 (start of the time series). In many European countries this August breaks several records.

In **Austria** it was the 4th warmest **August** since measurements began in 1767. **Germany** reported the 2nd highest mean monthly temperature for August since 1881. Also Wroclaw (**Poland**) experienced with 38.9°C an all-time high August temperature on the 8th. The 12th of August was the ninth consecutive day in Warsaw with a temperature of 32.2°C or higher. At the same time a great part of Europe had a rainfall deficit. Since 1st June, Warsaw has received less than half of the normal precipitation (172 mm). During the same time Belgrade recorded 47 mm total rain amount, which is less than 30% of the normal. In the **Ukraine** the precipitation deficit caused low river levels. In **Germany** this summer was the driest of the last 50 years. The affected area in **Portugal**

by drought on August 31st was for severe and extreme drought categories 74% that is the 2nd worst in 70 years (100% in 2005 and 73% in 2012).

This high temperature in combination with precipitation deficit stimulated wildfires in every country around the Mediterranean Sea e.g. Spain, Portugal (http://forest.jrc.ec.europa.eu/effis/).

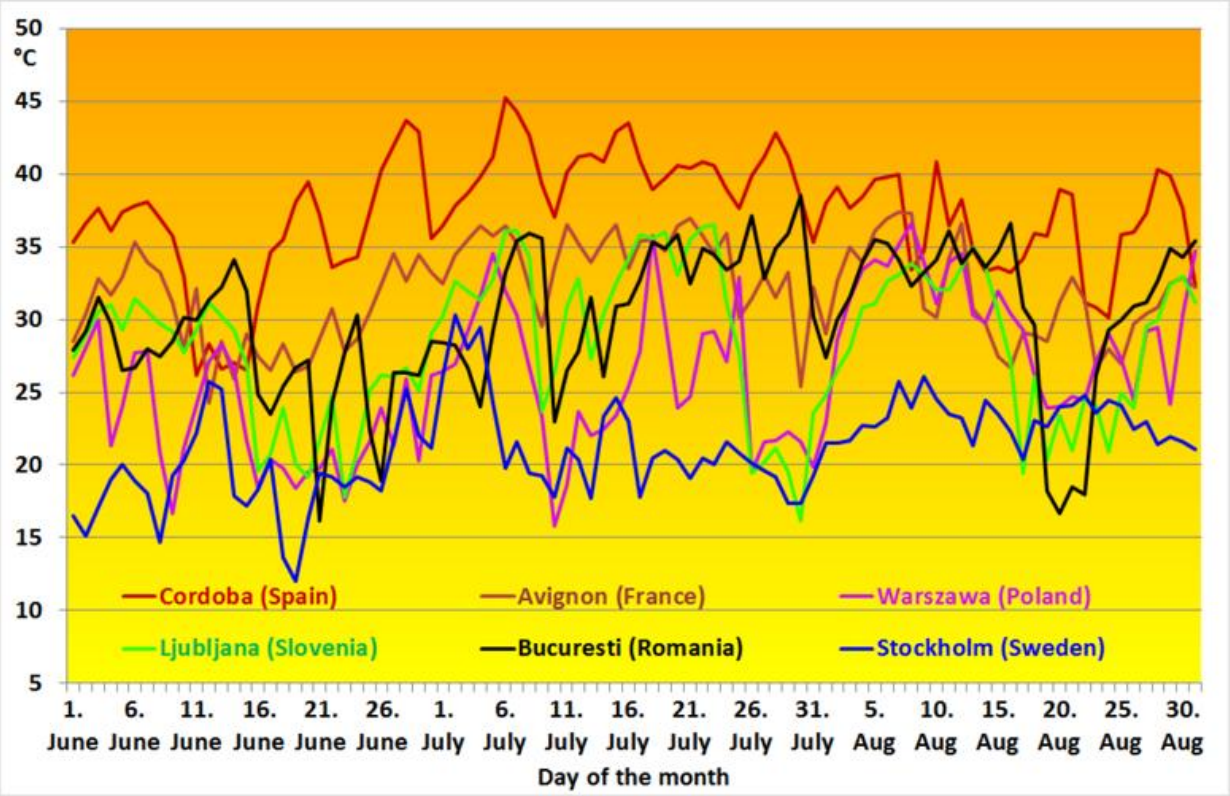

Figure 4.4: Daily maximum temperature (in °C) for several European SYNOP-stations from June to August 2015

From June to August 2015 several heat waves passed over different regions at different times. Southern Spain (at station Cordoba) noted most of the time more than 35°C and on the 6th of July even 45.2°C. In Avignon (southern France) the maximum temperature remained above 30°C from 25th June until 13th August (with the exception of 3 days). In Central Europe (at station Warszawa) and the Balkan (at station Ljubljana) 5 heat waves (maximum temperature above 30°C) were observable, at the beginning of June, at the beginning and in mid-July as well as at the beginning and the end of August. In eastern Europe (in Bucharest) the heat waves arrived some days later. In contrast, the heat wave reached northern Europe only on 2nd July with a maximum temperature in Stockholm (Sweden, the country wide maximum was 32.8°C) of 30.3°C.

Global: NOAA National Centers for Environmental Information, State of the Climate

The anomaly pattern of the temperature in **September 2015** was divided in two parts. The western part of Europe was colder than normal with anomalies below -2°C in France and above +4°C in the Ukraine, southern Russia and Turkey. The heat wave was shifted eastwards with maximum temperature above 40°C in Turkey and some new station records. In Israel, at Sedom, the minimum temperature on the 9th September was 36.5°C, which is the highest daily minimum temperature ever recorded in Israel. This temperature broke the record of Tiberias (36.0°C) from 1936 (WMO statement on the status of the global climate in 2015).

Most of central and eastern Europe had in **October 2015** negative temperature anomalies of down to -2°C. Scandinavia, the United Kingdom, Ireland and southern Europe showed positive anomalies of up to +4°C in central Turkey and Middle East. In the North between Greenland and Novaya Zemlya the anomalies reached values of more than +4°C.

Temperature anomalies in **November 2015** showed overall positive values of more than +4°C in central Europe, Finland and the extreme North. Some countries reported new records like Germany. In Germany the elevated stations had anomalies of more than +4°C (e.g. Hohenpeißenberg 4.3°C above the reference period 1981-2010). On average over France, it was +2.7°C warmer than normal, ranking the 3rd November among the warmest since 1900, behind 1994 and 2014. November was also exceptionally warm in a large part of Finland. At several observational stations in the southern and western parts of Finland, the month was even record mild.

In **December 2015** nearly whole Europe was more than +4°C warmer. Colder as normal it was in Greece, Turkey and parts of the Middle East (locally below -3°C) as well as southern and western Greenland and the northern Atlantic showed negative anomalies, especially in central Turkey, southern Greenland and the northern Atlantic. Germany observed with +5.6°C above normal (+0.8°C) its warmest December on record. The UK also noted the warmest December in a series from 1910. With 7.9°C it was 1.0°C warmer than the previous warmest December. It was also easily the warmest December in the Central England temperature (CET) series from 1659. Switzerland had the warmest December since the beginning of the measurements 1864, with record temperatures anomalies between 5.6 and 5.8 K above normal (1981-2010) on Jungfraujoch (3580 m a.s.l.), Säntis (2502m a.s.l.) und Grosser St. Bernhard (2472 m a.s.l.) which is 2°C above the last records. Estonia reported a monthly mean temperature +3.3ºC (anomaly 6.1ºC), the second place since 1961.

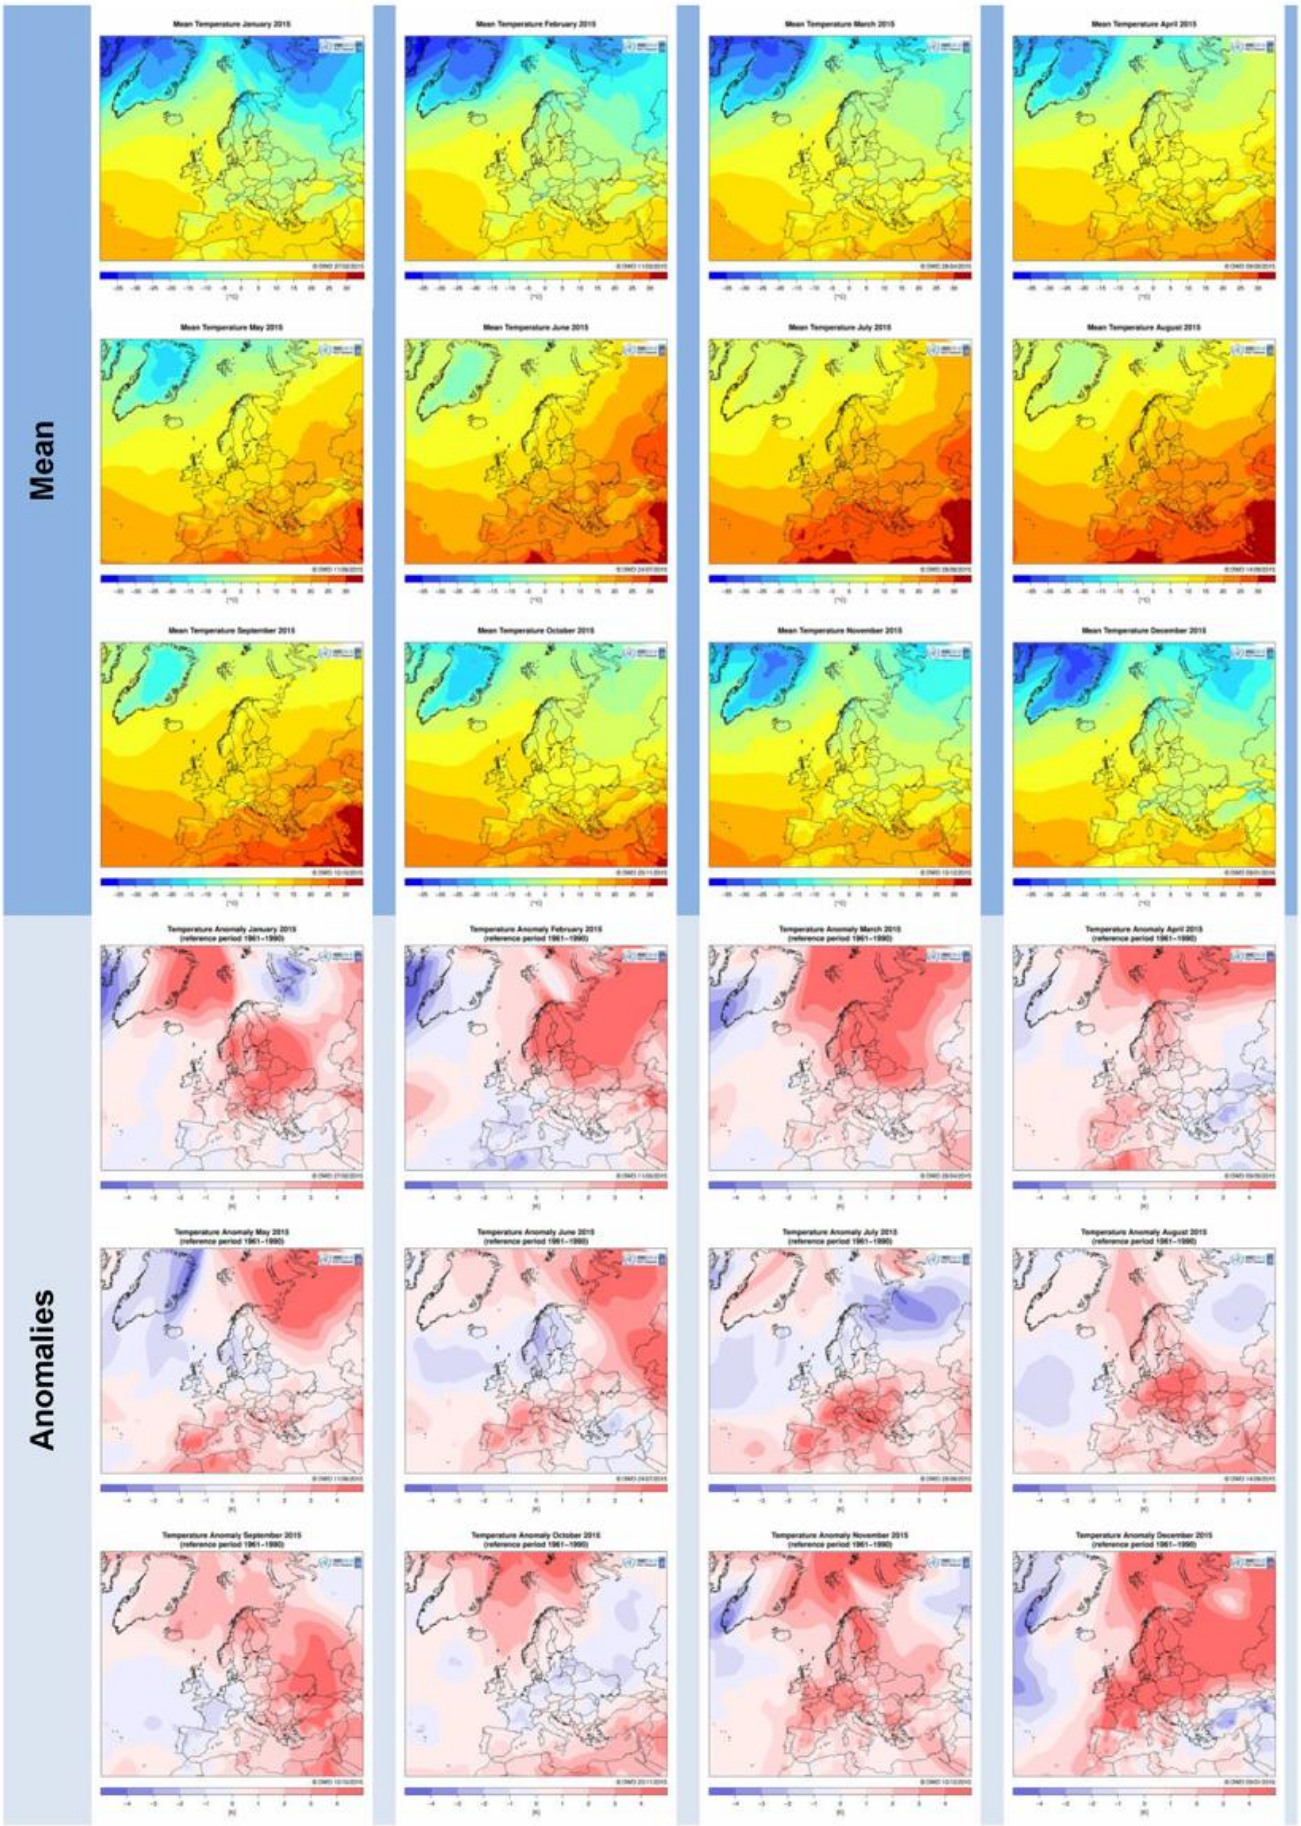

Figure 4.5: Mean and anomalies of temperature (in °C) for each month of the year 2015. (First row January, February, March, April)

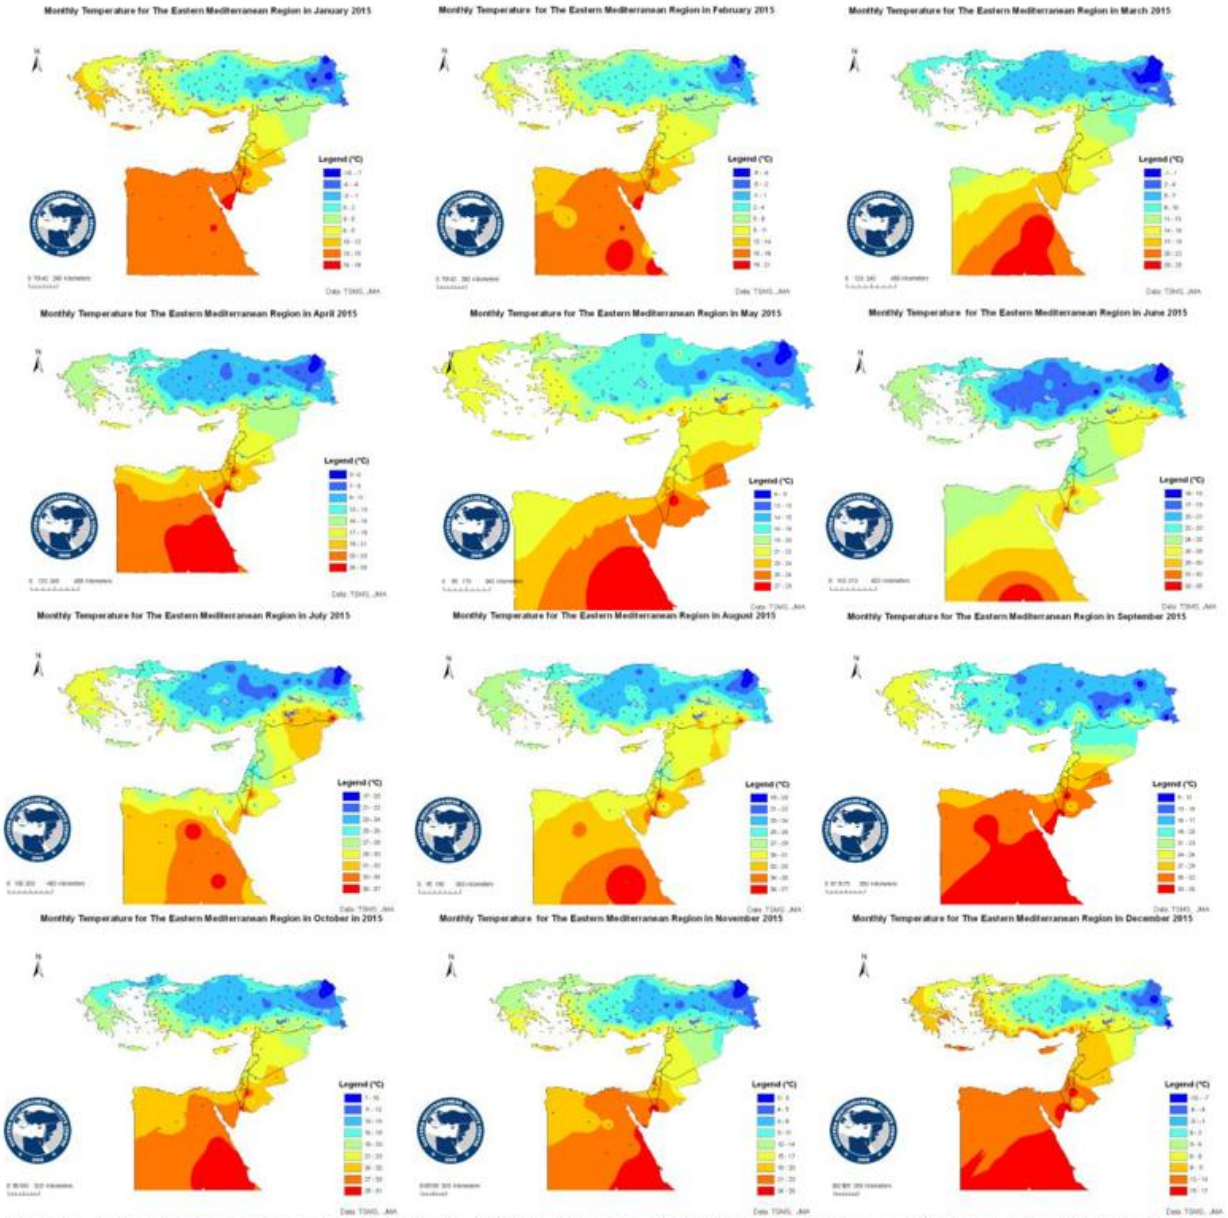

Figure 4.6: Monthly mean temperature (°C) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC).

4.3. Precipitation

According to the sunshine duration in **January 2015** most of central, eastern and northern Europe show higher than normal precipitation with values of more than 250% in Scotland, although it was very sunny. The overall UK rainfall total was 126% of the average. The West-Mediterranean was drier than normal except the coastal zone of northern Spain with partly more than 300 mm as reported by the national weather service AEMet. There was also widespread heavy rain over Cyprus that caused flooding and landslides (WMO statement on the status of the global climate in 2015).

Extreme precipitation in Scandinavia

In Finland precipitation levels for **January** were exceptionally high close to the western coastline and also in the area stretching from Kainuu to Sea Lapland. Precipitation volumes in these areas were nearly twice as high as normal for January. In western parts of the country many weather observation stations recorded the highest precipitation levels for January since 1961.

During January in a larger part of Lithuania registered 60-80 mm of rain and up to 85-110 mm in the western part, equivalent to 150–200% of the long term mean.

In Norway the monthly total precipitation was 140% at some stations up to 400% of the normal; at Eikemo 782.3 mm (279% of the normal).

In Sweden station Piteå reported a new record of 133.6 mm for January since 1860. In this month also several other station records were broken in Sweden.

Links/References:
Finnish Meteorological Institute: January saw high precipitation and wide temperature fluctuations.
Norway: Været i Norge - Klimatologisk månedsoversikt - Januar 2015

In **February 2015** most of central Europe, southern Scandinavia, the Baltic States and south-west Iberian Peninsula were drier than normal with values less than 20% of the long term mean. South-eastern Europe, Norway and the British Isles were wetter than normal. Most parts of Austria reported a precipitation deficit of more than 50%, at station Kollerschlag only 8% of the long term mean was registered. Monthly precipitation totals for whole Norway were 135% of the normal. Some stations received between 250% and 350% and others in the south only 25% of the normal. The highest amount was measured at station Lurøy with 467.0 mm or 237%. The relative precipitation anomaly in Portugal ranged from values of 10% in Castelo Branco to 100% in Portimão Compared with the average values the accumulated monthly precipitation in northern Spain exceeded 200%, at some stations even 300%. The precipitation amount in Croatia for February ranged between 37% and 300% or 15 and 99 mm. Heavy rain also affected countries in southern Europe with flooding in parts of Albania, the Former Yugoslav Republic of Macedonia, Greece and Bulgaria (WMO statement on the status of the global climate in 2015).

In **March 2015** most of western Europe and Russia were drier than normal with values less than 50% of the long term mean. South-eastern Europe, Norway and Scotland were wetter than normal. The precipitation amount for Portugal in March were much lower than the respective normal values throughout the country and ranged from 0.4 mm in Vila Real to 55.4 mm in Viana do Castelo. The percentage values were less than 50% relative to the normal in the north and central part and less than 75% in much of the southern region. In France the precipitation deficit was 20% below normal, locally in the centre of Brittany about 50%. In contrast, in Corsica the precipitation amount often exceeded 250 mm, at station Campile a new record was set with 406 mm (normal for March 63 mm). The average rainfall of Spain was calculated to 58 mm, which exceeded the average of the month (reference period: 1981-2010) by about 25%. In the east of Spain the precipitation amount reached values of more than 300% and led to new all-time record of precipitation for March at the observatories in Castellon de la Plana, Teruel and Almeria. Romania registered in the south-eastern part precipitation amounts of 150-200% of the long term means (1981-2010).

In **April 2015** precipitation was lowest at some places in the central and eastern Mediterranean such as Sicily, southern Greece, southern Turkey, parts of the Middle East, but also at few places in Hungary with less than 10 mm for the whole month of April 2015. In Austria at Klagenfurt the

second driest April since 1813 were registered, which led to forest fires (WMO 2015). Highest precipitation totals were measured in northwest Spain, southern France and near eastern coasts of the Black Sea with more than 100 mm in April, locally more than 150 mm. Northern and eastern Europe received more precipitation than normal, in some regions more than 250%. Some stations in Northern Norway received 2.5 to 3.5 times of the normal precipitation.

Precipitation anomalies for **May 2015** were heterogeneous distributed. Most parts of western Europe from Poland, Czech Republic, France, and Iberian Peninsula were drier than normal with values less than 20% of the long term mean in Spain. Most of Italy, Albania, and from Greece to eastern Romania and Moldova was also drier than normal. Scotland, Scandinavia, the Alpine region with western Balkan as well as Slovakia, eastern Poland, the Ukraine and parts of Belarus and Russia showed positive precipitation anomalies. In northern Europe precipitation was caused by cyclonic activities whereas in southern parts precipitation was mainly caused by thunderstorms.

Very wet May in Scandinavia

Precipitation in Finland ranged from below 100% in the south-east to more than 225% in the north and west parts of the country.

Monthly precipitation for Norway was 175% of the normal, and it was the second wettest **May** in a series that stared in 1900, surpassed only by the May of the year 1949. Some stations in the north and the southeast received more than 3 times of the normal rainfall. It was relatively dry in parts of northern and central Norway with 50% to 75% of the normal precipitation. The wettest station was Hovlandsdal with 363.4 mm (265% of normal).

In Sweden May was very wet or extremely wet for almost the entire country. Several stations with more than 100-year long measurement series hit their old monthly record. In Stockholm it was the wettest May since 200 years.

Finland: May 2015 Statistics
Norway: Klimatologisk månedsoversikt Mai 2015

Monthly precipitation for **June 2015** showed high positive anomalies in Scandinavia and northern Russia of more than 70 mm. In the south-eastern part of Europe also high positive anomalies occurred with peaks over central Turkey and north of the Black Sea with values of more than 70 mm. A band of above normal precipitation extended from the Black Sea through Ukraine to northern Russia. Central and eastern Europe received partly below 25 mm or a deficit of up to 75 mm from Croatia through Austria and Hungary up to the Baltic States and northern Russia. While the Pyrenees recorded above normal precipitation, the rest of Spain and Portugal still had a precipitation deficit and drought.

Monthly precipitation for **July 2015** showed high positive anomalies of more than 70 mm in UK, Ireland, northern Germany, Scandinavia and northern Russia. Southern Europe (Serbia, Italy, Spain and Portugal) received partly below 25 mm or locally a relative anomaly of below 20%. While the north-eastern part of Spain measured above normal precipitation, the rest of Spain and Portugal, France, and a band from southern Germany up to the Ukraine still had a precipitation deficit and drought. On the 4th and 5th July severe thunderstorms with hail crossed the Netherlands, Belgium and northern Germany with 2 fatalities and a loss of 400 Million Euro (MunichRe). This low pressure system with storm (26.2 m/s at station Münster/Osnabrück, Germany), hail (9 cm in diameter) and heavy rain caused flash floods, and damage on numerous houses and vehicles.

Precipitation anomalies for **August 2015** were above normal in most parts of western and southern Europe while northern and eastern Europe were drier than normal. It rained less than normal in an area from Massif Central (France), Switzerland, Austria, southern Germany, Czech Republic, Poland to Scandinavia and from the Baltic Sea to the Black Sea with values less than 20% of the long term mean. Central Russia was wetter than normal with anomalies of more than 70 mm. While in southern Norway precipitation amount reached up to 341.9 mm (197% of normal) at station Sand i Ryfylke (Rogaland), central Norway received at station Skjomen–Stiberg (Nordland) only 18.1 mm or 26% of the normal. In France new records were set at station Gonneville (Brittany)

with 178.4 mm (more than three times of the normal amount) and Montpellier with 234.2 mm (nearly seven times of the normal amount)

In **September 2015** western Europe from Portugal to Norway was drier than normal. Eastwards of this band a second band of above normal precipitation was located from France to northern Finland. The next band with drier conditions followed from south Germany and Czech Republic, Poland, the Baltic States to northern Russia joined by a wetter zone from Greece and Turkey to Belarus and Russia. The southern part of Russia and eastern Ukraine were dominated by a precipitation deficit. Most of these precipitations were due to thunderstorms with severe rainfall. The precipitable water anomaly maps showed for the whole Mediterranean values of up to 8 mm or more than 3 standard deviations. Two peaks were remarkable one above Costa Brava/Gulf of Lions and the other western off the Spanish/French Atlantic coast. In Ireland, stations in Galway and Mayo saw September-record 24 hour rainfall totals over 100 mm on 11th and 13th September leading to flooding (WMO statement on the status of the global climate in 2015).

Scandinavia received in **October 2015** little precipitation, except central and northern Norway. The region of the deficit ranged from the Baltic States, northern Poland to Belarus, eastern Ukraine and western Russia with monthly totals below 10 mm. In southern Norway and Sweden new extreme low precipitation records were broken by many stations. Western Europe and eastern Spain received below normal precipitation, partly below 40%. In Ireland almost all stations reported their driest October in five to 12 years and also Estonia had its driest October since 1961. In contrast, south-eastern Europe the relative precipitation anomalies were partly above 250%. In mid-October, heavy rain in Bosnia-Herzegovina led to flooding in Mostar and Stolac city (WMO 2015).

In **November 2015** most of northern Europe received above normal precipitation. In Norway total precipitation of more than 700 mm/month was measured. Southern Europe showed a precipitation deficit below 40%, especially central and northern Italy as well as the western Balkan, Iberia and Turkey. Austria received only 50% of the precipitation amount, at some places even 2%.

In **December 2015** the precipitation pattern over Europe was divided in two parts of opposite precipitation anomalies.. The very dry part was extended from the Mediterranean to France, Germany, Poland and Ukraine with less than 20% precipitation. Austria noted its second driest December since 1858; Hungary its 3rd driest since 1901 The wetter part encompassed UK, Ireland, northern Greenland, Denmark, Norway, Finland, southeastern Caucasus and Russia with anomalies of more than 150%. In Ireland most stations across the country reported 2-3 times of their normal rainfall for December. Wettest conditions were in county Cork where nearly all stations measured more than 300% of normal. Roche's Point reported the highest percentage of average with 342 % (340.6 mm), and its highest measured value at this station for December since 1955. In Norway the monthly precipitation was 165% of its normal. It was the 4th wettest December since 1900. Some stations in southern and western Norway measured between 300% and 400% of normal precipitation.

Extreme precipitation and floods in northern UK in December 2015

December was a record-breaking month in the UK, dominated by unseasonably mild and moist tropical maritime air masses and a marked absence of frost, particularly in the south. Frequent deep depressions and frontal systems - including storms Desmond, Eva and Frank - brought strong winds and heavy rain to the north at regular intervals. In detail they brought record-breaking rainfall over much of Scotland, Wales and northern England. Severe flooding affected Cumbria for much of December, and became widespread across North Wales, northern England and Scotland after Christmas. With 198% of average rainfall, it was the wettest December, and calendar month, in the UK series. Rainfall reached 2 to 4 times the average in the west and north. 341.4 mm fell at Honister Pass (Cumbria) in 24 h on the 5th, a new UK record for any 24-hours. In fact of the storms and the high precipitation fallen trees and power cables leading to power cuts. Record-breaking rainfall totals brought widespread flooding of roads and rail routes, several bridges were washed away and many properties were flooded. In January, the Association of British Insurers (ABI) estimated the final bill for the flood damage caused by storms Desmond, Eva and Frank to homes, businesses and motor vehicles to be £1.3 billion.

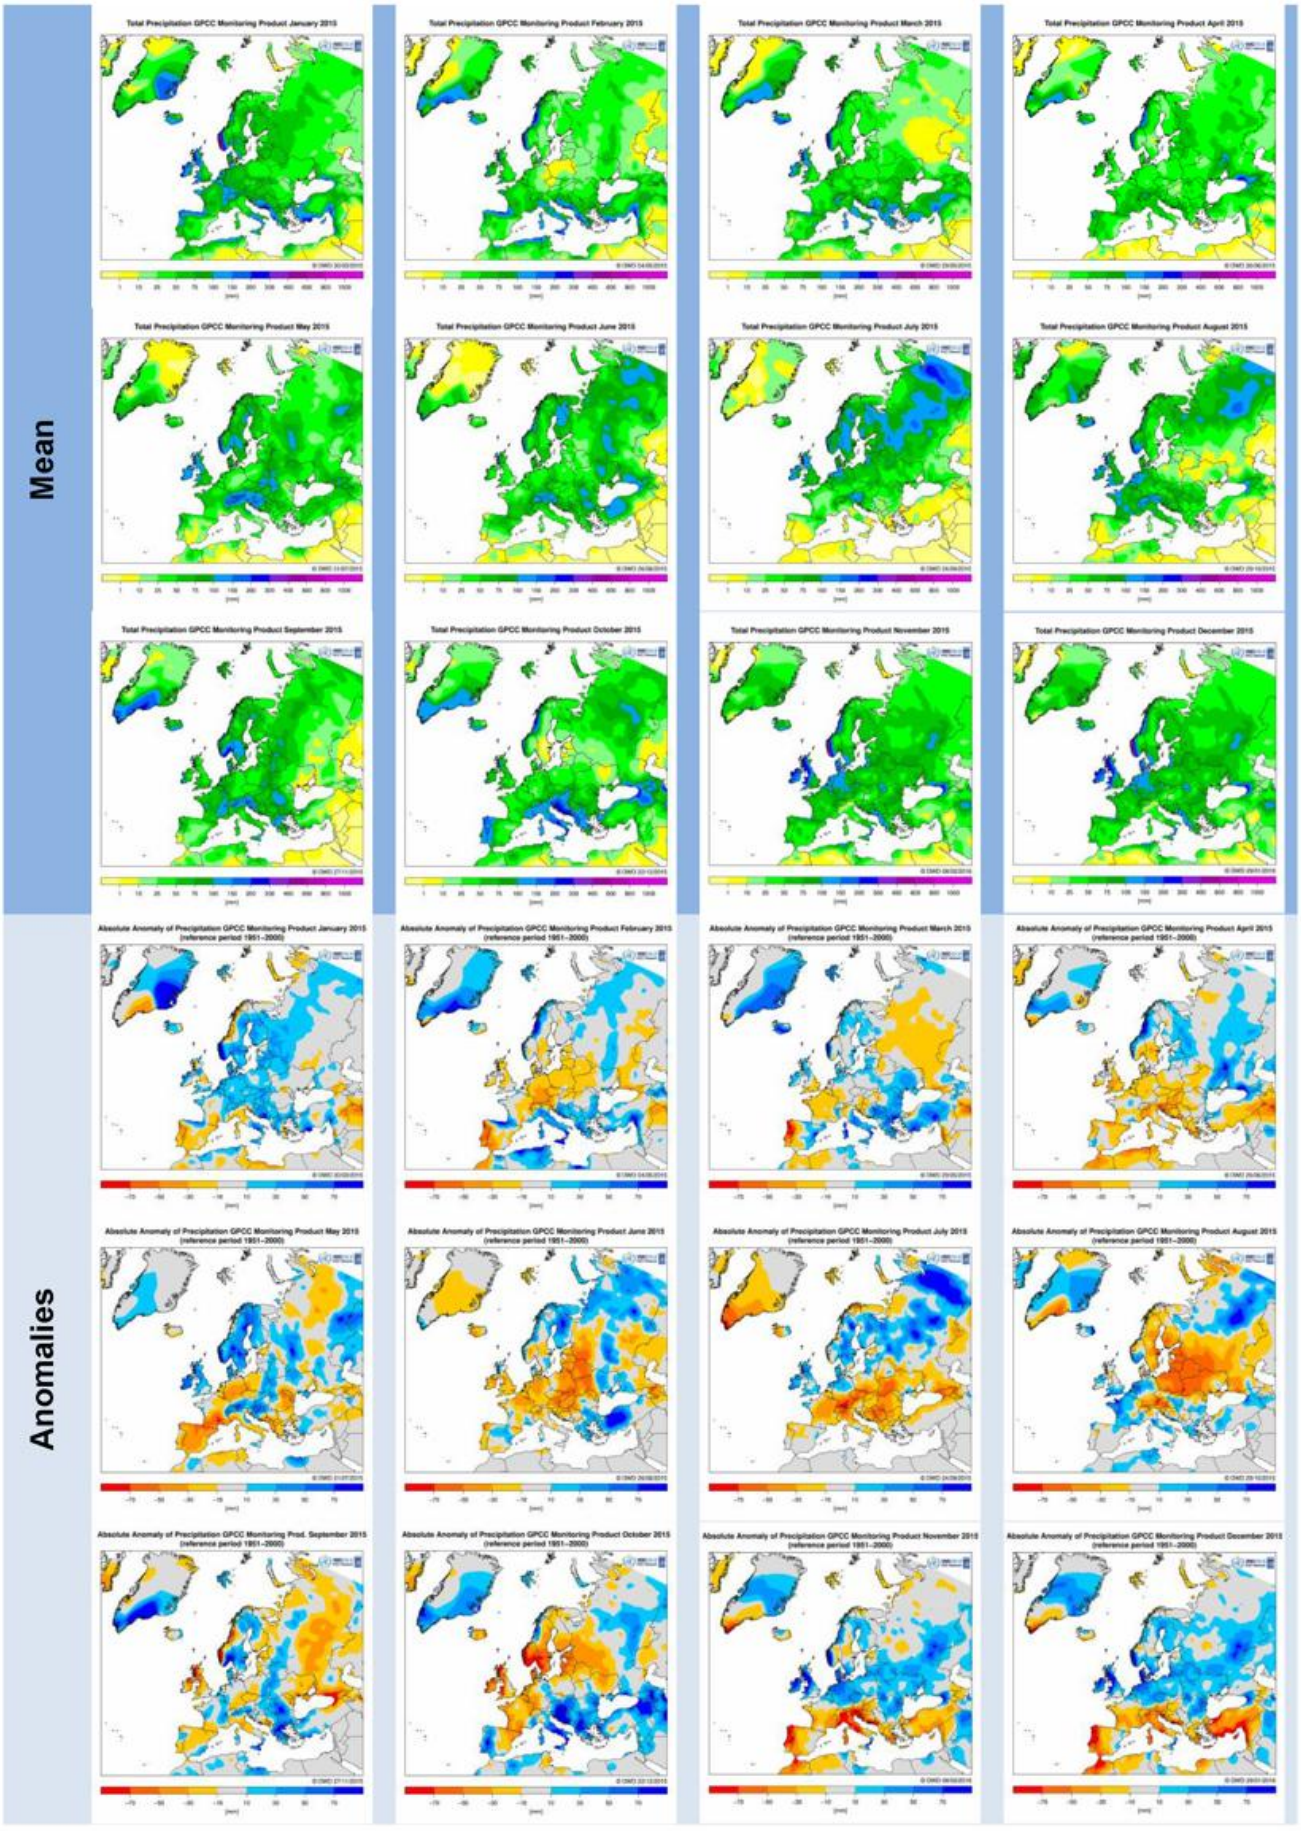

Figure 4.7: Mean and anomalies of precipitation (in mm/month) for each month of the year 2015. (First column January, February, March, April)

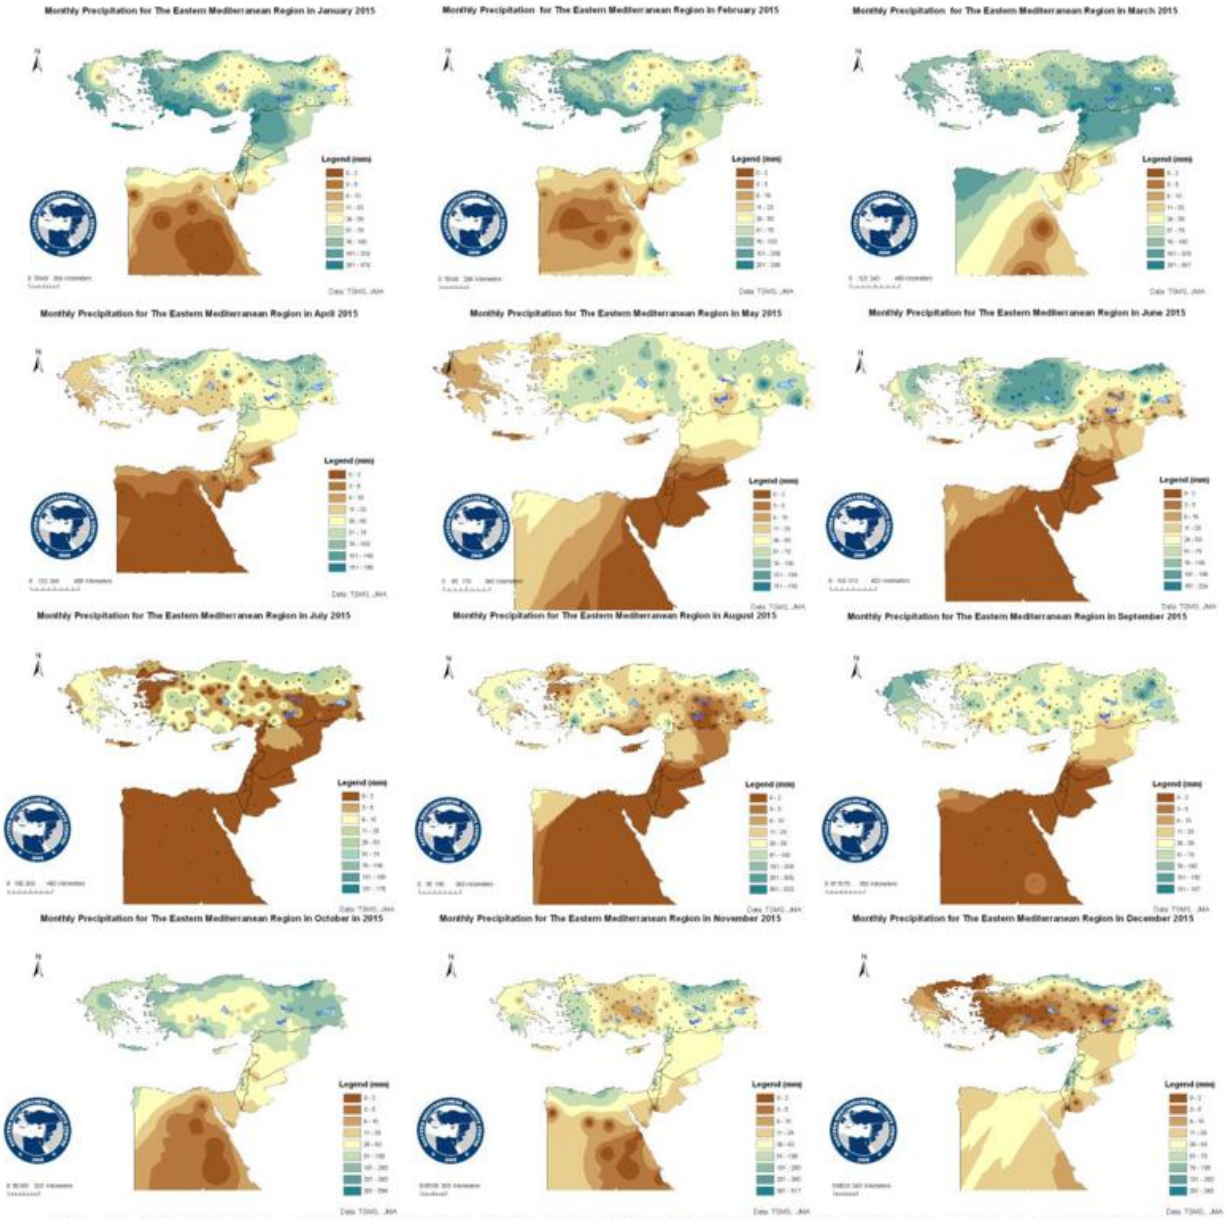

Figure 4.8: Monthly precipitation totals (mm) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC).

4.4. Sunshine duration

In **January 2015** most of central, eastern and northern Europe had lower than normal sunshine. The Mediterranean from Iberia to Turkey showed positive anomalies of the sunshine duration with values of more than 150% in Spain, Sardinia and Romania. In the United Kingdom the sunshine was well above normal in most places, especially eastern areas, and the UK received 126% of average sunshine hours. It was the UK's equal- 5th sunniest January in a series from 1929.

In **February 2015** more sunshine than normal showed central Europe with a maximum of more than +50% an area at the border between Germany and Poland. Austria reported at station Hohenau an der March (Hohenau upon March) a surplus of +44% while in the south-western part of Austria stations showed a deficit of -30% to -37%.

March 2015 was characterised by positive anomalies of sunshine duration over a large part of Europe except southern France and south- eastern Europa. South-western France had a deficit below 50% of normal and a surplus of 30% in the north-west. On 20 March 2015 there was a partial solar eclipse.

In **April 2015** the prevailed high pressure over western Europe determined positive anomalies of sunshine duration covered the western part of Region VI. UK received 143% of the average sunshine hours; that was the sunniest April since 1929. Germany received 134% of the normal sunshine hours. The north-eastern part of Europe had less sunshine than normal.

In **May 2015** positive anomalies of sunshine duration - accompanied by warmer and drier condition - covered mainly the eastern part of Region VI. For example, the highest reported sum of sunshine duration in Portugal was approximately 360 hours that is somewhat below the maximum value of northern Russian with 370 hours.

In **June 2015** the dry air from Africa induced positive sunshine anomalies in southwest and central Europe while Scandinavia and east Mediterranean obtained less sunshine than normal.

In **July 2015** southern and central Europe received more sunshine while northern (except Norway) and western Europe registered less than the average. The highest reported sum of sunshine duration in Greece was 418 hours.

In **August 2015** the high pressure over Scandinavia resulted in above normal sunshine duration over most of Scandinavia, the Baltic States, Poland and north-western Russia with values of more than 50% or 100 hours. This caused also above normal temperature and precipitation deficit in this region. For Stockholm results show that the current sunshine duration was only one hour below the record from 1955.

In **September 2015** in most parts of Europe the sunshine duration was below normal except the United Kingdom, Spain, western France, Poland, Scandinavia, east Ukraine and west Russia. In Wales obtained 170.2 hours or 137% of the 1961-1990 averages and West-Scotland 144.3 hours or 142% of the normal. In western Poland shone the sun more than 190 hours 60 hours (+25%) longer compared to the long term mean (1961-1990). Southern Sweden was also sunnier than normal with 235 hours at station Hoburg.

In **October 2015** the high pressure over Scandinavia together with the subsidence caused lower cloud amounts and more sunshine. This weather situation resulted in relative anomalies of more than 150% in Sweden and Finland. Sweden reported new records of sunshine duration for several stations like Umeå (162 h or 172%).These positive anomalies extended to the Black Sea, while the rest of Europe received less sunshine than normal in conjunction with above normal precipitation.

In **November 2015** most of southern Europe showed above normal sunshine. The Balkan received locally more than 150% of sunshine. In Austria it was the sunniest November since the nationwide sunshine measurements began in 1925.

In **December 2015** most parts of Europe recorded positive anomalies between 105% and more than 150% of normal sunshine duration. In Austria it was the sunniest December on record with 190% of normal. The station Villacher Alpe measured 233 h, which was 76% more than normal. Germany noted its second sunniest December on record since 1951. There were many other European countries which measured a record December. Sunshine deficit reported Ireland, UK, western Greenland, Portugal, parts of Spain, some places in the Mediterranean region, Denmark, and Hungary. Western Romania had a sunshine duration below 95%, parts of Russia and Finland actually below 25%.

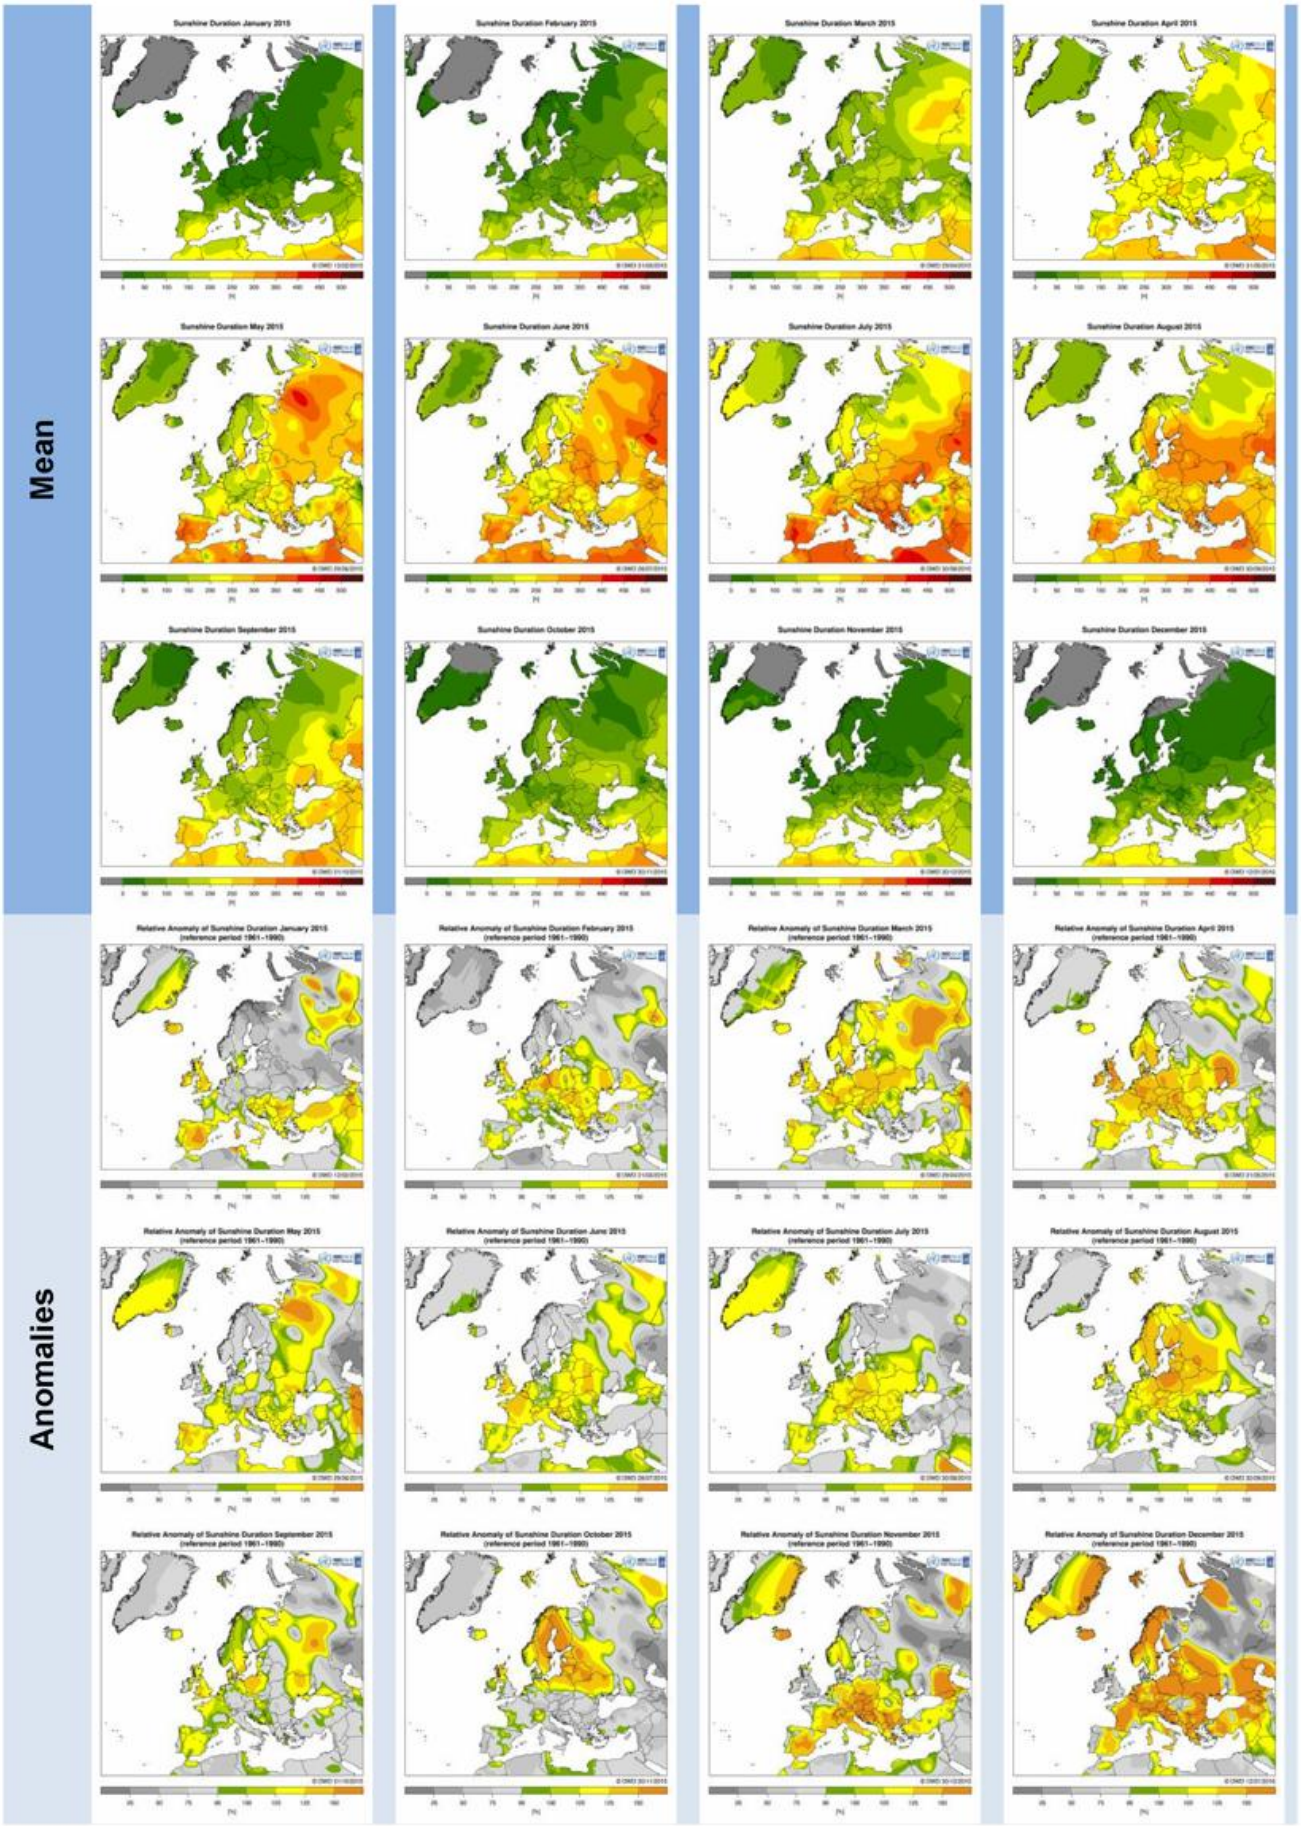

Figure 4.9: Mean of sunshine duration (in hours) and relative anomalies (in %) for each month of the year 2015. (First column January, February, March, April)

4.5. Maps of monthly climate extremes and events

The following maps are based on different data (as noted the legend in parentheses) and should summarize the weather conditions in each month of the year 2015.

From **January to March** 2015 in northern and eastern Europe the monthly temperature were 4°C warmer than normal and also the number of warm days were above normal. The areas at the Norwegian and Greenland coasts were affected by strong wind gusts. In **February** the Iberian and France had more colder days than normal.

In nearly whole Europe **April** had more warmer days than normal.

In **May** and **June** northern, central, western and southern Europe was wet and warm but had also a few colder days than normal.

In **July** it became warmer and dryer than normal in the south part of Europe while Scandinavia and the UK had more wetter and colder days as usual.

Whole Europe had more warm and wet days in **August** with anomalies above 4°C in Balkan, Poland and Ukraine.

In **September** western Europe was affected by more cold days while central and northern Europe showed again higher number of wet and warm days.

Central Europe showed in **October** more cold days than usual. The Balkan and southern Europe noted a higher number of very wet and sometimes warm days. While northern Europe had more warm days than normal with strong wind gusts at the Atlantic coast.

During **November** most parts of Europe showed a higher number of warm and wet days. Norway, the UK, Denmark, the Bretagne and in the Gulf of Lions were affected by strong wind gusts in November.

The **December** showed in whole Europe again more warm days than normal, but northern Europe was wetter and southern Europe dryer than normal. There were also strong wind gusts in Scandinavia, the UK and Greenland.

The Monthly Event Map contains information about the extreme anomalies of temperature, precipitation and wind gusts. Points are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (>=32 m/s) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

Legend of Figure 4.10:

- Anomaly of very wet days > 0 (ECAD)
- Wind gusts (≥ 32 m/s) (SYNOP)
- Anomaly of warm days > 0 (ECAD)
- Anomaly of cold days > 0 (ECAD)
- Anomaly of TG ≤ -4K (CLIMAT and ship obs.)
- Anomaly of TG ≥ 4K (CLIMAT and ship obs.)
- Aridity index < -1.5 modified SPI (GPCC)
- RR ≥ 150% of climatology (GPCC)

Based on climatology 1961-1990 (GPCC climatology: 1951-2000)

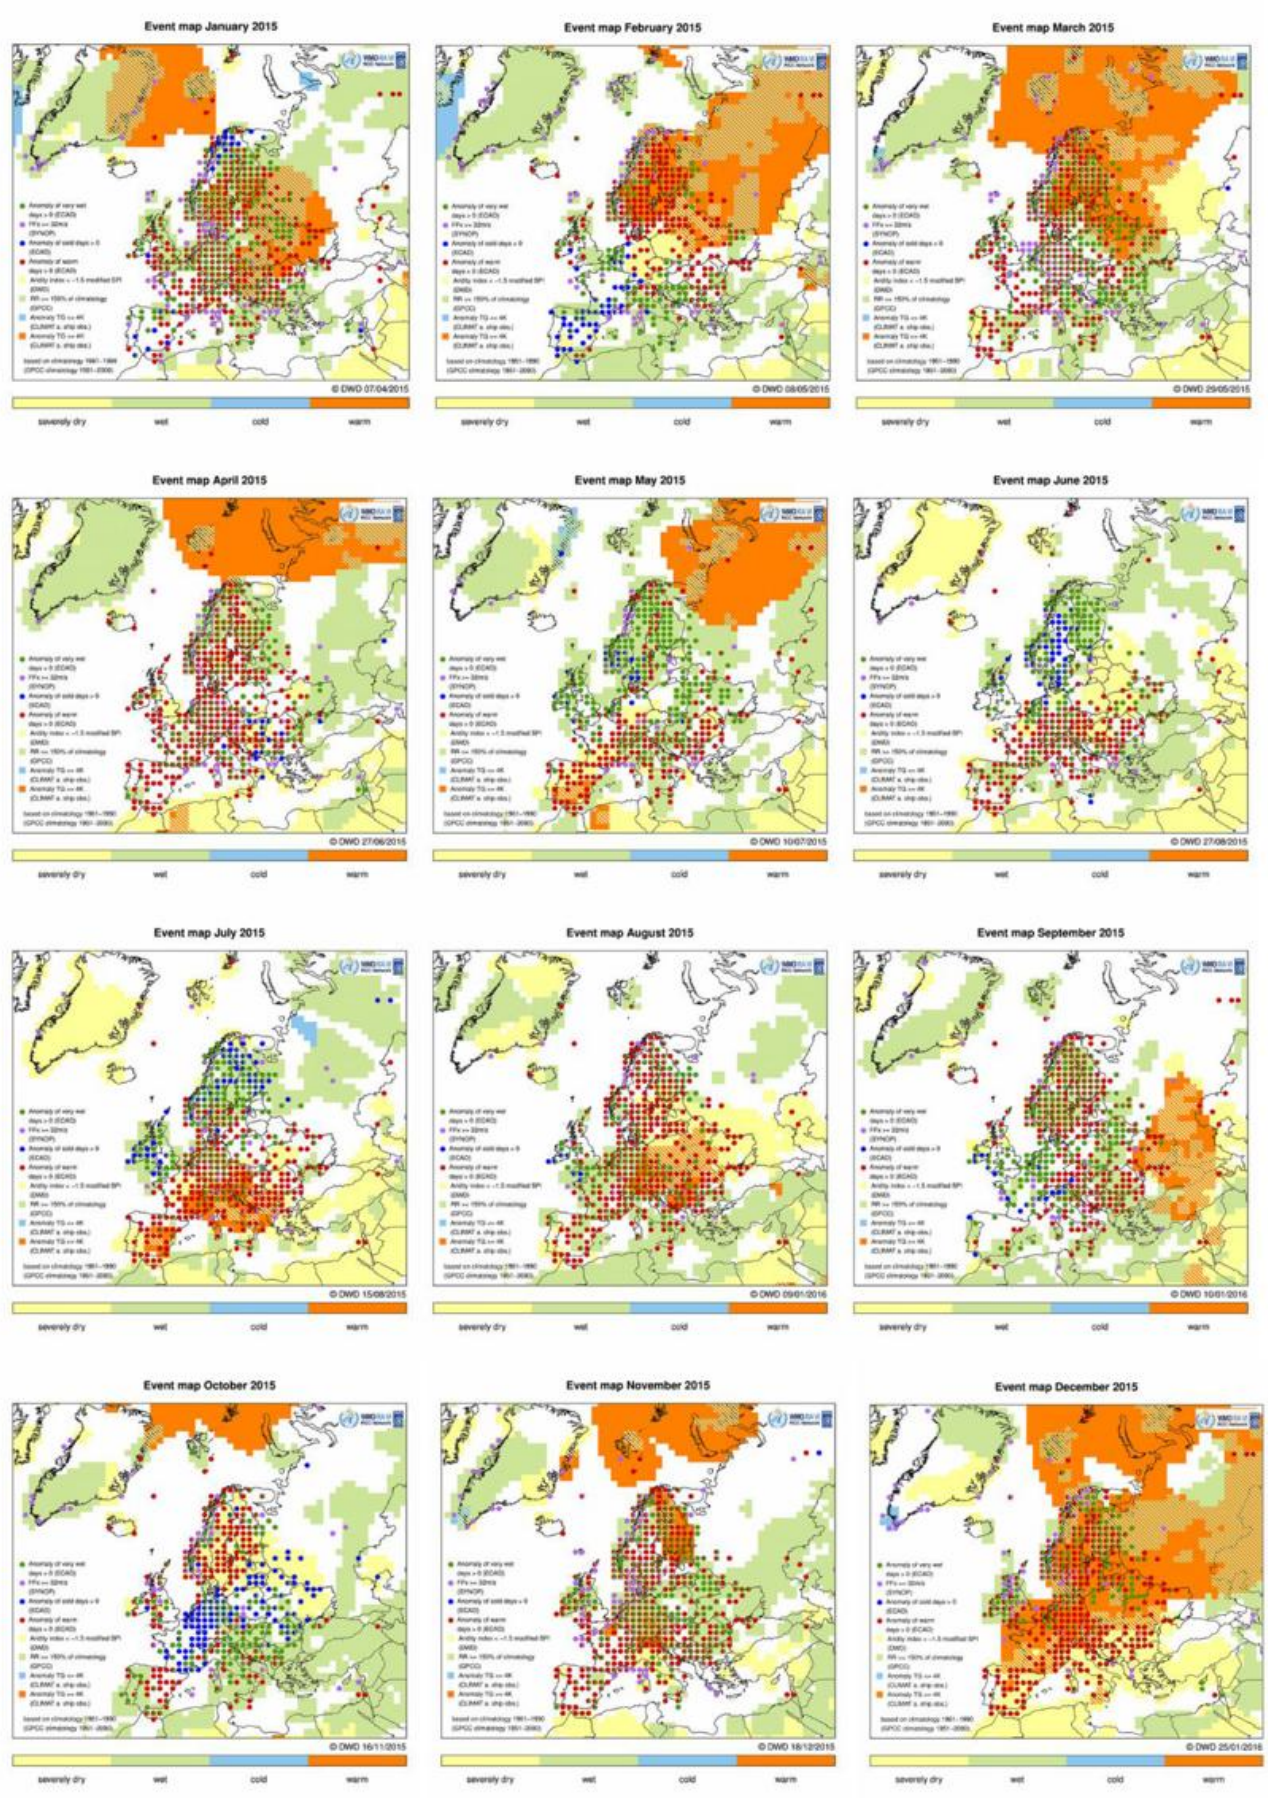

Figure 4.10: Maps of Climate Extremes for each month of the year 2015.

5. Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the national meteorological services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 sub-regions defined above (Figure 1.1). An overview about the contributed countries, the time series lengths and the area representativeness can be found in Table 5.1. Most are temperature time series. Each sub-region is at least represented by one country. Time series of precipitation totals are fewer but each sub-region is represented with at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries and they belong to different sub-regions.

After this, we present examples of the temporal development of other temperature related phenomena, such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Władysławowo.

Table 5.1: Availability of the long-term records of temperature, precipitation and sunshine duration from some participant countries.

Sub-region	Country	Temperature		Precipitation		Sunshine Duration	
		Spatial Mean	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station
Central and Western Europe	Austria	1768					
	Belgium		1833				
	France	1900					
	Germany	1881		1881		1951	
	Hungary	1901		1901			
	Luxembourg	1947					
	Netherlands	1910					
	Poland	1951					
	Switzerland	1864		1864		1959	
	United Kingdom	1910		1910		1929	
Nordic and Baltic Countries	Denmark, Greenland, Faroer	1873		1874		1920	
	Estonia		1866		1866		1953
	Finland	1847			1900		
	Iceland		1871				
	Latvia	1924		1924			
	Lithuania	1961					
	Norway	1900		1900			
	Sweden	1860		1860			
Iberia	Portugal	1931		1931			
	Spain	1965

Nordic and Baltic Countries - sunshine duration

Denmark

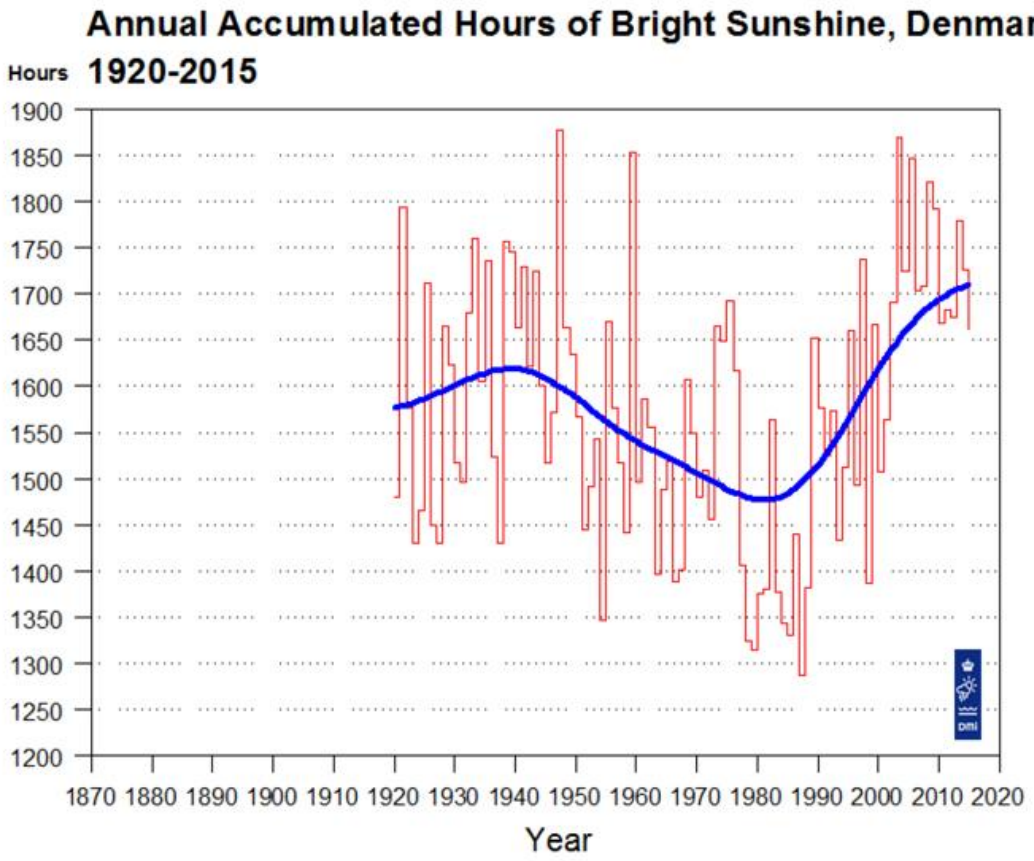

Figure 5.52: Time series of annual sunshine duration in hours for Denmark (Diagram as provided by the NHMS)

Note: DMI observed since 2002 the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. It should also be noted that all values before 2002 are adjusted in the best way possible ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990.
http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf

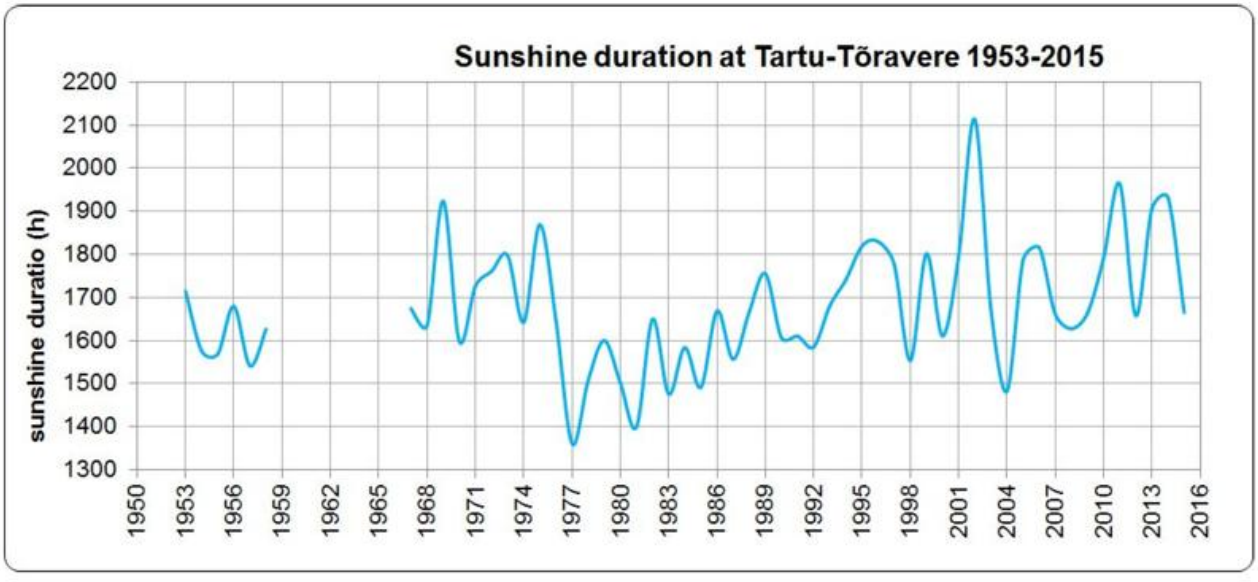

Figure 5.53: Time series of annual sunshine duration in hours for Estonia (station Tartu-Töravere, diagram as provided by the NHMS)

5.4. Other climate related variables

Sea level of the Baltic Sea (Poland)

Sea level

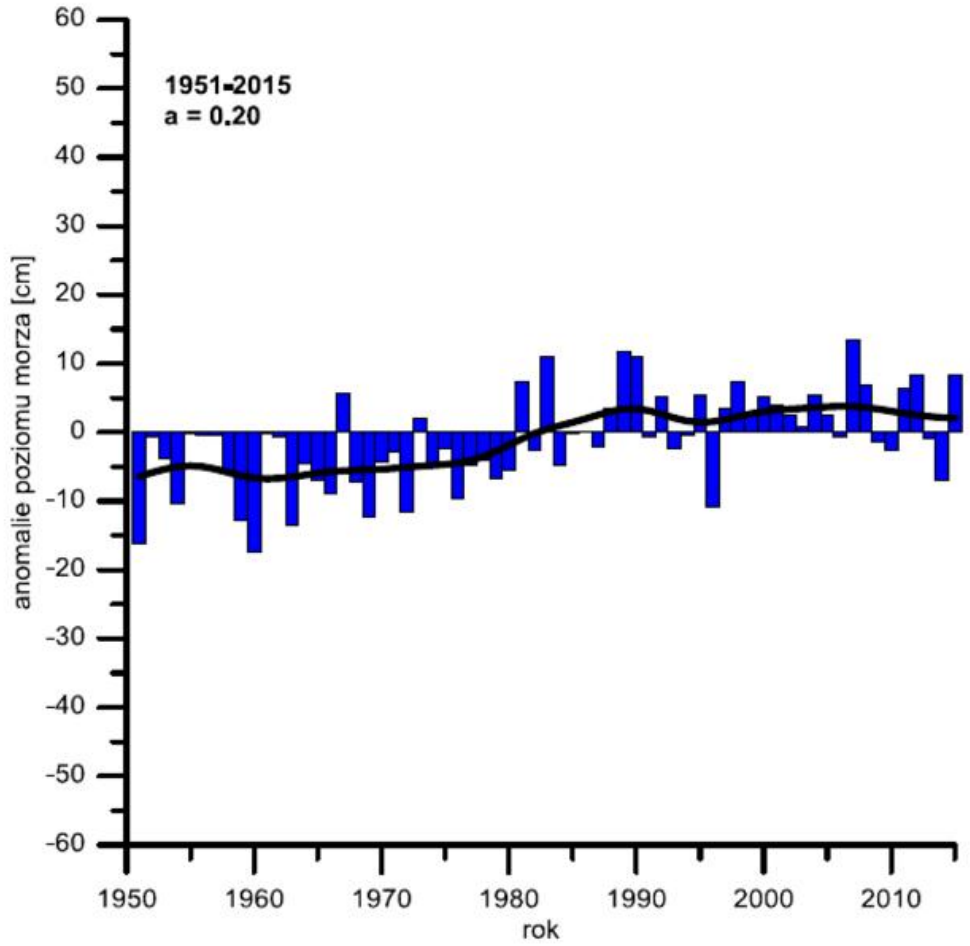

Figure 5.54: Mean annual sea level anomalies of the Baltic Sea in Władysławowo (1951-2015) in relation to the reference 1971-2000, smoothed by 10-years Gaussian filter (black line) and the value of the linear trend (cm/year, diagram as provided by the NHMS).

Recent decrease in the Caspian Sea level and consequences for the Kazakhstan's coastal zone

According to the observation data, the Caspian sea level has recently experienced wide fluctuations. During the last 35 years two periods can be singled out: 1) a sharp rise in the period 1978-1995; 2) a gradual fall in the period 1996-2015 (Figure 5.55). In 2015 the mean annual sea level was minus 27.96 m in the Baltic System of Elevations (BS), which is a decline of 1.34 m during the last twenty years.

This drop of the sea level can mainly be assigned to a change in the Volga River discharge, which results from the decrease in the precipitation over its catchment area due to climate change. In average for the period 1978-2005 the runoff of the Volga River during the first half of a year (phase of spring raising water and a high level of runoff) amounted to 165 km^3. But in 2015 it was less than 103 km^3.

Sea level reduced by more than 1 meter led to a change in the position of Caspian coastline in Kazakhstan's territory. In this Caspian region the sea bottom and the surrounding surface land have a very small slope, and even small changes in the sea level can lead to significant coastal flooding or drainage.

It should be noted that decrease in the sea level to a mark lower than minus 28.00 m will have a lot of negative consequences for its ecosystem. The shallowing of ducts, reduction of spawning areas, increase in salinization will lead to reduction of the areas of fish fodder grounds, and consequently to decrease in a fish crop, and as a result, to the problems for the fishing enterprises. Also decrease in sea level can significantly complicate economic activity in shallow coastal zones, especially as it concerns port constructions and shipping business.

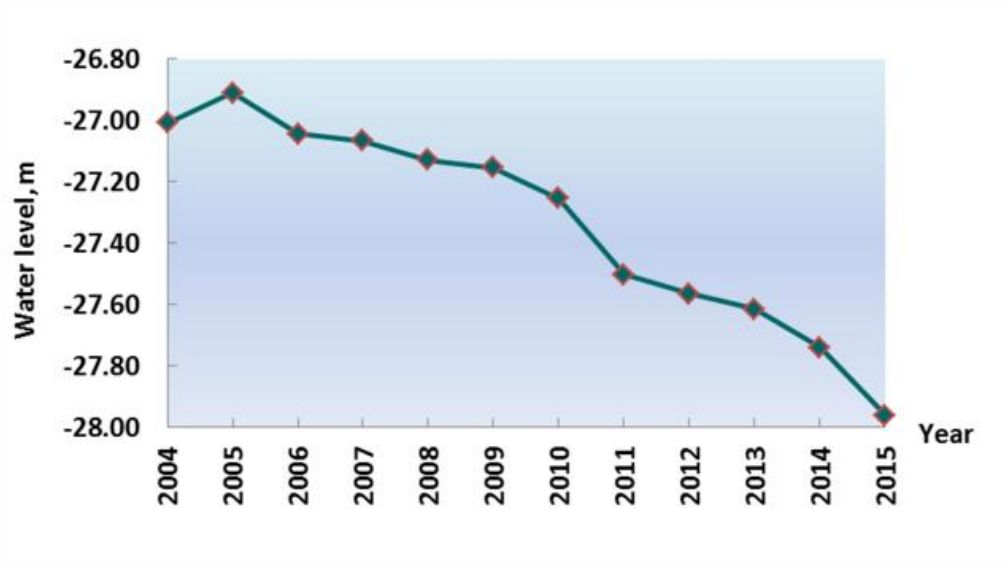

Figure 5.55: Annual Caspian Sea level from in situ observations during period 2004-2015 (m, Baltic System of Elevations)

6. Annex: Monthly and annual tables

Table 6.1: Statistical values of **annual** mean temperature and total precipitation and their deviations from the long term mean (1961-1990, CLIMAT Data) for several stations of the RA VI region.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 50 Members) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Global Climate and the State of the Climate published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ among the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes 4 parts: the annual, seasonal and monthly survey of the climate state in 2016 as well as contributions of the NMHSs to the long-term variability of selected parameters up to 2016 (section 5).

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collecting Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), operated by the Deutscher Wetterdienst
- Sunshine: CLIMAT data.
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

Sub-regional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC).

The following sub-regions are used in this Bulletin:

Central and western Europe (14 countries): *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, and United Kingdom*

Nordic and Baltic Countries (9 countries): *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, and Sweden*

Iberia (2 countries): *Portugal, and Spain*

Mediterranean, Italian and Balkan Peninsula (12 countries): *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia, and Turkey*

Eastern Europe (5 countries): *Belarus, European Russia, Moldova, Romania, and Ukraine*

Middle East (9 countries): *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, and Western Kazakhstan*

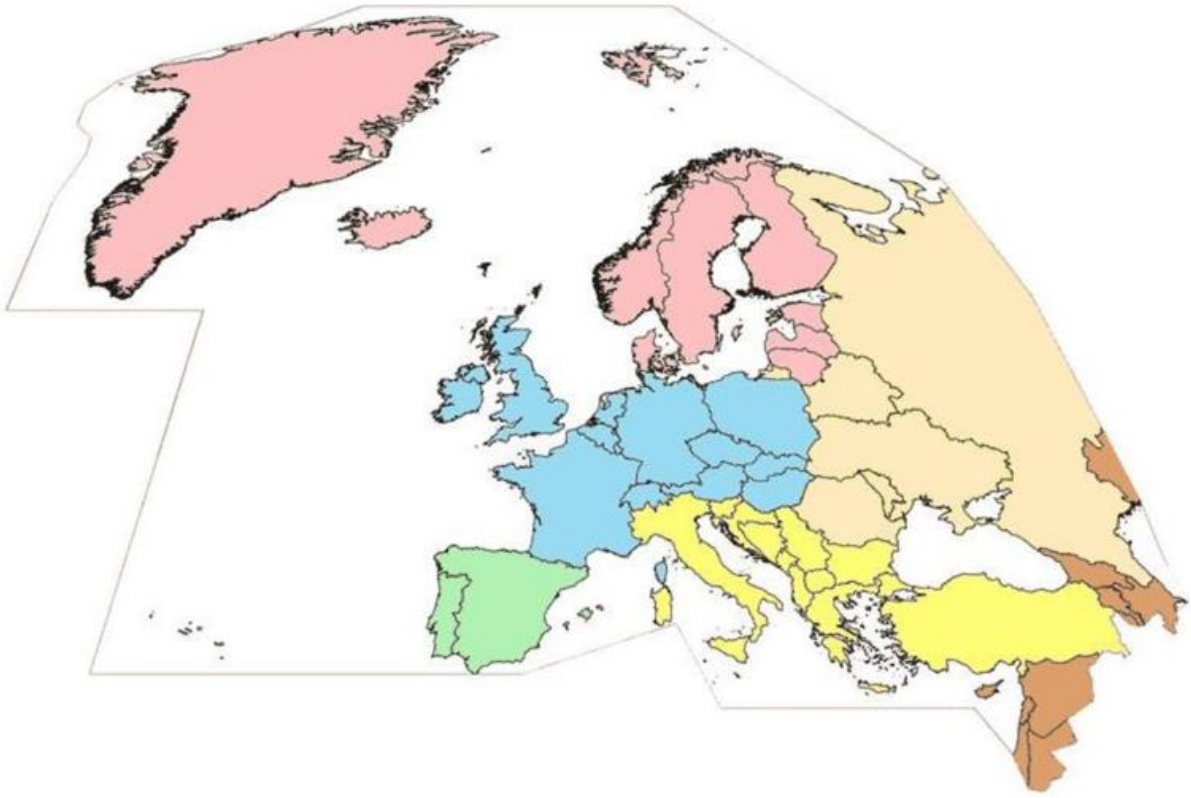

Figure 1.1: Definition of the 6 sub-regions used in this bulletin.

Box 1

Notable anomalies and events 2016

Anomalies

Temperature

- Record breaking year in many European countries (see Table 2.1).
- Cold spell at the end of April 2016 in Central Europe and the Balkans with significant agricultural damage.
- July to September extremely warm period in Portugal.
- Heat waves in Israel in April 2016.
- Several heat waves over central and southern Europe from June to September (The highest temperatures of 45.4°C was recorded at Cordoba, southern Spain, on 6 September).

Precipitation

- For Scotland, Wales and Northern Ireland the wettest, or equal-wettest winter on record.
- Extreme precipitation with flash floods in Central Europe during May and June.
- France noticed its driest July and August on record.
- Up to 600% of rain in Eastern Europe in October.

Sunshine Duration

- Central Europe experienced a very sunny December with more than 200% of normal.

Other Anomalies

- Early melting of Greenland's ice sheets due to record high temperatures.
- New pressure record of 1050.7 hPa in October 2016 in Sweden.

Events:

- Several winter storm series passed Europe from January to March 2016.
- Intense thunderstorms, extreme precipitation and floods in Central Europe in May and June 2016.

2. Annual survey

The climate of 2016 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2.5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2016 and anomalies related mainly to the normal period 1961-1990 of the selected essential climate variables: sea level pressure, surface air temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for individual countries. Long-term trends in temperature and precipitation indices offers section 2.2.

More detailed insight into the long-term variability of temperature, precipitation and also some other parameters from the individual countries are presented in section 5.

2.1. Annual averages and anomalies of selected essential climate variables

2.1.1. Sea level pressure

Generally, mean annual sea level pressure distribution in 2016 over the WMO Region VI is dominated by a low pressure trough in the polar area with the Icelandic low that extended from southern Greenland to Iceland. The second pressure system, the subtropical high pressure belt, extended from the centre over the Azores (Azores high) across southern and central Europe to European Russia.

In 2016 the mean sea surface pressure differs to some extent from the long-term mean with a reduced pressure especially in a region over and surrounding Greenland with anomalies of -2 to -4 hPa. South-eastern Europe also shows below normal anomalies. Higher pressure anomalies of up to +2 hPa occurred over southern and central Europe as can be seen from Figure 2.1 (right; normal period 1961-1990) indicating a stronger than normal NAO.

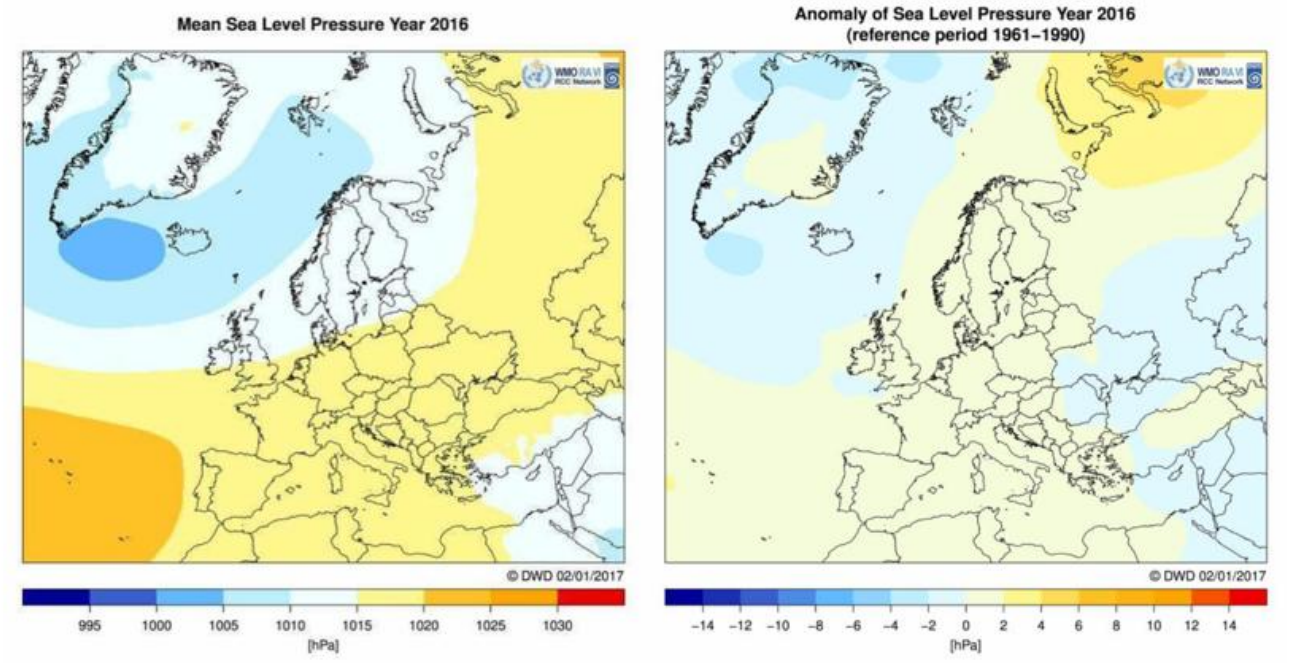

Figure 2.1: Annual mean of sea level pressure (left) and anomalies (right) for the year 2016 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.2. Temperature

In the entire European region (35°–75°N, 25°W–45°E) the year 2016 was warmer than normal with an anomaly of +0.58°C (base period 1981-2010) according to the E-OBS dataset. Many of the European countries reported new records (Table 2.1).

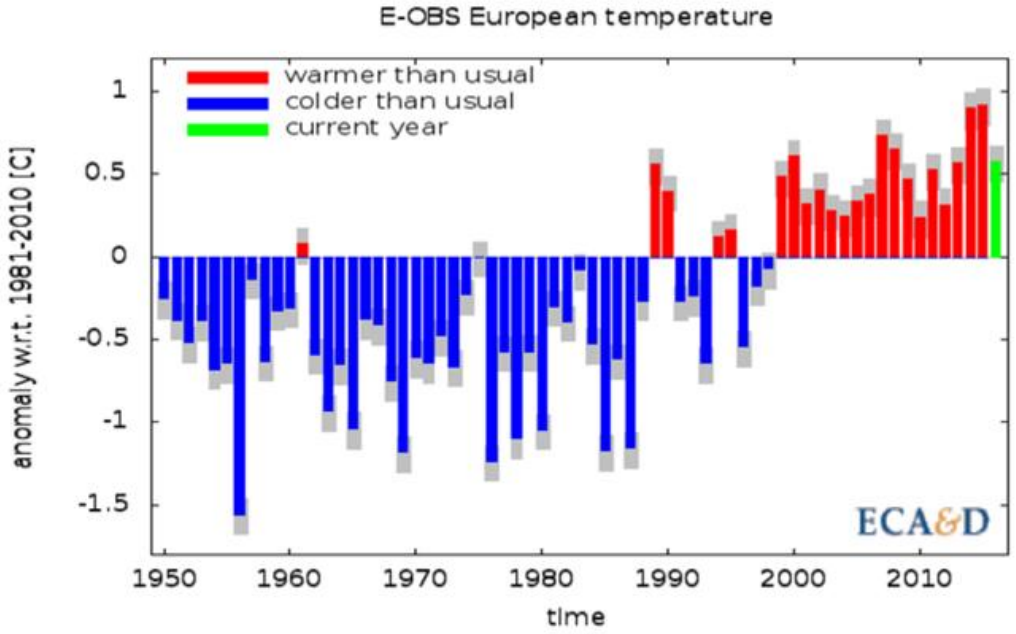

Figure 2.2: Annual temperature anomalies 1950-2016 for Europe (land area; 35°N-75°N and 25°W-45°E, reference period 1981–2010; based on the E-OBS dataset, van der Schrier et al. 2013). Grey bars indicate uncertainty of the value. (Source: Royal National Meteorological Institute Netherlands, KNMI).

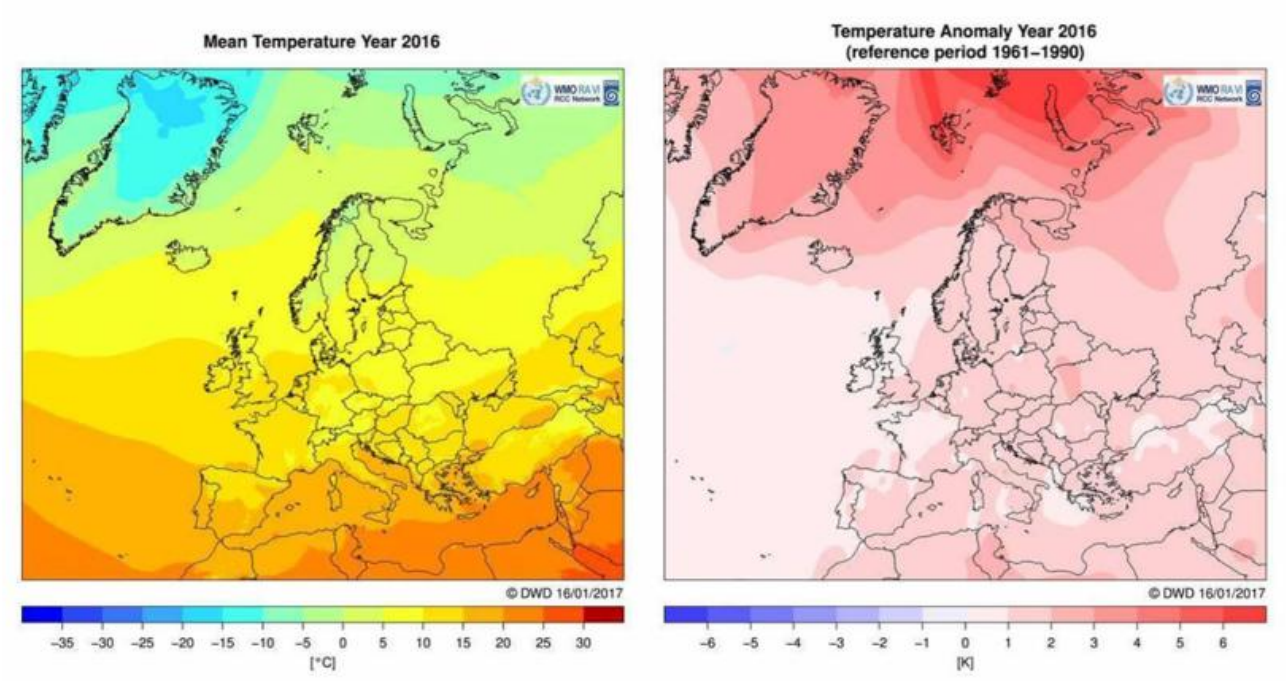

Figure 2.3: Mean annual temperature in °C (left) and anomalies (right) for 2016. (reference period 1961-1990, source: http://www.dwd.de/rcc-cm).

The highest annual anomaly of 2.71°C referred to 1961-1990 was observed in the sub-region Nordic and Baltic countries followed by Eastern Europe (1.89°C), the Middle East (1.46°C), Mediterranean, Italian and Balkan Peninsula (1.37°C) and Central and Western Europe (1.22°C). The sub-region Iberia showed the lowest anomalies of 1.21°C (Table 3.2). Most of the months in 2016 were warmer than normal (1961-1990) with remarkably consistent deviations of more than +4°C especially in northern Europe (cf. section 3.1.2 and 4.2).

The global annual land and ocean surface temperature for 2016 increased also to a record high 0.45°–0.56°C above the 1981–2010 average (Blunden und Arndt 2017) or 0.83°C ± 0.1 0°C warmer than the average for the 1961–1990 reference period (WMO 2017).

Table 2.1: Rank statistics and anomalies of annual temperature in 2016 from some participant countries as reported by the National Meteorological and Hydrological Services (NMHSs).

Country	Rank of annual temperature in 2016	start of time series	Anomaly in °C	Reference period

United Kingdom	below 10	1910	0.5	1981-2010

2.1.3. Precipitation

The annual precipitation amount was close to normal over many parts of continental Europe except for northern Scandinavia and parts of eastern and south-eastern Europe, where positive anomalies above 10 mm/month were recorded. Parts of Iberia, France, Italy, southern Scandinavia and southern Turkey showed drier conditions with anomalies below -10 mm/month and also values below the 0.1 percentile indicating a drought situation. The annual figures of the year 2016 give only rough hints of the regions with outstanding precipitation events. Detailed descriptions can be found in the seasonal (3.1.3) and monthly survey (4.3).

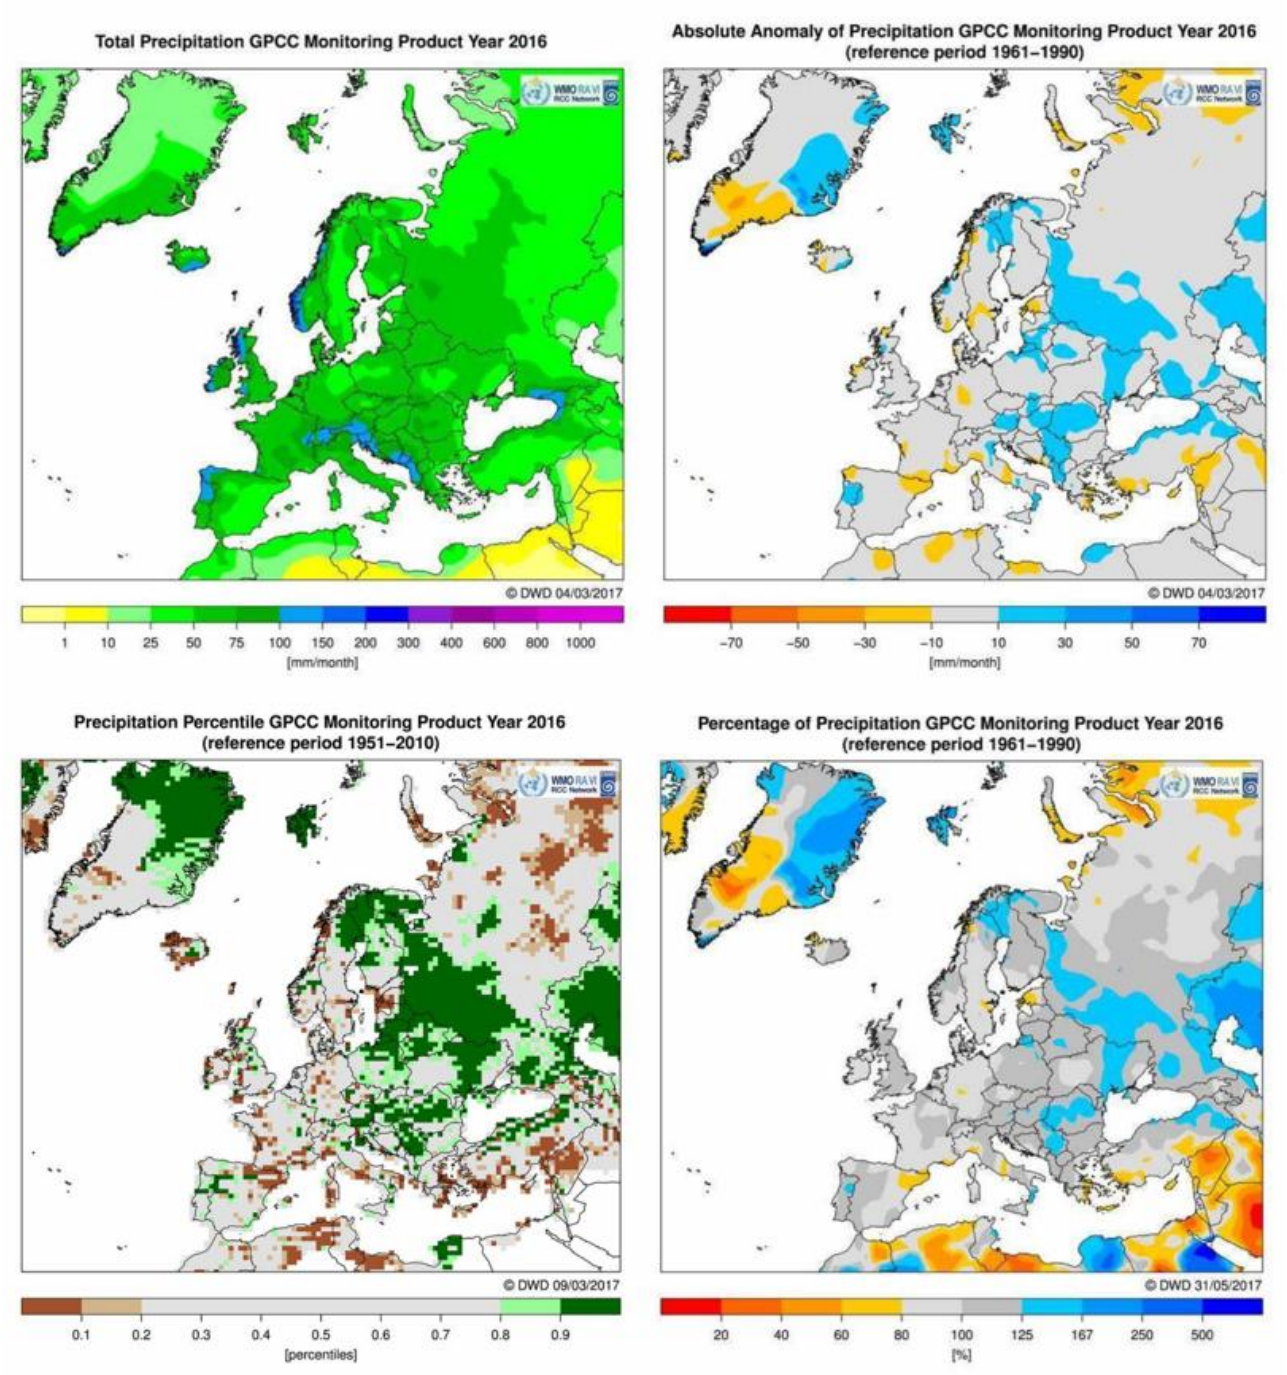

Figure 2.4: Total precipitation (left, top), anomalies (right, top) in mm/month, percentiles (left, bottom) and percentage of precipitation in % (right, bottom) for 2016. (reference period 1961-1990; source: http://www.dwd.de/rcc-cm).

2.1.4. Annual extreme values of temperature and precipitation

In this section an overview is given for the temperature spread and the extreme precipitation for each country. Absolute annual extreme values for 2016 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5 consecutive days with precipitation for each country in the WMO Region VI are given in Figure 2.5.

The spatial pattern of extreme temperature corresponds roughly to those of the temperature anomalies of 2016. The highest maximum temperatures (above 40°C) occurred primarily in sub-regions Middle East, Mediterranean, Italian, France and Iberian Peninsula. Maximum temperatures higher than 35°C were reported from most of the countries in central and eastern Europe, but also from the Balkans. The one-day precipitation totals (RX1) of more than 150 mm for individual countries are documented in several sub-regions; the highest value occurred in Slovenia (236 mm/day). Highest total precipitation on 5 consecutive days (RX5) (above 300 mm) was measured in Slovenia (429 mm), Italy (366 mm, only synoptic stations), Portugal (355 mm), France (354 mm), Turkey (334 mm) followed by Spain (321 mm).

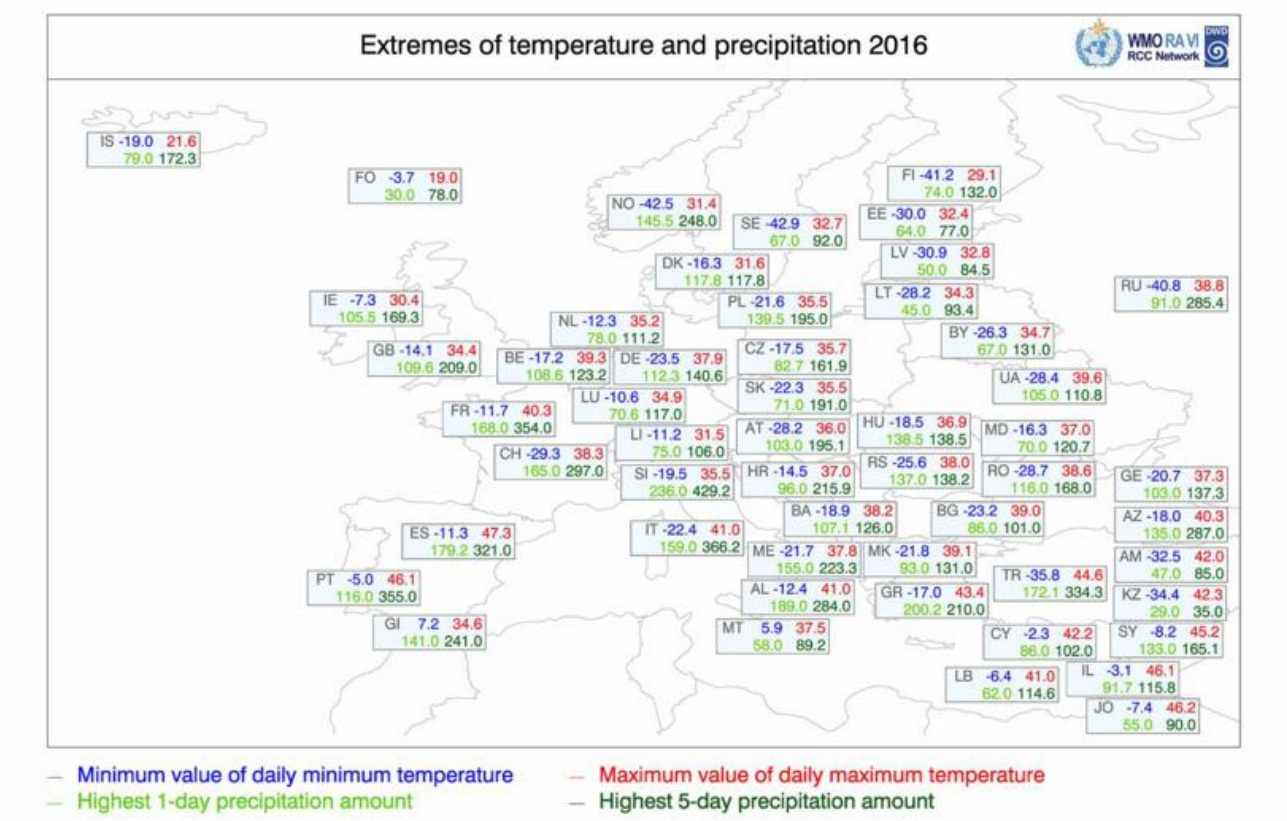

Figure 2.5: Annual extreme values for each country in 2016: first row: Internet country code, lowest daily minimum temperature (in °C, blue) and highest daily maximum temperature (in °C, red); second row: maximum daily precipitation totals (in mm, light green) and maximum 5-daily consecutive precipitation totals (in mm, dark green).

Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their Internet country codes. (Source: http://www.dwd.de/rcc-cm)

2.1.5. Sunshine duration

As expected, the annual sum of sunshine duration in 2016 showed from the south to the north generally gradual decreasing values. More than normal sunshine hours have been primarily noted in western, Central and southern Europe except in Portugal. Finland and north-eastern Europe had a sunshine deficit.

2016 was a sunny year in the Netherlands with a country-average of 1881 hours of sunshine, compared to the long time average of 1643 hours. June was the only month of the year with below average number of sunshine hours. The coastal station of Den Helder in the northwestern part of the Netherlands was the sunniest place. 2046 hours were recorded, almost 300 hours more than normal.

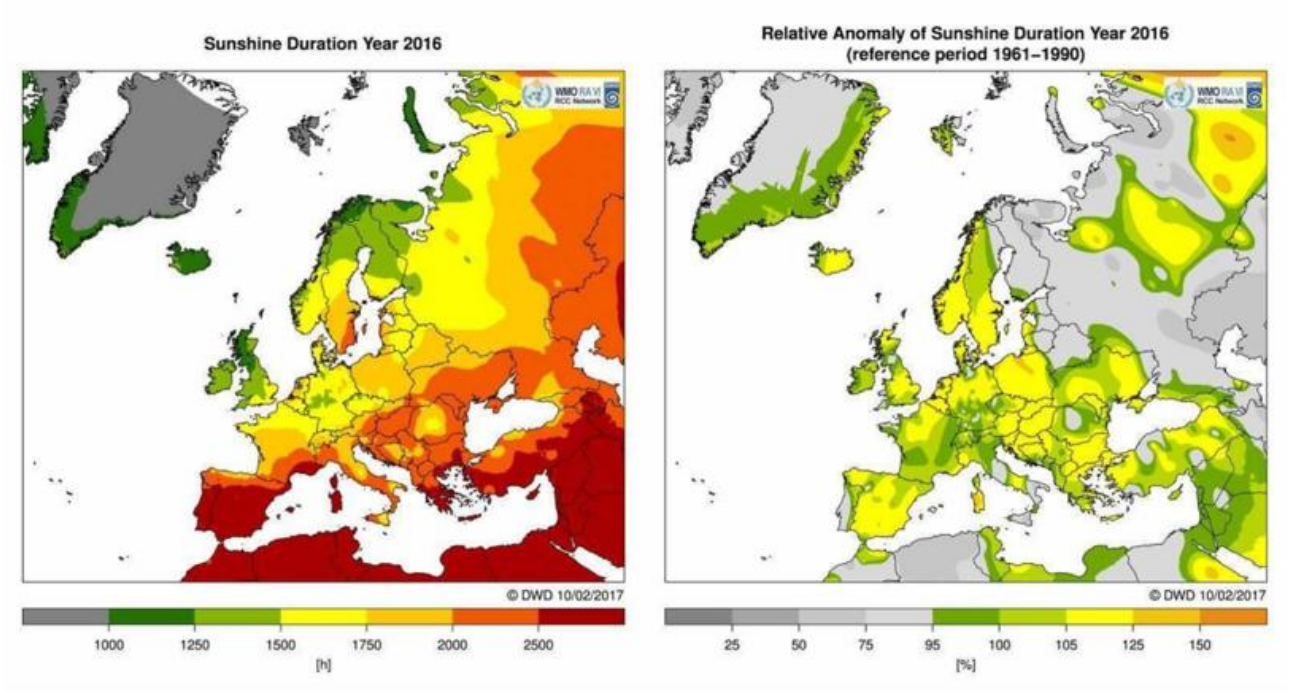

Figure 2.6: Annual sum of sunshine duration (left) and relative anomalies (right) for the year 2016 in hours with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.6. Drought situation

The drought index (SPI) in 2016 differed only slightly from its normal values. The anomalies in southern Europe, northern Germany and southern Sweden were slightly below normal while most of Europe was slightly wetter. In these areas annual precipitation was above normal linked with floods.

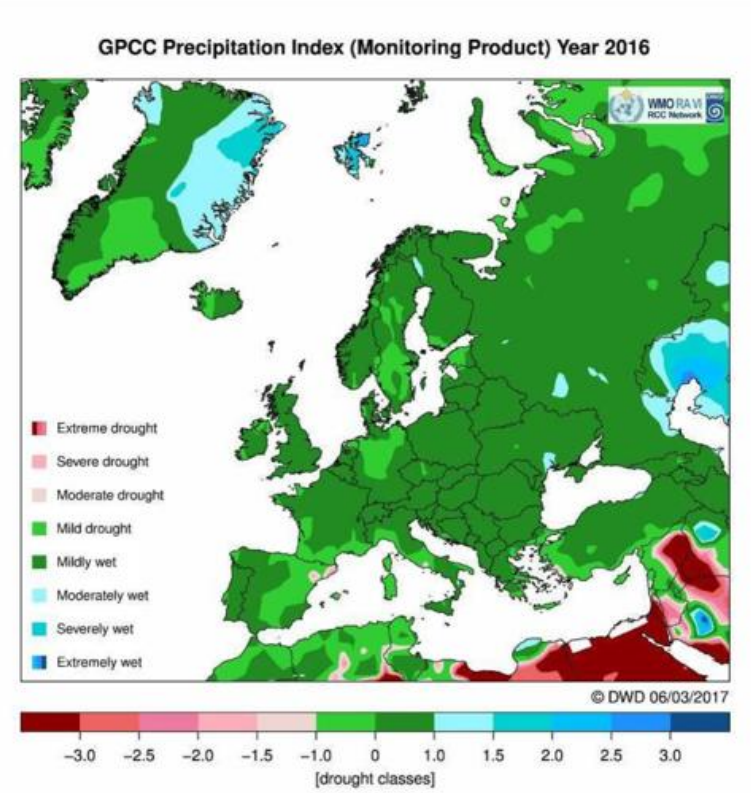

Figure 2.7: Annual modified Standardized Precipitation Index (DWD-SPI) for the year 2016 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.7. Snow cover

The snow-season 2015/2016 (September 2015 – August 2016) was warmer than normal and consequently in many low land areas in western and southern Europe no snow occurred at all. Apart from mountain areas, in central Europe partly occasional snow fall events occurred in November. As expected, towards northern and eastern Europe snow cover duration was longer and ended in April and May. In Switzerland, towards the end of the year, a stable zone of high pressure with a record lack of precipitation led to a significant lack of snow in mountains.

Last snow in low land areas over central Europe and Balkans occurred during last decade of April 2016 due to a cold wave in these regions. On April 28th the air temperature in Austria dropped below 0°C and in the lowlands of Carinthia and Styria a fresh snow cover was observed. In Klagenfurt (450 m) the depth of the snow cover was 15 cm. In these regions such an amount of fresh snow at the end of April was measured at last about 30 years ago.

Due to the high temperature in January in Austria the amount of days with snow cover below an elevation of 1000 m were 50 % lower than the average. However, the amount of fresh snow in the alpine regions north of the alpine ridge was 30 to 40 % above the average.

At the end of January 2016 there was a snow layer in Romanian mountains of up to 117 cm (Bâlea Lake), in southern Wallachia and northern Dobrudja (less than 8 cm). At the end of March, snow

layer was still present in high mountain areas of Romania, above 2000 m.a.s.l. measuring up to 155–160 cm.

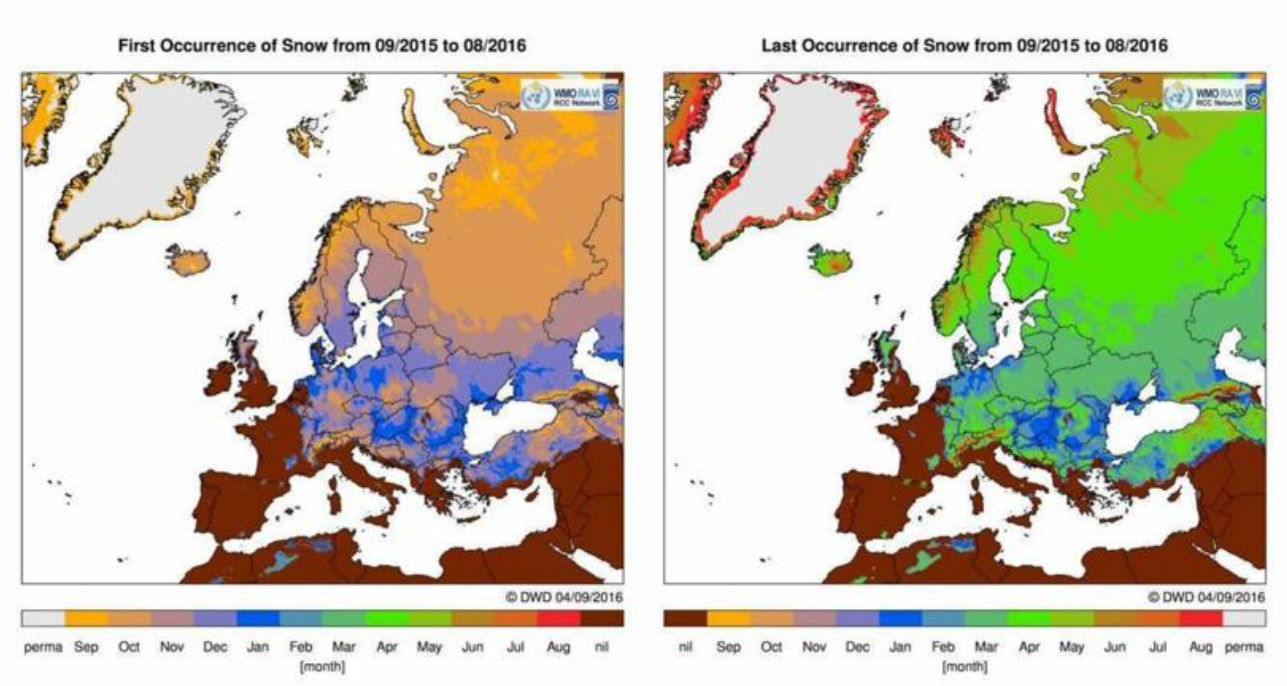

Figure 2.8: First occurrence of snow (left) and last occurrence of snow (right) during the snow-season 2015/2016. (Source: http://www.dwd.de/rcc-cm).

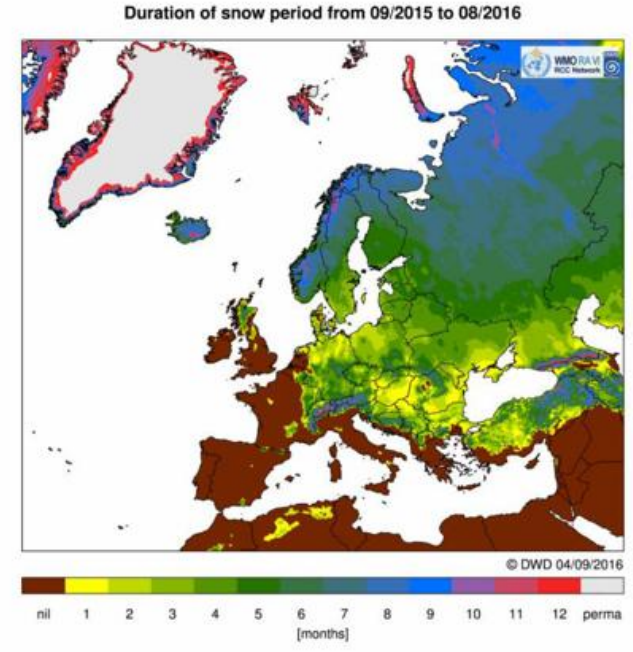

Figure 2.9: Duration of snow cover in the snow-season 2015/2016. (Source: http://www.dwd.de/rcc-cm).

2.2. Trends of temperature and precipitation indices 1951-2016

This section presents trends for selected temperature and precipitation indices for the period 1951-2016.

In northern, north-western and eastern Europe most stations showed an increase in the annual number of wet days (RR1) for the last 66 years while in southern Europe a decreasing trend prevailed. The decreasing and increasing trend at neighbouring stations, however, indicate inhomogeneities in the time series. The number of warm and wet days (WW) increased over whole Europe with exception of Greece. The annual numbers of summer days (SU) increased in Central and southern Europe while in north-western and northern Europe no significant changes were observed. Annual numbers of tropical nights (TR) showed increasing tendencies in the south-east part of Region VI while the north-western part noted no significant changes.

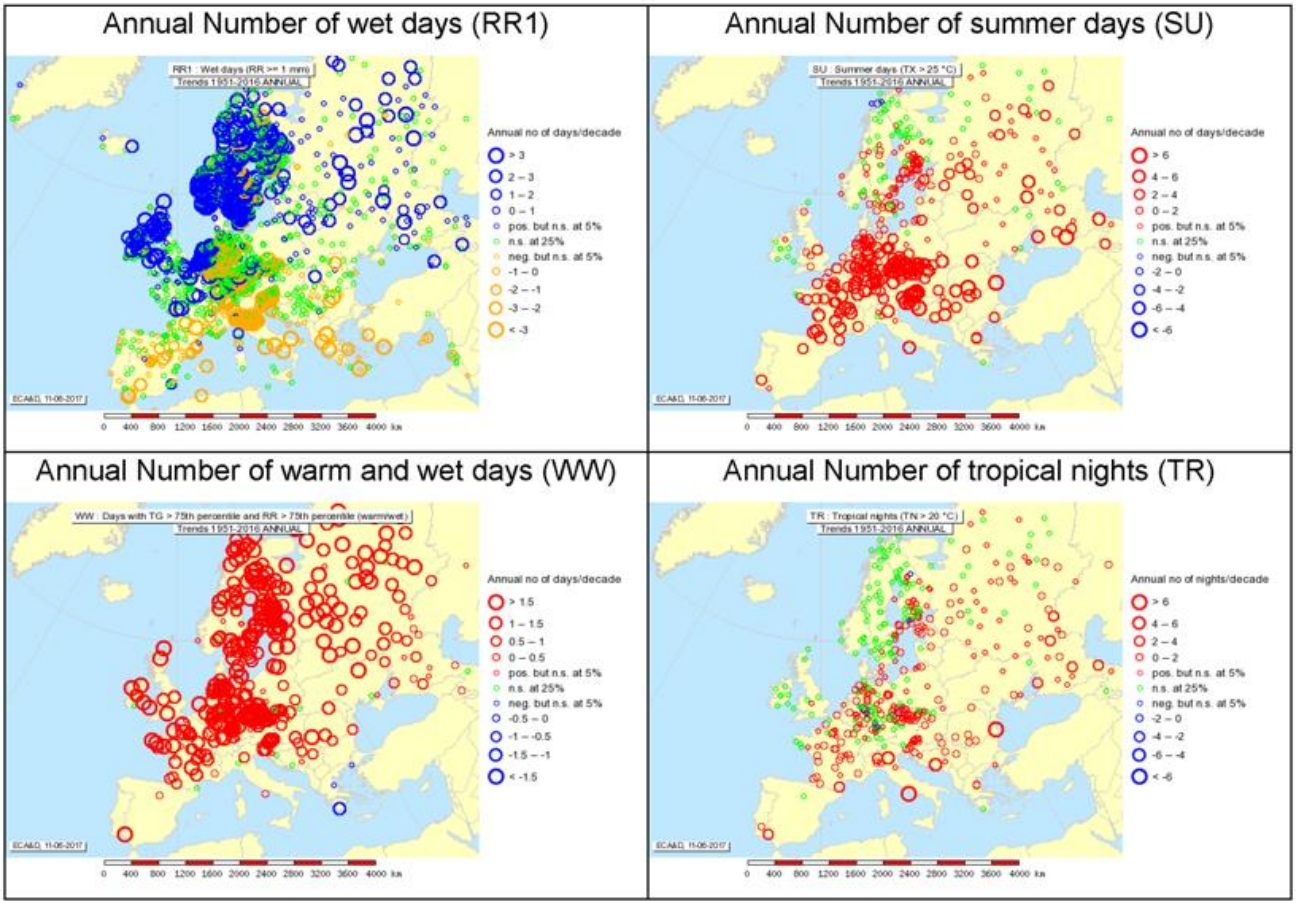

Figure 2.10: Trends of Selected Climate Indices 1951 to 2016 (Source: ECA&D, http://www.ecad.eu).

Legend of Figure 2.10:

1. **RR1, Number of wet days**: count of days where RR (precipitation > 1 mm)
   Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally effected.
2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) ≥ 25°C
3. **WW, Number of warm and wet days:** days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile
4. **TR, Number of tropical nights**: count of days where TN ≥ 20°C

2.3. Socio-economic impacts of extreme climate or weather events

North of Belgium (Flanders) was recognized as disaster area due to continuous and intense rainfall between the 27th of May and the 26th of June. Three persons were surprised by flash floods and died. The total amount of the damages was estimated at € 248.000.000 (90 % of the damages caused by flooding were agricultural damages).

27.-30.5.2016: Flash floods with severe storms: Germany, France and Netherlands; 8 people died. Overall loss was summed up by Munich Re to 1,400 Million US$. Dozens of houses, businesses, public buildings were damaged or destroyed. Bridges were destroyed, highways, roads, railways were blocked. Automobile plant flooded, production suspended. Crops were damaged or destroyed.

30.5.-8.6.2016: Floods in France; 5 people died. Overall loss was summed up by Munich Re to 2,400 Million US$. Rivers (Seine, Loing, Yonne) burst their banks. Numerous towns and villages were flooded. Thousands of buildings and businesses were damaged. Power outages, 25,000 customers without electricity. Farmland, vineyards were destroyed.

31.5.-7.6.2016: Flash floods and severe storms: Germany, Belgium and Switzerland; 9 people died Overall loss was summed up by Munich Re to 2,200 Million US$. Torrential rain, rivers burst their banks. Thousands of houses were damaged. Basements, underground car parks were flooded. 9,000 customers were without electricity.

22.-24.6.2016: Hailstorm Netherlands and Germany. Overall loss was summed up by Munich Re to 1,900 Million US$. Hundreds of vehicles were damaged. Solar panels were destroyed. Damage to greenhouses and agriculture.

The whole island of Madeira (Portugal) was stricken by forest fires on the 8th to 10th of August, with major impact in urban areas around Funchal. Economic losses were estimated to about 60 million Euros. Hundreds of homeless persons, thousands of displaced persons and a lot of damages (buildings, infrastructures, …)

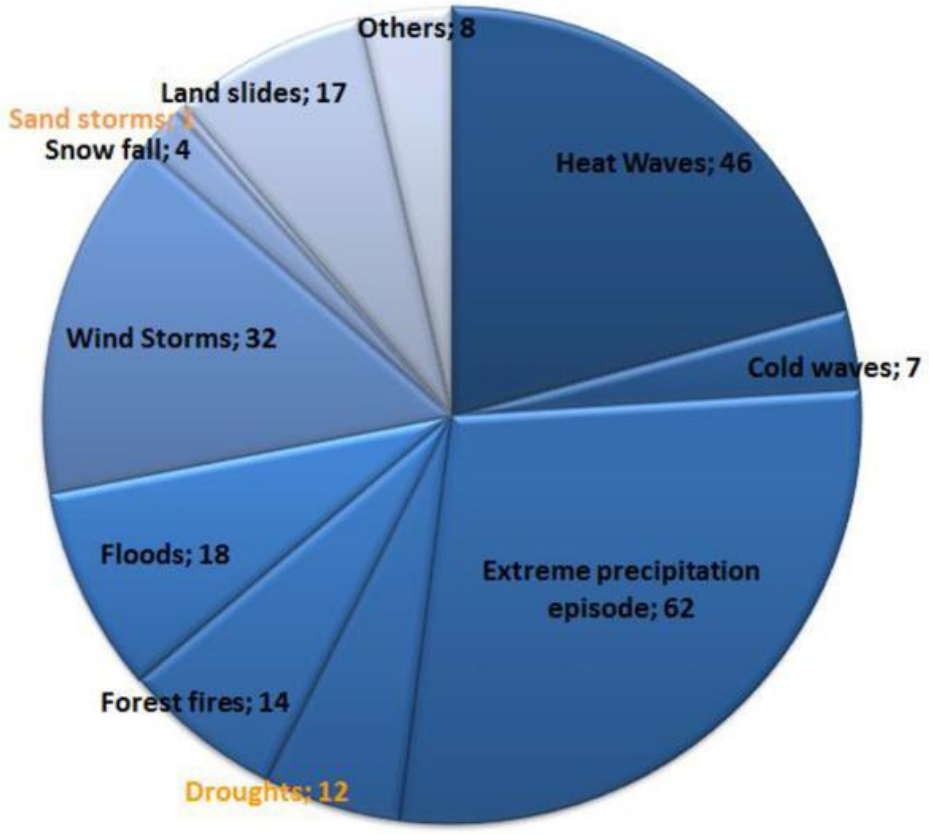

Figure 2.11: Observed extreme weather or climate events in 2016 based on 29 reports from NMHSs (total events reported for 2016: 221).

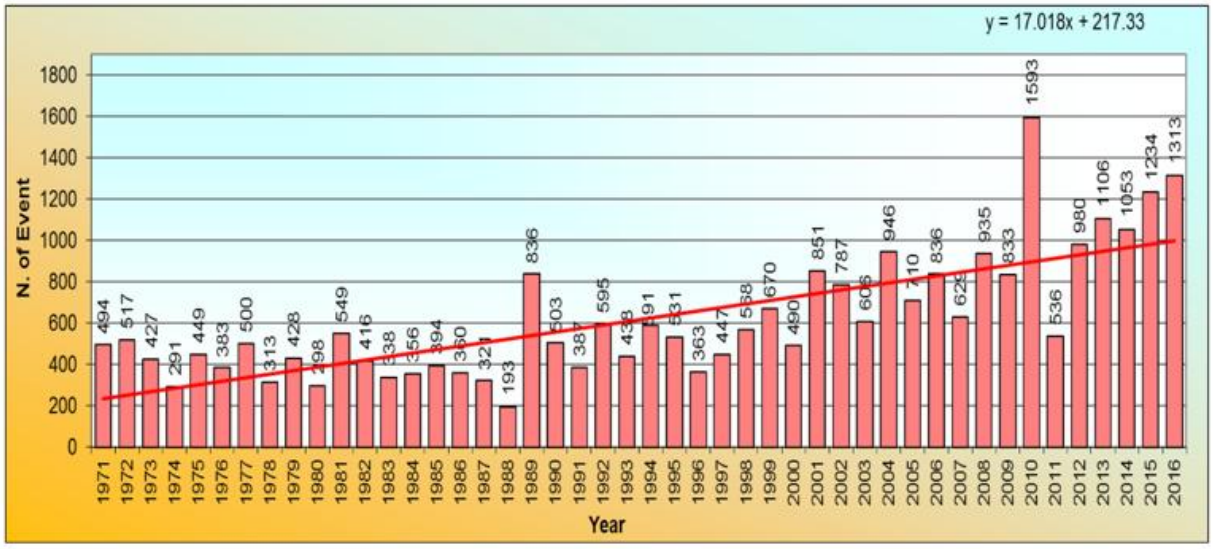

Figure 2.12: Annual count of extreme events per station occurred in Turkey from 1971-2016 (Diagram as provided by the NHMS).

The number of extreme events in Turkey in 2016 reached 1,313. (Figure 2.12). There is an increasing trend in extreme events (+17.0 events/year), possibly partly also due to improved observations and communication means.

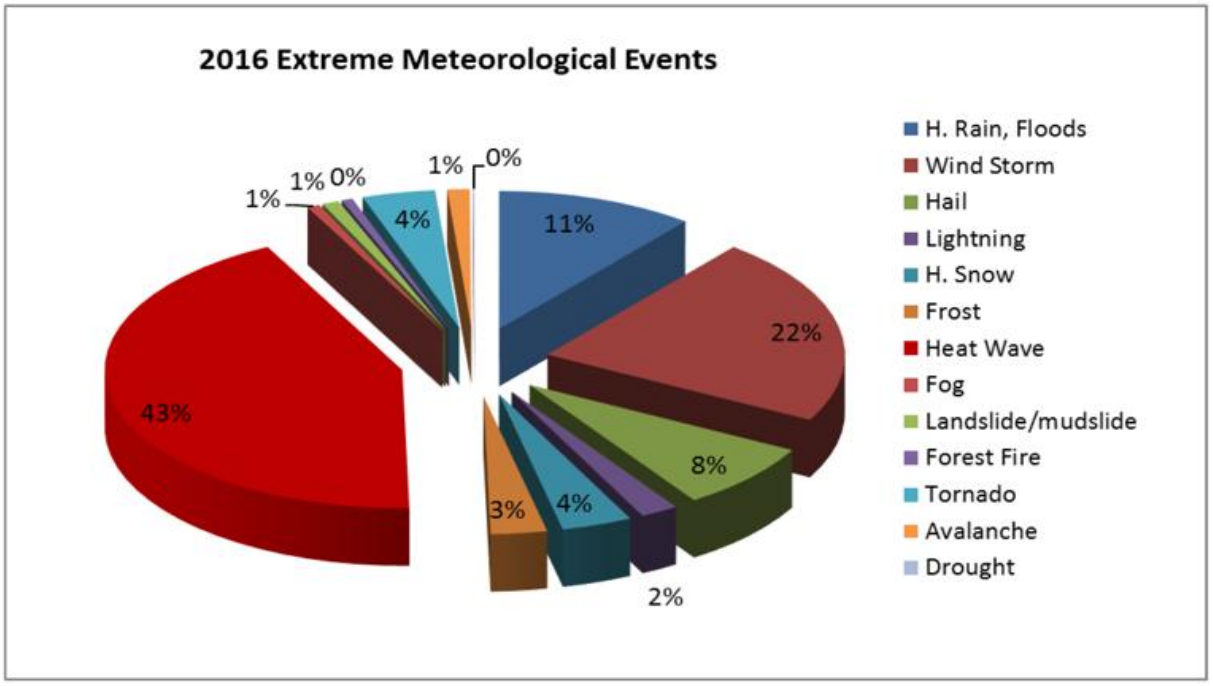

Figure 2.13: Distribution of extreme events occurred in Turkey in 2016 (Diagram as provided by the NHMS).

During 2016 most hazardous extreme events in Turkey were heat waves (43%), wind storms (22%), heavy rain/floods (11%), hail (8%), heavy snow (4%), tornadoes (4%), avalanches (3%), frost (3%) and lightning (2%). Also in addition 8 forest fires occurred in 2016.

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2016 and anomalies related mainly to the normal period 1961-1990 of the following selected essential climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. Seasonal averages and anomalies of selected climate variables

3.1.1. Sea level pressure and circulation indices

Pressure distribution in **winter 2015/2016** showed similar patterns for mean and anomalies. On seasonal average the Icelandic low showed a core pressure below 995 hPa and the Azores high a core pressure above 1025 hPa. This indicates that the two pressure centres were intensified compared to the reference period, but shifted to the south and associated with several storms in northern Europe. This explained, together with negative pressure anomalies in north-eastern Europe the high value of the East Atlantic Pattern (EA) of 2.0 (in December 2015 its value was 3.14). Ireland noted six named storms with season's highest gust of 37 m/s reported at both Belmullet, Co Mayo on December 23rd (Storm Eva) and Sherkin Island, Co Cork on February 8th (Storm Imogen).

In **spring 2016** both circulation centres, the Icelandic low and Azores high, were not well distinct. The Icelandic low with a centre pressure below 1010 hPa (or anomalies of more than +2 hPa related to 1961-1990) was located west of Iceland. The Azores high was less intense with negative anomalies.

Table 3.1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference.

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2015/2016	0.99	2.00	-0.54	-0.38	-1.46	-0.01
Spring 2016	-0.01	0.63	-0.74	0.24	-0.73	-0.27
Summer 2016	-1.36	1.44	-2.05	-0.70	0.37	0.29
Autumn 2016	0.46	1.15	-0.71	0.00	-2.34	-0.58

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In **summer 2016** both circulation centres were shifted southwards. Therefore high pressure over Greenland could develop with anomalies of more than 6 hPa. Most of Europe showed above normal pressure anomalies coincided with above normal sunshine duration and below normal cloud cover leading to several heat waves. Only northern and western Europe showed below normal anomalies. Above normal pressure anomalies ranged from the Azores high to northern Russia. The anomalous high pressure over Greenland extended to Iceland and north-western Scandinavia with anomalies of more than 8 hPa. The negative anomalies over central North Atlantic showed values below -2 hPa.

The calculated CPC- EA/WR (East Atlantic/West Russia Pattern) index with -3.30 for August 2016 was very extreme. Only once in the past 66 years a lower index value was calculated in March 1970 with -4.17. This negative index indicates higher precipitation over northern Russia.

The circulation pattern in **autumn 2016** was marked by a well-developed Icelandic low with its centre west of Iceland (below 1000 hPa). The anomalies around Greenland reached values below -4 hPa. The Azores-High was also well developed together with a second high over Russia and Kazakhstan with a core pressure above 1020 hPa. The centre of above normal pressure anomalies was located over the Barents and Kara Sea with values above 10 hPa.

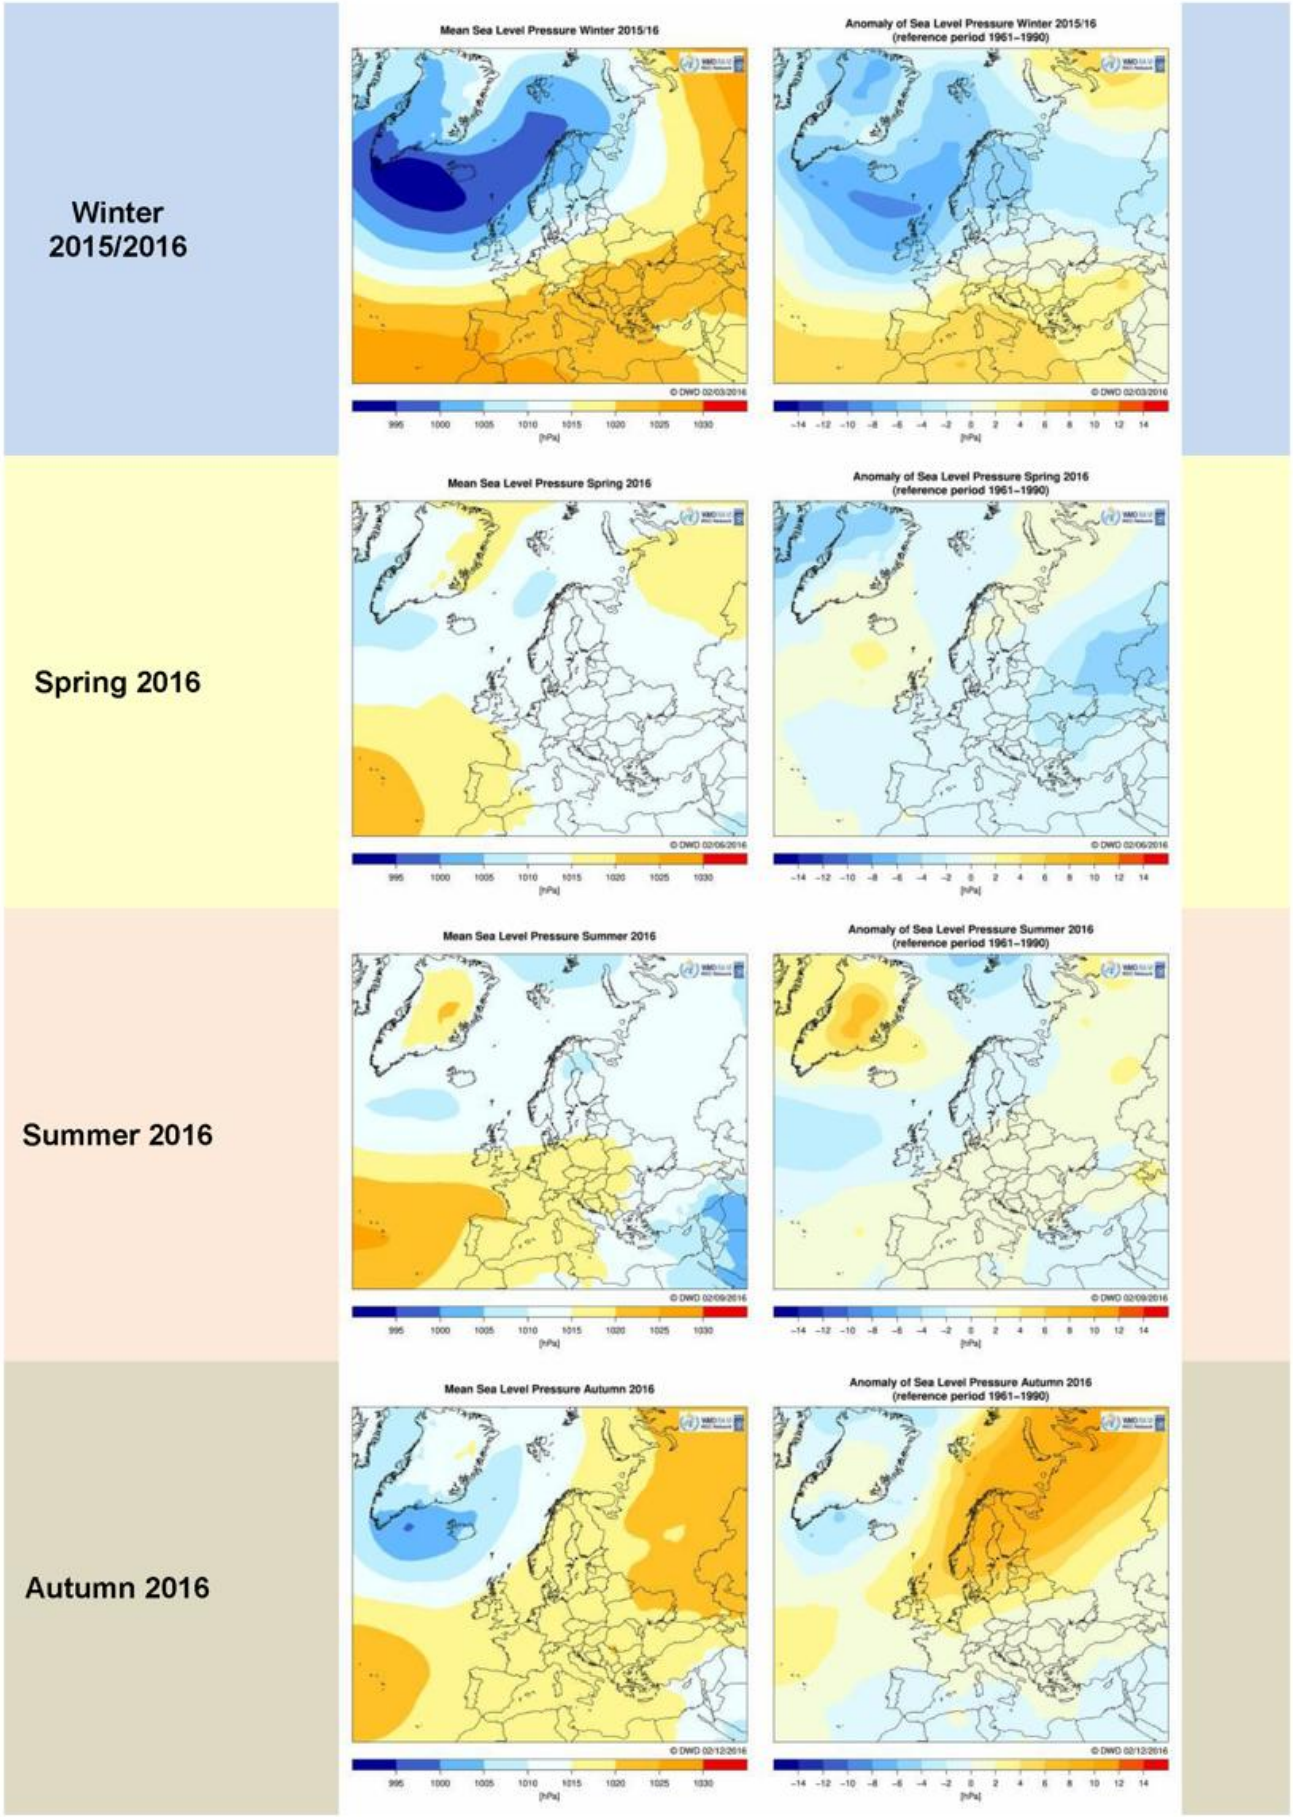

Figure 3.1: Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2015/2016, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.2. Temperature

On average for whole of WMO Region VI and sub-regions the temperature in all seasons in 2015/2016 (except Eastern Europe in autumn) was warmer than the normal period 1961-1990. In regional view, however, some differences existed (Tab. 3.2).

Table 3.2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2016 (reference period: 1961-1990)

Sub-Region	Winter 2015/2016	Spring 2016	Summer 2016	Autumn 2016	Year 2016
Central and western Europe	2.92	0.88	1.45	0.78	1.22
Nordic and Baltic countries	2.85	2.91	1.83	2.66	2.71
Iberia	1.82	0.23	2.08	1.12	1.21
Mediterranean, Italian and Balkan Peninsula	2.23	1.45	1.70	0.70	1.37
Eastern Europe	3.82	2.84	2.44	-0.05	1.89
Middle East	2.19	2.23	2.18	0.18	1.46

Temperature anomalies for **winter 2015/16** show lower than normal values only over the North Atlantic Ocean. All continental Europe showed higher than normal values. The highest positive anomalies occurred in the far North and East. For example Svalbard Lufthavn reported a temperature anomaly for winter of +9.9°C (+10.6 in February 2016) and Barentsburg +8.5°C. The observed temperatures in February in Finland were about +5°C higher than usual in many areas, in the east even 6-7°C higher than usual.

The winter season 2015/2016 was extremely warm for the whole territory of Slovakia up to +3.8°C (2.1°C-3.8°C) above normal (1961-1990). The winter in Switzerland was characterised by a temperature anomaly of +3.1°C compared to the normal values 1961–1990 and therefore the second warmest winter after the record winter 2006/2007. Above all the record warmth in December 2015 was outstanding, with a temperature anomaly of +4.6°C above normal values 1961–1990. It was more than +1°C above the previous December record from the year 1868.

Some ranks of warm winters based on web-available bulletins by NMHSs are given below:

Table 3.3: Seasonal rank statistics for winter mean temperature (2015/2016) as provided by the NMHSs.

Country	Rank	Anomaly in °C	Start of time series
Austria	2	+2.7	1767
Denmark	10	+1.7	1874
Germany	2	+2.7	1881
France	1	+2.6	1900
Hungary	6	+2.4	1901
Netherlands (station De Bilt)	2	+2.9	1706
Norway	30	+1.8	1900
Portugal	3	+1.25	1931
European Russia	3	+2.31	1939
Switzerland	2	+3.1	1864
United Kingdom	3	+1.8	1910

Spring 2016 was more than 2°C warmer in eastern and northern Europe than the reference period 1961-1990. Especially Arctic stations observed temperatures anomalies of more than +6°C. For example Svalbard Lufthavn reported a temperature anomaly for spring of 6.8°C. Only Spain and France showed normal or below-normal temperatures.

In **summer 2016** temperature anomalies for Europe were mostly positive with a maximum of more than +6°C over North-Eastern Europe. Due to higher cloud amounts Scandinavia and Western Europe showed the lowest temperature anomalies.
The temperature in Portugal in summer 2016 was after 2005 the second highest (since 1931) and climbed up to 44.8°C at station Mora on the 8th August. In Spain this summer reached the third rank (since 1956, after 2003 and 2015) with a maximum temperature of 42.3°C at Seville and Morón de la Frontera on 19th July.
During summer 2016 Swedish weather was variable. One of the most interesting features was a very warm spell in late August. Norrköping reported 32.7°C on 26 August. This was the highest temperature in Sweden during 2016 and the highest temperature ever recorded in Sweden that late in the season. Summer air temperatures in 2016 over European Russia were +2.31°C higher than the long-term average. This value ranks third in the period 1939-2016.

July to September extremely warm period in Portugal

(Contribution from IPMA, Instituto Português do Mar e da Atmosfera)

In July, the average monthly maximum and minimum air temperature values exceeded or equalled the previous highest values at some meteorological stations (Table 3.4). However, no daily maximum or minimum air temperature records were reported.

Table 3.4: Highest average monthly maximum and minimum air temperature values, July 2016

Maximum Temperature (°C)			*Minimum Temperature. (°C)*		
Meteorological station	**July 2016**	**Historical highest**	**Meteorological station**	**July 2016**	**Historical highest**
Miranda Douro (1943)	34.4	33.4 /2015	**P. Douradas (1941)**	16.9	16.8 /2006
Bragança (1941)	32.3	32.2 /2013	**Elvas (1941)**	17.8	17.5 /1946
Fundão (1959)	35.0	34.6 /2010	**Beja (1941)**	18.9	18.6 /1989
Anadia (1941)	32.4	31.6 /2010	**Faro (1966)**	16.3	15.8 /2010
Mora (1956)	36.6	35.2 /1990			
Lisboa/ I.G. (1941)	31.1	30.9 /2010			
Pegões (1941)	34.6	34.4 /1946			
Setúbal (1941)	32.8	32.1 /2010			
Alvalade (1941)	35.2	34.9 /1946			
Elvas (1941)	38.0	36.6 /2010			
Beja (1941)	35.9	35.9 / 1974			

During this month and in particular between days 14 and 19 and from 23 to 29 maximum and minimum temperature values were higher than normal daily values, being even higher than the 90th percentile.

In the second half of July there was persistence of very high daily temperature values, which only for short periods of time were interrupted.

This extremely warm weather situation continued in August (Figure 3.2). From 5th to 14th occurred a prolonged period of warm weather, daily average maximum temperature for mainland Portugal was above 31°C. On 7th and 8th the country's average surpassed 38°C, and in some regions daily temperature values greater than 43°C (Figure 3.3) were recorded.

On August 7th, historical highest values of maximum temperature were exceeded in Porto/P.R, Porto/S. Gens, Braga, Leiria and Mora. The highest value of minimum air temperature, 27.9°C, occurred in Lisbon/Geofísico on 7th and equalled previous historical maximum on 2nd of August 2003.

On August 7th and 8th, tropical nights occurred in about half of the territory, which associated with very hot or extremely hot days (maximum temperature ≥35 or 40°C) contributed to a marked and prolonged heat discomfort.

Between August 5th and 13th, there was a heat wave (duration between 8 and 9 days) in the regions of Lisbon and Setúbal (Torres Vedras/Dois Portos, Lisboa/Geofísico, Santarém/Fonte Boa, Setúbal and Alcácer do Sal), North (Braga), and Centre (Lousã and Anadia).

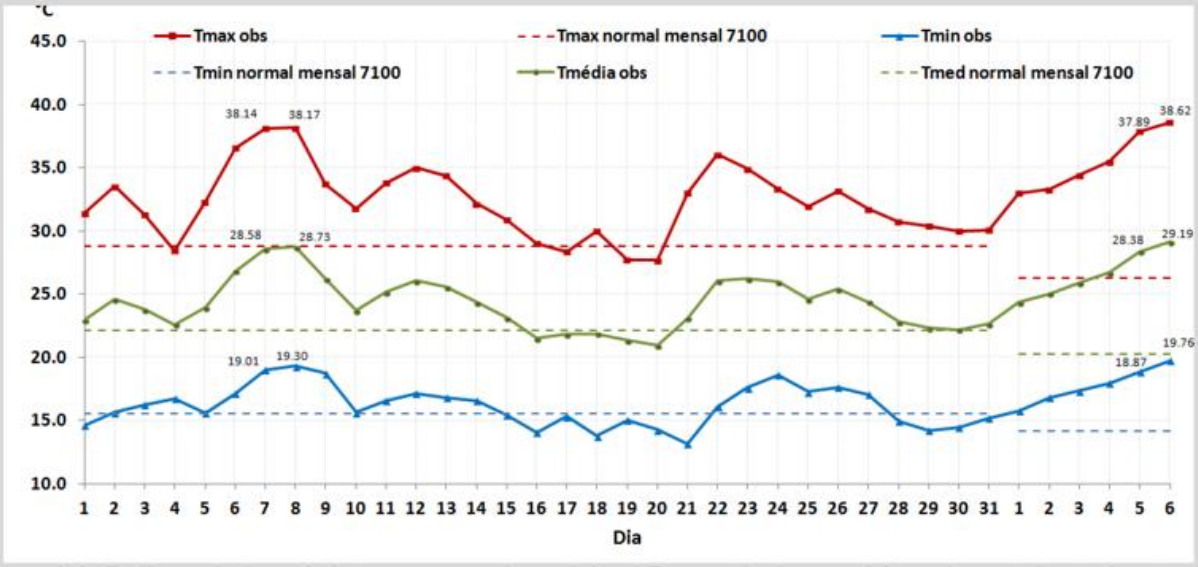

Figure 3.2: Daily evolution of air temperature in mainland Portugal, observed from August 1st to September 6th2016, (Tmax, Tmédia and Tmin respectively designate maximum, mean and minimum temperature; the dashed line represent the monthly normal 1971-2000 values).

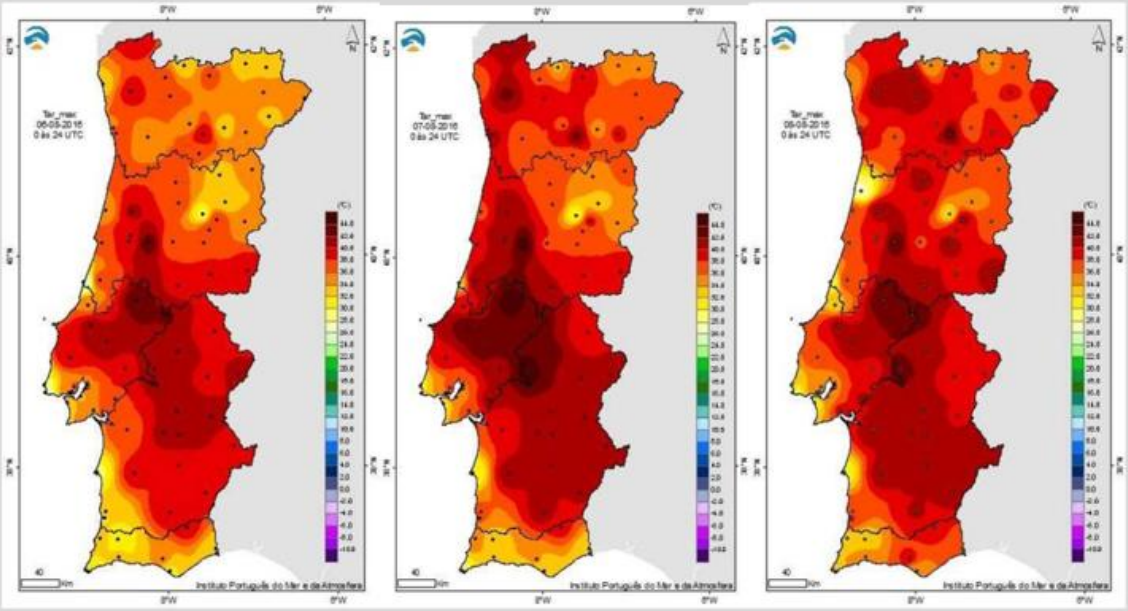

Figure 3.3: Daily maximum air temperature maps, August 6th, 7th, and 8th (left to right).

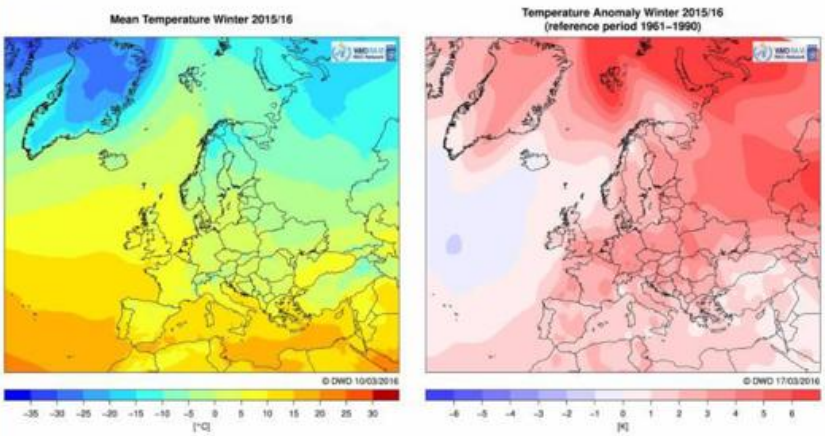
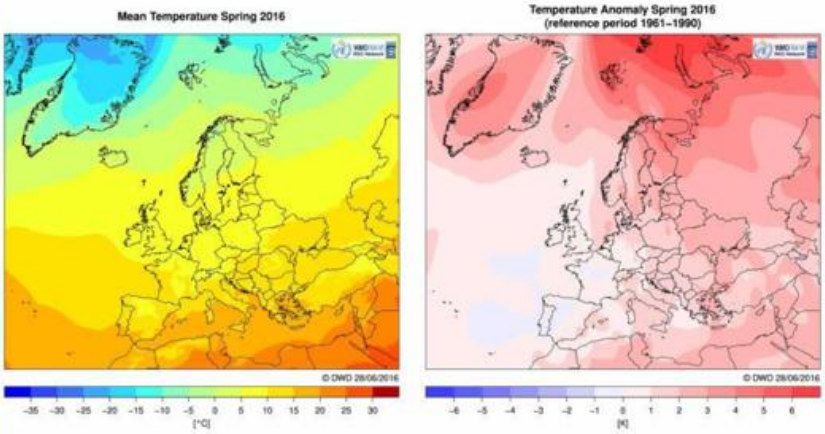
Autumn 2016 was characterized by warmer than normal conditions in nearly whole Europe. Especially the region north of Spitzbergen and Russia was partly more than +6°C warmer. Svalbard Lufthavn, for example, reported a temperature anomaly for autumn of +7.4°C and Isfjord Radio of +6.4°C. Only Eastern Europe with temperature anomalies below 0°C was colder than the reference period 1961-1990.

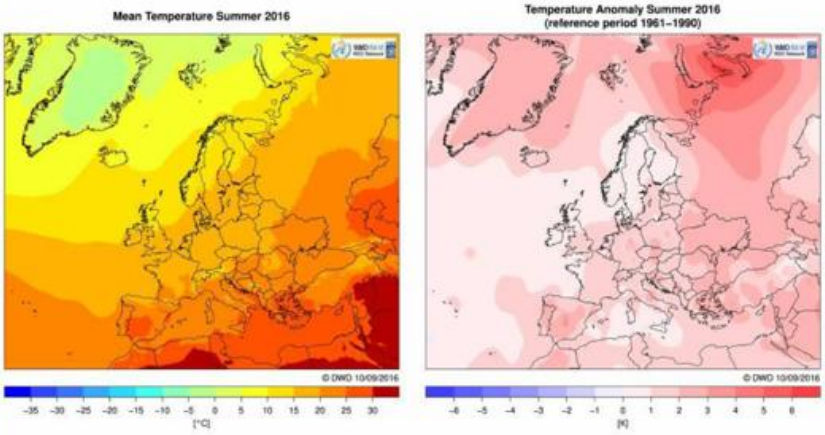
Winter 2015/2016



Spring 2016



Summer 2016



Autumn 2016

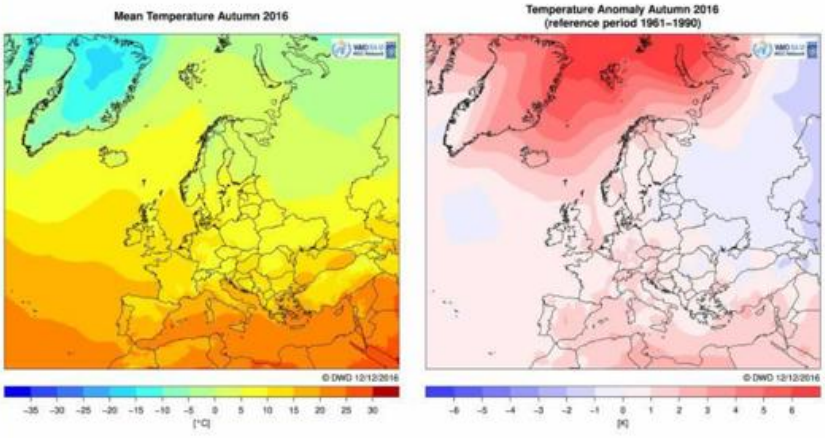


Figure 3.4: Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2015/2016, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.3. Precipitation

Precipitation anomalies in **winter 2015/16** showed higher than normal values in East Europe as well as in southern Norway, Ireland, western and northern UK, also in northern Iberia. The precipitation amount in Central Europe was around normal while southern Europe received less than normal. In the United Kingdom winter 2015/16 was second-wettest in a series from 1910, with only winter 2013/14 being wetter. In all three winter months above normal precipitation amounts were registered. For Wales, Scotland and Northern Ireland, it was the wettest or equal-wettest winter in the series. Rainfall totals for the winter varied from less than 150 mm across parts of East Anglia to more than 1000 mm across upland areas in the north and west; Capel Curig recorded over 2000 mm. Ireland reported that over half of stations measured their wettest winter on record. Seasonal percentage of the long term mean rainfall values ranged from 134% at Mace Head (total seasonal rainfall 514.2 mm) to 248% at Roche's Point, Co Cork (total seasonal rainfall 682.8 mm). The northern part of Portugal reported more than 150% of precipitation although for the whole country the amount was quite normal. On 13th February station Lamas de Mouro measured 184.2 mm/24h. In the north the winter totals amounted at station Cabril to 1054 mm. Station Faro in southern Portugal received only 87 mm as winter totals or 36% of normal. Southern Europe and the Mediterranean region showed this winter a precipitation deficit visible in the relative precipitation anomalies.

Ice conditions on the Caspian Sea in 2016

(Source: Kazakhstan Hydrological and Meteorological Service)

Winter season of 2015-2016 on the Caspian Sea was soft with an unstable ice cover in a northern shallow part of the Caspian Sea. Formation of the young shore ice begun on November 1, and primary types of ice appeared on November 9. Landfast ice along all northeast coast of the sea formed at the end of December 2015. Maximum ice thickness (17 cm) was observed at the northeast coast of the Northern Caspian Sea. At the eastern coast of the Caspian Sea, the ice cohesion was constantly changing. But no observations of ice thickness in this area were made.
In the third decade of January 2016 process of the ice formation reached the central deep-water part of the Northern Caspian Sea. Maximum ice thickness in this area reached 7 cm.
Exemption from the ice in the middle part of the Caspian Sea started on February 16, 2016. The northern coast of the Caspian Sea was completely freed from ice on March 10, 2016.
The ice season of winter 2016-2017 began on 3rd of November 2016 when the first ice phenomena were recorded. It should be noted that it was the earliest appearance of an ice cover for the last 30 years. Before 2016, the earliest date was November 6 (1988).

Precipitation anomalies for **spring 2016** showed more than normal precipitation in Eastern Europe, the Balkans, France and western Iberia. Northern and Central Europe as well as the Middle East showed some precipitation deficit. The surplus in Spain was 34% above the average coming from several episodes of intense rainfall.

Precipitation anomalies in **summer** were highest in northern Scandinavia and northern European Russia with more than 150%. Southern Italy and Greece as well as eastern Turkey were wetter than normal due to convection. Iberia, France, Germany, Ukraine, Bulgaria and western Turkey showed a precipitation deficit.
The relative anomaly for whole of Spain was 51%. In Germany violent thunderstorms brought catastrophic quantities of rain to some areas in early June. In 48 hours from 1 to 2 June, Simbach/Inn reported more than 180 mm and in a flash flood seven people died. The highest daily amount of 150.7 mm was recorded on 23 June in Groß Berßen.

Precipitation anomalies for **autumn 2016** were below normal in most of Europe and Middle East. Only Balkans, Eastern Europe and southern Italy showed wetter conditions. For Romania monthly precipitation amount for October was 103.6 mm (138% of the normal, 1981–2010). Most anomalies at weather stations exceeded 100% and anomalies were extremely large in Moldavia, where they exceeded 350%. The highest anomaly was recorded at Galaţi weather station, 802% or 294.7 mm.

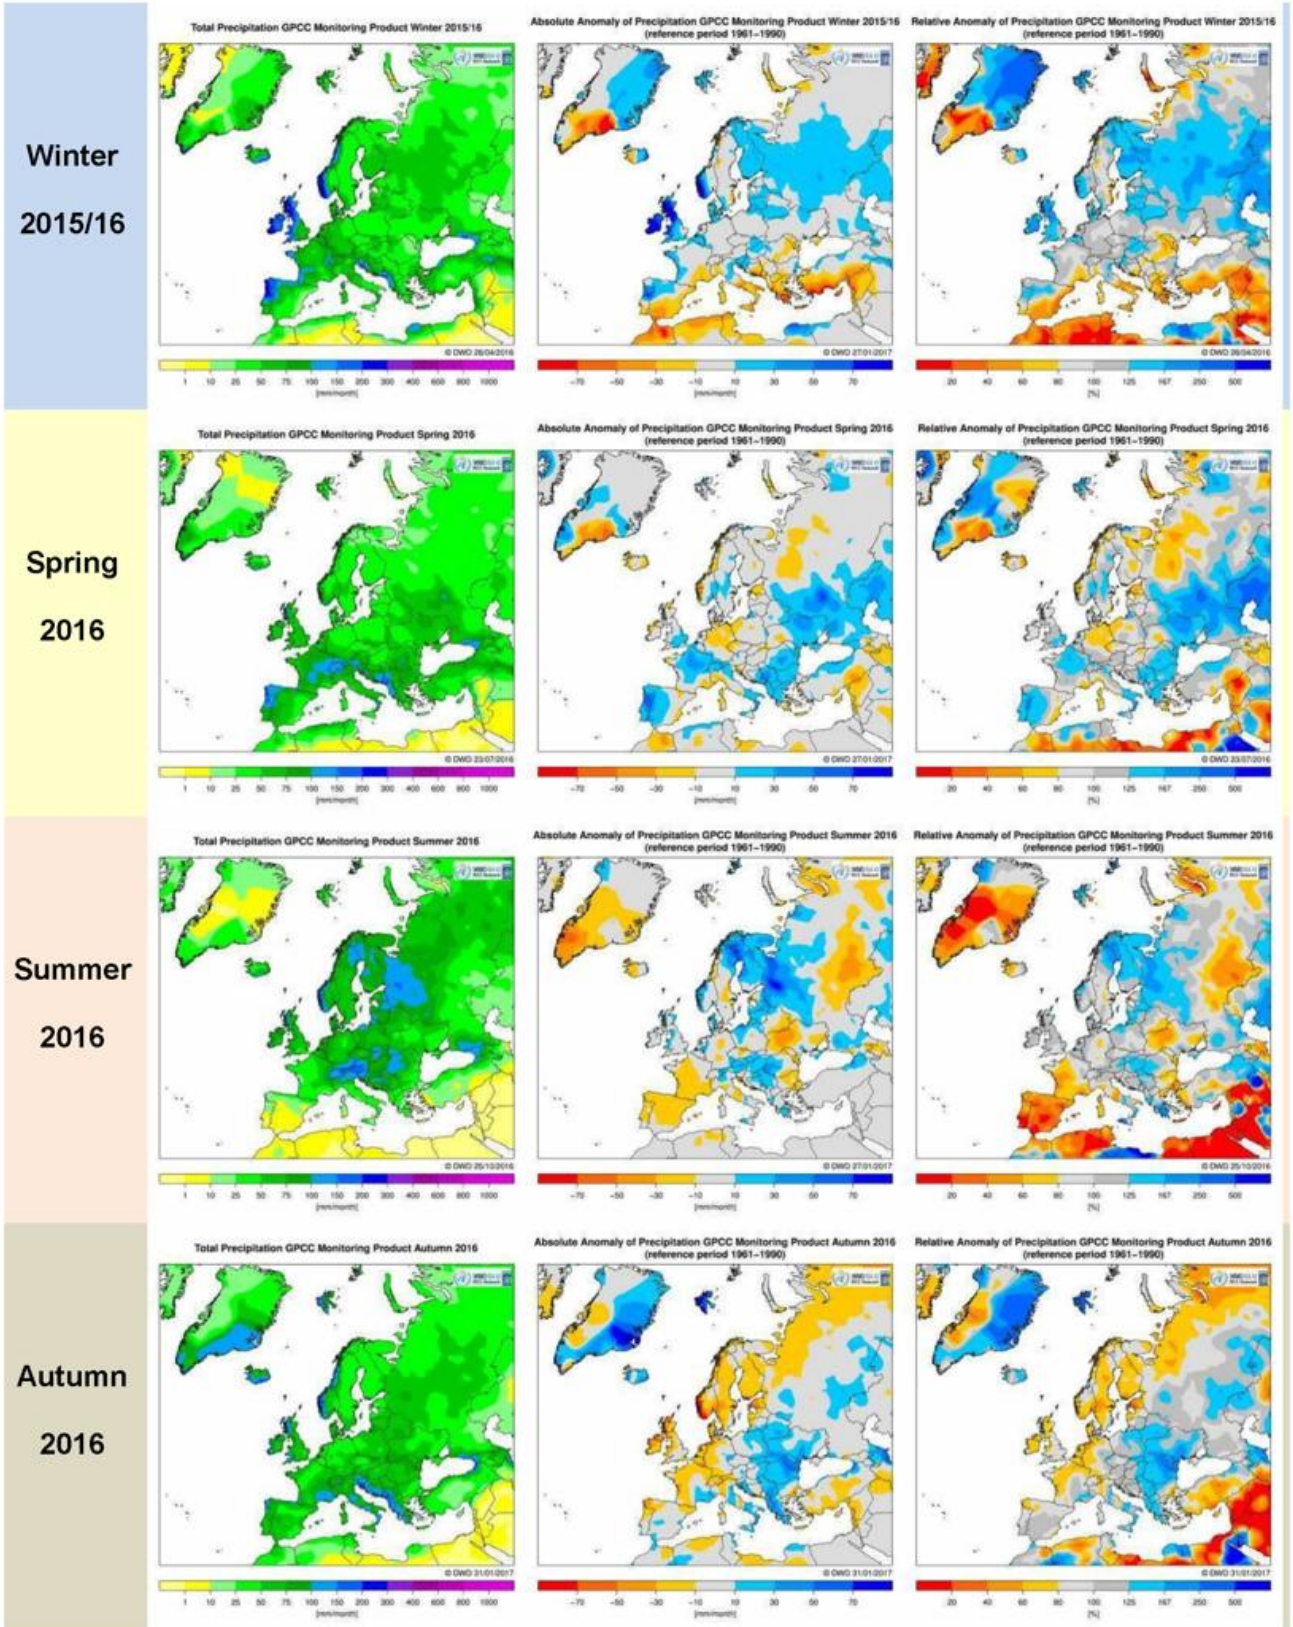

Figure 3.5: Seasonal total precipitation (left, in mm/mon), absolute anomalies (middle, in mm/mon) and relative anomalies (right, in %) in 2015/2016, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.4. Sunshine duration

Many parts of Europe received more than average sunshine in **winter 2015/16**. Only western Iberia, United Kingdom, Finland and Russia noted below normal sunshine. This coincided well with above normal cloud cover in Western Europe. South-western Europe showed less clouds and more sunshine than normal in winter 2015/16.

In **spring 2016** most of Europe registered above normal sunshine duration. Sunshine deficit is reported for southern European Russia, Romania, France and southern Germany. Poland experienced a surplus of sunshine of more than 160 hours at the coastal areas of the Baltic Sea.

Due to higher pressure in **summer 2016** over most of Europe sunshine duration anomalies were also positive with up to 125% in Iberia and Eastern Europe. Only the Baltic States, Finland, northern Scandinavia and Western Europe showed less sunshine and more cloud cover.

In **autumn 2016** most of Western Europe and Middle East registered above normal sunshine duration. Cloud cover in Eastern Europe was above normal and related to the extreme precipitation. The Netherlands' average of about 432 hours of sunshine (normal 320 hours) in autumn ends in the top ten of sunniest autumns since the beginning of observations. All three autumn months were sunnier than normal.

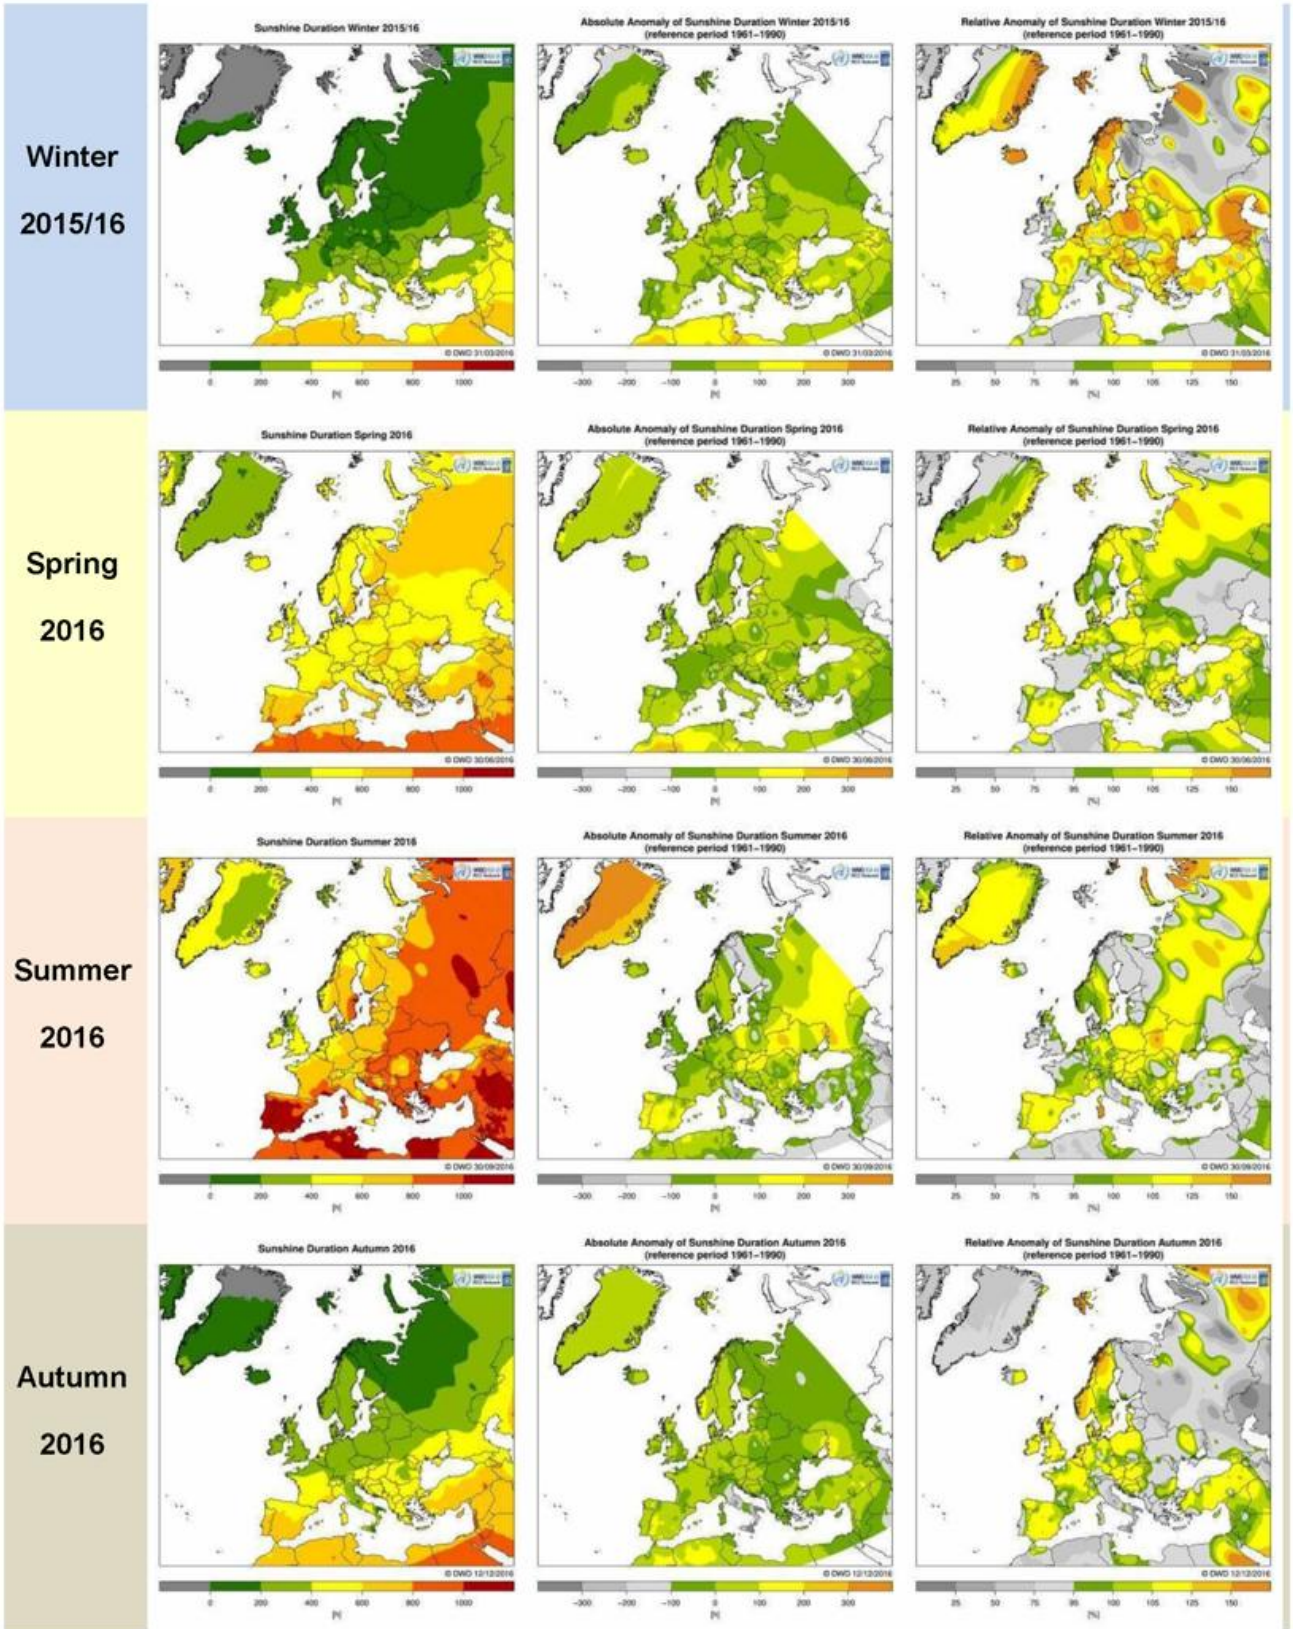

Figure 3.6: Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and relative anomalies (right, in %) in 2015/2016, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.5. Drought

Winter 2015/16 was wet in Western and Eastern Europe. In Central Europe, Mediterranean and Balkans this winter was drier than normal.

Spring 2016 was very wet and the mean precipitation over Spain was 34% higher than normal. Mean precipitation for this season exceeded its normal value in most of Spain but it was lower than normal on some southeast peninsular areas, south of Aragón, Ibiza and Canary Islands.

Summer in Spain was, as a whole, very dry, with an average precipitation value almost half of its normal value. August was the driest month. Rainfall was below normal over most of Spain.

A severe drought occurred in France from July to September when only 45% of normal rain fell. The drought was accompanied by frequent fires in southern France with burned houses and forests. With an average precipitation deficit of 60% for France August 2016 was the driest August months in the period 1959-2016, followed by 1991, 1962 and 1961.
From late summer to mid-October there was a drought in Ukraine. Northern, north-western and central regions were mostly affected by the drought. It was an abnormal phenomenon for these areas. The total rainfall during August - September amounted to 20-40% of the norm, in many parts of Zhytomyr, Vinnytsia, Kyiv, Khmelnytsky, Ternopil, Cherkasy and Kirovohrad regions the rainless period was 45-58 days. Due to drought dry soils formed extremely adverse conditions for sowing winter crops for 2017 harvest year.
In August, south-eastern and Ural regions of European Russia experienced precipitation deficit. The Orenburg, Chelyabinsk, Samara and Astrakhan Regions, as well as Kalmykia and Dagestan received less than 40% of monthly precipitation normal, which gave rise to the onset or exacerbation of drought in these regions. According to the Ministry of Agriculture, in the Orenburg Region alone, the drought-related damage was about 23.5 Mio €.

On the whole, **autumn** was dry in Spain. It began with a very dry September, with a mean precipitation 46% lower than normal, followed by a little bit less dry October, and ending with a wet November with monthly average precipitation 33% higher than normal.

October in Israel was warmer than average and dry with exception of a short significant weather event in the south. Except for some rainfall amounts at the beginning and at the end of the month, November was almost also entirely dry. The drought in Israel from October to November 2016 with rainfall amount of only 5-15% of the average for the same period is a rare event in Israel. Damage was very high especially due to wildfires and urban fires. The firefighting services had to deal with more than 1500 fires, and at least 39 of them were major ones. The largest fire occurred in Haifa, where hundreds of apartments were completely destroyed leaving 1600 people homeless. 75,000 residents, about a quarter of the city's population, were evacuated from 11 neighbourhoods. The cost of damages from the fire in Haifa was estimated at more than US$100 million.

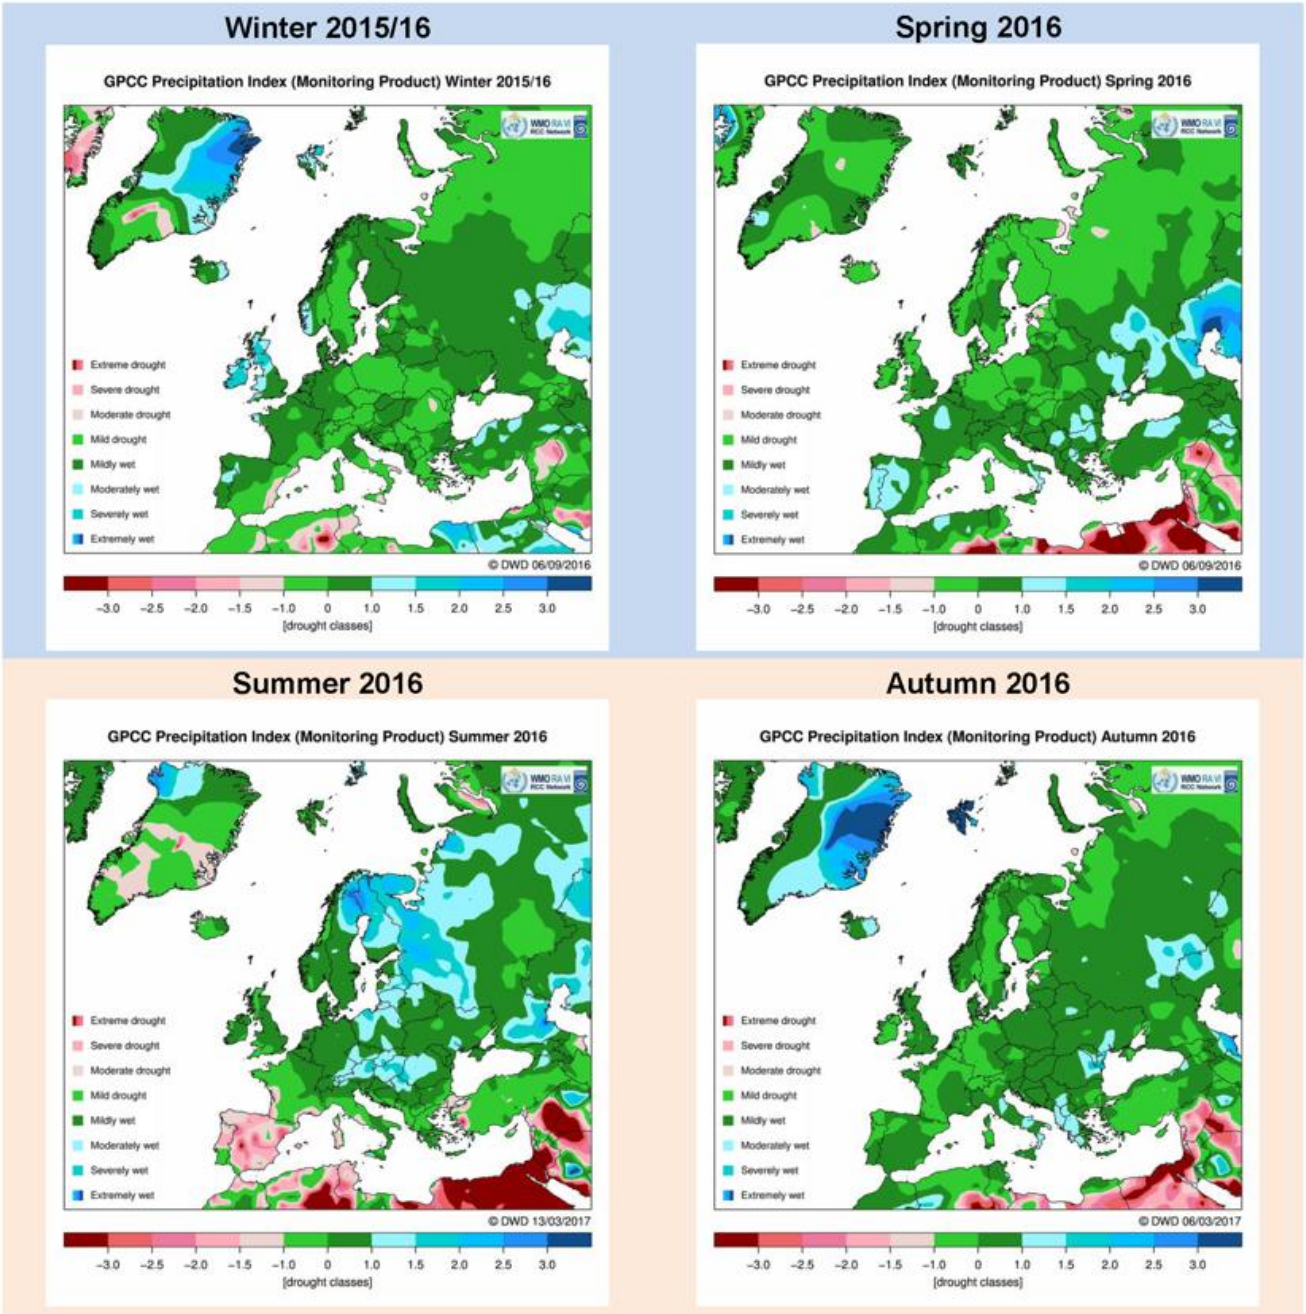

Figure 3.7: Seasonal standardized precipitation index (SPI, left, in drought classes) and anomalies (right) in 2015/2016, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2016 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each month as well as monthly overviews of extremes and notable events.

4.1. Sea surface pressure and circulation indices

This chapter about atmospheric circulation provides information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based on the Monthly Bulletins on the Climate in WMO RA VI and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4.1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the Arctic Oscillation, for January to December 2016.

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2016	1	-0.37	1.01	-0.5	-0.68	-2.63	-1.449
2016	2	1.35	1.85	-2.39	-0.54	-2.33	-0.024
2016	3	0.37	0.71	0.26	-0.23	-0.23	0.28
2016	4	0.26	0.97	-0.5	-0.11	-1.59	-1.051
2016	5	-0.67	0.22	-1.99	1.05	-0.36	-0.036
2016	6	-0.13	0.41	-1.85	-0.95	-1.07	0.313
2016	7	-1.72	1.82	-1.01	-0.7	-0.24	0.085
2016	8	-2.24	2.08	-3.30	-0.44	2.43	0.472
2016	9	0.74	3.48	0.13	-0.99	-1.31	0.781
2016	10	0.96	0.42	-1.33	1.05	-2.94	-1.917
2016	11	-0.31	-0.45	-0.93	-0.06	-2.78	-0.611
2016	12	0.35	0.87	1.52	-1.18	-1.1	1.786

Note that all values are standardized with reference to the period1981-2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

Very intense winds were observed during 9th and 10th **January 2016** at several locations over northern *Italy*, with observed wind maxima reaching values of 46 m/s at Lago Scafaiolo, 42 m/s at Loiano and 36 m/s at Madonna dei Fornelli, indicating hurricane strength wind over a large area of the region.
Strong wind and persistent precipitation from January 3rd to 11th occurred in *Portugal*. In the 3 day period ending on January 11th, maximum gusts equal to or greater than 19 m/s (70 km/h) observed at surface stations were recorded in 38% of the meteorological stations, with the highest values occurring in Guarda (31 m/s or 111 km/h) and Mogadouro (103 km/h). In more than 60% of the stations there was a mean wind speed greater than or equal to 30 km/h. The Azores Islands were hit on the 15th by Hurricane Alex (category I) that last for 12 hours, first tropical cyclone formed in the Atlantic basin during January since 1938.
During 29th–31st January Winter Storm Marita (Gertrude) passed Western Europe from *Ireland* (Malin Head 36 m/s on 29th), the *United Kingdom* (47 m/s at Lerwick and Baltasound (both Shetland) on the 29th) to Scandinavia. High wind speeds with gusts of up to 47 m/s (170 km/h) occurred together with heavy rain inducing flash floods and landslides. Several houses, schools,

hotels damaged. The Overall losses were summed up by Munich Re to 160 Million US$. Fallen trees caused road closures with rail and ferry traffic disrupted.

On **February** 1st storm Norkys (Henry) came with highest wind gusts of 36 m/s. Followed by storm Ruzica (Imogen) on 7th and 8th with highest gusts of 38 m/s at Sherkin Island (*Ireland*). The following days storm Ruzica reached Central Europe. The overall losses were summed up by Munich Re to 220 Million US$. High wind speeds, heavy rain, high waves up to 19 m and floods were observed.
A storm hit on 14.02.2016 the west coast, Centre and south regions of *Portugal* with maximum gusts of 33 m/s (at Porto) together with hail and thunderstorms. Approximately 75% of the stations registered maximum wind gusts above 19 m/s (70 km/h). The highest values, above 28 m/s (100 km/h) occurred in the highest altitude sites of the Centre and South and the western coastal regions of *Portugal*. During 12-15, 19, 26 February, meteorological station Zhalanashkol (Almaty region, *Kazakhstan*) – measured hurricane wind from southeast with gusts up to 34-36 m/s, 9-25 hours long.

On 2nd **March** 2016 highest wind gust with 37 m/s (133 km/h) at Mace Head (*Ireland*) was measured during storm Aloisia (Jake). The highest 10-minute wind speed occurred at the same location with 27 m/s. At the same day a wind gust of 36 m/s was recorded at Aberdaron (Wales, UK). Storm Jeanne passed northwestern *France* during March 27 and 28 with wind gusts ranging from 30 to 40 m/s over the coasts of the English Channel and generally between 25 and 30 m/s in interior areas with 35 m/s at station la Hague. The north side of the Alps saw on the 31st March a foehn storm with gusts of 49 m/s (176 km/h) at station Zugspitze (*Germany*) or 27 m/s at station Sonnblick (*Austria*) and 25 m/s at station Saentis (Switzerland).

Seven days in **April** (1st, 6th, 10th, 11th, 25th, 26th and 28th) had gale-force winds in *Ireland* with the strongest and most widespread winds reported on the 6th. Both the highest 10-minute mean wind speed and highest gust were recorded at Mace Head on this date with 19 m/s (70 km/h) and 27 m/s (96 km/h), respectively. From 4-9 April 2016 two depressions (named in Germany Luana and Myrna) moved from *Norway* via eastern *Scotland*, *France* (24 m/s on 06th at Boulogne-sur Mer) and *Switzerland* to the south of *Spain* with locally heavy rainfall and northerly winds. From 10-16 April 2016 again two depressions (named in Germany Ortrun and Petra) with low temperatures brought rain and snow to Western Europe. Western *France* (42 m/s on 10th Ile d'Ouessante) and northern *Spain* observed extreme wind gusts, flooding, and damages.

In **May 2016** thunderstorms occurred in Southern Europe with high winds. At station Penhas Douradas (*Portugal*) a maximum wind speed of 33 m/s on 7th May was registered. In *Spain* a wind gust of 27 m/s was observed on 8th May at station Puerto de Navacerrada. The mistral and the tramontana have frequently blown on the Mediterranean regions. They were violent on 1st May, exceeding 100 km/h in the lower Rhone valley with 31 m/s (111 km/h) at station Orange and in Roussillon with 42 m/s (152 km/h) at station Cape Béar (Pyrénées-Orientales).

In **June 2016** thunderstorms continued in Central Europe with locally extreme precipitation, flooding and tornadoes.

On **July** 21st 2016 a tornado with category F2 hit Karlstein (Waldviertel region, state of Lower *Austria*). With wind gusts up to 61 m/s (220 km/h) many trees were uprooted or snapped. Additionally hailstorms with hailstone sizes up to 4 cm drew a line of massive damage in the same region (agriculture loss estimated to be 1 million Euro on 3.500 ha).

Severe storm in southern part of Lithuania on 11 July 2016

(as provided by the Lithuanian Hydrometeorological Service)

In July, several surges of tropical air into Lithuania formed strong convection phenomena. The most outstanding of them was a very violent storm in the south of the country in the afternoon on 11 July (Figure 4.1).

Figure 4.1: The development of Arcus cloud shelf over Vilnius, 11 July, 2016 (Photo: Tadas Kantautas, LHMS).

After a very warm (15-17 °C) and a rather stuffy night on 11 July, daytime air warmed up quickly. Tropical air surge into Lithuania formed, in the cyclone's warm sector, a convergence zone with thunderstorm cells, which moved from seaside to eastern regions. Maximum temperature in the southern and eastern regions jumped to 25...30 °C, in the western - to 22...24 °C. In the evening, convection became especially active in the hottest south-eastern part of the country. On 11 July at about 18h, Vilnius was approached by impressive shelf cloud formed of powerful Cumulonimbus arcus, which caused a squall followed by severe thunderstorm and heavy rain. Daily amount of precipitation varied greatly: in many places between 2-14 mm, in the south-eastern part of the country in locally 7-25 mm and 16-22 mm in the western part. During the thunderstorms in south-eastern regions, squalls reached 15-20 m/s. And after the passage of storm clouds, air temperature fell by 6-8 degrees within 3 hours. In addition, during the storm, meteorological stations in Kaunas and Vilnius recorded small hail. That entirety of dangerous phenomena conformed to the criteria of a disastrous meteorological phenomenon – severe storm. Luckily no significant damage has been done.

In the evening, the warm front and mesoconvectional system left our country, and by night Lithuania was approached by a cold front moving from the west.

A strong windstorm (Rauli) on **August** 27th caused forest damage in southern and central parts of *Finland* with approximately 200,000 households without power at some points. Strongest gusts with 24.9 m/s were measured in Vaasan Klemettilä and Kuopio Maaninkaa (http://www.ilmastokatsaus.fi/2016/08/29/rauli-nousi-myrskyjen-raskaaseen-sarjaan/).

Sea level pressure in **September** 2016 was dominated by several systems. The Azores high was shifted to the south with a core pressure of more than 1025 hPa. The Icelandic low showed a core pressure below 1000 hPa. A second low was located over southern Russia. Above normal

pressure anomalies ranged from the Azores high and Scandinavia to northern Russia with values above 4 hPa over the Baltic States. The negative anomalies over central North Atlantic showed values below -8 hPa and those over southern Russia and Kazakhstan values below -6 hPa. The East Atlantic Pattern (EA) with an index value of 3.48 was exceptionally high.

October 2016 was dominated by high pressure in Sweden with a reading of 1050.7 hPa at Sveg on 5th October. This is the highest air pressure ever recorded in Sweden in October. In Denmark a high pressure of 1045.5 hPa at Skagen on 5th October, also break the October record. A storm reached on 25.10.2016 the northern region of Portugal with a maximum gust of 28 m/s.

On 21 **November**, windstorm (to 34 m/s) was recorded in Cherkessk (North Caucasus, Russia) during two hours and 52 minutes. Power and water supply was disrupted, roofs were damaged and trees were toppled.

Corvo Islands (Portugal, Eastern North Atlantic) was hit by a storm on 8th of **December** with a maximum gust of 41 m/s. Storm "Barbara" hit Ireland during the 23rd and 24th of December with highest wind gust of 31 m/s and storm "Conor" the following days (December 25th and 26th) with highest wind gust of 32 m/s. During the same days a storm named "Urd" hit the northwestern parts of Jutland (*Denmark*) with wind gusts of up to 37.8 m/s at station Torsminde. Windstorm "Theresa" caused a number of damages in *Austria* at the beginning of December, while cyclone "Barbara" occurred from December 27th to 28th. For both events the majority of damage, like uprooted trees and damaged roofs, was reported in the eastern part of Austria.

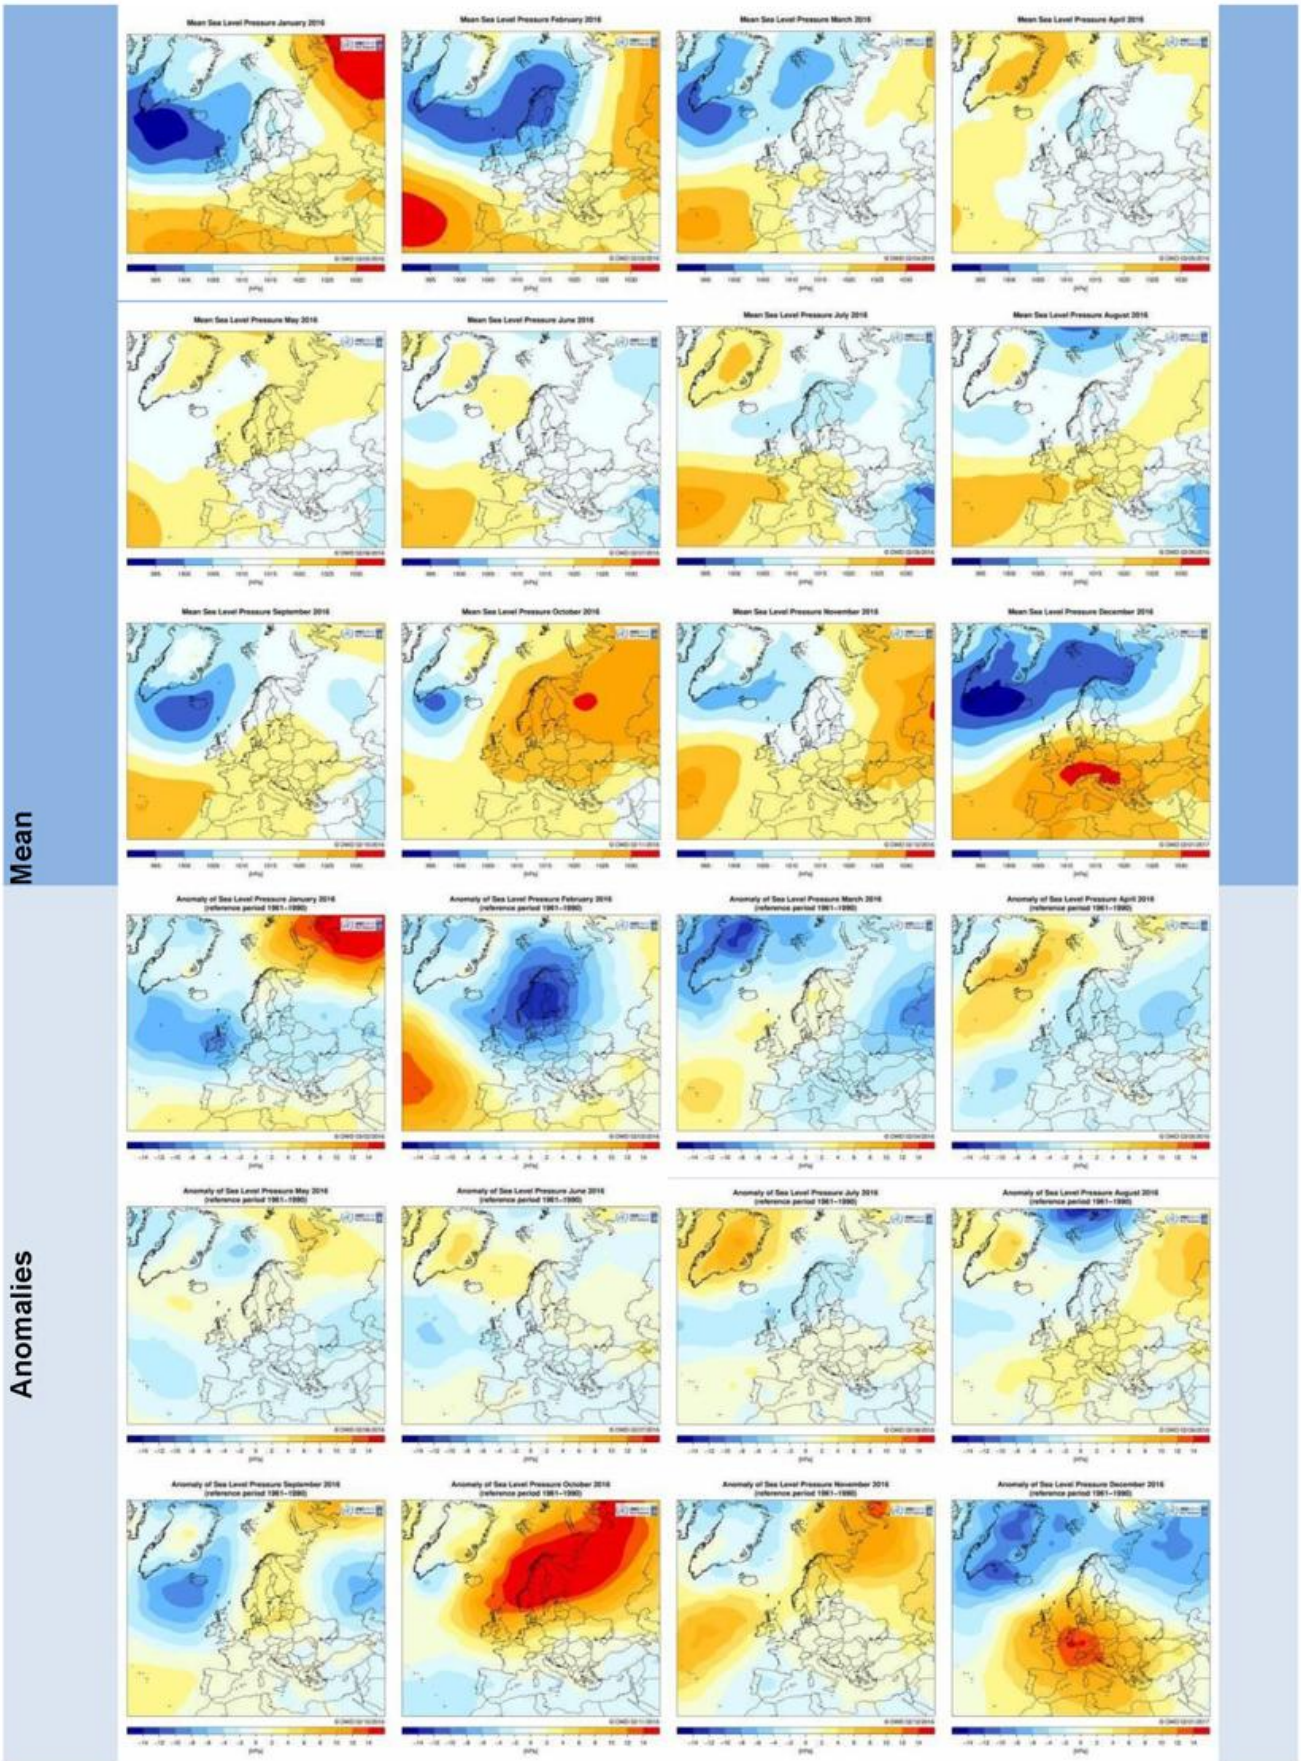

Figure 4.2: Mean and anomalies of sea level pressure in hPa for each month of the year 2016. (First row January, February, March, April; reference period 1961-1990).

4.2. Temperature

In most of the months and sub-regions it was warmer than normal as can be seen from Table 4.2. The Nordic und Baltic Countries had positive anomalies throughout the whole year 2016 and in Eastern Europe anomalies above +7°C occurred.

Table 4.2: Monthly and annual area average temperature anomalies in °C for each sub-region in the year 2016 (reference period: 1961-1990).

Region	Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.
Central and western Europe	1.22	1.61	2.72	0.71	0.68	1.25	1.51	1.49	1.37	2.67	-0.53	0.21	1.02
Nordic und Baltic Countries	2.71	2.67	4.06	4.52	2.38	1.84	1.83	2.28	1.39	2.53	2.59	2.86	3.58
Iberia	1.21	2.42	0.78	-0.36	0.54	0.50	1.79	2.28	2.17	1.47	1.60	0.28	1.09
Mediterranean	1.37	1.30	4.25	1.46	2.75	0.15	1.88	2.02	1.21	1.14	0.18	0.79	-0.65
Eastern Europe	1.89	-0.84	7.44	3.35	2.99	2.17	1.44	2.68	3.19	1.02	-0.07	-1.11	0.44
Middle East	1.46	0.94	4.52	3.07	2.58	1.03	1.80	1.32	3.43	0.41	0.57	-0.45	-1.75

From 24 to 26 **January** 2016 the *United Kingdom* was in an unusually mild south-westerly airflow, reminiscent of the situation through much of December 2015. On 24 January daily maximum temperatures approached or exceeded 15.0°C in the London area, around Chester, Carlisle, Edinburgh and Inverness and were particularly high in the north-west Highlands with 16.5°C at Achnagart, Highland. New national daily minimum temperature records were set: For Wales, 12.5°C at Gogerddan, Ceredigion on 25th exceeded 12.4°C at Rhyl (Denbighshire) on 10 January 1971. For Scotland, 12.6°C at Achnagart, Highland on 25th exceeded 12.2°C at Elgin (Moray) on 10 January 1971 and Strathallan (Perthshire) on 10 January 1998. For Northern Ireland, 13.1°C at Magilligan, (Londonderry) on 25th exceeded 12.6°C at Belfast, Danesfort on 10 January 1998. January in Sweden was cold with -42.9°C at Nikkaluokta on 7 January, which was the lowest temperature in Sweden during 2016 and also the lowest temperature in the country since 2001.

In **February** several unusually warm episodes occurred in *Switzerland*. At Berne the fifth-highest February daily maximum since observations began in 1864 was registered (16.4°C). With regard to minimum values, a remarkable cold spell occurred from 15 to 20 of February, due to an invasion of polar cold air that affected all of *Spain* including Canary Islands. On 17th February the coldest temperatures were registered with -11.3ºC at Puerto de Navacerrada station, -9.8 ºC at Teruel, -9.3 ºC at Molina de Aragón, -8.2 ºC at Burgos airport and -8 ºC at Soria.
Well-above-normal temperature (monthly mean temperature in the area *Czech Republic*) was recorded in February (+4.1°C above normal 1961-90). February was from strongly up to extremely warm for the whole territory of Slovakia up to +6.0°C (3.1-6.0°C) above normal (1961-1990). Absolute daily maximum for Slovakia was exceeded for February (20.3°C) measured in south west of Slovakia. In the Former Yugoslav Republic of Macedonia February was characterized with highest values for mean monthly air temperature and the deviation was +5°C to +7°C. The absolute maximum temperature for February was exceeded in Skopje, Kriva Palanka and Berovo 24.3°C, 22.0°C, 21.7°C, respectively. During this month the deviation of the mean monthly maximum and minimum temperature was also evident, exceeding 8°C on some stations.
The anomalous warm weather was observed in *Moldova* in February, when the average air temperature was +3.3 to +5.5ºC, which is 6-7°C above the norm, and observed for the first time on 60% of the territory of Moldova, and for the second time during the whole period of observations across the rest of the territory. In *Romania* during 2-3; 13-16; 22-23 February positive deviations of

the mean air temperature of more than 4°C from the climatological normal occurred countrywide (highest deviation was 7.3°C at Sf. Gheorghe, south-eastern Transylvania); the maximum temperature monthly record was exceeded at 43 weather stations.
The highest air temperature anomalies in the *Ukraine* were recorded in February (+5.0°C to +8.0°C). February was the warmest for the entire period of meteorological observations. Maximum temperatures reached +15°C to +23°C, which was above absolute maximum in many regions. A vast heat island formed in the north of Western Siberia covering entire *European Russia* and Siberia in February. Maximum positive anomalies of mean monthly air temperature in the center of the island exceeded +10°C. On 2nd February, for example, daily temperature absolute maxima were exceeded in Lipetsk and Maikop; the previous temperature record in Maikop in 2010 was exceeded by 4.1°C, now being 23°C. It was the 2nd warmest February since 1961 in most parts of Georgia, with very high deviations of +3 up to +6°C in the central and southern regions.

March 2016 was the warmest in the northern part of *Sweden*. The heat culminated on 15th when the temperature at station Haparanda, whose measurement series started in 1859, set a new heat record for March with 11.8°C. In *Norway* 11 stations registered new March records. Mean temperature for March 2016 in the *Arctic* were partly more than 10°C above normal. At station Svalbard Lufthavn monthly mean temperature was -6.9°C (8.8 °C above normal), station Hopen (Norway) registered -4.4°C (9.3°C above normal), station Barentsburg -6.5°C (8.0°C above normal), Isfjord Radio -5.4°C (6.6°C above normal) and Ny-Ålesund -7.5°C (6.7°C above normal).
Russia reported the fifth warmest March since records begun and new daily temperature records. In St-Petersburg, on 28 March, the record was broken that persisted for more than 100 years, since 1903. Diurnal air temperatures attained 13.9°C. Temperature anomalies in *Kazakhstan* reached values of up to +9°C, in *Moldova* about +5 to +7°C above the long term mean and the absolute maximum temperature reached +24.4°C on 31th March at station Ceadîr-Lunga.

Cold wave over central Europe and the Balkan during the last decade of April 2016

Polar air reached central Europe and the Alps on 24th of **April**, causing minimum daily air temperatures to drop below 0°C in many parts of Germany and north-eastern France. On 25th of April, the cold air mass with negative temperatures arrived in Austria and affected major parts of the Czech Republic, Poland, and the Baltic countries. The following day (26th of April) was characterised by negative temperatures in Austria, Poland, Slovakia, the western half of Hungary, Slovenia, Croatia and locally in the central Balkan regions (JRC, 2016). The cold wave, reached Austria, from 25th to 29th of April 2016 with frost causing agricultural losses of more than 305 Mio €.
The most remarkable event in Slovenia was a cold spell towards the end of April. After an exceptionally warm period in the first twenty days of April a cold spell due to the intrusion of polar air masses brought snow in lowland and fruit trees, vines and some crops were seriously affected. Phenological development of fruit plants was exceptionally early; therefore the most temperature sensitive phenological phases of opening of flower buds, full flowering and young fruits coincided with freezing air temperatures recorded during the night of April 26. At the end of April (20.-30.4.2016) a period of ground frost occurred in Slovakia and caused extensive damages on crops and fruit trees and it was recorded as a significant period of spring frost in Slovak history.

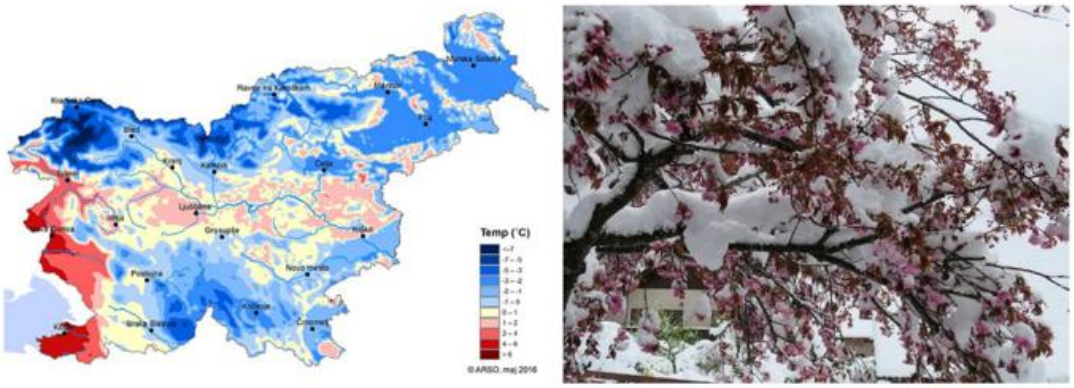

Figure 4.3: Minimum air temperatures (left) recorded on April 26, 2016, that caused spring frost of fruit trees, vine and crops (provided by the Slovenian Meteorological Service)

Heat waves in Israel in April 2016

(Text as provided by the Israel Meteorological Service)

April was much warmer than normal in Israel. The average daily maximum temperature was 3-5°C above normal and the daily minimum 2-4°C above it. In the Coastal Plain, Jezreel Valley and the Negev it was the warmest April ever recorded regarding daytime temperatures (figure 4). Two prolonged heat waves occurred during the month, the first one on April 1-10th and the second one on April 19-27th. Each one included Sharav events. On April 8-9th temperatures reached 35-36°C in the Coastal Plain and the Negev and 37-39°C in the Arava. In the second heat wave 35-37°C were recorded in the Coastal Plain and the Negev and 37-39°C in the northern and eastern valleys on April 19-21st. The most significant Sharav was on April 26th with 39-40°C in the Coastal Plain, the Negev and the Jordan Valley.

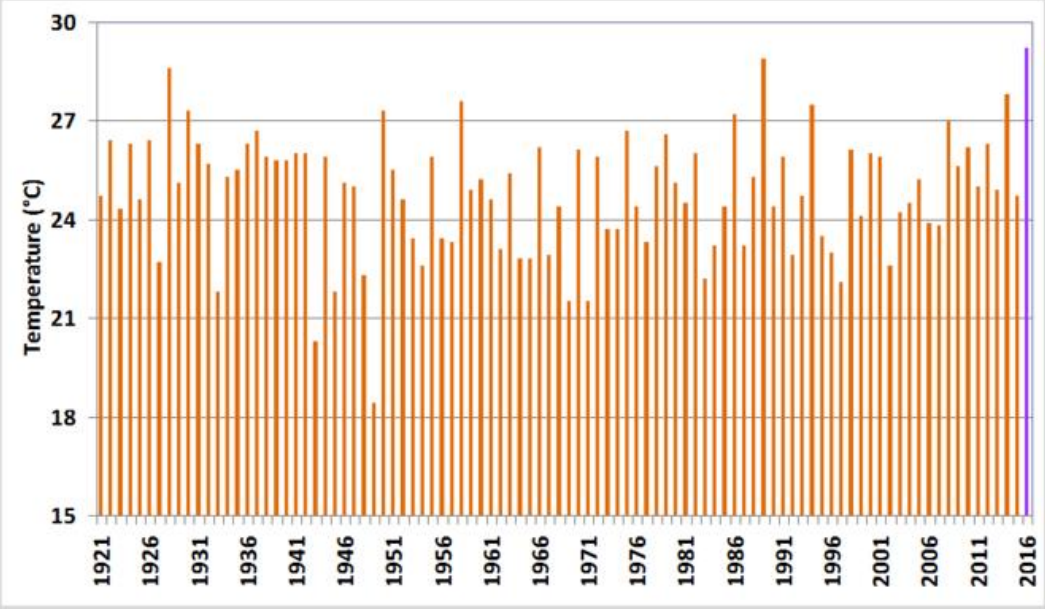

Figure 4.4: Average daily maximum temperature (°C) in Bet Jimal (Judean Foothills) in April 1921-2016 (Source: Israel Meteorological Service).

On 17th and 18th of **April** the highest daily maximum air temperature in *Serbia* of 32.0°C was registered in Loznica and Negotin, respectively. Negotin observed record-breaking maximum air temperature for the month of April, breaking the previous record of 31.0°C set on April 27, 1930. 17 April 2016 marks as the warmest 17 April in Serbia since the records at 23 main meteorological stations began. Maximum air temperature in *Moldova* on 18th of April exceeded for the first time during the whole period of observations in the second decade the extreme value of +28°C ..+31°C.

This **May** the Arctic was again warmer than in the reference period. Svalbard Airport (Spitsbergen, *Norway*) noted a new record high average temperature of 1.4°C (or 5.6°C above normal). Bear Island (Bjørnøya, Norway) was the mildest Norwegian Arctic station with a mean temperature of 2.8°C, 4.2°C above normal and the hottest May recorded at this station. Station Isfjord Radio registered 4.4°C and Ny-Ålesund 5.0°C above normal (also the hottest May ever). According to the *Finnish* Meteorological Institute (FMI), the average temperature in May was 3-5°C higher than usual in most parts of Finland. Except for the western part, deviations were exceptional and occurred on average once every 30 years. The all-time record for the average temperature in May was broken at about 20 observational stations. In *Sweden* several stations registered new monthly temperature records for May. Denmark registered the 3rd warmest May since 1874 (with 1993). The country wide average temperature was 12.9°C, which is 2.1°C above the 1961-90 reference period.

A significant heat wave occurred in **Israel** on May 14th -16th. At its peak, temperatures reached 40-42°C in the Coastal Plain, 42-43°C in the Negev and the Northern Valleys and 45-46°C in the Jordan Valley and the Arava. The daily maximum temperatures are not record-breaking, yet the 3-day length of the heat wave is unusual. Spring time is usually characterized by short-term Sharav events that usually prevail for no more than 24-36 hours. It should also be noted that nocturnal temperatures were high with daily minimum temperatures of 30-32°C in the Dead Sea Region, 28-29°C in the Judean and Samarian Mountains and 24-26°C in the Galilee. The daily minimum temperature of 28.5°C in Jerusalem on May 16th is a record high for May in Jerusalem for more than 100 years.

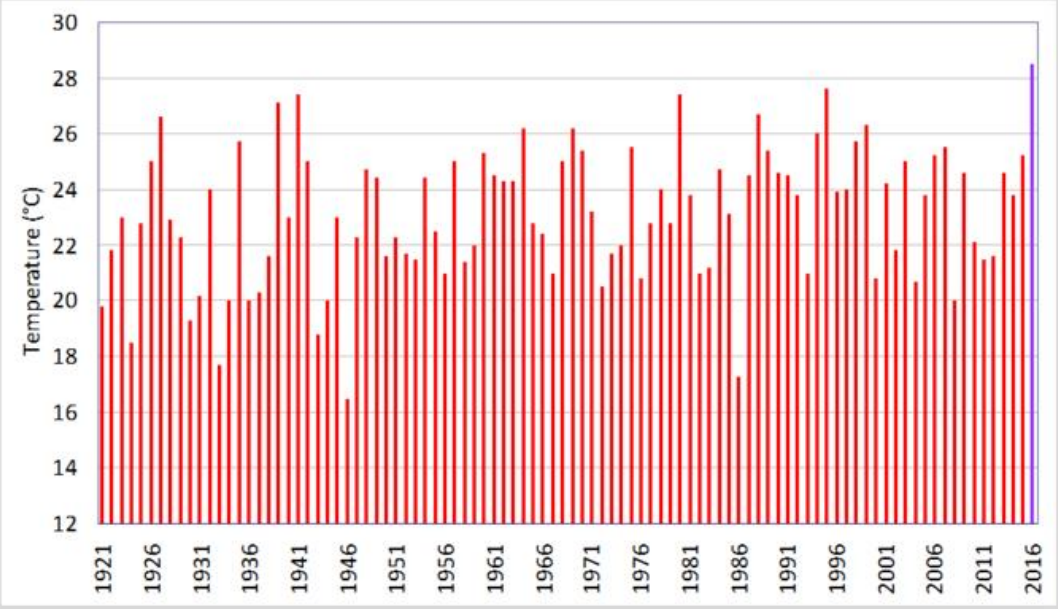

Figure 4.5: Highest daily minimum temperature (°C) in Jerusalem for each year in May 1921-2016 (Source: Israel Meteorological Service)

June started with high temperature in northern Europe. The Baltic States noted anomalies of up to +7°C. On the 9th of June a new record braking temperature was measured at station Nuuk, Greenland, with 24.8°C. From the 15th until the end of June Eastern Europe reported high temperature anomalies of more than +9°C. A second wave moved from Spain on the 22th June 2016 northward reaching on 24th Poland and on 26th the Baltic States with anomalies of more than +10°C. In *Lithuania* many stations registered temperatures of more 30°C, at stations Alytus and Pasvalyje even 35°C. This heat affected also Belarus, Ukraine, Moldavia, Romania, the Balkans, Turkey and the Middle East. During 18-21 June 2016, a 4-day heat wave event (Tmax ≥ 40°C) affected the eastern part of the *Greek* mainland with a maximum temperature of 43.4°C at station Sparti (Lakonia). June was also much warmer than normal in Israel and in most stations it ranks as the warmest on record. The average daily maximum temperature was 2.5-3.5°C above normal and in many stations it was more than 1°C higher than the previous record.

A heat wave occurred in *Slovakia* from 21.-26.6.2016 therefore June was from strongly up to extremely warm for the whole territory of Slovakia up to +4.2°C (1.8-4.2°C) above normal (1961-1990). The anomalous hot weather, on the territory of the republic of *Moldova*, was also observed in the third decade of June, when the average air temperature per decade was with 4-6°C above the norm, which in this decade is observed for the first time during the whole period of observations.

After one of the hottest June 2016 in the history of *Russia*, the heat continued to intensify in **July**. This was especially noticeable in the European part and above all in the Russian North. In southern Russia the temperature climbed to +40°C and more. New temperature records came from the Barents Sea. In northern Russia this July was hottest in history of meteorological observations and anomalies from long term mean exceeded 4-8°C. In the Arctic at Svalbard Airport (*Norway*) monthly average temperature was 9.0°C (3.1°C above normal). For Svalbard Airport this was the warmest July since July 1998 (8.2°C). Ny-Ålesund also had a record warm July with average temperature of 6.9°C (2.0°C above normal). A heat wave from 24-26 July occurred in

northern and southern parts of Lithuania with maximum temperatures of 30-35.4°C. In *Moldova* the maximum temperature reached values of 37°C at station Dubasari and the numbers of hot days (maximum temperature ≥ 30°C) summed up to 13-20 (3-10 days for the reference period). The average maximum temperature in *Portugal* in July, 32.19 °C, was well above normal with an anomaly of +3.47 °C; it was the highest value since 1931 (the previous warmest month of July occurred in 1989).

August 2016 was the warmest August in the western **Kazakhstan** for the period 1936-2016. The positive anomalies were 5-6°C above the reference period 1961-1990. From 8th of August onwards until 14th (with short interruptions) the maximum temperatures were 40°C-43°C over most of western Kazakhstan. From 8-10, 12-14 August, Atyrau region, suffered by very strong heat (maximum temperatures of +40 up to +42°C) and from 13-14 August, West-Kazakhstan region, very strong heat, +40 … +43 °C.

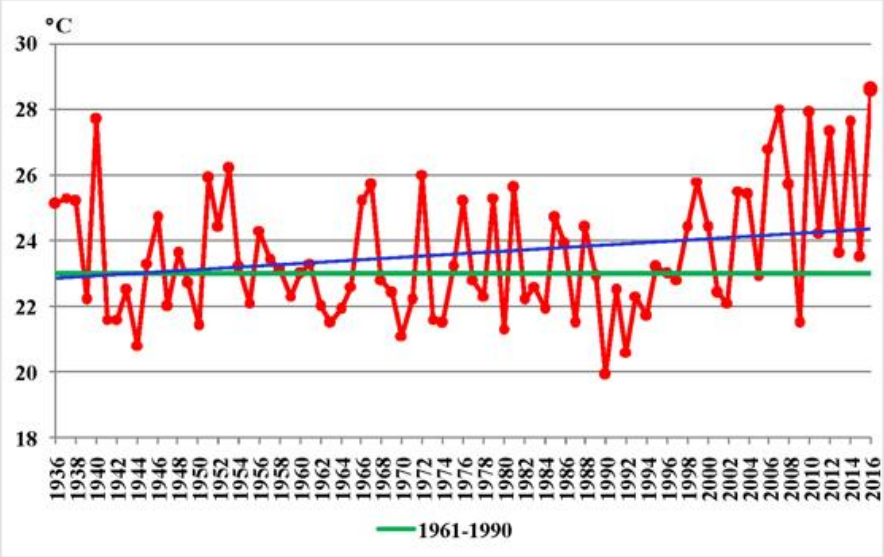

Figure 4.6: Monthly mean temperature (°C) in Taipak (western Kazakhstan) in August from 1936-2016 (Source: Kazakhstan Hydrological and Meteorological Service)

Between 5th and 13th of **August** a heat wave occurred in *Portugal* (duration of 8 to 9 days) in North, Centre, Lisbon and Setúbal regions. On 7th and 8th of August, almost half of Portuguese territory recorded tropical nights, combined with very hot or extremely hot days (maximum temperature ≥35 or 40 °C), which lead to a pronounced and extended heat distress.

The heat wave reached *France* from 23rd to 27th of August with 35 to 38°C. Temperatures in Paris have passed twice the previous record for a late August. They reached 36.6°C on the 24th, an unprecedented value in the capital after 20th of August since the beginning of the recordings in 1873.

A heat wave also occurred from 23rd to 28th of August 2016 in *Luxembourg*. The maximum air temperature of 34.9°C recorded on the 26th of August at Findel Airport is the highest air temperature ever recorded during the third 10-day period of August since 1947.

From 22nd of August onward a high pressure zone from the west moved over Middle Europe and remained in place until 28th of August. In *Switzerland* north of the Alps, helped by the maximum of sunshine duration, daily maximum temperatures rose up to 30°C and above from 25th of August onwards in many places. There were record values for the period from 25 to 31 August. In Geneva the daily maximum reached 33.5°C on 27 August, in Basel 33.8°C. In Geneva it was clearly the highest value for end of August since observations started in 1864. Basel had a similarly high daily maximum with 33.7°C on 28 August 1992.

Extremely hot weather occurred in *Portugal* during the 5th and 6th of **September** when 72% of meteorological stations reported new daily historical records. September 6th was the warmest day of the year in Portugal with average mean air temperature of 29.2°C; the average maximum and minimum air temperatures, 38.6 °C and 19.8 °C, respectively, were the highest values of 2016. The most remarkable event in *Spain* in September 2016 was the significant high temperatures

spell in the beginning of September that mostly affected Peninsular area and Baleares islands. In this period 36 principal Spanish meteorological stations exceeded their maximum absolute temperatures ever recorded in September, and at several stations these values were exceeded by more than 3ºC. Likewise, many meteorological stations registered their peak maximums of the astronomic Summer in this period, reaching up 45.4ºC in Córdoba-airport on 6th of September, 44.8 ºC in Sevilla-airport on 5th of September and 44.6ºC in Murcia, also on 5th of September. In many south peninsular stations and stations located in the interior of Galicia the maximum temperatures were higher than 40 ºC during this spell.

A short heat wave from 12th to 15th of September brought exceptionally high temperatures to south-east England, accompanied by some torrential downpours causing flash flooding. On 13 September, Gravesend (Kent) recorded 34.4°C, the *UK*'s highest temperature of the year and the highest September temperature since 1911; this value being around 14°C above the long-term (1981-2010) average. Daily minimum temperatures for 14 September were also exceptionally high, at a few locations exceeding 20°C. The heat was associated with a southerly flow of air from France and Spain, with the humidity leading to thunderstorms bringing intense downpours and causing flash-flooding. Several locations recorded hourly totals exceeding 30 mm.

Monthly mean air temperature of 17.4 °C recorded at Findel Airport is the second highest value recorded in September since 1947 in *Luxembourg*, nearly breaking the existing record from 2006 (17.5 °C). The *Netherlands* registered the third warmest September since the beginning of regular measurements in 1706. This year the monthly temperature of the area average for *Germany* was 16.9°C, together with the year 2006 the highest value ever observed since 1881. Highest daily maxima were observed in the west of Germany at station Trier-Petrisberg with 34.2°C on the 12th and 13th of September and a number of 16 summer days. In *Norway* September 2016 was the warmest since measurements begun in 1900. 43 stations reported new records for September mean temperature and 16 stations new records for maximum temperature. In *Denmark* too September 2016 was the warmest (with September 1999 and 2006) since measurements begun in 1874. September was warmer than August, which has only happen once since 1874, in 1949. In *Sweden* September was warm or very warm, especially in the middle of the month with a maximum temperature of 28.2°C at station Målilla on the 15th. Locally September was warmer than August which is an unusual feature. Monthly mean temperature over the area of the *Czech Republic* in September was + 3.0°C above normal (1961-90). A heat wave also occurred in *Slovakia* from 7.9.-16.09.2016, therefore September was very warm and in the south west part extremely warm up to 4.3°C (1.1 - 4.3°C) above normal. Monthly mean of maximum temperature was up to 5.0°C above normal 1961-1990 and monthly mean of minimum temperature was up to 4.5°C above normal 1961-1990. Station Dudince registered a maximum temperature of 32.4°C on 12th of September.

South of the Alps, in the Valais and in western *Switzerland*, continuous high pressure influence in the first half of the month led in parts to the warmest September since observations began in 1864. New September records were the result: Locarno-Monti registered +3.6°C above the normal values 1961–1990, Sion +3.8°C and Neuchâtel +3.0°C. In Lugano the record of +3.1°C was again reached while in Geneva the record of +3.2°C was closely missed (2016: +3.1°C). In lower altitudes of northern Switzerland it was – overall – the fourth-warmest September since observations started in 1864.

At the beginning of **October** a strong high pressure area was established over *Scandinavia* and northern Russia guiding cold air to Europe. Therefore, this October was in many parts of Europe colder than normal. The cold period started from the 3rd of October and ended on 22nd. The colder period remained for ten days in the Alpine region and moved then to the east. In *Switzerland* the anomalies reached for several days 5-6°C below the long term mean, in higher elevations even -9°C. The snow line reached the 1000 m level in Switzerland and also in Austria. The monthly average temperature in *Germany* for October was 8.6°C or -0.6°C below the 1981-2010 reference period and therefore it was the first month in 2016 below the long term mean. At station Crni Vrh (*Serbia*) it was the second coldest October on record since the measurements began at that meteorological station. The average air temperature in *Latvia* was 4.9°C or -1.9°C below the monthly norm. At station Daugavpils both absolute monthly maximum and absolute monthly minimum temperature were observed with +19.7°C on 2nd and -6.2°C on 13th of October, respectively. The temperature anomalies in *Lithuania* were 1.5°C-2.5°C below the mean of the reference period. In October, the heat island above north-eastern regions of *Russia*, which formed

as early as September, became more intensive. Mean monthly air temperature anomalies in the Nenets Autonomous Area and Novaya Zemlya attained 6-7°C. Heat ridge dropped on the Upper- and Mid-Volga regions; however, mean monthly air temperature anomalies in these regions were not higher than 1°C. The rest of European Russia was slightly colder than is usually recorded, with mean monthly air temperature anomalies being -0.5 to -1.5°C. It was particularly cold late in the second ten-day period in Northern Caucasia; heavy snowfalls occurred in individual regions of Kabardino-Balkaria, Chechnya and Dagestan.

In Northern and Eastern Europe **November** was colder than normal. At station Folldal-Fredheim (*Norway*) the minimum temperature reached -33.5°C on the 8th of November. In *Latvia* ten new daily minimum temperature records were broken in November.Over most of European *Russia*, November was cold with monthly air temperature anomalies of 2-4°C below normal. In St-Petersburg, the first ten-day period was the coldest for the last 46 years. At the same time, air temperature rose to record-breaking values in southern European Russia due to penetration of subtropical air masses. On 9th of November, temperature records were broken in many cities of Northern Caucasia. Temperature in polar regions, e.g. at Vize-Island (Kara Sea, Russia), with a monthly mean of -4.3°C, showed the highest deviation from normal with +16.8°C.

Scandinavia in **December** was much warmer than normal with monthly temperature anomalies e.g. of +7.4°C above the reference period of 1961-1990 at station Fagernes (*Norway*). Anomalies of more than +6°C occurred also in Sweden, in northern Sweden even +8.4°C at station Kvikkjokk-Årrenjarka. The Arctic stations also showed anomalies above +7°C or more. Svalbard airport had a mean monthly temperature of -6.0°C (+7.4°C above normal).

The spatial distribution of temperature anomalies showed an area of negative values in eastern European *Russia* with maximum anomalies in the center of the area attaining -12°C. At the end of the second ten-day period, mean daily air temperature were 15-20°C below normal. On the coastal regions around the Black Sea temperature anomalies were below normal for example at station Constanta (Romania) -2.0°C, in Odessa (*Ukraine*) -1.2°C. In Greece the monthly temperatures were well below the climatic values. The temperature dropped in the last decade of the month below -3°C, with snowfall in several regions of the country, including areas of Attica. Athens reported a monthly temperature of 9.0°C and an anomaly of -3.0°C. Tiran (*Albania*) measured a temperature anomaly of -3.7°C. In *Spain* there was a could spell during the two last days of December with -11.0°C in Molina de Aragón on 30th of December, -8.2°C in Burgos on 31st of December and -7.3°C in Valladolid airport also on 31st of December.

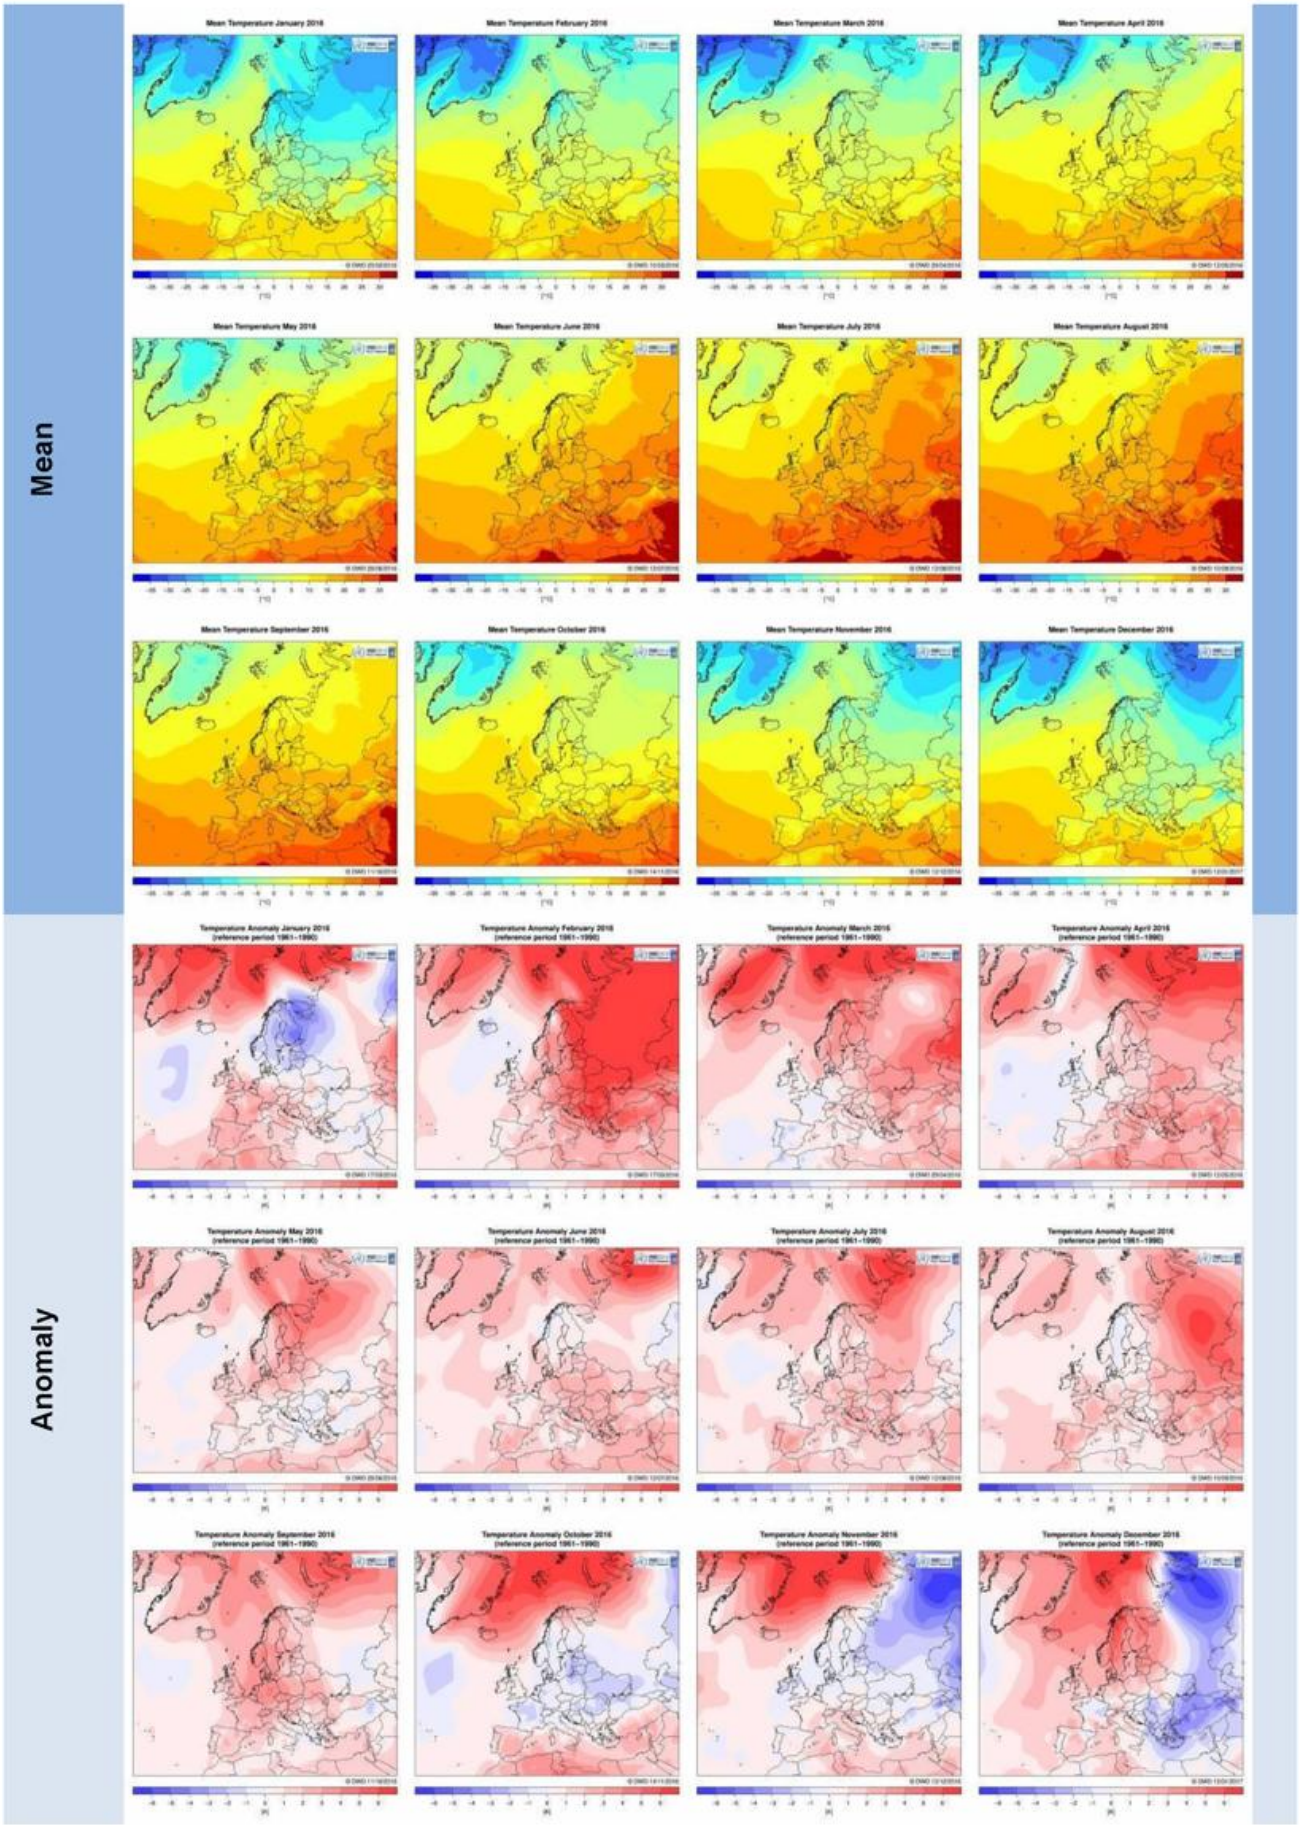

Figure 4.7: Mean and anomalies of temperature (in °C) for each month of the year 2016. (First row January, February, March, April, …; reference period: 1961-1990).

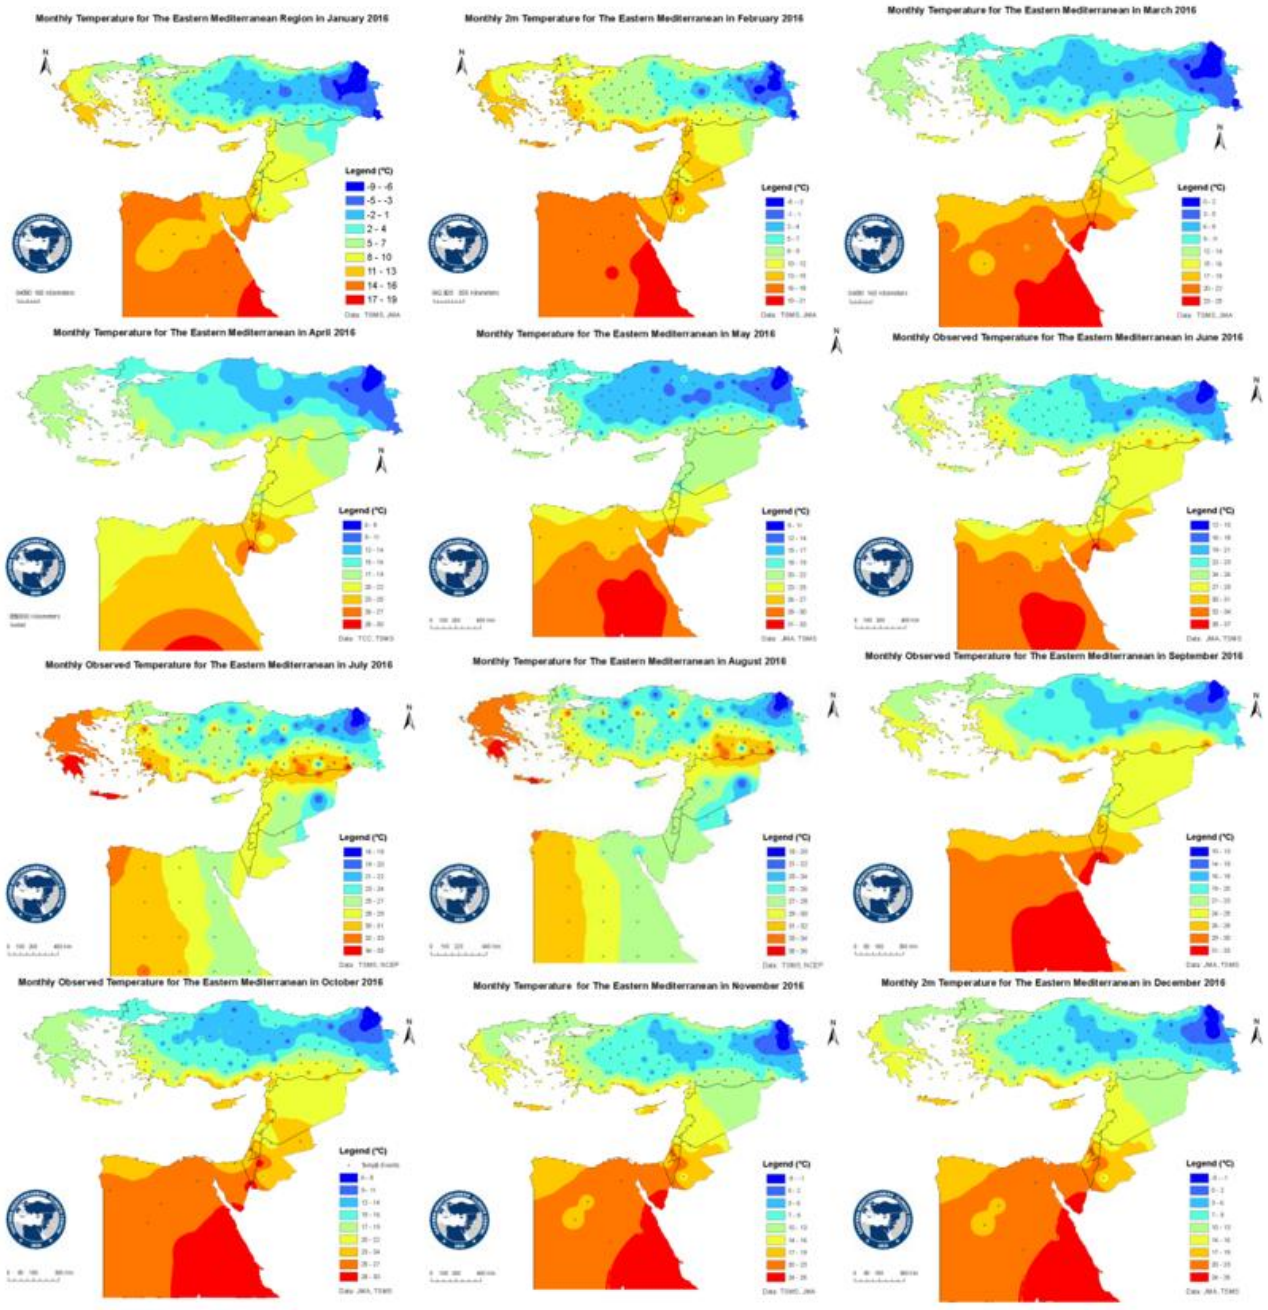

Figure 4.8: Monthly mean temperature (°C) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC).

4.3. Precipitation

From 9th to 11th of **January** 2016 an extreme precipitation episode in *Portugal* occurred with 120 mm/48h. On 12th January Flores Island (Azores, Portugal) saw an exceptional precipitation event of 96 mm/24h. The first week of January saw persistent rain affecting parts of the *British Isles*, particularly eastern Scotland and north east England. Parts of Aberdeenshire exceeded their monthly average January rainfall in the first three days of the month and two to three times the normal monthly rainfall by the 7th. Widespread flooding affected these regions. It was the wettest January on record for eastern Scotland. In *Serbia*, stations Nis and Zajecar observed the highest precipitation totals since the records at these main meteorological stations began. The previous January record of 98.1 mm for Nis was set in January 2012, whilst the current January record measures 101.3 mm. In January 2016, Zajecar received 105.6 mm of precipitation surpassing the previous January record of 94.7 mm set in 1987. North of the Alps in *Switzerland*, January brought a lot of precipitation with new records at some meteorological stations i.e. Eschenz at Lake of Constance region registered 185 mm, while St. Gall with 164 mm and Basel with 132 mm recorded their second-highest January totals. On 2nd of January in *Austria* freezing rain and black ice caused major traffic interruptions and rear-end collisions in the eastern part of Styria. In some parts of Salzburg and Upper Austria the lack of precipitation led to drinking water scarcity in some townships. From 11th to 12th of January in the southern parts of Carinthia heavy rain and snowmelt were triggering local floods. Record high snow accumulation was measured on January 8th in Merikarvia (Finland). The snow depth rose 73 cm during one day.
In western *Kazakhstan* precipitation up to 24 mm occurred across most parts of the country; 27 to 107 mm in the western parts. On the 2nd January, meteorological station Peshnoy (Atyrau region, western Kazakhstan) registered very heavy snow of 40 mm.

Extreme precipitation episode during 7-8 January 2016 in **Israel** Rainfall amounts of 100-130 mm within less than 24 hours. A significant precipitation event on January 7-8th, was characterized by significant rainfall amounts in the Lower Galilee and Jezreel Valley (Israel, Figure 4.9), where 100-130 mm fell within less than 24 hours (more than 80 mm in 6 hours).

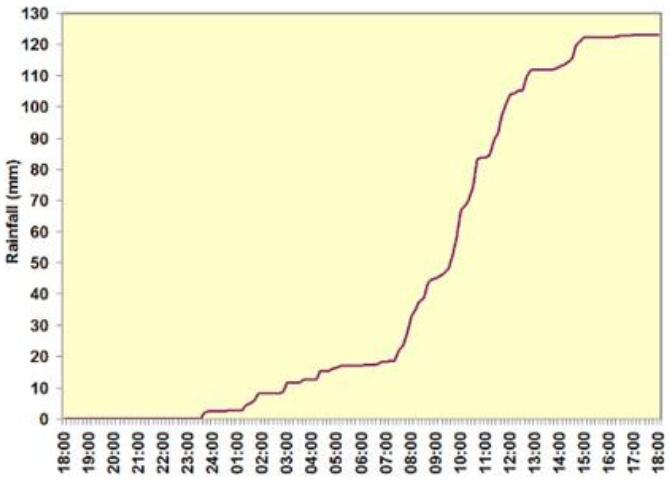

Figure 4.9: Accumulated rainfall (mm) in Newe Yaaar (Jezreel Valley) on January 7-8th 2016 (Source: Israel Meteorological Service).

An extreme precipitation episode on 26th **February** 2016 occurred in *Ireland*. Some Cork stations reported 24-hour rainfall totals of up to 90.9 mm. Record high February precipitation of 131.6 mm measured in Kouvola (*Finland*) narrowly surpassed the old record of 130.8 mm from 1990. Finland experienced the second wettest February, behind only 1990 with an anomaly of 240% of the average. With an average cumulative precipitation amount of 65.9 mm for whole of Latvia, February was the 2nd wettest since 1924. An extreme precipitation episode was also registered in *Portugal* from 10th to 14th February with 200 mm/120h.

In *Spain* **March** 2016 was characterized by several precipitation episodes but most rain fell in the last decade. Station La Coruña measured a total precipitation of 292 mm (200 mm in the last decade). Western France was affected by the same storms and at station Biarritz 183 mm precipitation was registered. Even higher amounts occurred in the Pyrenees at station Bustince-Iriberry with 233 mm.
England and Wales were affected by storms and extreme precipitation at the beginning (Storm Jake on 2nd) and the end (Storm Katie on the 28th) of March with plenty of sunshine in between. Strong winds in England and Wales caused several damages and losses. Roads were closed due to fallen trees, flights were diverted or cancelled. On 17th March Calabria (*Italy*) was affected by heavy rain with storm caused two fatalities after their car crashed in the floods of river Turina. The

wettest March for *Serbia* with maximum precipitation sums surpassed previous records at several stations e.g. Zlatibor with 220.9 mm (last record from 2006 190.4 mm) and 80.3 mm on March 7th. *Greece* was also affected by thunderstorms with gale-force winds of 40 m/s on the 18th. The total rainfall for six days (12-18 March) at station Zagora was 430 mm and for the whole month 501.6 mm. This resulted in floods and damages.

During 15-20 **April** ice jam on the Sukhona River (European *Russia*, Vologda Region) caused flooding. The water level in the Sukhona rose nearly as high as 10 m. The city of Velikyi Ustyug and another 24 human settlements with the population of about 40 thousand people found themselves in the zone exposed to flooding. The total flood-related damage was more than 300 million rubles (0.5 Mio €). From 10.-16.04.2016 two depressions (named Ortrun and Petra in Germany) with low temperatures brought rain and snow to Western Europe. Western *France* and northern *Spain* observed extreme wind gusts, flooding, and damages. At station Guarda in *Portugal* a daily total precipitation of 90.4 mm was measured on the 15th of April.

Unseasonably warm and unsettled weather dominated late **May** in *Sweden*. The station Ed in southwestern Sweden reported 83.1 mm on 24 May. This was the highest daily amount in Sweden during 2016 and one of the highest daily amounts ever for the month of May.
From the end of May until beginning of June disastrous thunderstorms hit Central Europe. 8 people died in *Germany*, *France* and *Netherlands* due to flash floods, severe storms and land slides causing an overall loss of 1400 Million US$ (Munich Re). Dozens of houses, businesses, public buildings and bridges were damaged or destroyed. Highways, roads, railways were blocked. Crops damaged or destroyed and other related impacts. In Germany precipitation of 90 mm within one hour induced a flash flood in Braunsbach on 29th of May with death and a lot of damage.
In *France* from 28 May to 6 June heavy precipitation of 80 to 120 mm caused rivers to rise and other related impacts. Highest five-day totals of 150.7 mm were measured at station Aubigny-sur-Nère and 118.2 mm at Fontainebleau. Such events have a return period of 10 to 50 years, the extreme ones of 100 years. Rivers Seine, Loing and Yonne burst their banks and flooded numerous towns and villages and 5 people died. Thousands of buildings and businesses were damaged. 25,000 customers were without electricity and farmland and vineyards were destroyed. The overall losses were summed up to 2400 Million US$ (Munich Re).
In *Switzerland* locally there were totals of 210% to 225% of normal values. Lucerne registered 270 mm, Château d'Oex 239 mm and Thun 198 mm; at all these stations it was the May with the most precipitation since observations began in the 19th century.
24 hour precipitation in Laneia of 79.9 mm was the highest daily precipitation for May in *Cyprus*, since 1967. In Agios Mamas 67.3 mm was the highest daily precipitation amount for May since 1971. These extreme precipitation events together with severe hailstorms caused a lot of damage.
The highest daily precipitation amount in *Czech Republic* on 31th May was 145.8 mm. The 1 hour precipitation amount (129.3 mm) was probably the highest ever recorded in the area of Czech Republic.

May 2016 was the wettest May in the western **Kazakhstan** with 240% of the long-term mean. Some stations received more than 3 and even 6 times of the normal rainfall (Atyrau, 653%, Figure 4.10).

Heavy precipitation was recorded in southern European *Russia* in May, with most of it falling in the third ten-day period. In the Rostov Region, Krasnodar Territory and Astrakhan Region, monthly precipitation totals were above normal by 2-3

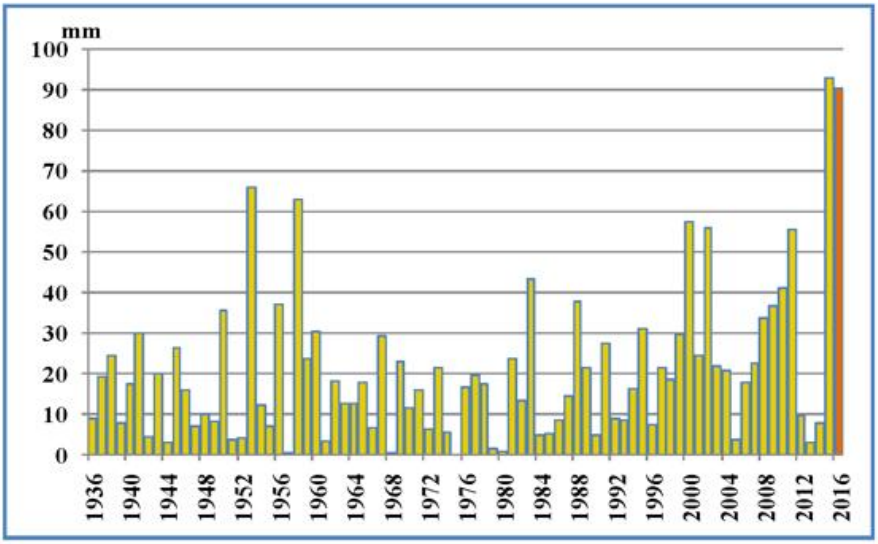

Figure 4.10: Monthly rainfall (mm) in Atyrau (western Kazakhstan) in May (Source: Kazakhstan Hydrological and Meteorological Service).

and even 5-6 times, respectively.

In Central Europe the thunderstorms and extreme rainfall from end of May continued at the beginning of **June 2016**. The high temperatures again induced in the 3rd decade heavy and at times thundery downpours with a lot of damages.
From 31 May until 7 June severe storms with torrential rain that rivers burst their banks together with flash floods occurred in *Germany*, *Belgium* and *Switzerland*. Thousands of houses were damaged. Basements, undergrounds and car parks were flooded. 9,000 customers remained without electricity and 9 people died. The Overall losses for this period were summed up by Munich Re to 2200 Million US$. In Belgium 3 persons were surprised by flash floods on the 2nd, 5th and 6th of June. Flooding due to intense rainfall in the Region Brussels (*Belgium*) on the 7th and the 23rd of June 2016. Continuous and intense rainfall in Belgium between the 27th of May and the 26th of June. The total amount of damages was estimated at 248 Million €. During June 2016 21 thunderstorm days (normal: 12,7d) were observed, the highest value since 1928 and 2 days more than the previous record of 1991. Monthly amount of precipitation for June 2016 in *Luxembourg* was 135 mm, the 4th highest ever recorded for June since 1947.
The Bavarian town Simbach/Inn (*Germany*) will be remembered for a long time as 7 people died after braking of a dam and resulting flooding on 1st of June. On the 3rd June 80 persons were injured on the music festival „Rock am Ring" by lightning strikes. Also several tornadoes were observed during the first days of June in Germany.
From 22nd-24th of June a hailstorm crossed the *Netherlands* and *Germany* with hundreds of vehicles damaged, destroyed solar panels, greenhouses and agriculture. The overall loss was summed up by Munich Re to 1,900 Million US$. June was very wet with record sums of precipitation in *The Netherlands* on some of the stations in the southeastern part of the country. Station Ysselstein (Limburg) recorded 277 mm. On a number of days heavy showers caused substantial damage. On June, 23rd, hail with a diameter of 5-10 cm fell in the province of Brabant, causing damage of approximately 500 Million €. In the *United Kingdom* thunderstorms caused local flooding, lightning damage and related impacts in parts of the country. It was a very wet month in Aberdeenshire, England and Wales, with some regions receiving in excess of twice normal rainfall. It was the fourth wettest June on record for East Anglia.
In Switzerland thunderstorms in first half of the month brought heavy precipitation and local flooding. Towards the middle of the month humid air from the Mediterranean triggered severe precipitation in southern and eastern Switzerland. The surface already soaked by previous June rainfalls reacted with mudslides and flooding to this heavy precipitation, leading to major damage locally. Lake Constance and Walensee overflowed and the Rhine burst its banks. In the last third of the month torrential rains again caused severe weather damage in the eastern half of the Switzerland. In *Denmark* a new rain intensity record of 5.4 mm/min was registered in a thunderstorm on June 23rd.
June was excessively dry in east *Slovakia* (27%-48% of normal 1961-1990), but excessively wet in some parts of west Slovakia where storms occurred (up to 153% of normal 1961-1990). At station Zrenjanin, *Serbia*, record-breaking June precipitation totals of 187 mm was observed, exceeding the previous record of 173.7 mm set in June 1981. During 25-26 June 2016 a barometric low moved from northern part of Africa towards *Greece*, and affected the south Ionian Sea and Peloponnese prefecture causing severe thunderstorms with heavy rainfalls, with daily totals in Tripoli of 157.7 mm and Megalopoli (Arkadia) of 213.0 mm.
In *Romania* precipitation amount (128.3 mm) was 52% higher than the climatological normal. Rain amounts recorded during showers were frequently exceeded 25 mm and sometimes were even in excess of 50 mm. On the 2nd of June, more than 150 mm accumulated in very narrow spots in Moldavia and on the 13th up to 105.5 mm rain fell at Costeşti, Vâlcea county.
In June there were a large number of strong local rains, hail and squalls in the *Ukraine*, in some areas downpours reached the criteria of natural phenomena. The highest monthly rainfall (for the period of observation 1961-2015) was marked on the weather station Voznesensk (Mykolaiv region), 212 mm or 326% of the monthly norm. In *Belarus* on 28th of June a very heavy rain with up to 118 mm/12h was observed. On 5th June, heavy shower took place in Vladikavkaz (North Caucasus, *Russia*); 50.5 mm of precipitation fell in 20 minutes, with the shower being accompanied by large hail (30 mm) and strong wind (28-32 m/s) for 12 minutes. As a result, glass panes and roofs of 699 buildings, as well as cars and agricultural crops on a 365 ha area was damaged and more than 2500 trees were toppled and rooted away. Two persons were injured.

On 7 **July**, heavy shower was recorded in Belaya Kalitva (Rostov Region, *Russia*) that brought 84 mm of precipitation in 40 minutes. The shower was accompanied by hail of 15 mm in diameter and wind as strong as 23 m/s. Precipitation amount in *Georgia* was above the norm by 30-90% approximately, whereas in some mountainous regions of Adjara and west Caucasus 170-380 mm monthly sums were observed that was 2-3 times more than normal. Intensive rainfall (90-100 mm) causing landslides and flooding and significant infrastructure damage was observed in west Georgia regions (Adjara-Guria-Imereti) on 8-9 July. Several hail events occurred in eastern and southern regions at the end of the month. In *Belarus* 03 and 13 very heavy rain occurred with up to 76 mm/8h.

In the night of 6th to 7th of July the amount of precipitation reached 81 mm within 12 hours at Sīļi (south east *Latvia*), which is 110% of July normal precipitation amount, never recorded in the climatological archives (Observations started in 1944) with previous highest daily precipitation amount of 76.7 mm observed in 2001. An extreme precipitation happened on 6 July in *Lithuania* at Skuodas town with 53,4mm/12h.

Heavy precipitation in Northern Poland, 13-14 July 2016

(provided by the Institute of Meteorology and Water Management, IMGW)

Due to the passage from the south of Europe of a deep mesoscale cyclone with very active frontal system heavy precipitation occurred in the whole area of Poland. Specific threat was related to the convection rainfall. The spatial range of Cumulonimbus clouds was enlarging due to the advection of colder air from the Baltic Sea. The tops of clouds associated with the front reached 10-11 km. The Northern Poland was affected by particularly heavy rain, whose daily totals exceeded 100 mm and locally it was even about 150 mm. Late afternoon and early evening the cities of Gdańsk and Gdynia, located on the coast of the Baltic Sea were hit by the torrential rain with total reaching almost 140 mm in Gdańsk Rębiechowo Airport. In some parts of the cities the sum of rain was even greater (e.g. the meteorological station of University of Gdańsk in the central districts of the city recorded above 150 mm of rain). Several places in Gdańsk were flooded, which caused serious damages. It was the highest sum of precipitation recorded in Gdańsk, where the regular meteorological observations have started in the first half of the 18th century. The previous on occurred in July 2001, when the value of 127 mm was recorded, also in Rębiechowo Airport.

The spatial distribution of precipitation totals recorded in Poland on the 13th and 14th July 2016 is presented in following figures.

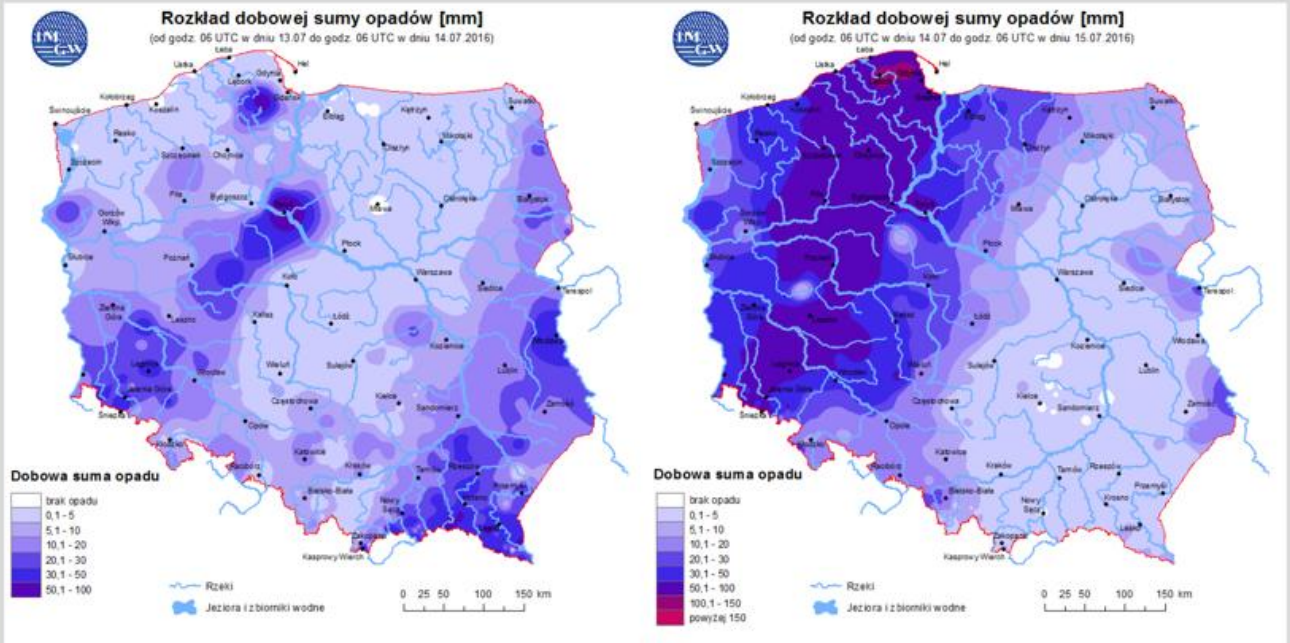

Figure 4.11: Spatial distribution of daily precipitation totals in Poland, 13th (left) and 14th (right) July 2016 (source: provided by the Institute of Meteorology and Water Management, IMGW).

Excessive rainfall and flooding on the 23rd of July in *Belgium* caused 8 entities (Limburg and Flemish-Brabant). On the 21st of July 2016, in *Luxembourg* 3 station records concerning the

precipitation intensity occurred at the station of Findel airport operated by Meteolux (absolute maximum since 1947). The maximum intensity in 60 minutes amounted to 47.5 mm, in 3 hours to 58.1 mm, in 12 hours to 60.4 mm. These intensities are the highest ever recorded since 1947. On the 22nd of July 2016 two station records of precipitation intensity for July occurred (absolute maximum since 1947). The maximum intensity in 30 minutes amounted to 28.4 mm, in 24 hours to 70.6 mm. These intensities are the highest ever recorded for July since 1947 at the Findel station. At station Christnach operated by ASTA, which was closer to the maximum intensity of the event, a daily sum of 68.6 mm has been measured and a maximum intensity of 51.0 mm in one hour and 20.3 mm in 10 minutes. The quasi-stationary convective cell formed above the Ernz Valley and caused thunderstorms with heavy rainfall. Radar-based precipitation values reached about 50 mm with some peak values of 80 mm to 90 mm near the small towns of Medernach and Ermsdorf between 17:30 UTC and 18:45 UTC. Torrential convective rainfall triggered catastrophic flash floods. The river White Ernz flowing through the towns of Ermsdorf, Medernach and Larochette reached exceptionally high water levels of 223 cm at Larochette.
The highest daily precipitation sum in *Serbia* of 137.1 mm was registered in Negotin on July 16, breaking the previous record of 67 mm set on July 5, 1970. July was extremely wet (up to 340% of normal 1961-1990) almost at the whole territory of *Slovakia*. Some extremely daily precipitation totals occurred in July (e.g. station Dolná Poruba) when the intensity of rain reached on 27.07.2016 91 mm/30 min. and 110 mm/1h (128 mm/d) what means occurrence once for 200 up to 500 years. At station Revúca the daily precipitation totals on 29.7.2016 reached 112 mm/d (53.2 mm/1h), at station Zverovka on 31.7.2016 136 mm/d and on 17.07.2016 at station Kremnica 110 mm/d, Kremnické Bane 128 mm/d (79.8 mm/h). This caused flooded houses and streets.

In Former Yugoslav Republic of *Macedonia* monthly sum of precipitation in **August** was below average in Berovo, Stip and Strumica, while in Mavrovo, Ohrid and Bitola twice as the average values and in Skopje and Demir Kapija three times higher than the average. On the 6th of August the wider urban and rural areas of Skopje was under influence of severe weather event with catastrophical consequences associated with torrential rainfall, a lot of thunderstorm lightning and flash flooding. This disaster caused huge material and economy damages and human victims. Daily precipitation amount in Skopje on 6th of August was exceeded, reaching 92.9 mm. The amounts of precipitation that instrument registered were with record- breaking intensity which can appear once in a thousand years.
In central *European Russia*, very heavy rains caused by an active atmospheric front occurred on 14-15 August. In Moscow, along with daily precipitation maximum (25.2 mm in 1887), monthly (59 mm in 2003) and summer (63 mm in 1970) precipitation maxima were also exceeded. In the interval from 18:00 on 14 August through 18:00 on 15 August 102 mm of precipitation were recorded by meteorological station Moscow (Balchug).

Average precipitation sum in **September** in *Latvia* was 21.6 mm, which is 33% of the normal. This was the 2nd lowest monthly precipitation amount in September in Latvia ever recorded (since 1924). Within a few days, Afritz (*Austria*) was affected by several landslides. Following rain events caused local flooding especially on the northern side of the Alps.
During 6-9 September 2016 a cut-off upper level low at the SW of *Greece* affected mainly the west part of Greece and caused severe thunderstorms with heavy rainfalls, floods, landslides, and locally tornadoes with 6 causalities. During the 6th station Kerkira reported a daily amount of 113.3 mm/d and station Kalamata 132.6 mm/d while at station Araxos 66.1 mm/12h occurred and on the 7th at station Geraki 200.2 mm/d. Continuous heavy rainfalls affected several areas of the country causing power outages, large damage to networks, crops, infrastructure, roads and public and private property due to flash floods.
In *Russia* heavy rains in September in the Upper and Mid-Volga Region and the Urals stopped the drought. Monthly precipitation normal was also exceeded substantially in the Krasnodar Territory. For example, Novorossisk received 220 mm of precipitation, which is four times as much as the monthly normal. In *Belarus* September was the driest month, with 24 mm of precipitation, or 42% of the norm. Therefore fires occurred from 05 to 21.09. in Gomel and Brest region.

From 4-6 **October** *Belarus* experienced very heavy rain with up to 100 mm/48h at station Zhitkovichi. On 11-13 October due to a cyclone moving from the Balkans there were long and very strong storms and wind up to 25-31 m/s in the *Ukraine*. In Mykolaiv and Odessa 50-78 mm of rain fell during 12 hours. In Odessa and Bolgrad (Odessa region) during 20-26 hours fell up to 104-107

mm of rain. Houses were flooded, traffic was interrupted, numerous cases of fallen trees and tall cranes, and losses of lives were recorded. The state of emergency was declared in Odessa. In Odessa and Bolgrad (Odessa region) during the month fell up to 700% of the monthly rainfall – 180 and 201 mm, respectively. These weather stations recorded daily maximum of rainfall - 104 mm (Bolhrad) and 103 mm (Odesa), amounting up to 4 times the monthly norms.

The amount of precipitation in *Moldova* for the month was on the territory 85-185 mm, which surpassed 3-6 times the monthly norm and on 60% of the territory in this month was observed for the first time during the whole period of observations. The mean monthly precipitation amount at country level in *Romania* (103.6 mm) was 138% larger than the climatological normal (1981–2010). Positive deviations were very large, exceeding 100% at most weather stations and extremely large in Moldavia, where they exceeded 350%. The widest deviation was recorded by Galaţi weather station, 802% or 207.8 mm with 90.6 mm at 11th October followed by flooding. The highest monthly precipitation amount recorded in Romania in October 2016 was 294.7 mm at station Cudalbi, in Galaţi county.

On the 3rd October 2016 *Ireland* experienced an extreme precipitation event in the Kerry region with daily totals at station: Roads (Kells Bay) 159.4mm (opened 1996), Derriana 156.5mm (opened 1993), The Glen (Ballinskelligs) 166.5mm (opened 1985), Knightstown 182.0mm (opened 2006), Cloone Lake 198.6mm (highest ever reported for October).

Severe weather event in the South of Portugal, 23rd to 25th October

(as provided by the Instituto Português do Mar e da Atmosfera, IPMA)

In the period 23rd to 25th October 2016, adverse weather conditions occurred, in the north and central coastal regions on 23rd of October and on days 24 and 25 in the southern regions of the Montejunto-Estrela mountain system.

On day 24, the southern regions were affected by instability lines where numerous convective cells were formed successively, most of them with super cell characteristics, with intense electric activity, causing heavy precipitation, strong wind and tornadoes. Some impacts on structures associated with extreme wind events that, due to their occurrence very localized, were not detected in the network of meteorological stations of the IPMA.

In the southern region, the highest precipitation amounts in 24 hours occurred between 11 hours UTC on day 24 and 11 UTC on day 25, and were higher than 50 mm (radar/udometer method), in some locations of the municipalities of Vila do Bispo, Silves, Almodôvar, Loulé and Faro, in the Algarve, and in the municipalities of Beja, Vidigueira and Portel, in the Alentejo. In particular, in the period from 17 to 22 UTC, hourly values were greater than 10 mm, and 3-hourly values greater than 25 mm.

The highest daily rainfall values recorded in the IPMA and APA station network were 27.9 mm in Portel (from 20 to 21 UTC on day 24) and 26.3 mm in Sagres (10 to 11 UTC on day 25). The highest values accumulated in 3 hours were recorded in Portel, 41.4 mm (from 20 to 23 UTC on the 24th) and in São Barnabé 39.9 mm (from 18 to 21 UTC on the 24th).

The highest concentration of atmospheric electrical discharges, about 2/3 of the total recorded in the whole period under analysis, occurred on the 24th, between 19 and 23 UTC.

There was an early start of the snow season in southern *Sweden* early in **November**. Stockholm reported a new record for greatest snow depth in November with 47 cm in the evening of 9 November.

In the period from 22 to 27 of November, due to a cold and unstable air mass, there were heavy showers and thunderstorms in almost whole *Portugal*. In the North and Centre snowfall occurred at altitudes above 1200 m on days 22 and 23, decreasing to 900m on 25 of November.

During 26-30 November 2016 a 5-day severe weather event affected mainly the west and eastern part of *Greece*, including Attica, the capital of *Greece*, and caused extended floods due to continuous rainfalls. on 26-27 at the station Zakinthos 183.4 mm/48h; on 28-29 at station Mitilini 177.2 mm/36h; on 29 at station Kos 86.2 mm/12h. Flooding also affected Athens the capital city of Greece, where several Metro-underground stations and roads had been closed.

Flood of 21-26 November 2016 in Piedmont (northern *Italy*) with 165 mm in 24 hours in Piaggia on 23 November, cumulative value for the 24 November was 385 mm at station Barge. The highest peak in 24 hours throughout the event was reached between the 24. and 25.11., with 436 mm at

station Barge. The highest overall values for this 5 day period: in the upper Val Tanaro the station Piaggia (CN) recorded a total of 632.6 mm/5d.

Forest fires November 22-27th in Israel

(provided by the Israel Meteorological Service)

Widespread fires both in urban areas and wildfires enhanced by conditions of strong easterly winds and extreme dryness Hundreds of apartments completely destroyed mainly in Haifa, 75,000 residents evacuated. Cost of damages estimated at more than $100 million. It was a very dry month with average relative humidity 15%-20% below the long-term average in northern and central Israel, which is record-breaking. In Bet Dagan, for example, the average monthly relative humidity at 08:00 and 20:00 L.T. (06 and 18 UTC) was 50% compared to a long-term average of 68%-70%. This is the lowest value ever recorded for these hours in comparison to all months, not only to November.

The monthly amount of precipitation of 7.3 mm in **December** 2016 is the 2nd lowest ever recorded for December since 1947 in *Luxembourg*. North of the Alps and in the Alps of *Switzerland* a stable high-pressure zone led to the month with the least precipitation in many areas since observations started in 1864. In several regions of the western half of the Plateau and in the Valais December did not receive any precipitation at all.

December was very dry in most of Slovakia but extremely dry in south of middle *Slovakia* (Novohrad and Gemer region) where locally only 2%-4% of normal (1961-1990) rain occurred. Rainfall has experienced a record deficit of about 80% on average across the France. Only Corsica was very wet with a particularly intense episode on the 19th and 20th. On the eastern half of the island, the monthly accumulation exceeded one and a half times the normal. This deficit of precipitation resulted in a very low snow cover on all the massifs, with the exception of the Southern Alps and the Corsican Mountain. December 2016 thus ranks first among the driest December in the period 1959-2016, dethroning December 2015.

Heavy rainfall events from 16th to 22nd December affected to a big area of the southeast *Spain* from Valencia to Almeria, as well to Ibiza and Mallorca Islands. The precipitation accumulated during this event was more than 450 mm in some stations of north Mallorca and more than 350 mm in southeast of Valencia. The maximum values of the series were exceeded in many stations, both the maximum monthly precipitation values and the maximum daily precipitation values. The highest amount of rain accumulated in 24 hours in a principal station was reported on 18th December in Alcantarilla (Murcia) with 112 mm, 109 mm in Murcia and 103 mm in Palma de Mallorca-airport.

December was rainiest since 1992 and coldest since 1994 in *Israel* with monthly totals of 250-300 mm in the northern and central Coastal Plain, which is 200%-250% of normal. Large rainfall amounts in December eliminated the shortage of rainfall at the end of November.

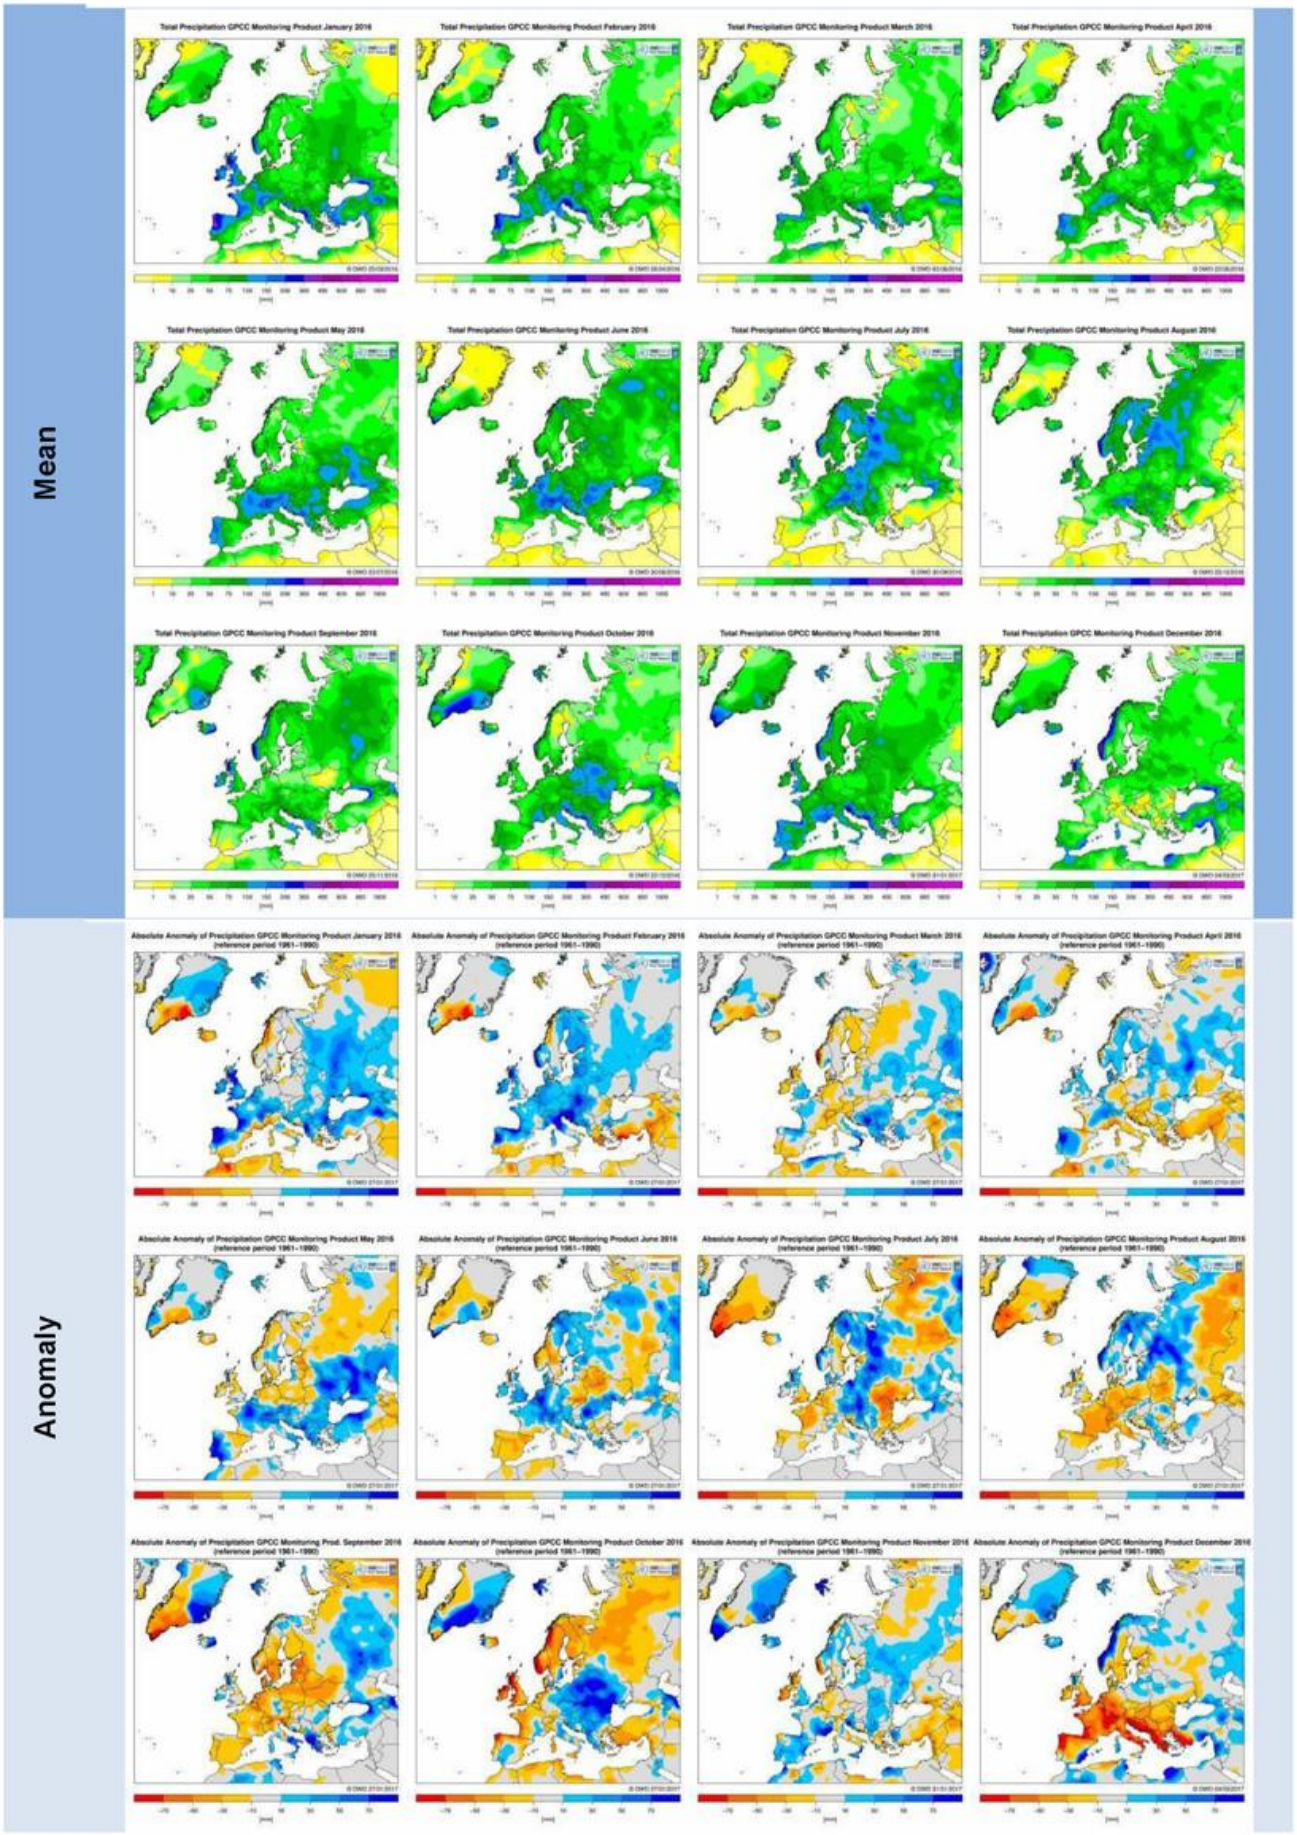

Figure 4.12: Mean and anomalies of precipitation (in mm/month) for each month of the year 2016. (First column January, February, March, April, … ; reference period 1961-1990).

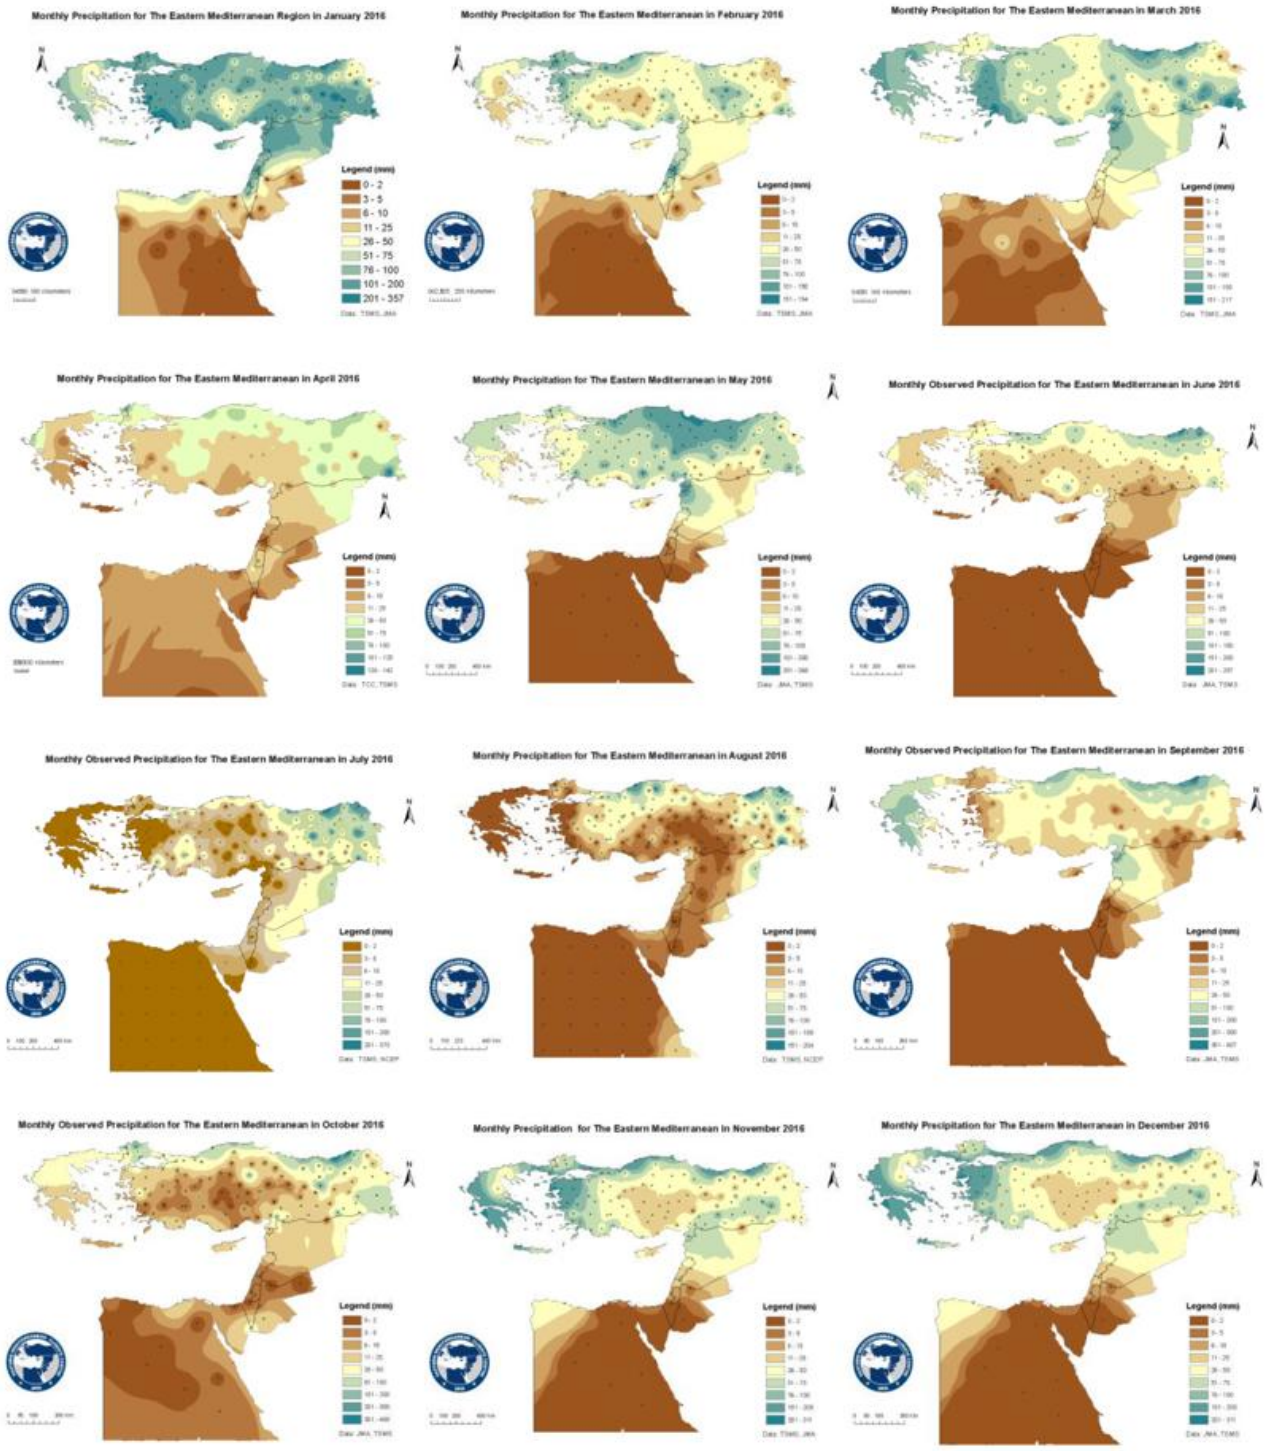

Figure 4.13: Monthly precipitation totals (mm) for the Eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC).

4.4. Sunshine duration

In **January 2016** most of central Europe, southern Scandinavia and the Baltic States had more sunshine than normal. The Mediterranean from Iberia to Turkey showed negative anomalies of sunshine duration, except Central Italy, the Balkans and the region around the Aegean Sea. Northern Scandinavia and parts of Russia actually had only below 25% of normal sunshine. January in *Latvia* with 53.7% more than normal sunshine duration experienced a very sunny month. Reykjavik had 4.7-times more sunshine than the average from 1961-1990.

In **February 2016** sunshine duration showed few areas with positive anomalies over Ireland, the UK, western France, Benelux countries, southern Sweden (with new records in the south), eastern Spain, central Italy, Greece, Bulgaria and Turkey. The other parts received below normal sunshine.

In **March 2016** sunshine duration showed some areas with positive anomalies over Ireland, the UK, western France, Benelux countries, Finland, southern Spain, central and northern Italy, Greece, Bulgaria and Turkey. The other parts received mostly below normal sunshine.

Sunshine duration in **April** showed in great parts above normal anomalies especially in north-west and south-east Europe (Northern Poland measured a surplus of 60 hours). Only France (in the east locally a deficit of 30%), Switzerland and Russia received below normal sunshine.

Monthly sunshine in **May 2016** showed high positive anomalies over the northern half of Europe, United Kingdom, Ireland, Spain, northern part of Central Europe and the Middle East. Estonia registered an average of 375 hours of sunshine, which is 136% of the normal (276 hours).

Sunshine duration in **June** showed below normal values in Central Europe, northern Italy and northern Scandinavia. Iberia and Eastern Europe had a surplus of sunshine of more than 125% in Spain and Poland. In Great Britain sunshine was generally below average except in Shetland and north-west Wales, and it was the dullest June on record in south-east and central southern England. The United Kingdom overall average sunshine was only 81%, making it the seventh dullest June in the series.

Sunshine duration in **July** had a surplus of sunshine in Iberia and Western Europe while central and north-western Europe showed below normal values. Monthly sunshine totals in Ireland were lowest at station Knock Airport with 78.2 h (59% of the long term mean) its dullest July in five years. A band of higher sunshine duration occurred from central Scandinavia to the Balkans and back to northern Russia with a maximum over south-western Ukraine.

In **August** in a band from Iberia and Western Europe to southern Russia a surplus of sunshine occurred while northern Europe showed below normal values. In France several stations reported new records of monthly sunshine hours. Monthly sunshine totals in Ireland were lowest at station Knock Airport with 83.6 hours (67% of the long-term average). Northern Scotland and England also reported higher than normal sunshine duration.

In **September 2016** in most parts of Europe the sunshine duration was above normal except the United Kingdom, western France, the Central Mediterranean and European Russia. In Central Europe the surplus of sunshine was widely more than 50% of the normal. In north-western Poland the sun shone more than 260 hours, 120 hours above the norm. The consequence of this surplus of sunshine was positive temperature anomalies and heat waves.

In **October 2016** most of Europe was cloudy and dull. Only some western parts (Scandinavia, France, the United Kingdom and Ireland) received more sunshine. In Turkey sunshine duration was also above normal.

The map of sunshine duration in **November** shows a very irregular pattern. The mountain regions of the Pyrenees and Alps were very cloudy, also southern Italy and Eastern Europe. United Kingdom reported 130% of the normal, the third sunniest November in a series from 1929. In Malta the bleakest and wettest month in 2016 was November, with only 150.1 hours of sunshine and 90 mm of rain recorded.

In **December 2016** many parts of Europe recorded positive anomalies above 150% of normal sunshine duration because of high-pressure weather. In Austria it was the 2nd sunniest December on record (after December 2015) and at many stations in Switzerland it also was the sunniest December since the beginning of their data series in 1959. In France also several records were broken with more than 200% and even more than 250%.

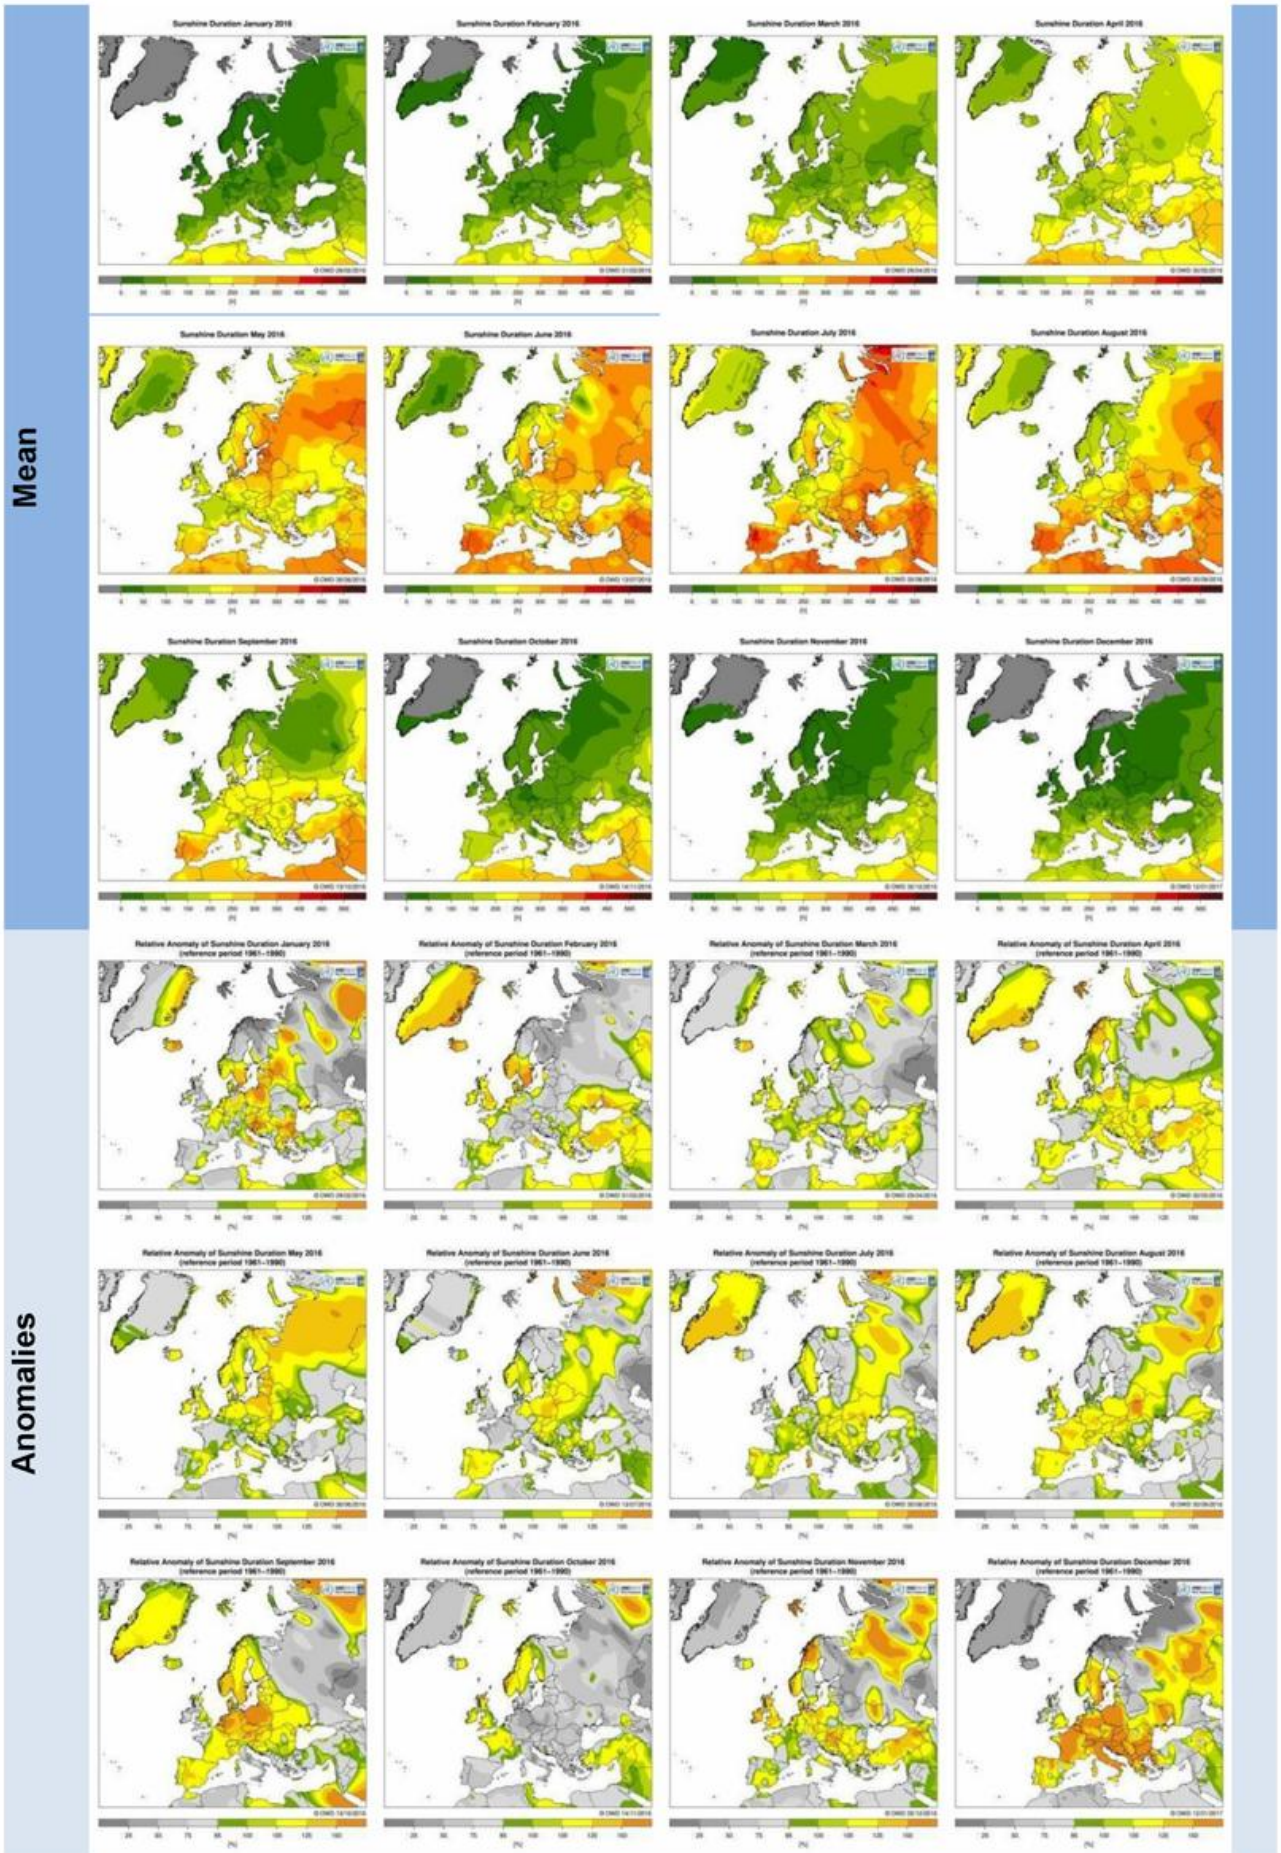

Figure 4.14: Mean of sunshine duration (in hours) and relative anomalies (in %) for each month of the year 2016. (First column January, February, March, April, … ; reference period 1961-1990).

4.5. Maps of monthly climate extremes and events

The following maps are based on different data (as noted in the legends in parentheses), and is meant to summarize weather conditions in each month of the year 2016.

In **January 2016** Scandinavia was down to -4°C colder than normal and the numbers of cold days were above normal. Central and southern Europe showed more warm days than usual. The areas at the Norwegian and Greenland coasts were affected by strong wind gusts and also the Bretagne, the Gulf of Lions and the coast of the Adriatic Sea. Most of Europe was wetter than usual.

In **February** more warm days than normal could be found in Europe in combination with more precipitation and storms on the coasts of Western Europe.

Warmer days in **March** occurred in Northern and Eastern Europe with strong wind gusts at the Atlantic and Mediterranean coasts. In most parts of Europe the very wet days were abnormally high.

In nearly the whole of Europe **April** had more warmer-than-normal-days in combination with very wet days, only in Ireland and western UK cold days were more usual.

In **May** more than usual warm and wet days were registered except over the Balkans where some cold days occurred.

June was wet and warm in many parts but also drier than normal in Iberia.

As several month before **July** became warmer and dryer than normal in the south-west part of Europe while the North and East had more wetter days as usual.

The southern part of Europe had more warm days in **August** with drought situation in France and Iberia. Scandinavia had more wet days and locally some colder days. Eastern Europe had in many parts a precipitation surplus.

In **September** the North Sea coasts were affected by wind gusts and no anomalies of cold days existed.

Central, northern and Eastern Europe showed in **October** more cold days than usual. Eastern Europe noted a higher number of very wet days. The Gulf of Lions and the Aegean Sea were affected by thunderstorms with strong wind gusts.

During **November** southern parts of Europe showed a higher number of warm and wet days. Norway, the UK, Denmark, the Bretagne and in the Gulf of Lions were affected by strong wind gusts in November. Northern observed more cold days than normal

The **December** showed in the western part Europe again more warm days than normal, but northern and Eastern Europe was wetter and southern Europe dryer than normal. Several cyclones with strong wind gusts passed over Scandinavia, the UK, Central Europe up to Greece.

The Monthly Event Map contains information about the extreme anomalies of temperature, precipitation and wind gusts. Points are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (>=32 m/s) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

Legend of Figure 4.10:

- Anomaly of very wet days > 0 (ECAD)
- Wind gusts (≥ 32 m/s) (SYNOP)
- Anomaly of warm days > 0 (ECAD)
- Anomaly of cold days > 0 (ECAD)
- Anomaly of TG ≤ -4K (CLIMAT and ship obs.)
- Anomaly of TG ≥ 4K (CLIMAT and ship obs.)
- Aridity index < -1.5 modified SPI (GPCC)
- RR ≥ 150% of climatology (GPCC)

Based on climatology 1961-1990 (GPCC climatology: 1951-2000)

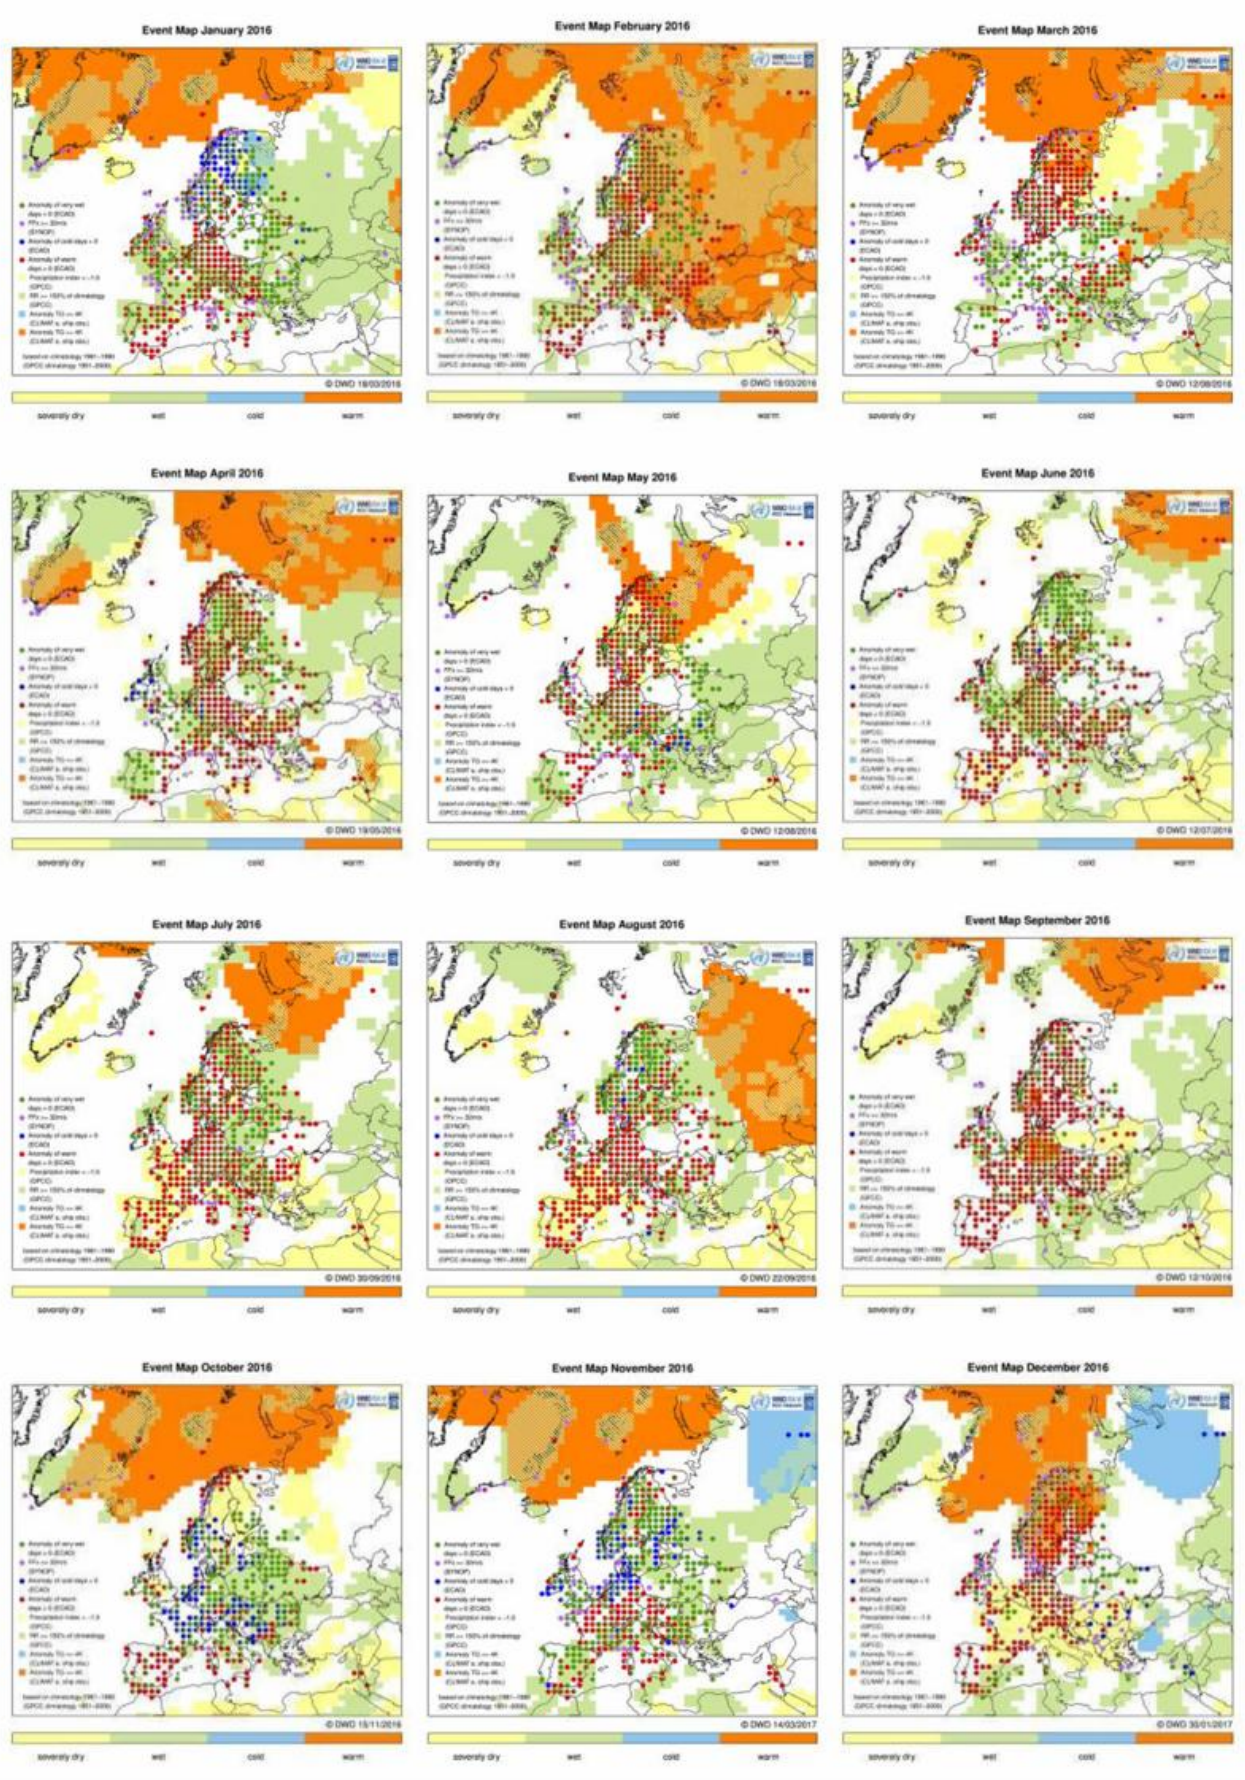

Figure 4.15: Maps of Climate Extremes for each month of the year 2016.

5. Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the National Meteorological and Hydrological Services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 sub-regions defined above (Figure 1.1). An overview of contributing countries, time series' lengths and area representativeness can be found in Table 5.1. Most are temperature time series. Each sub-region is at least represented by one country. Time series of precipitation totals are fewer but each sub-region is represented by at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries, belonging to different sub-regions.

After this, we present examples of the temporal development of other temperature-related phenomena, such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Władysławowo.

Table 5.1: Availability of the long-term records of temperature, precipitation and sunshine duration from some participant countries.

Sub-region	Country	Temperature		Precipitation		Sunshine Duration	
		Spatial Mean	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station
Central and Western Europe	Austria	1768					
	Belgium		1833				
	France	1900

Central and Western Europe - precipitation totals and anomalies

Switzerland

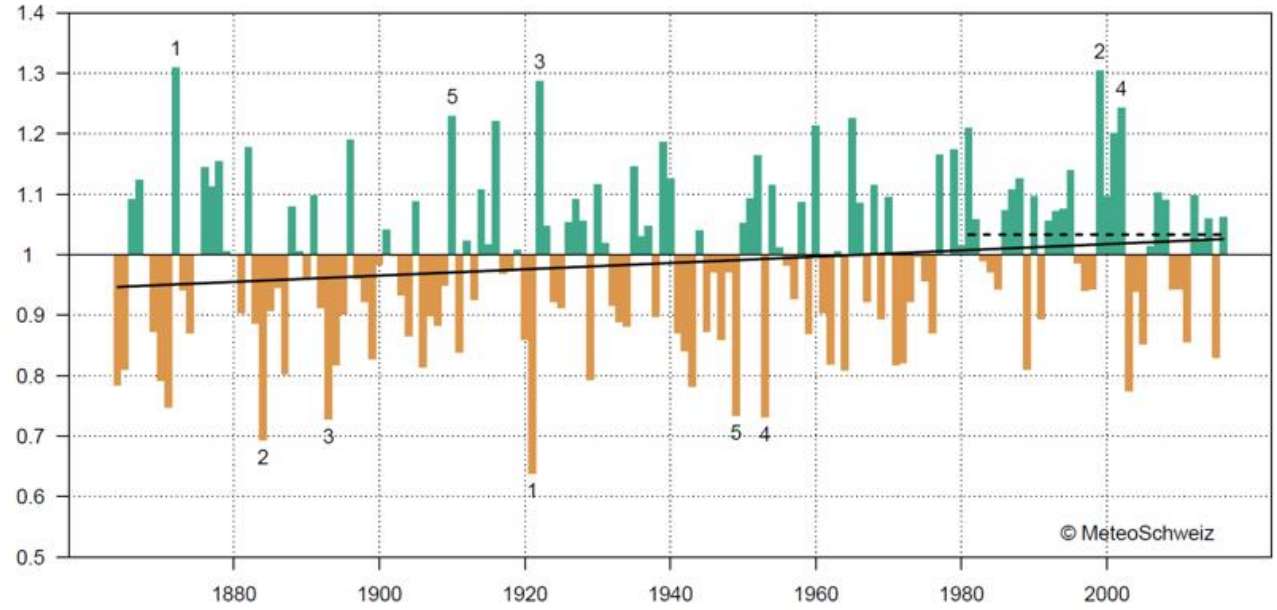

Figure 5.39: Time series of annual precipitation anomalies in relation to the mean of 1961-1990 for Switzerland for the period 1864–2016. Color bars represent anomalies in respect to the long-term mean 1961–1990 and green indicates positive and bronce negative anomalies. The black line represents the linear significant trend (5.2%/100y). The black dashed line represents the mean 1981–2010. (diagram as provided by the NHMS)

United Kingdom

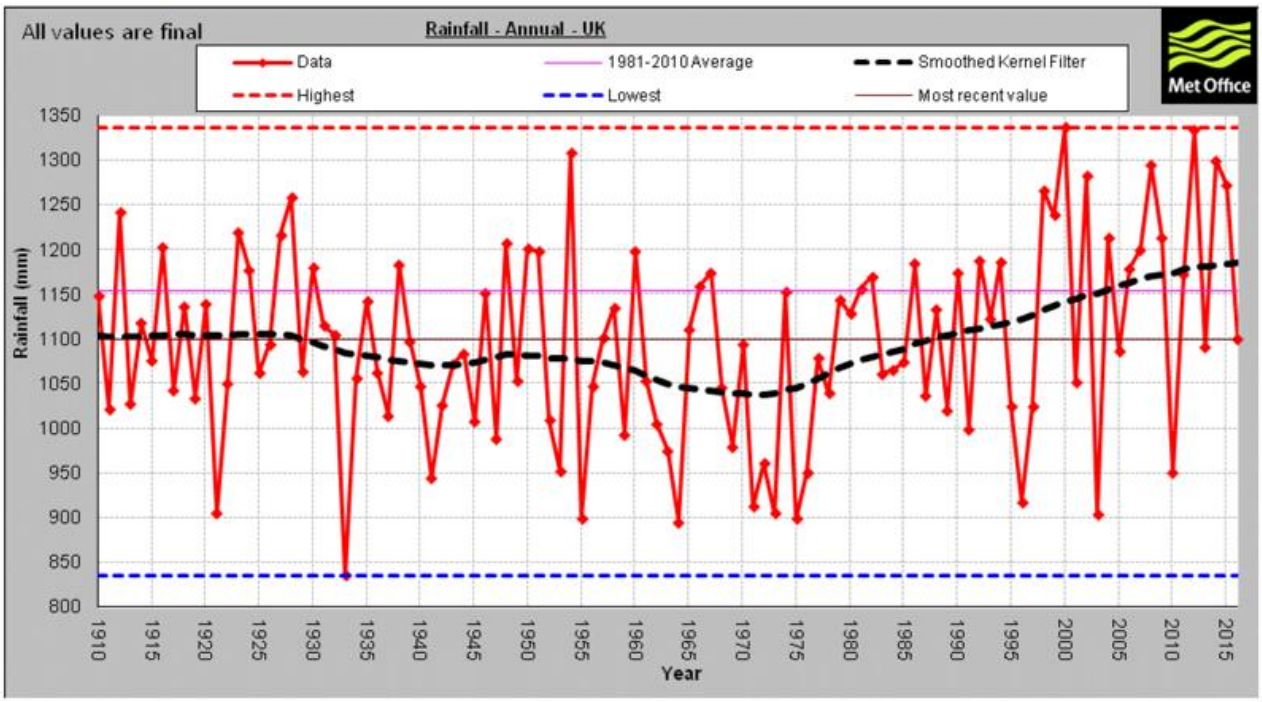

Figure 5.40: Time series of annual precipitation totals in mm/year for the United Kingdom for the period 1910-2016 (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Denmark, Estonia, Finland, Latvia, Norway, Sweden

Denmark

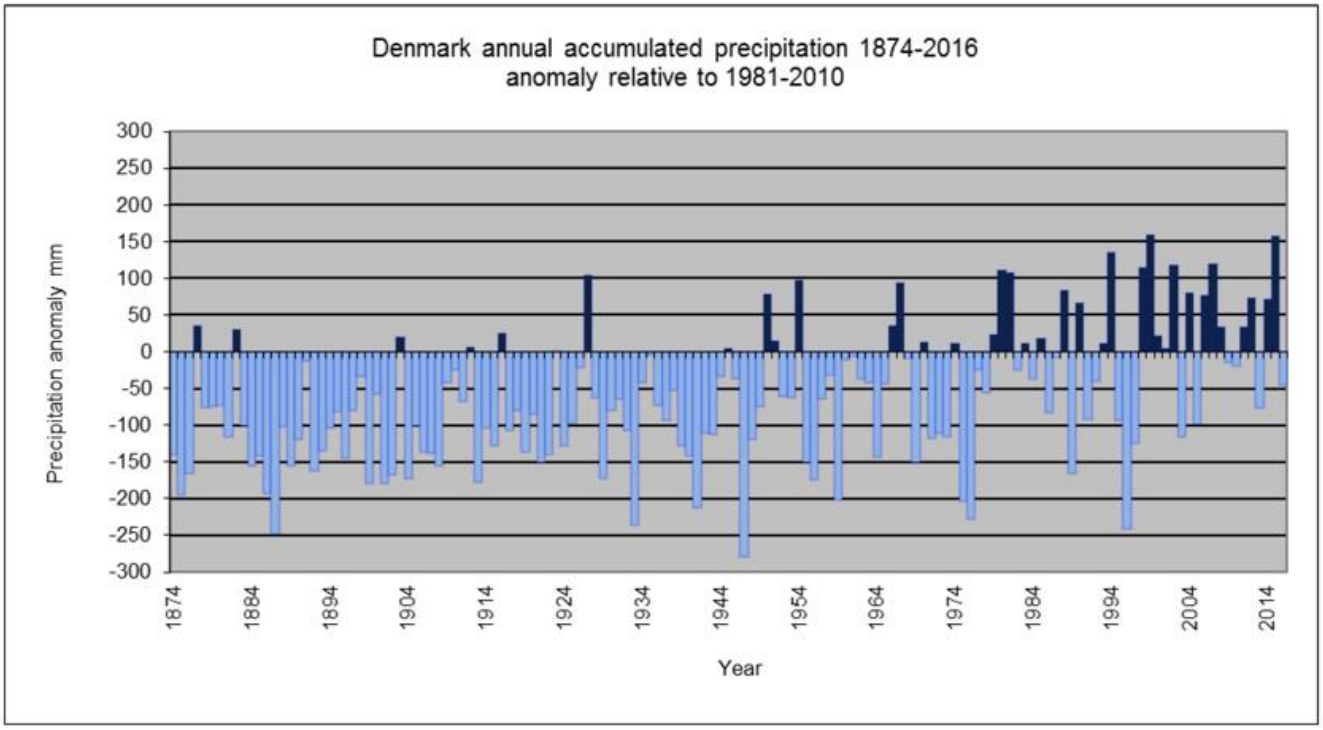

Figure 5.41: Time series of annual precipitation totals in mm/year for Denmark: anomaly relative to 1981-2010 (Diagram as provided by the NHMS)

Estonia

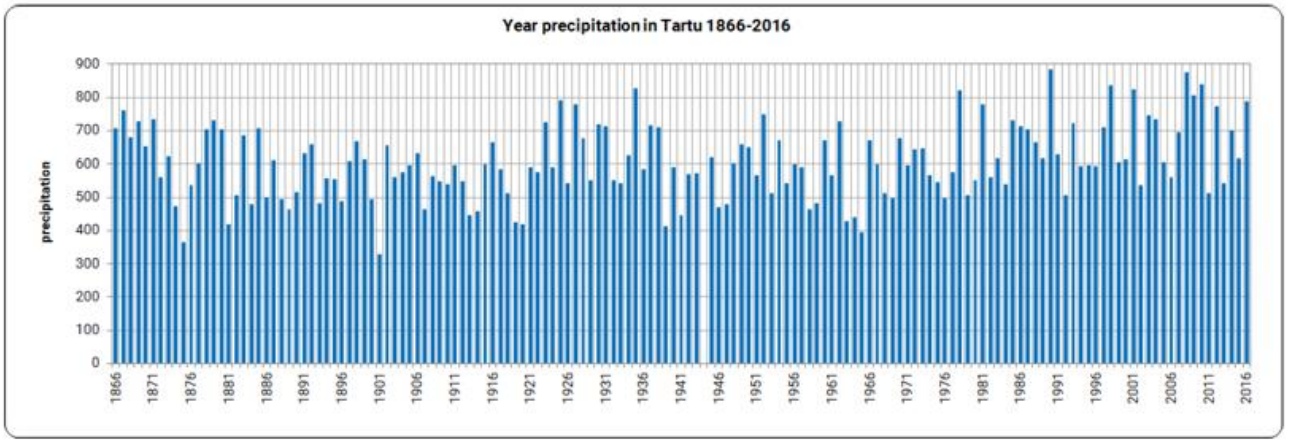

Figure 5.42: Time series of annual precipitation totals in mm/year at station Tartu, Estonia (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Finland

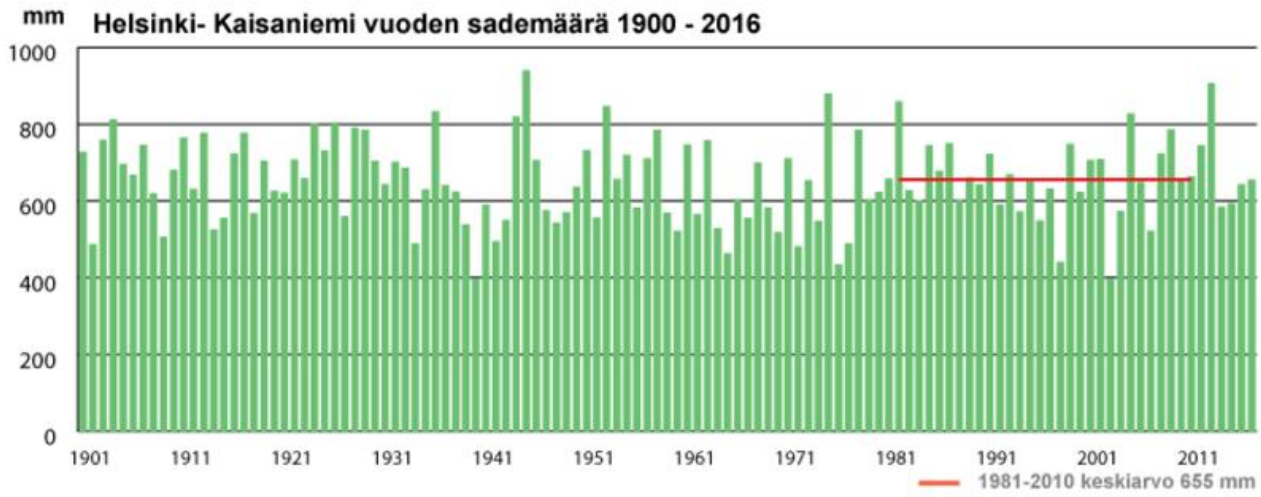

Figure 5.43: Time series of annual precipitation totals in mm/year at station Helsinki, Finland (Diagram as provided by the NHMS)

Latvia

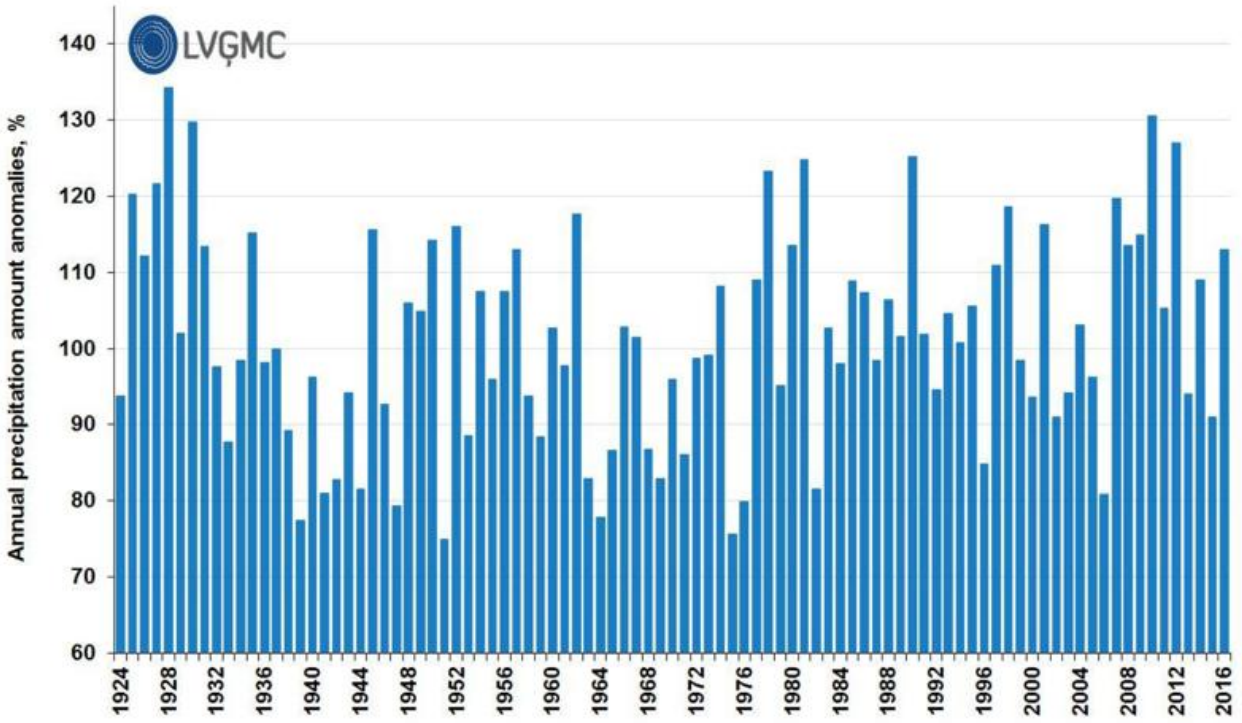

Figure 5.44: Time series of annual precipitation totals in relation to the mean of 1961-90 for Latvia (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Norway

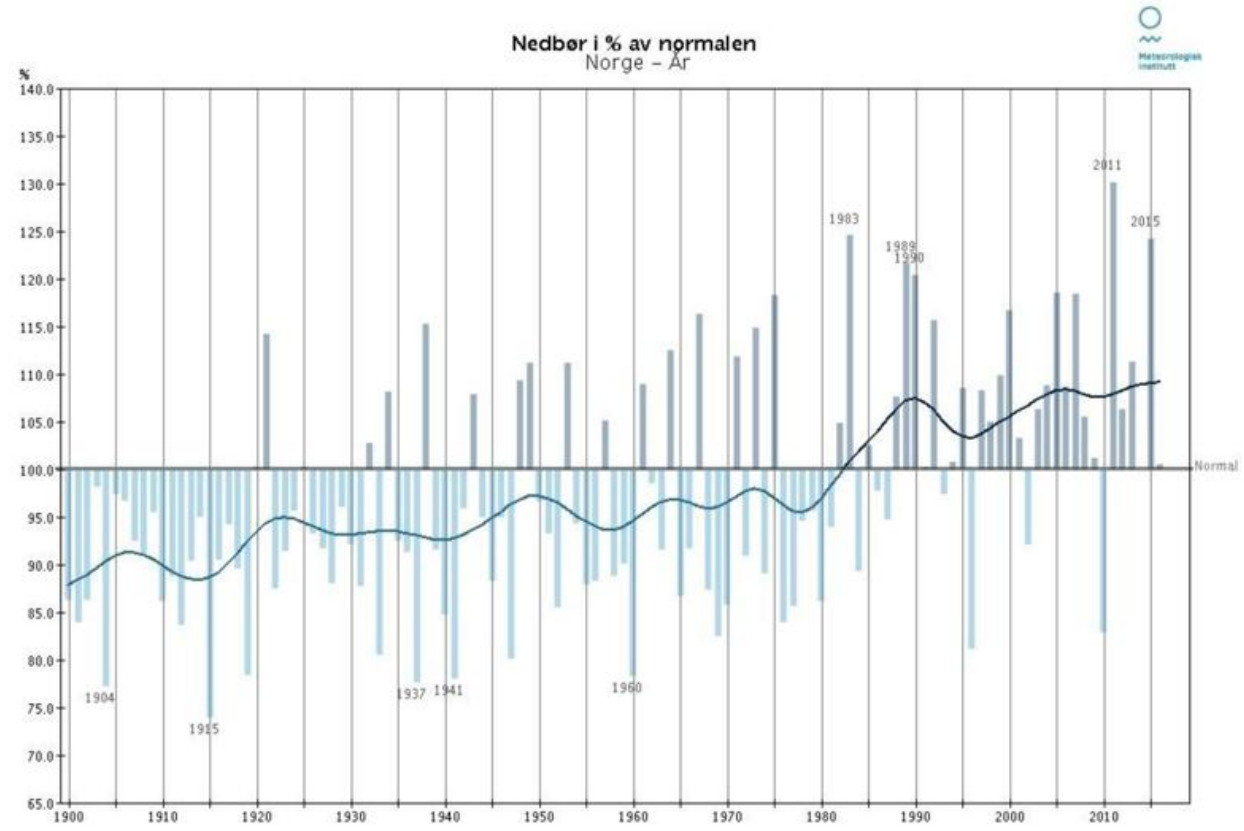

Figure 5.45: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Norway (Diagram as provided by the NHMS)

Sweden

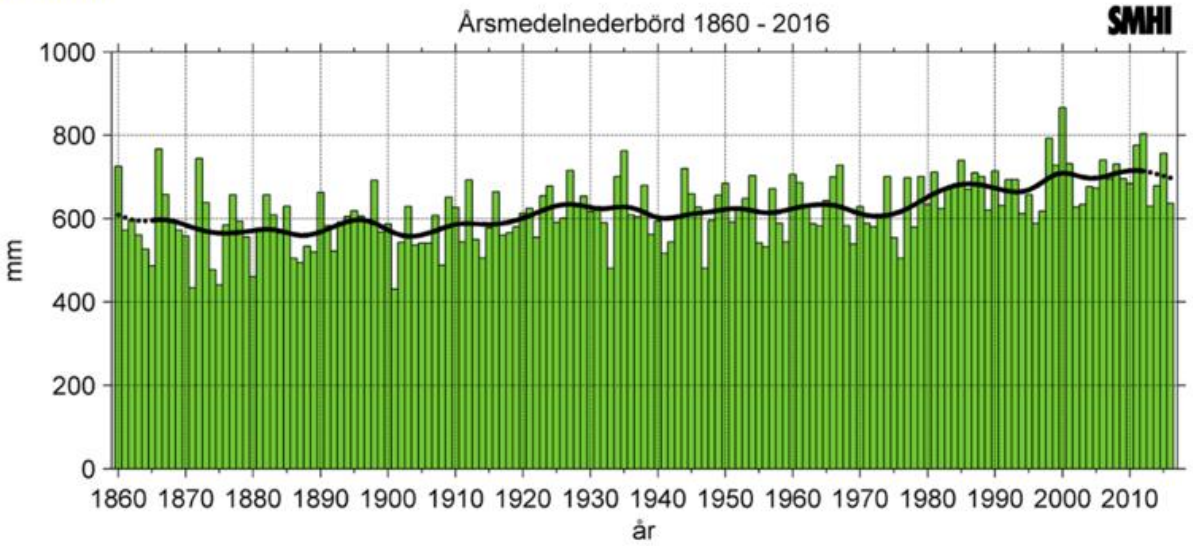

Figure 5.46: Time series of annual precipitation totals in mm/year for Sweden (Diagram as provided by the NHMS)

Iberia - precipitation anomalies

Portugal

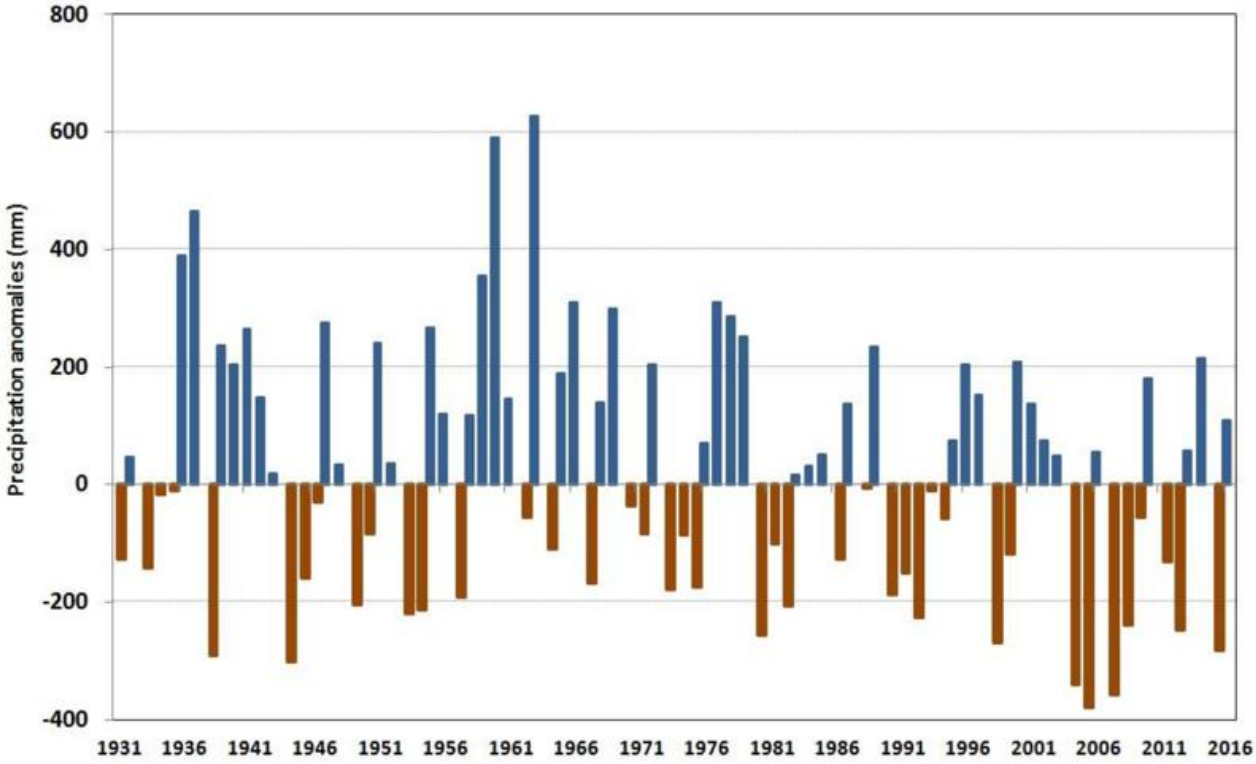

Figure 5.47: Time series of annual precipitation totals in mm/year (deviations from the mean of 1971-2000) for Portugal (Diagram as provided by the NHMS)

Spain

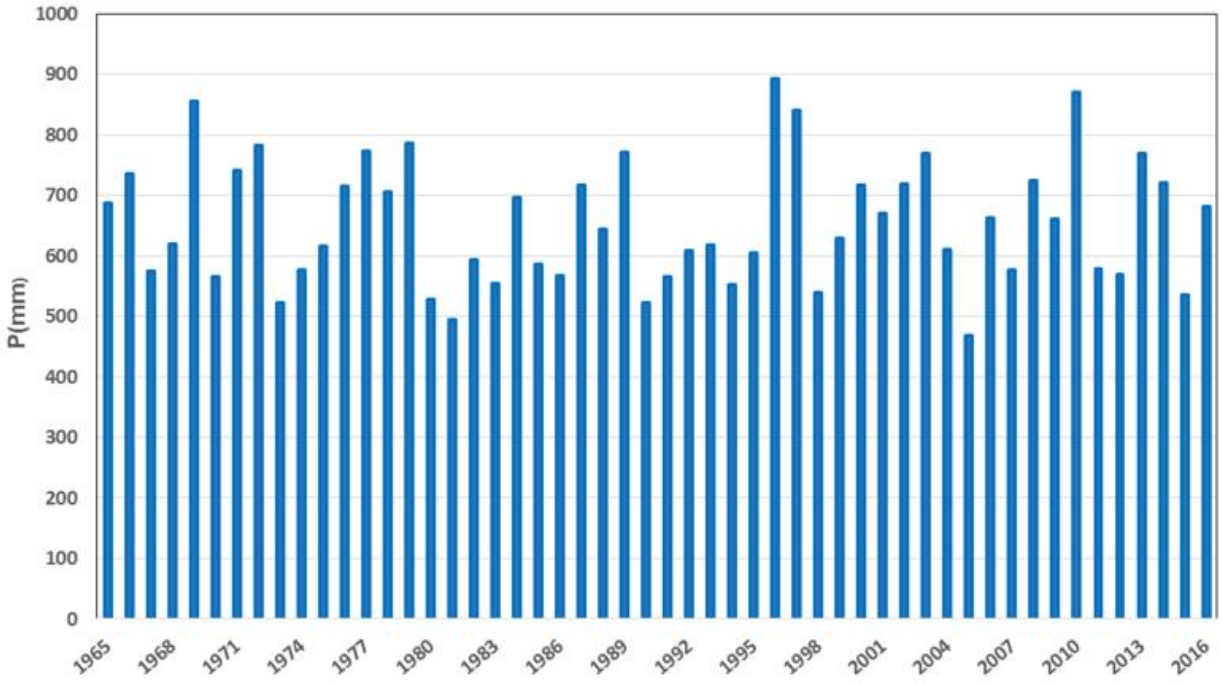

Figure 5.48: Time series of annual precipitation totals in mm/year for Spain (Diagram as provided by the NHMS)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Italy, Slovenia, Turkey

Italy

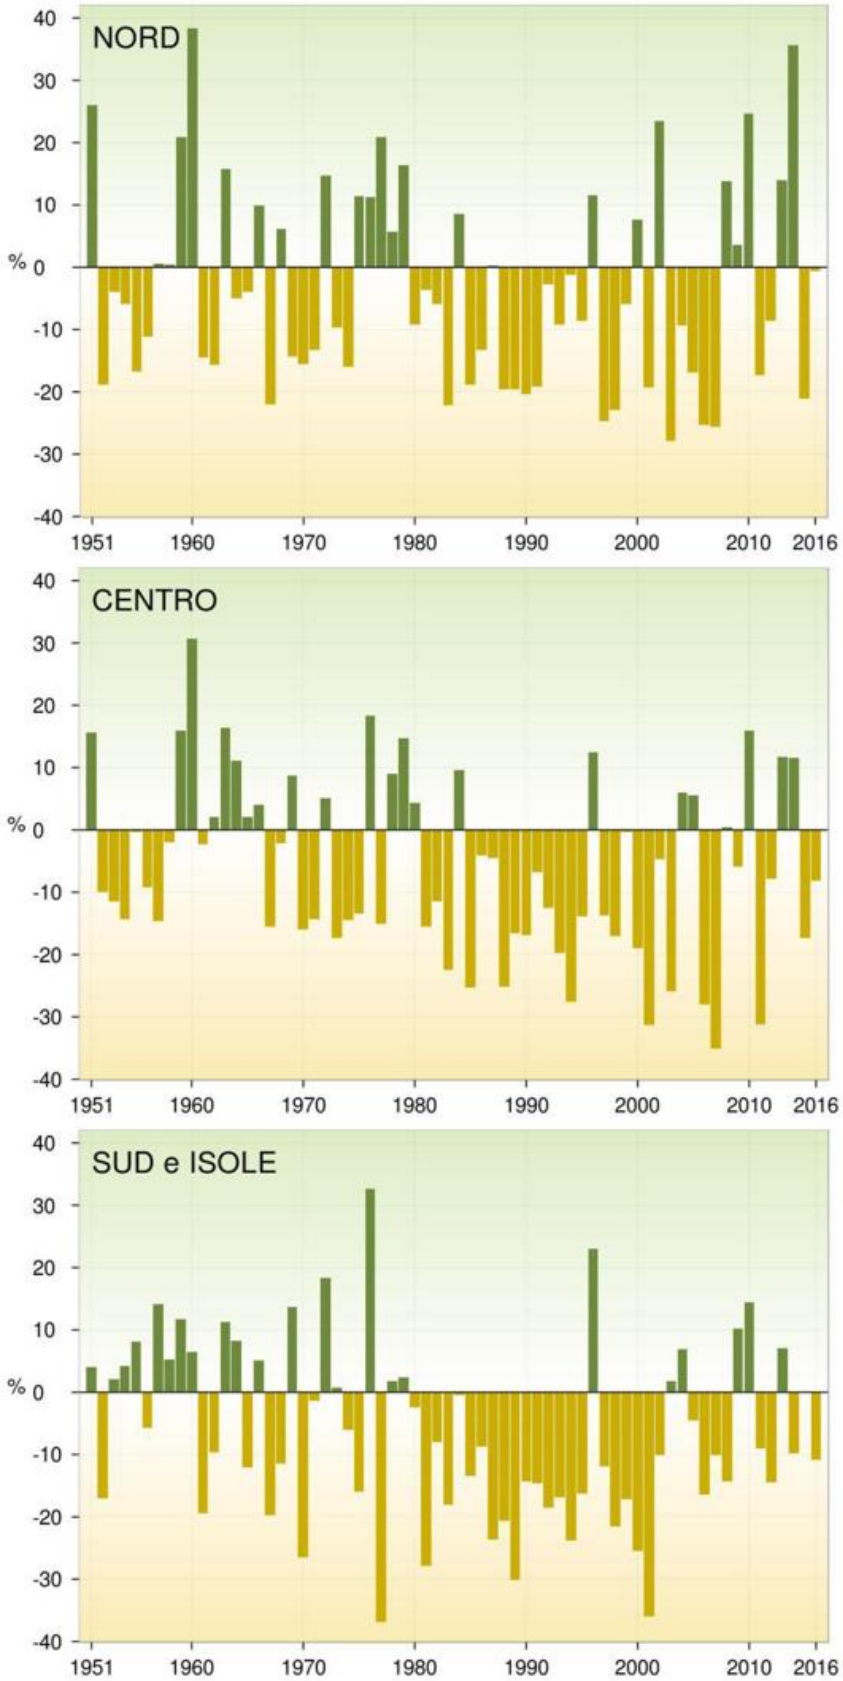

Figure 5.49: Time series of annual precipitation anomalies in relation to the mean of 1961-90 for north (top), Central (middle) and southern Italy (bottom, diagrams as provided by ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Slovenia

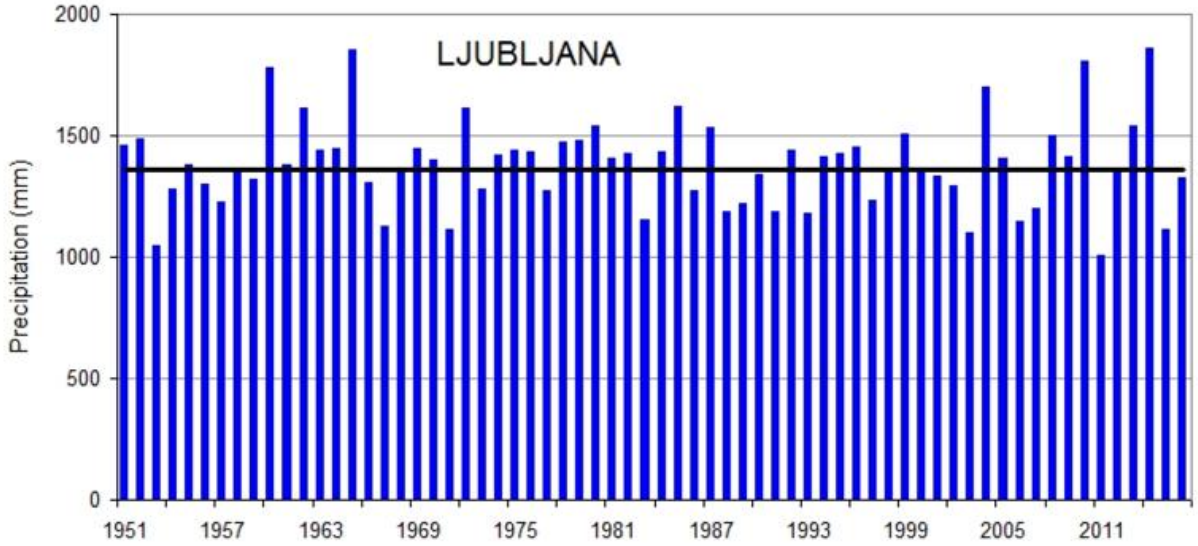

Figure 5.50: Time series of annual precipitation totals in mm/year for station Ljubljana 1951-2016 (diagram as provided by the NHMS)

Turkey

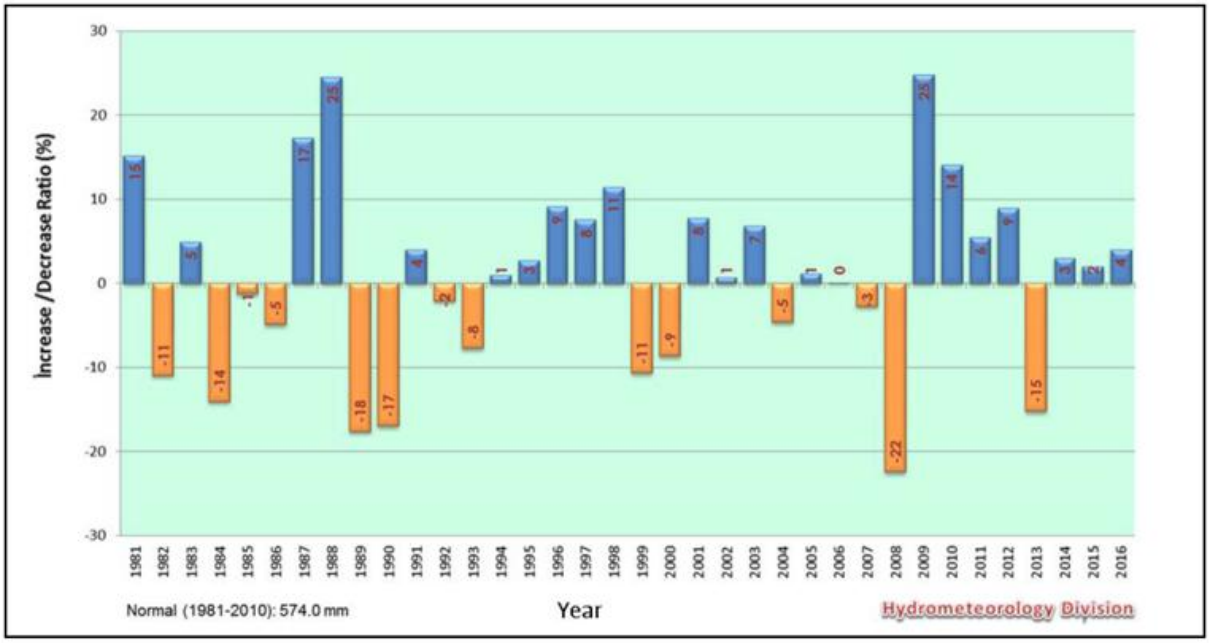

Figure 5.51: Time series of annual precipitation anomalies in relation to the mean of 1981-2010 for Turkey (Diagram as provided by the NHMS)

Eastern Europe - precipitation anomalies

Belarus, European Russia, Ukraine

Belarus

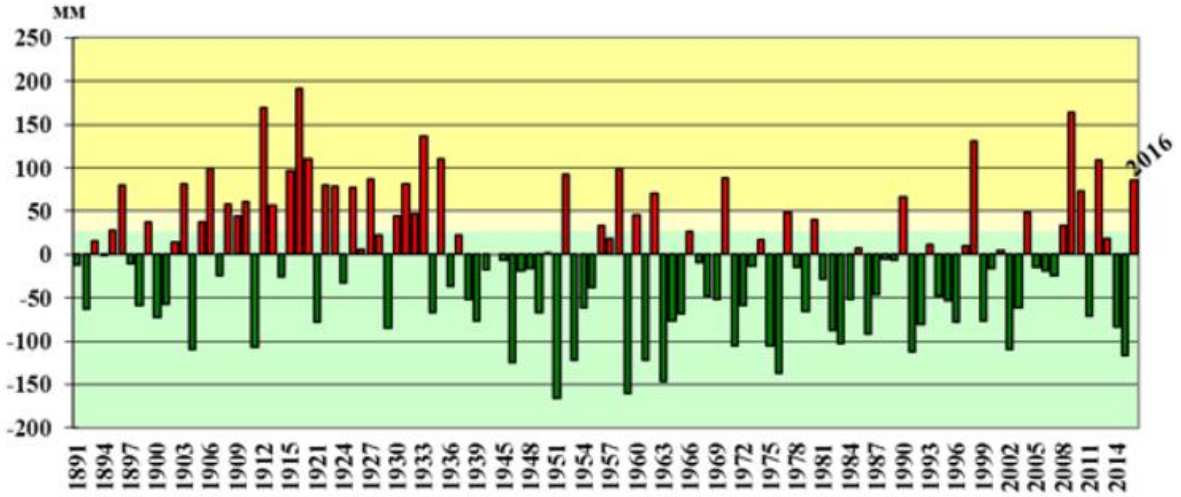

Figure 5.52: Anomalies of annual precipitation totals for Belarus 1891-2016 (base period: 1961-1990; Diagram as provided by the NHMS)

European Russia

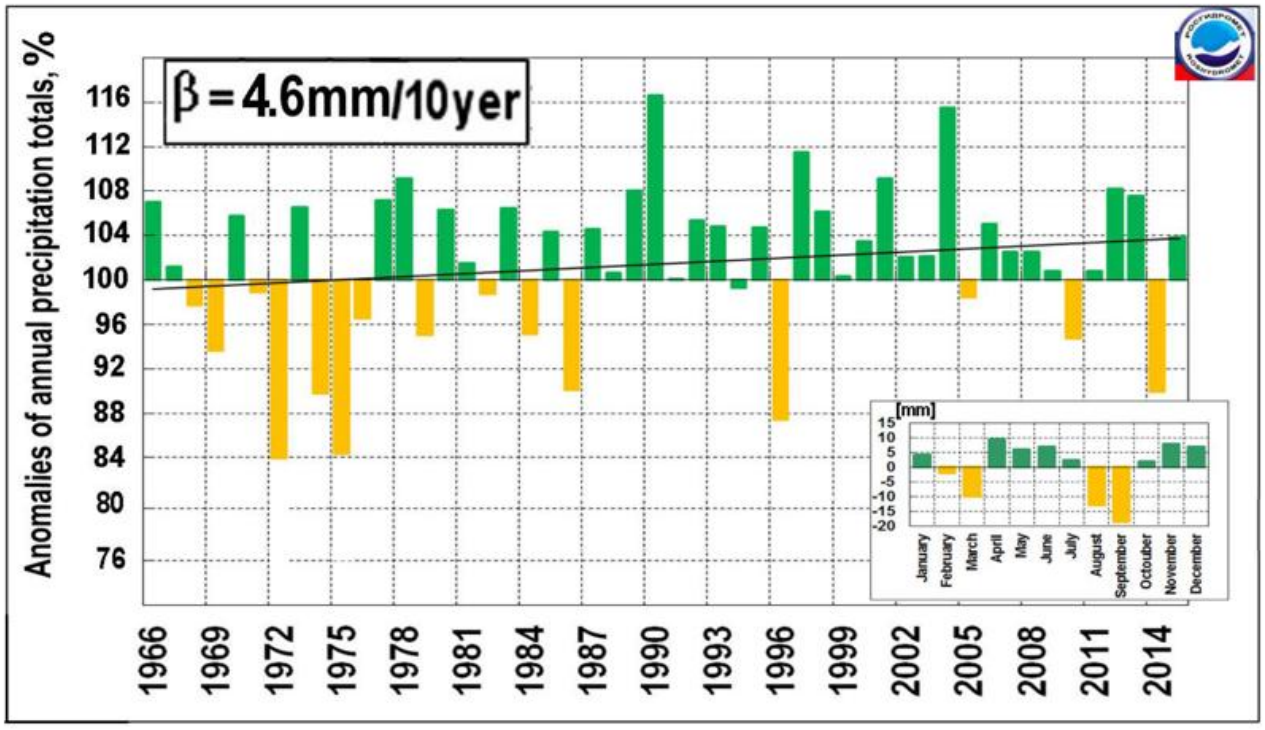

Figure 5.53: Time series of annual precipitation totals in relation to the mean of 1961-1990 for European Russia (Diagram as provided by the NHMS)

Eastern Europe - precipitation anomalies

Ukraine

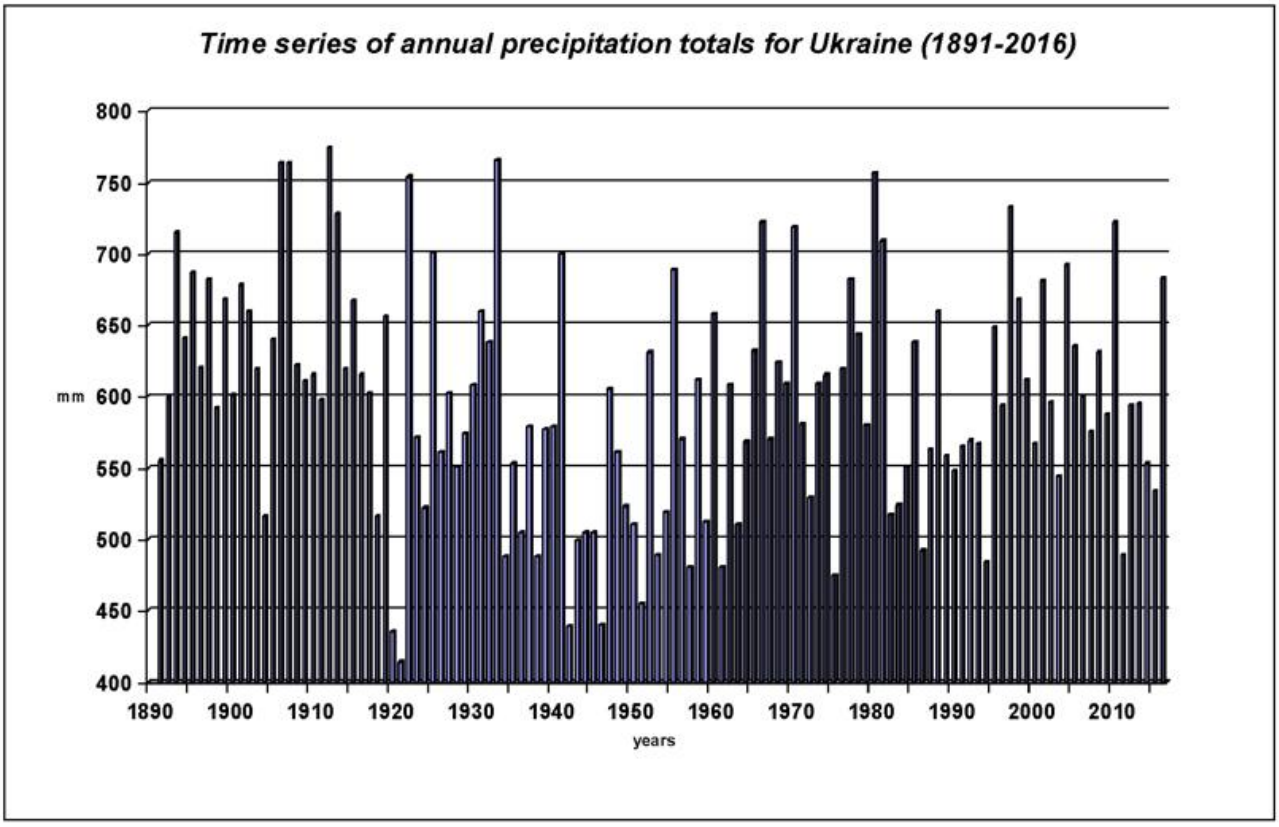

Figure 5.54: Time series of annual precipitation totals for Ukraine (Diagram as provided by the NHMS)

Middle East - precipitation anomalies

Georgia

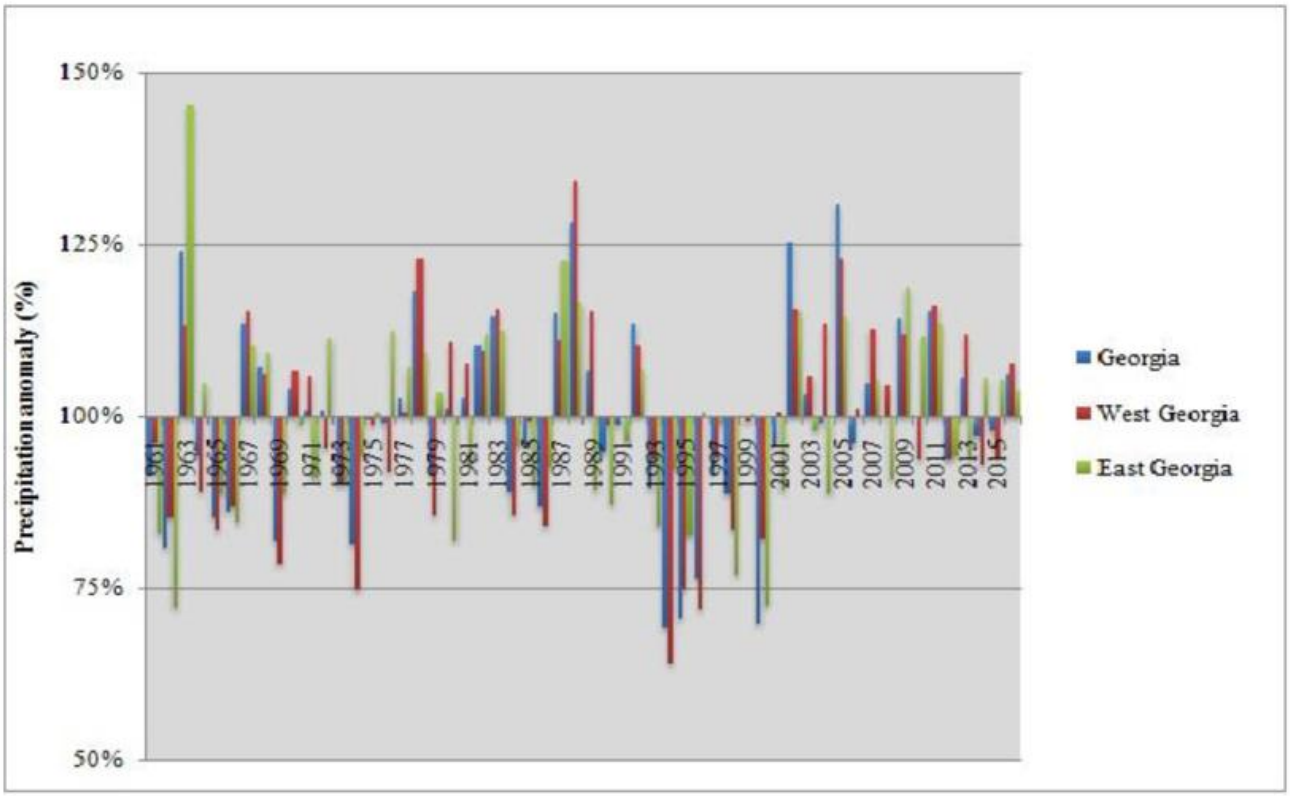

Figure 5.55: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Georgia (Diagram as provided by the NHMS)

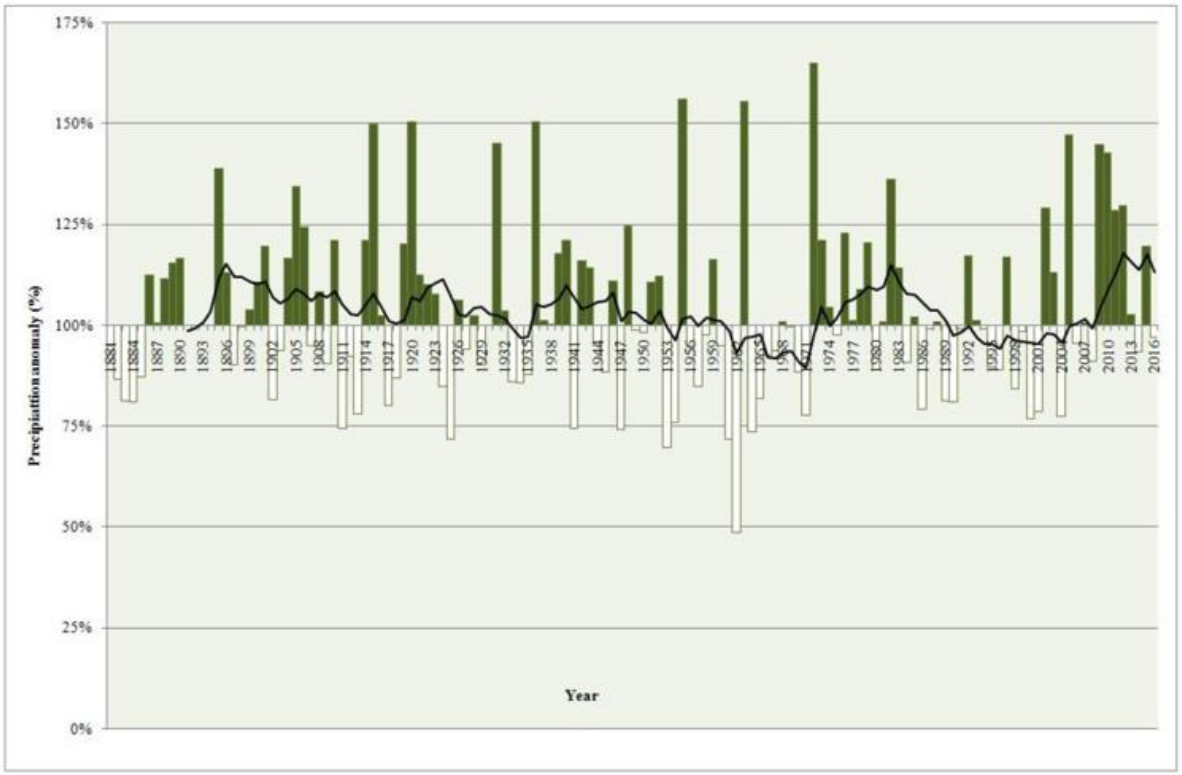

Figure 5.56: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Tbilisi, Georgia (Diagram as provided by the NHMS)

Middle East - precipitation anomalies

Kazakhstan

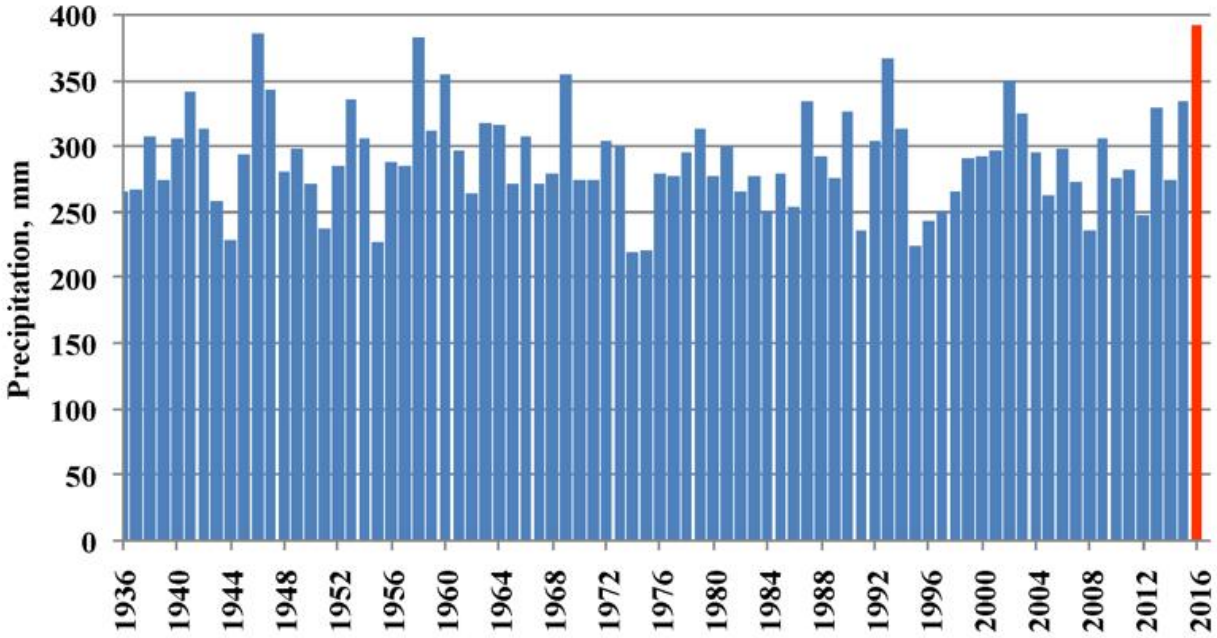

Figure 5.57: Time series of annual precipitation totals across Kazakhstan for the period 1936-2016. The year 2016 was a historical maximum of precipitation (392 mm, or 137%), the previous one was in 1946 (386 mm, or 135%) (Diagram as provided by the NHMS)

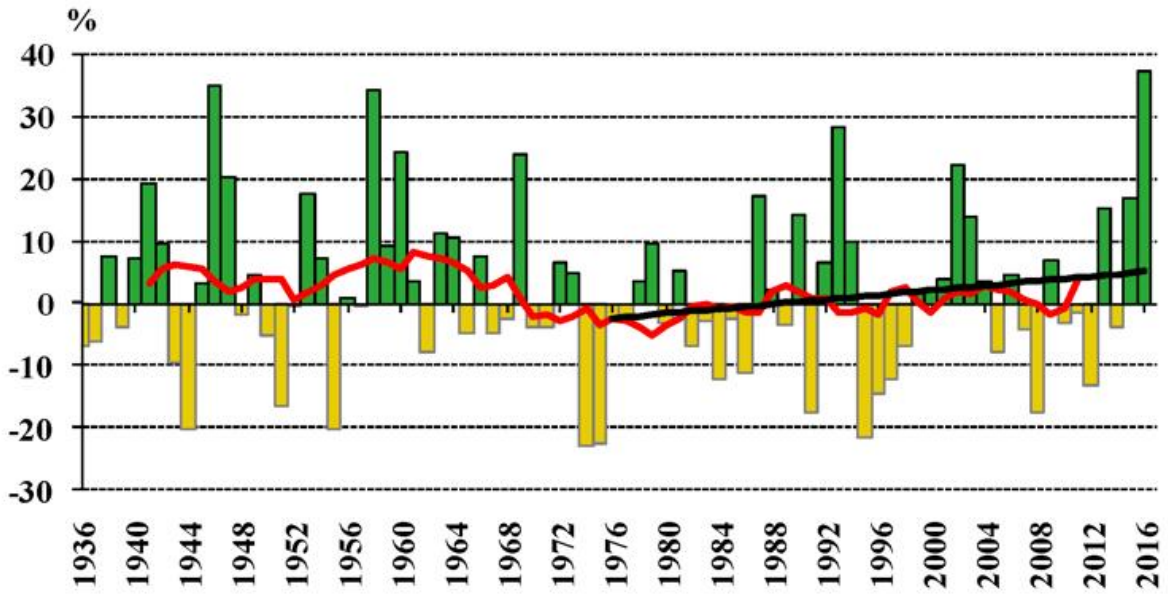

Figure 5.58: Time series of annual precipitation anomalies 1936-2016 across Kazakhstan with 11-year running mean in relation to the mean of 1961-1990 (diagram as provided by the NHMS)

5.3. Sunshine duration

Central and Western Europe - sunshine duration anomalies

Germany, Switzerland, United Kingdom

Germany

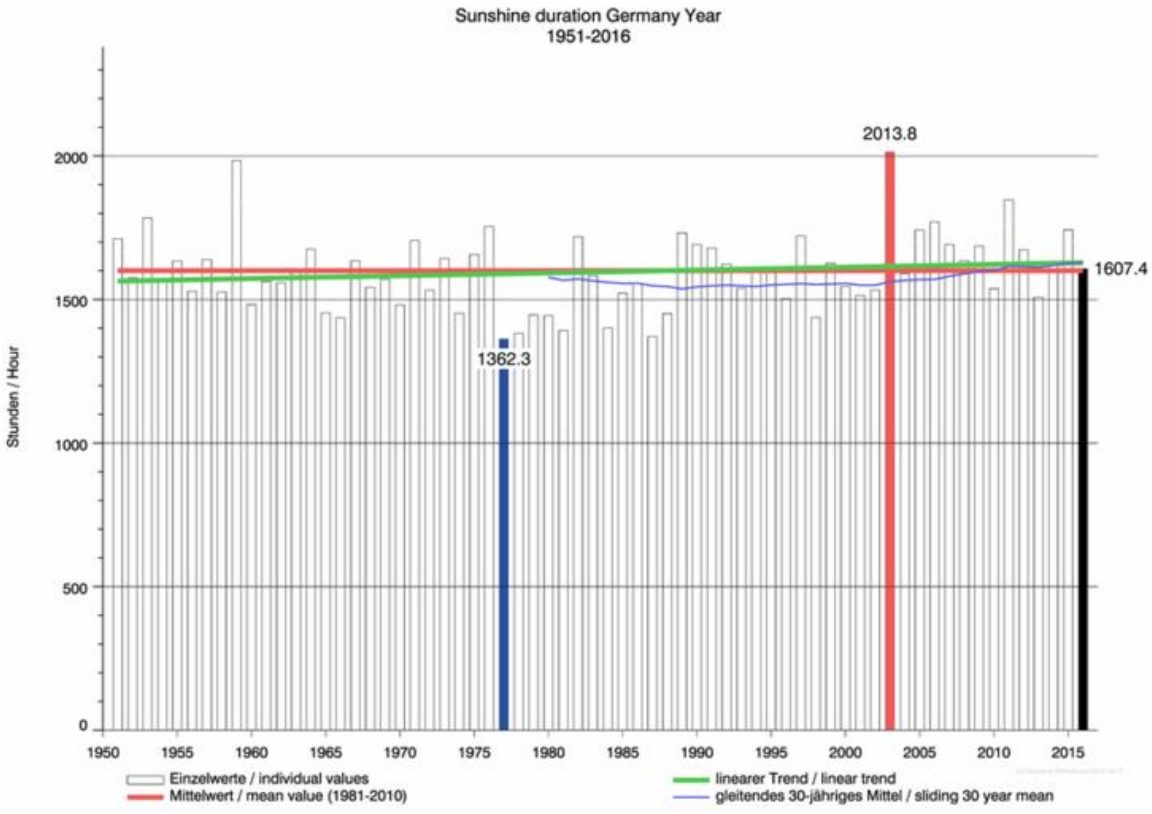

Figure 5.59: Time series of annual sum of the sunshine duration in hours for Germany (Diagram as provided by the NHMS)

Switzerland

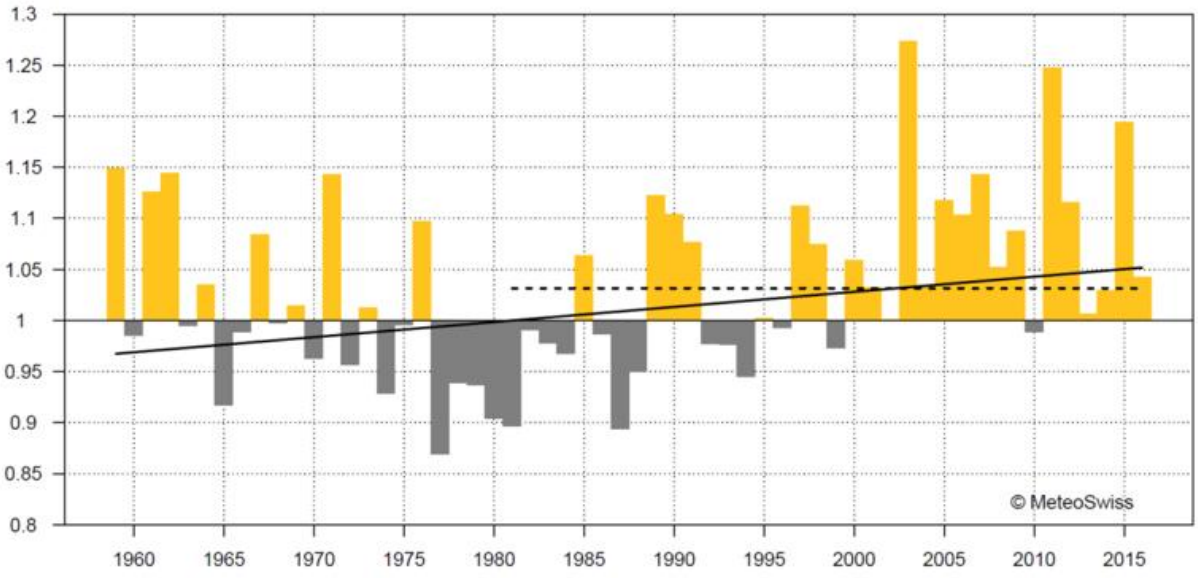

Figure 5.60: Time series of the yearly sunshine duration [ratio] for Switzerland 1959–2016. Color bars represent anomalies in respect to the long-term mean 1961–1990 and yellow indicates positive and grey negative anomalies. The black line represents the linear significant trend (1.48 %/10y). The black dashed line represents the mean 1981–2010 (diagram as provided by MeteoSwiss).

Central and Western Europe - sunshine duration anomalies

United Kingdom

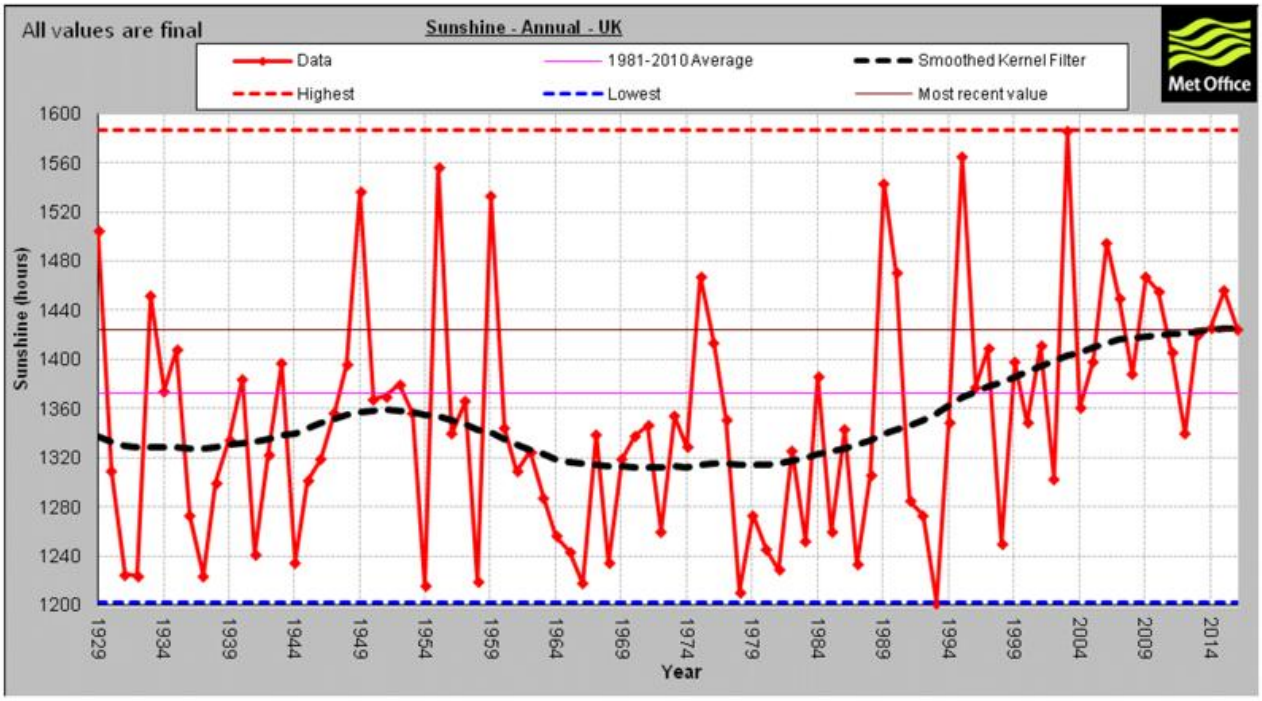

Figure 5.61: Time series of annual sum of the sunshine duration in hours for United Kingdom (Diagram as provided by the NHMS)

Nordic and Baltic Countries - sunshine duration

Denmark

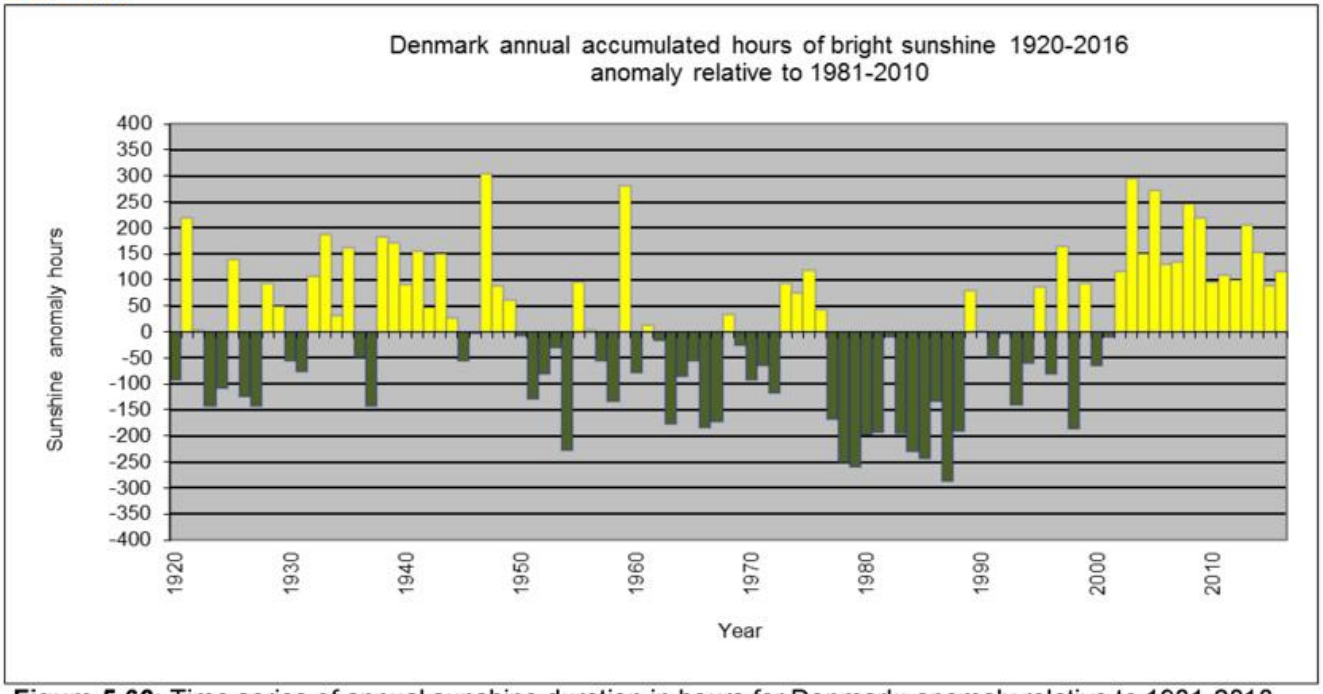

Figure 5.62: Time series of annual sunshine duration in hours for Denmark: anomaly relative to 1981-2010. The values are calculated national average based on a number of selected stations. (Diagram as provided by the NHMS)

Note: *OBS! DMI has since 2002 observed the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. I should also be noted that all values before 2002 are adjusted ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990.*
http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf
Data up to 2015 are published in DMI report series, No. 16-02 John Cappelen (ed)(2016): Denmark - DMI Historical Climate Data Collection 1768-2015.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 50 Members) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Global Climate and the State of the Climate published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ among the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes 4 parts: the annual, seasonal and monthly survey of the climate state in 2017 as well as contributions of the NMHSs to the long-term variability of selected parameters up to 2017 (section 5).

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collecting Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), operated by the Deutscher Wetterdienst
- Sunshine: CLIMAT data.
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

Sub-regional monthly maps are provided by the Eastern Mediterranean Climate Centre (EMCC).

The following sub-regions are used in this Bulletin:

Central and western Europe (14 countries): *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, and United Kingdom*

Nordic and Baltic Countries (9 countries): *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, and Sweden*

Iberia (2 countries): *Portugal, and Spain*

Mediterranean, Italian and Balkan Peninsula (12 countries): *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia, and Turkey*

Eastern Europe (5 countries): *Belarus, European Russia, Moldova, Romania, and Ukraine*

Middle East (9 countries): *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, and western Kazakhstan*

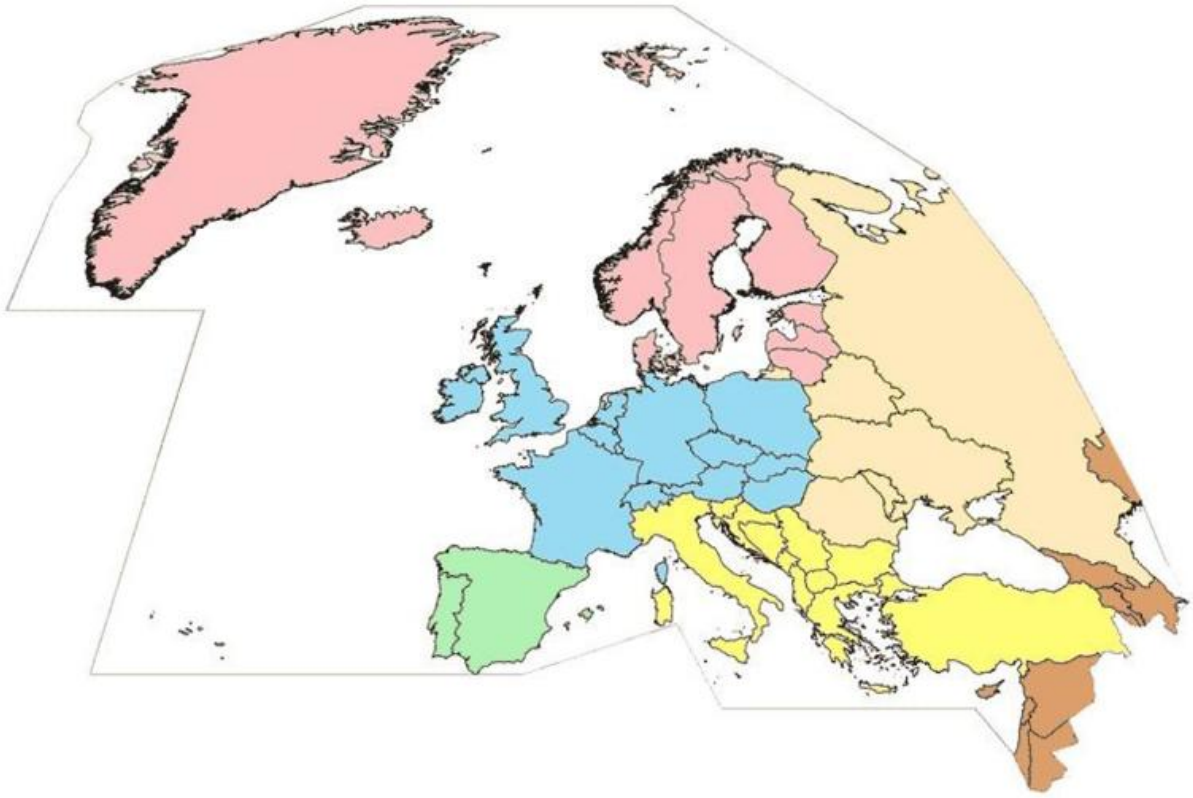

Figure 1.1: Definitions of the 6 sub-regions used in this bulletin.

Box 1

Notable anomalies and events 2017

Anomalies

Temperature

- Record breaking warm year in many European countries (see Table 2.1).
- Cold spell at the end of April 2017 in Central Europe and the Balkans with significant agricultural damage.
- April to December extremely warm and dry period in western and central Mediterranean.
- Several heat waves over central and southern Europe from June to September (The highest temperatures of 46.9°C was recorded at Cordoba airport, southern Spain, on 13th of July).

Precipitation

- Meteorological drought between April and December in Portugal.
- The wettest station in 2017 was Gullfjellet (Bergen, Norway) with 5057 mm.

Sunshine Duration

- Central Europe experienced a very sunny January with more than 200% of normal.

Other Anomalies

- Little snow in winter 2016/17 in the Alps.

Events:

- Several **forest fires** in Portugal in June and October.
- **Medicane** "Numa" in Central Mediterranean in November 2017.
- New Swedish air pressure record was recorded for September with 1044.1 hPa
- In **Slovakia** maximum wind gust of 61.6 m/s (222 km/h) occurred at Lomnický štít (2634 m a.s.l.)
- Ex-Hurricane **Ophelia** crossed Ireland and the United Kingdom with wind speeds of up to 49 m/s

2. Annual survey

The climate of 2017 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2.5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2017 and anomalies related mainly to the normal period 1961-1990 of the selected climate variables: sea level pressure, surface air temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for individual countries. Long-term trends in temperature and precipitation indices offers section 2.2.

More detailed insight into the long-term variability of temperature, precipitation and also some other parameters from the individual countries are presented in section 5.

2.1. Annual averages and anomalies of selected essential climate variables

2.1.1. Sea level pressure

Generally, mean annual sea level pressure distribution in 2017 over the WMO Region VI is dominated by a low pressure trough in the polar area with the Icelandic low that extended from southern Greenland to Iceland. The second pressure system, the subtropical high pressure belt, extended from the centre over the Azores (Azores high) across southern and central Europe to European Russia.

In 2017 the mean sea surface pressure differs to some extent from the long-term mean with a reduced pressure especially in a region over Greenland and northern Russia with anomalies of -2 to -4 hPa. Southeastern Europe also shows below normal anomalies. Higher pressure anomalies of more than +2 hPa occurred over southern France and the Bay of Biscay as can be seen from Figure 2.1 (right; normal period 1961-1990) indicating a slightly stronger than normal NAO.

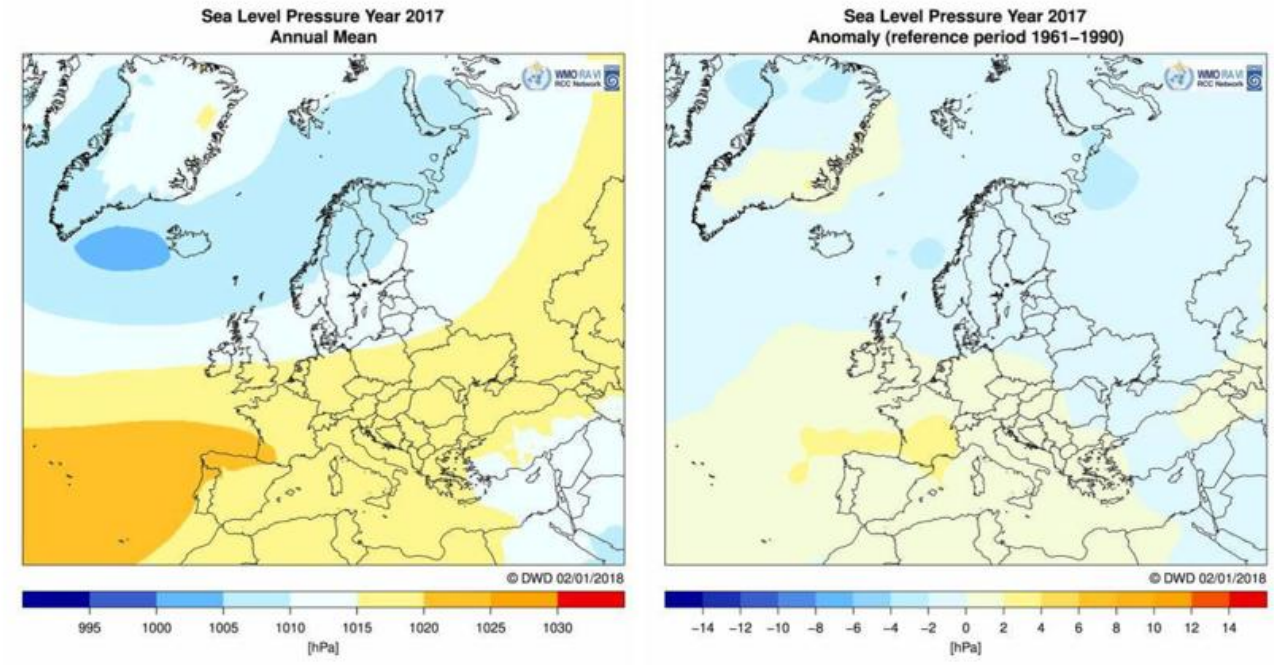

Figure 2.1: Annual mean of sea level pressure (left) and anomalies (right) in hPa for the year 2017 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.2. Temperature

In the entire European region (35°–75°N, 25°W–40°E) the year 2017 was warmer than normal with an anomaly of +0.86°C (base period 1981-2010) according to the E-OBS dataset. Many of the European countries reported new records (Table 2.1).

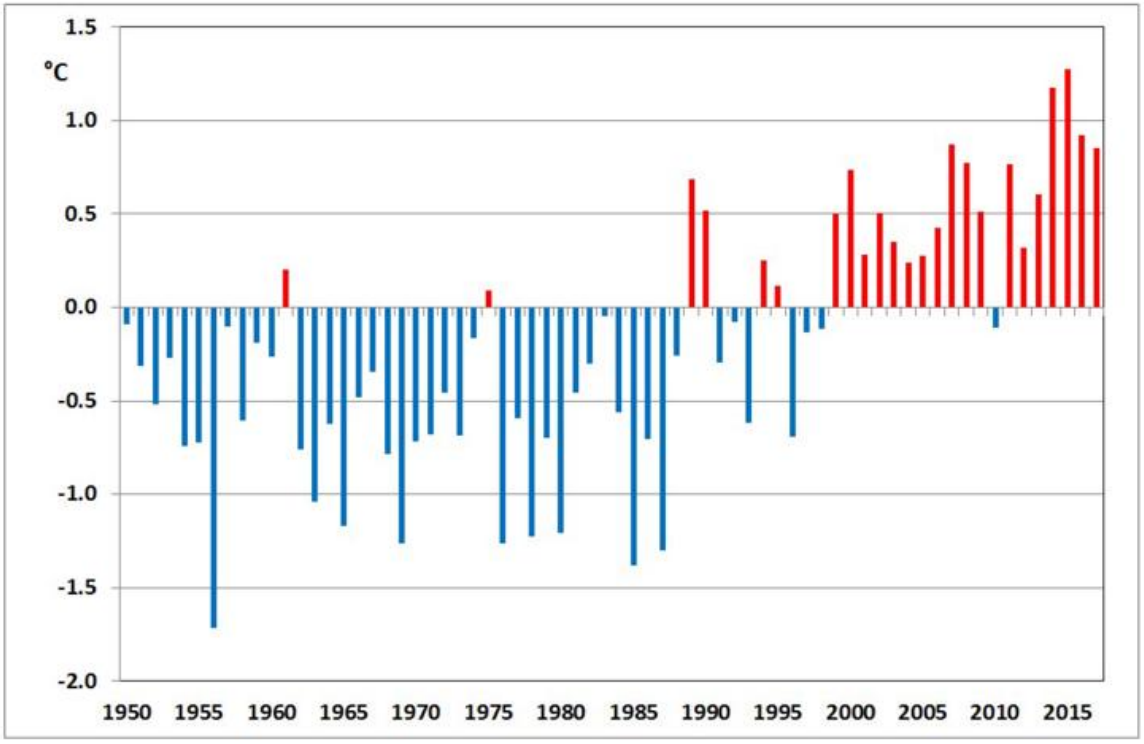

Figure 2.2: Annual temperature anomalies 1950-2017 for Europe (land area; 34°N-71°N and 25°W-40°E, reference period 1981–2010; based on the E-OBS dataset, van der Schrier et al. 2013). (Source: Royal National Meteorological Institute Netherlands, KNMI).

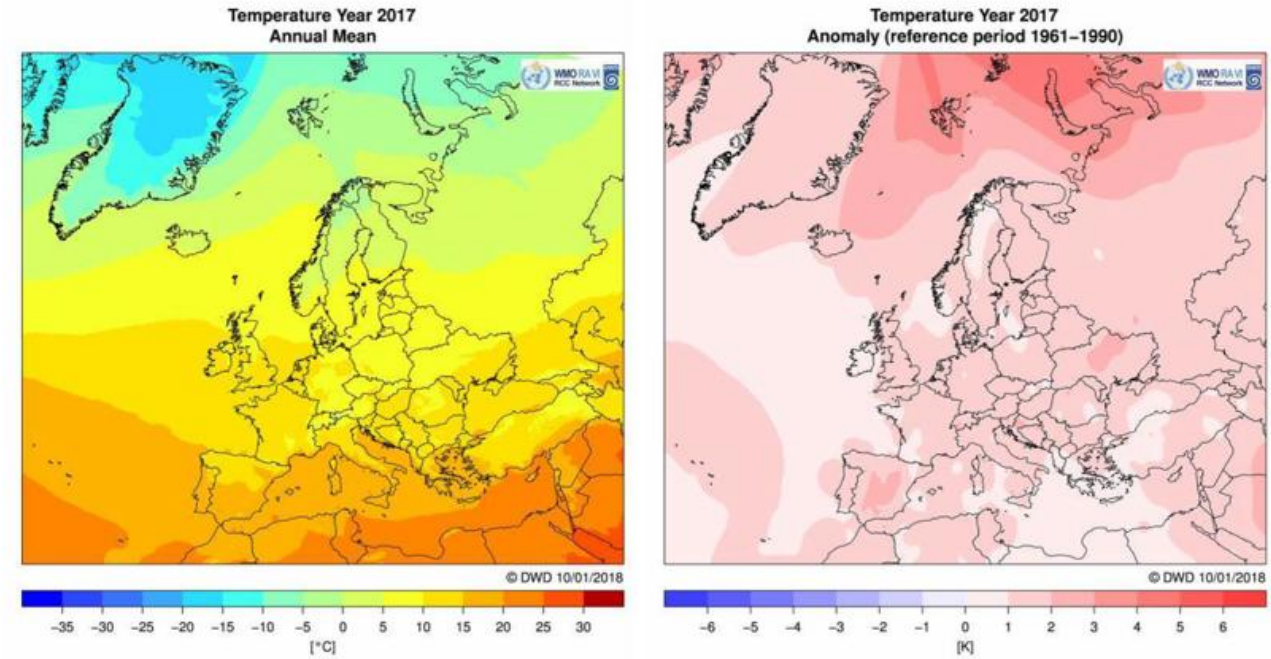

Figure 2.3: Mean annual temperature in °C (left) and anomalies (right) for 2017 (reference period 1961-1990, source: http://www.dwd.de/rcc-cm).

The highest annual anomaly of 1.52°C referred to 1961-1990 was observed in the sub-region Nordic and Baltic countries followed by Iberia (1.49°C), eastern Europe (1.47°C), the

Mediterranean, Italian and Balkan Peninsula (1.44°C) and Middle East (1.42°C). The sub-region Central and Western Europe showed the lowest anomalies of 1.35°C (Table 3.2). Most of the months in 2017 were warmer than normal (1961-1990) with remarkably consistent deviations of more than +4°C especially in northern Europe (cf. section 3.1.2 and 4.2).

The global annual land and ocean surface temperature for 2017 ranked as the second or third highest, depending on the dataset, 0.38° – 0.48°C above the 1981–2010 average (Blunden, Arndt und Hartfield 2018) or 1.1 °C ± 0.1 °C above pre-industrial levels (WMO 2018).

The **Norwegian Arctic** in 2017 was again warmer than usual with an annual mean temperature of -2.2 °C (4.4 °C above normal) in Svalbard airport and -2.2 °C (4.2°C above normal) at Hopen.

This year 9 heat waves were reported from **Portugal**, starting in April and ending in November.

Table 2.1: Rank statistics and anomalies of annual temperature in 2017 from some participant countries as reported by the National Meteorological and Hydrological Services (NMHSs).

Country	Rank of annual temperature in 2017	Anomaly 1961-1990 in °C	Anomaly 1981-2010 in °C	start of time series
Europe (35°–75°N, 25°W–40°E, E-OBS)	15	+0.86	+0.35	1951
Austria	9	+1.6	+0.9	1767

United Kingdom	5		+0.7	1910

2.1.3. Precipitation

The wettest stations in Norway in 2017 were Gullfjellet (Bergen, Hordaland) with 5057 mm, Kritle (Etne, Hordaland) 4309 mm and Hundseid in Vikedal (Vindafjord, Rogaland) 4238 mm (154 % of the normal).

The 2017/2018 rainfall season in **Israel** had a very dry start with limited rainfall amounts in October, November and December. In most parts of Israel it was the driest start of the rainfall season since 1999. Detailed descriptions can be found in the seasonal (3.1.3) and monthly survey (4.3).

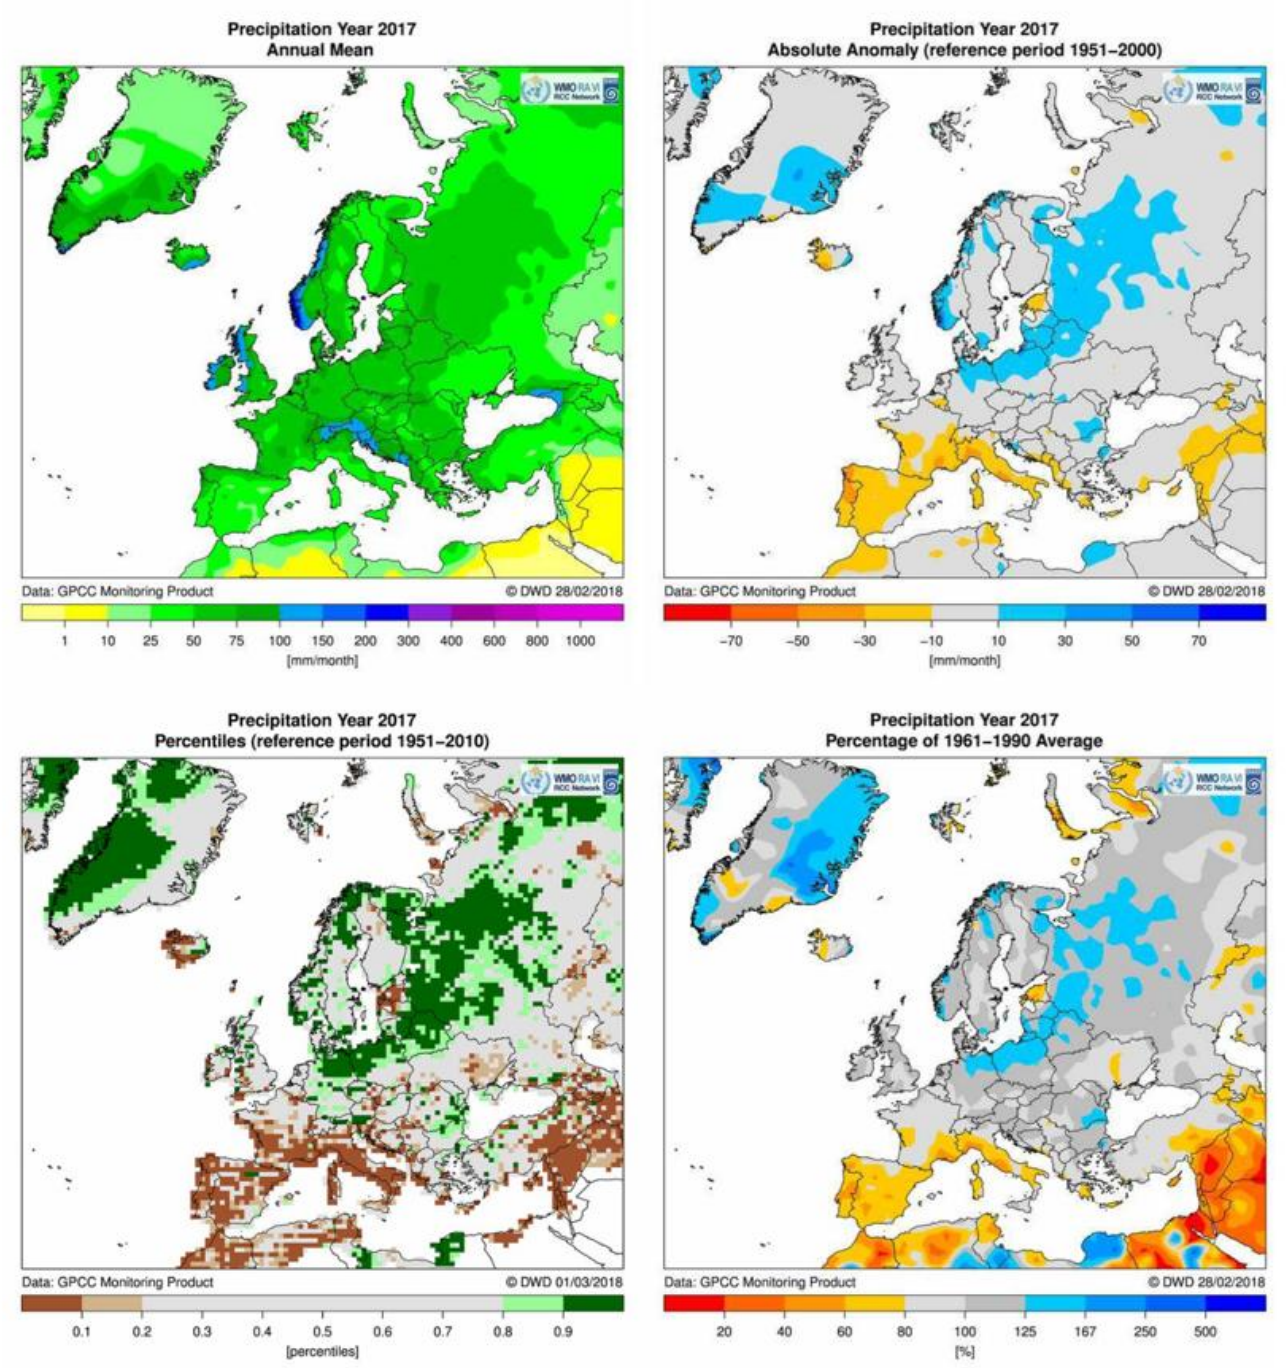

Figure 2.4: Total precipitation (left, top), anomalies (right, top) in mm/month, percentiles (left, bottom) and percentage of precipitation in % (right, bottom, reference period 1951-2010) for 2017 (reference period 1961-1990; source: http://www.dwd.de/rcc-cm).

2.1.4. Annual extreme values of temperature and precipitation

In this section an overview is given for the temperature spread and the extreme precipitation for each country. Absolute annual extreme values for 2017 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5 consecutive days with precipitation for each country in the WMO Region VI are given in Figure 2.5.

The spatial pattern of extreme temperature corresponds roughly to those of the temperature anomalies of 2017. The highest maximum temperatures (above 40°C) occurred primarily in sub-regions Middle East, Mediterranean, Italian, France and Iberian Peninsula, but also from the Balkans. Maximum temperatures higher than 35°C were reported from most of the countries in central and eastern Europe.

The one-day precipitation totals (RX1) of more than 150 mm for individual countries are documented in several sub-regions; the highest value occurred in Italy (359 mm/day). Highest total precipitation on 5 consecutive days (RX5) (above 300 mm) was measured in Slovenia (592 mm), Italy (469.8 mm), Croatia (369.6 mm), Turkey (333 mm) followed by Norway (300 mm).

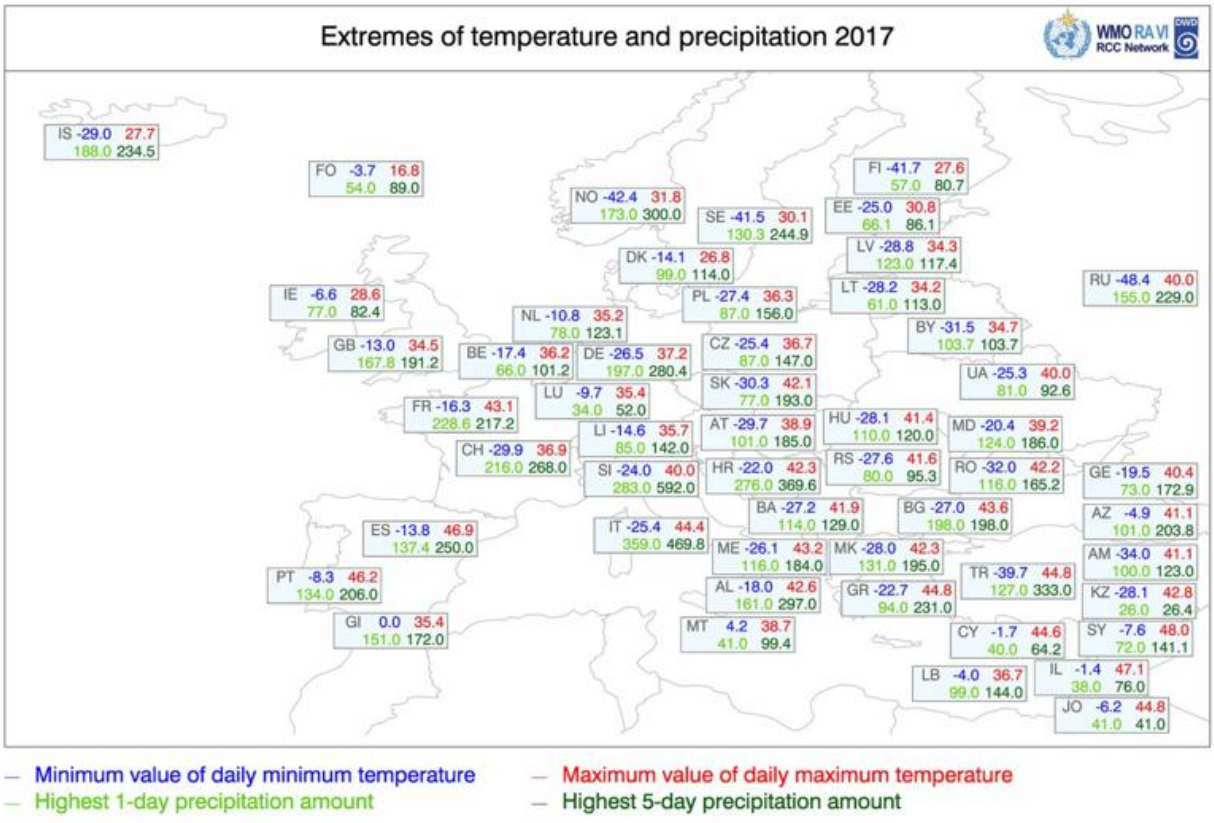

Figure 2.5: Annual extreme values for each country in 2017: first row: Internet country code, lowest daily minimum temperature (in °C, blue) and highest daily maximum temperature (in °C, red); second row: maximum daily precipitation totals (in mm, light green) and maximum 5-daily consecutive precipitation totals (in mm, dark green).

Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their Internet country codes. (Source: http://www.dwd.de/rcc-cm)

2.1.5. Sunshine duration

As expected, the annual sum of sunshine duration in 2017 showed from the south to the north generally gradual decreasing values. More than normal sunshine hours have been primarily noted in southern Europe, the western Alpine region, most parts of the Balkans and southern Russia. Finland and northeastern Europe had a sunshine deficit.

North of the Swiss Alps and in southern Ticino the annual total of sunshine duration amounted to 110 % to 120 % of normal values 1981–2010. The other parts of **Switzerland** recorded 100 % to 110 % of normal values. Lugano and Locarno-Monti in Ticino registered the sunniest year, some other regions of Switzerland the third- or fourth-sunniest year in the homogenous measurement series extending over more the 50 years.

The sunshine duration from January to December 2017 in **Austria** was 17 % above the climatological mean.

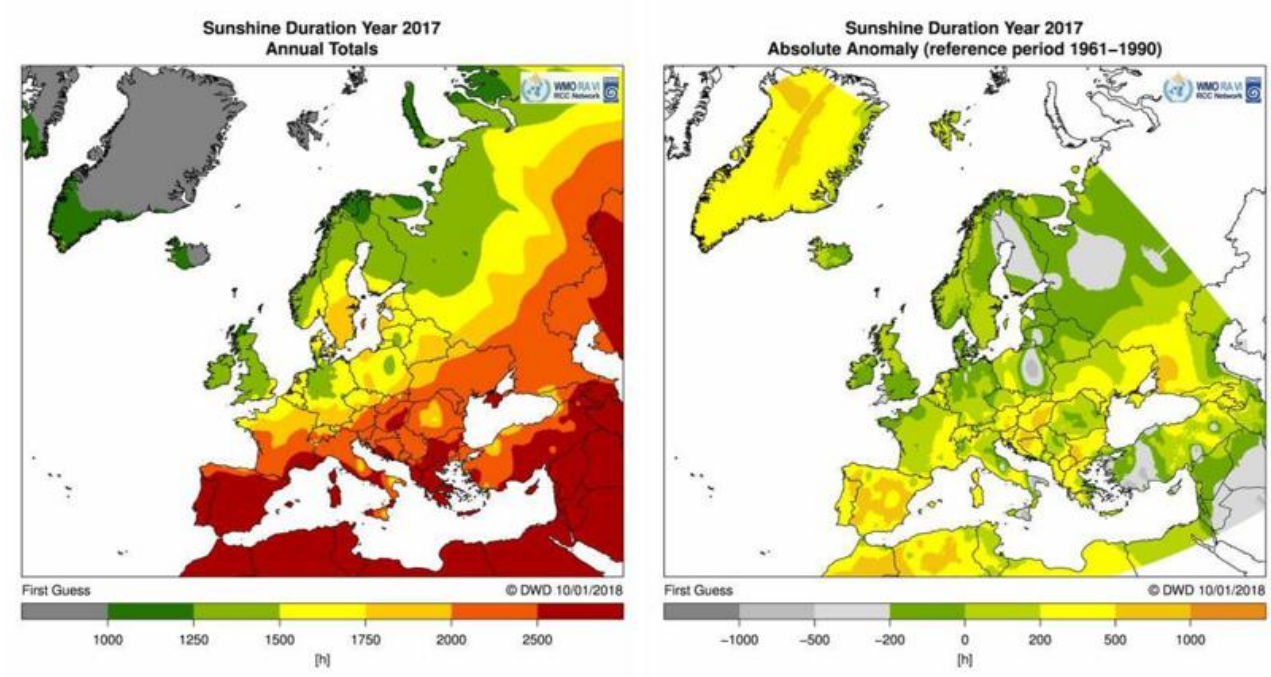

Figure 2.6: Annual sum of sunshine duration (left) and absolute anomalies (right) for the year 2017 in hours with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.6. Drought situation

At the eastern part of the Mediterranean, in **Cyprus**, there was also a drought from February to December 2017. The area average precipitation for February was 14% of normal (1961-90) and therefore the lowest for February since 1901, and Area Average Precipitation for December=33% was among the 10 worst for December also since 1901.

The year 2017 has been very dry in **Spain** as a whole. The annual mean precipitation was about 475 mm, which is around 27% lower than the mean normal value, according to the reference period 1981-2010. This big negative anomaly was mainly due to the rainfall deficit generated along the autumn and the spring quarter. According to the available information, the year 2017 has been the second driest year since the serial beginning in 1965, only below 2005 year with an annual mean precipitation of 468 mm.

Meteorological drought between April and December in Portugal

(Contribution from IPMA, Instituto Português do Mar e da Atmosfera)

The period from April to September 2017 (dry half-year) was extremely warm and extremely dry in mainland Portugal.
In this period, the conjugation of well below normal precipitation values and above normal air temperature values, especially the maximum temperature, resulted in the occurrence of high evapotranspiration values and significant soil moisture deficits. This previous conditions led to the beginning of a drought situation in mainland Portugal.
In the beginning of the new hydrological year (October 2017), the precipitation deficit increased, due to the occurrence of precipitation values well below normal in October and November. The period, from April to November, was the driest since 1931 (precipitation about 30% of normal).
Table 1 shows the percentage of the territory in the different classes of PDSI index between April and December 2017.
This meteorological drought began in April and persisted until the end of the year. This drought situation differs from previous cases since severe classes of the index started later (late June). Due to lack of rain and above normal evapotranspiration the territory percentage affected by severe and extreme drought increased in the beginning of the autumn (by the end of October 100 % of territory was in severe and extreme drought). In previous drought situations autumn precipitation near or above normal led to an effective reduction of drought severity (Figure 2.7).

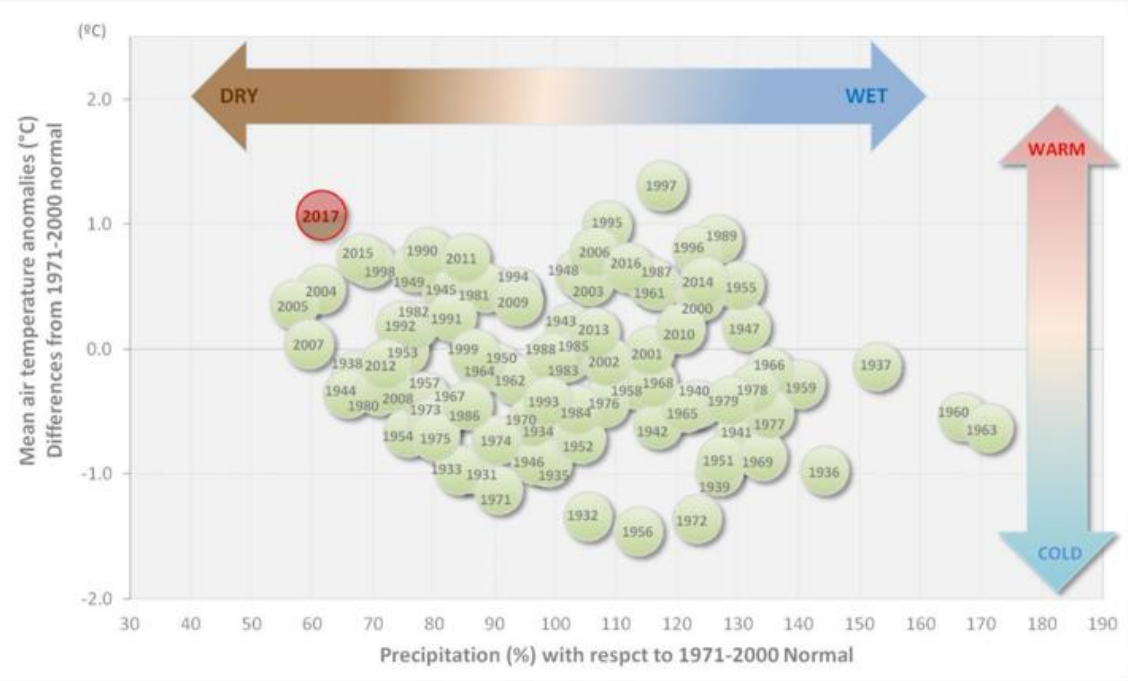

Figure 2.7: Annual mean air temperature and precipitation anomalies (1931 – 2017) (Difference (°C) and percentage (%) from 1971-2000 normal).

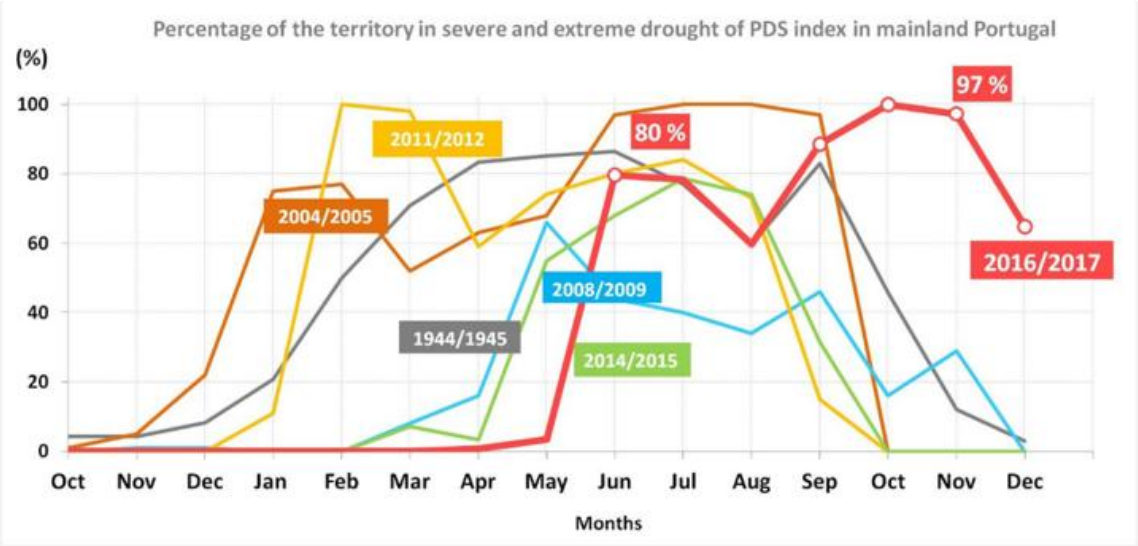

Figure 2.8: Monthly evolution of the percentage of the territory of Portugal in severe and extreme drought, according to the PDSI index, for historical drought situations (1944/45; after 2000: 2004/05, 2008/09, 2011/12, 2014/15 and 2016/17).

In many parts north of the **Swiss** Alps annual precipitation reached 70 to 90 % of the normal values 1981–2010. Alpine areas received mostly 90 to 115%, southern valleys of the Valais, however, only 60% to 80% of normal values. South of the Alps annual precipitation amounted to 80 to 95% of the normal values.

Monthly precipitation amounts between January and June 2017 in **Luxembourg** were all lower than the climate normal (about 34% on average). Most of all, April (5.3 mm) ranked on number two of the driest months at Luxembourg/Findel-Airport since station history in 1947, only exceeded by April 1996 with only 4.9 mm.

Drought also occurred during winter, spring and summer in the most southwestern part of **Slovakia** (1500 km^2) with agricultural losses in crop yields (spring crops, sunflower, maize).

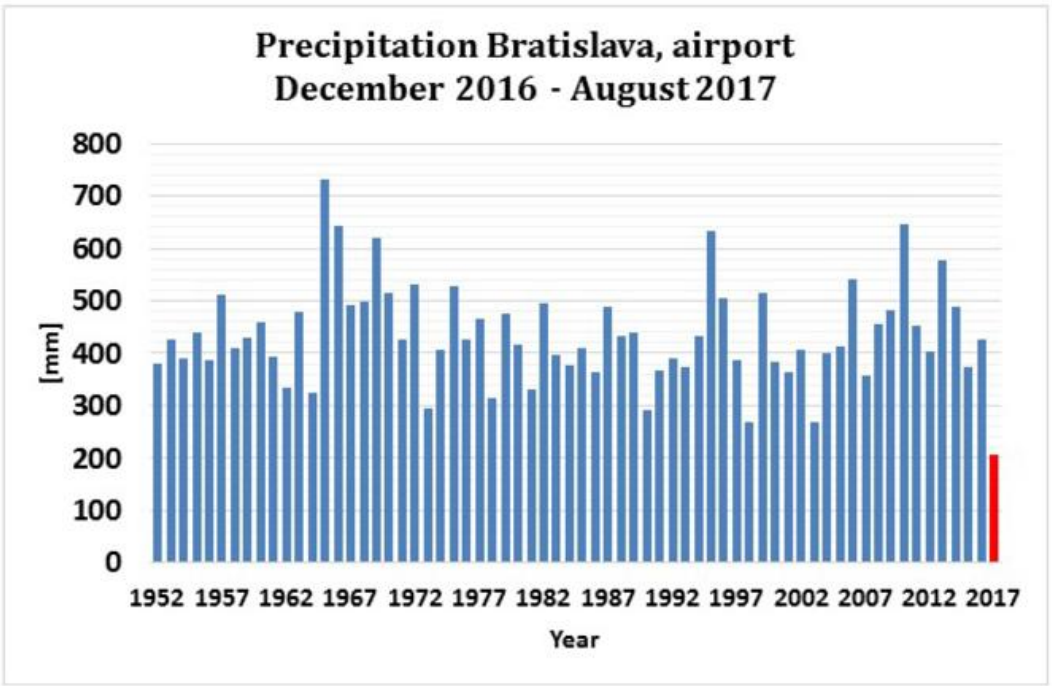

Figure 2.9: Precipitation at Bratislava, airport (Slovakia) for December 2016 - August 2017. (Diagram as provided by the Slovak Hydrometeorological Institute)

In **Italy**, from January to October 2017 below normal precipitation intensified the drought situation with low water levels in rivers and reservoirs and harvest losses.

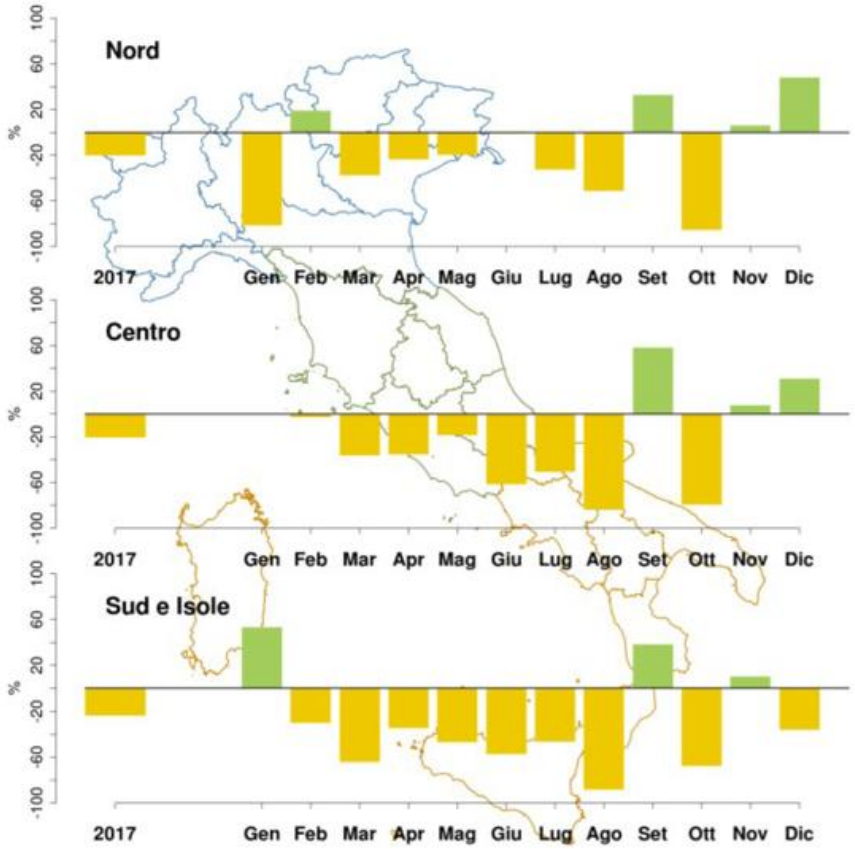

Figure 2.10: Annual and monthly precipitation anomalies for 2017 expressed in percentage of the normal value (1961-1990) for northern, central and southern Italy (including the Islands; diagram as provided by **ISPRA** – Istituto Superiore per la Protezione e la Ricerca Ambientale).

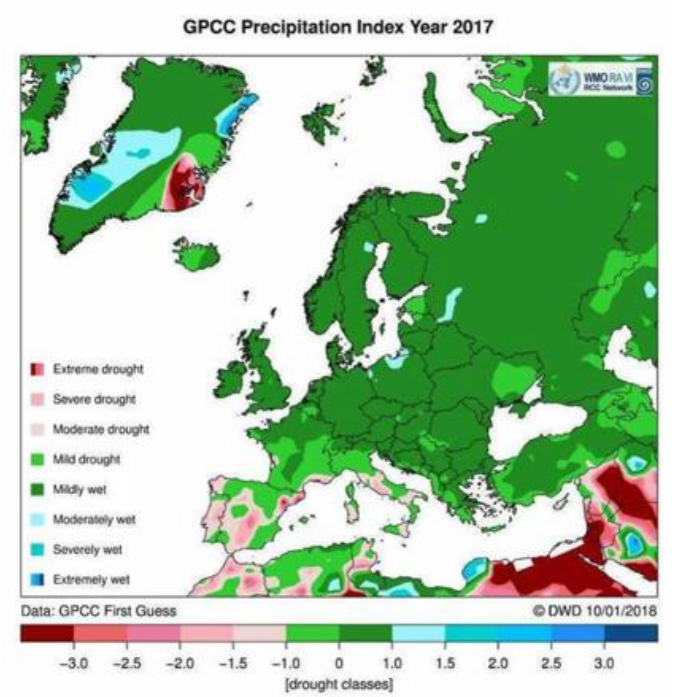

Figure 2.11: Annual modified Standardized Precipitation Index (DWD-SPI) for the year 2017 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.7. Snow cover

The snow-season 2016/2017 (September 2016 – August 2017) was warmer than normal and consequently in many low land areas in western and southern Europe no snow occurred at all. Apart from mountain areas, in central Europe partly occasional snow fall events occurred in November. As expected, towards northern and eastern Europe snow cover duration was longer and ended in April and May. In Switzerland, the thin winter snow cover in 2016/17 was at close to record-breaking levels. In western Switzerland and in the Valais only 30 to 50 % of the normal precipitation (mainly snow) values were recorded.

Last snow in low land areas over central Europe and the Balkans occurred during last decade of April 2017 due to a cold wave in these regions. In April a cold surge led to unusual accumulation of fresh snow in Austria. Especially in the area of the Ybbstaler Alps to the Wienerwald the amount of fresh snow within 24 hours reached from 20 to 125 cm. At the weather station Annaberg (Lower Austria, 911 m) the amount of fresh snow on the 20th of April was 125 cm.

The snow layer in Rumania was present throughout January everywhere in the country, maximum snow depths measured on the platforms of the weather stations, especially on 10 - 11 January reaching up to 175 cm in the mountain area (Făgăraş Mountains), up to 62 cm in Wallachia, up to 41 cm in Transylvania, up to 40 cm in Dobrudja, up to 35 cm in Moldavia, up to 26 cm in Oltenia, up to 22 cm in Maramureş, up to 20 cm in Banat and up to 16 cm in Crişana.

On 20-21 April, when the weather cooled markedly in Rumania and the deviations of the mean daily air temperatures were of the order of -10 ... -15ºC, rainfalls turned into sleet and snow in most part of Moldavia and locally in Transylvania.

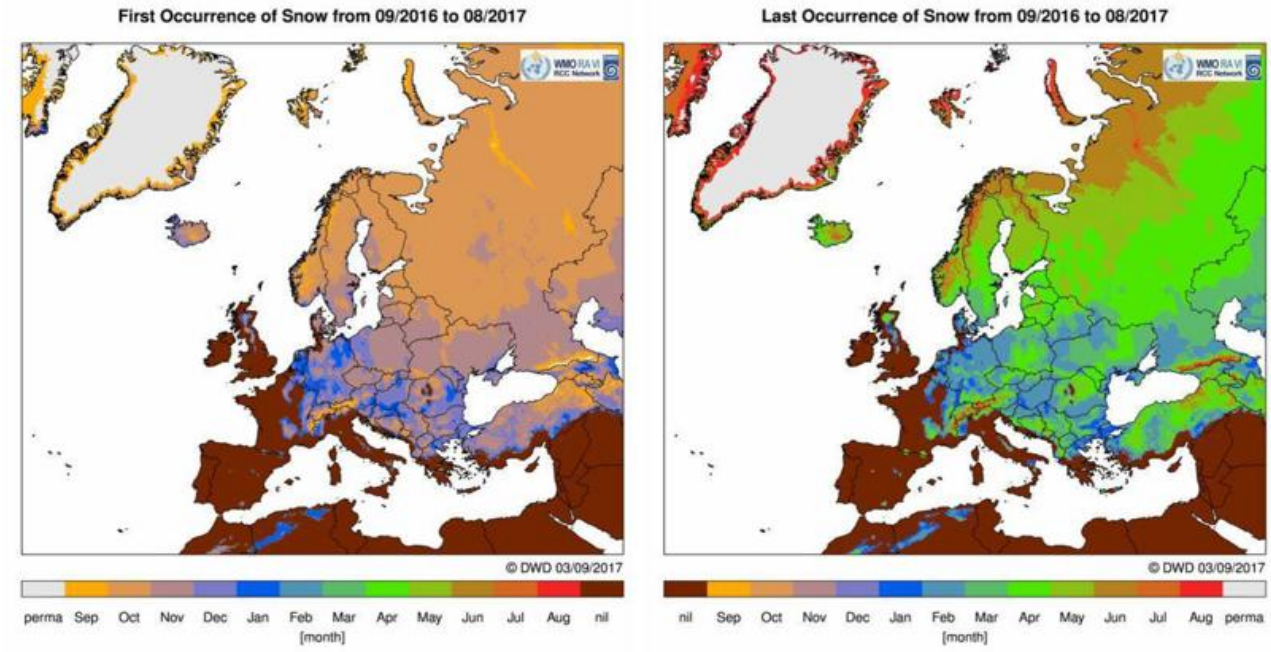

Figure 2.12: First occurrence of snow (left) and last occurrence of snow (right) during the snow-season 2016/2017. (Source: http://www.dwd.de/rcc-cm).

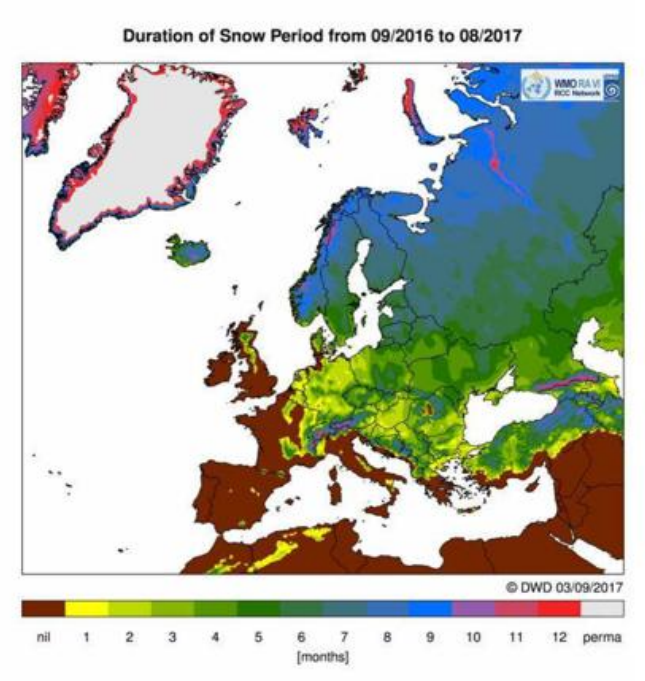

Figure 2.13: Duration of snow cover in the snow-season 2016/2017. (Source: http://www.dwd.de/rcc-cm).

2.2. Selected climate indices for 2017

This section presents selected temperature and precipitation indices calculated based on the station-based ECA&D (European Climate Assessment & Dataset; http://www.ecad.eu) dataset. Annual climate index maps are shown as well as anomaly and trend maps. The following climate indices are considered:

1. **RR1, Number of wet days**: count of days where RR (precipitation > 1 mm) Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally effected.

2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) ≥ 25°C

3. **WW, Number of warm and wet days:** days with TG (daily mean temperature) > 75th percentile
   and
   RR > 75th percentile

4. **TR, Number of tropical nights**: count of days where TN ≥ 20°C

The map with the number of wet days (RR1, uppermost left panel) clearly depicts the dry conditions prevailing in 2017 with less than 60 wet days in most parts of Spain and Portugal, but also along the Côte d'Azur and over Italy. The anomalies of the number of rainy days with respect to the 1961 to 1990 mean show that the area with less than normal wet days extends even further north additionally covering France and large parts in southeastern Europe. The northwestern, Central and northeastern part of Europe (for example Great Britain, Netherlands, Germany, Scandinavia) on the contrary experienced more than normal wet days which also resulted in above-normal precipitation amounts (see section 2.1.3).

Looking at the number warm and wet days (WW) it appears that above-normal numbers of WW were registered in most parts of Europe in 2017, also in the (drier) southern part. Only very locally, the number of wet and warm days was fewer than normal.

The anomaly map for the number of summer days (SU) illustrates the longer-than-normal summer conditions in 2017 over large parts of Europe. There is a North-South dipole structure visible dividing the area in a northern part which experienced less than normal summer days (Scandinavia) and a southern part where more than normal summer days were counted (central and southern parts of Europe). A feature that is also visible in the seasonal temperature anomalies for summer shown later (see Figure 3.3).

The anomalies of tropical nights do not show a clear pattern for 2017: there are positive and negative anomalies without a clear discrimination of regions. This suggests that there are only small deviations from the long-term mean and thus near normal numbers of tropical nights. Only a small band along the Mediterranean coast actually experienced a larger positive anomaly of more than 30 tropical nights more than usual.

Figure 2.15 shows the trend maps for the selected climate indices based on the years 1951 to 2017. In northern, northwestern, central and eastern Europe most stations showed an increase in the annual number of wet days (RR1) for the last 67 years (mostly greater than 3 days per year per decade) while in southern Europe a decreasing trend prevails. The decreasing and increasing trends at neighbouring stations, however, indicate inhomogeneities in the time series. The number of warm and wet days (WW) has increased over almost whole Europe by more than 1.5 days per year per decade. Only the Greek stations show negative WW trends of up to -1.5 days per year per decade. The annual numbers of summer days (SU) have increased in central and southern Europe and partly in eastern Europe, while stations in northwestern and northern Europe do not indicate any significant trend. Annual numbers of tropical nights (TR) show an increasing trend in the southeastern part of Region VI but values are generally small with 0 to 2 days per year per decade. In the northwestern part no significant trends are found.

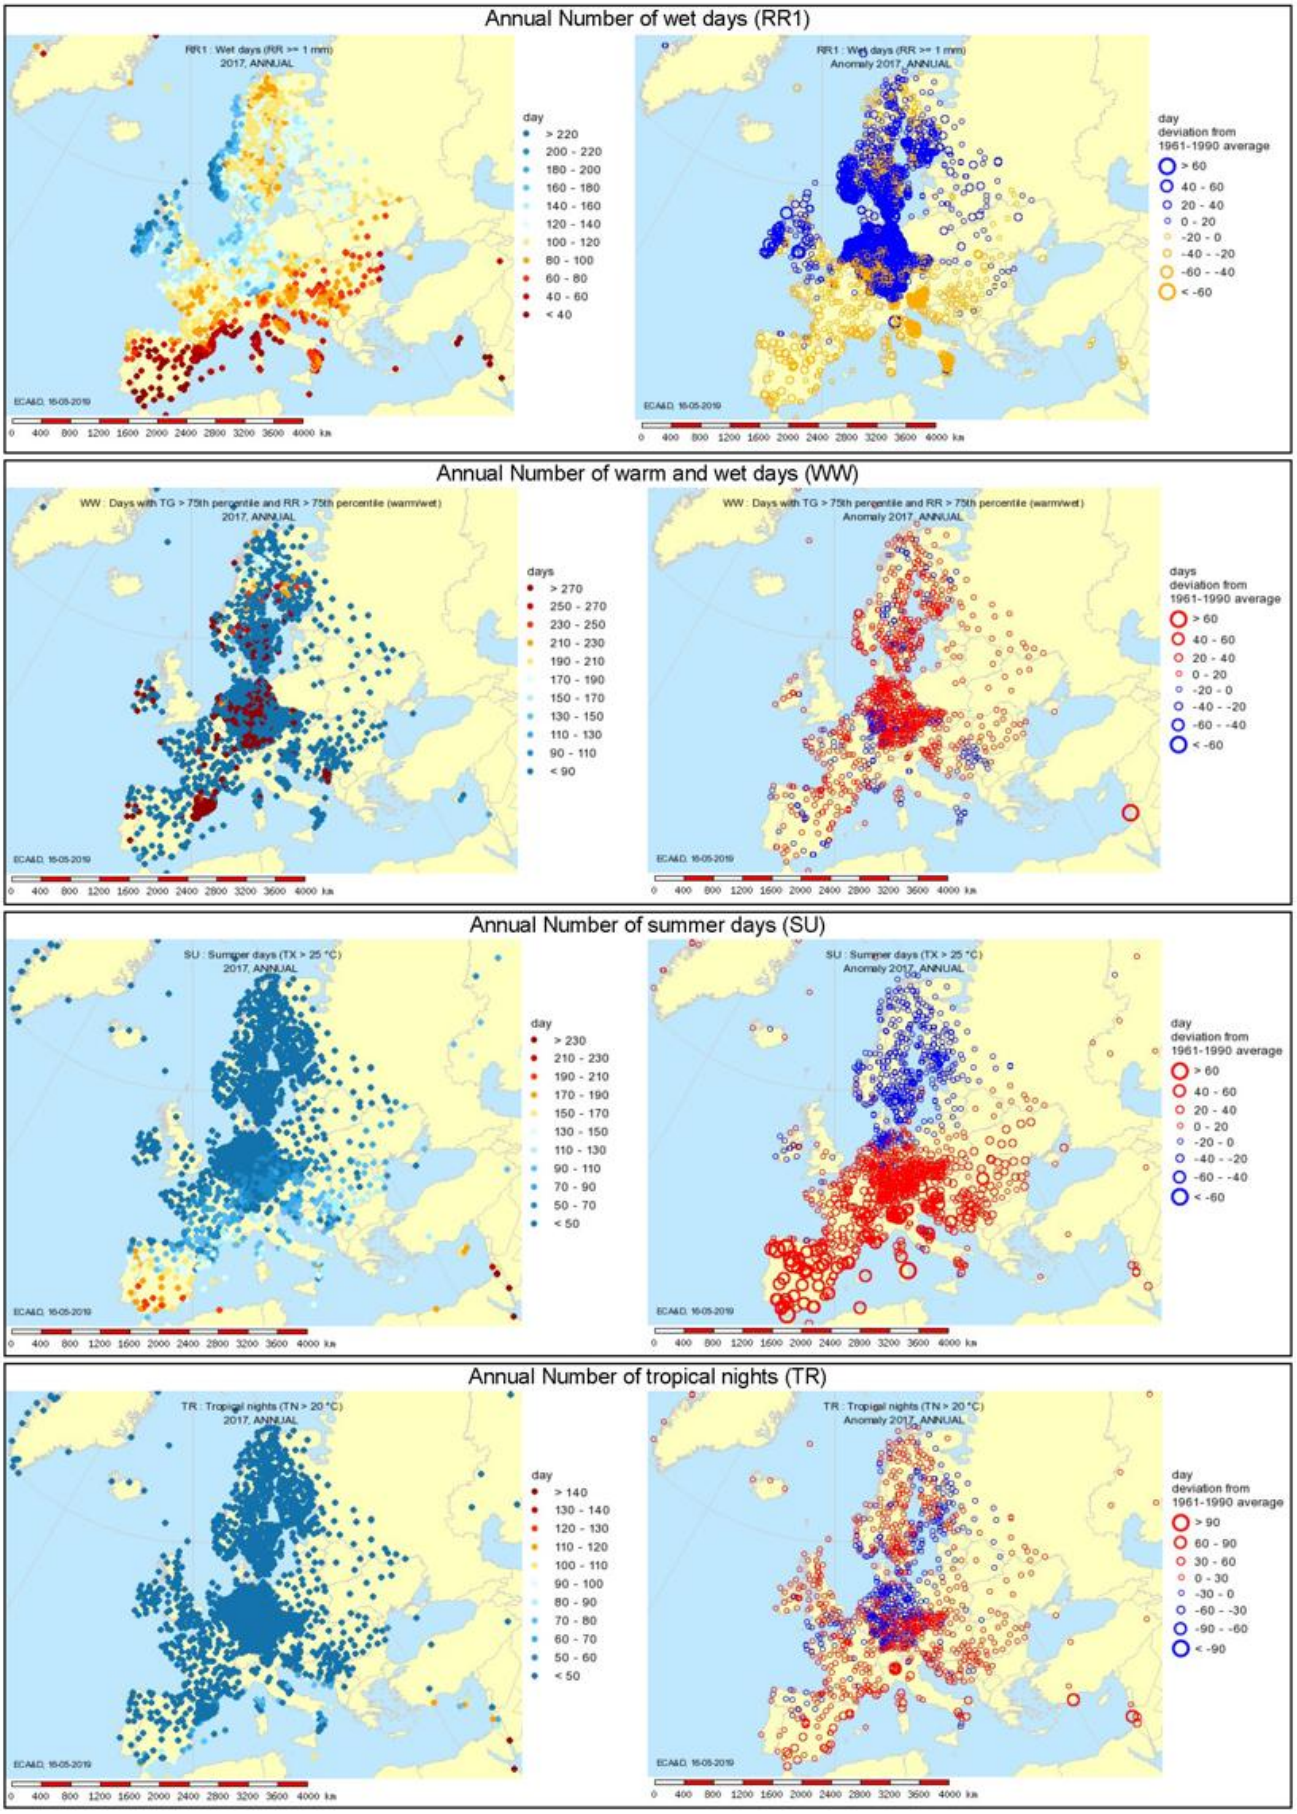

Figure 2.14: Selected Climate Indices for 2017 (left) and their anomalies (right) with respect to the 1961 to 1990 reference period (Source: ECA&D, http://www.ecad.eu).

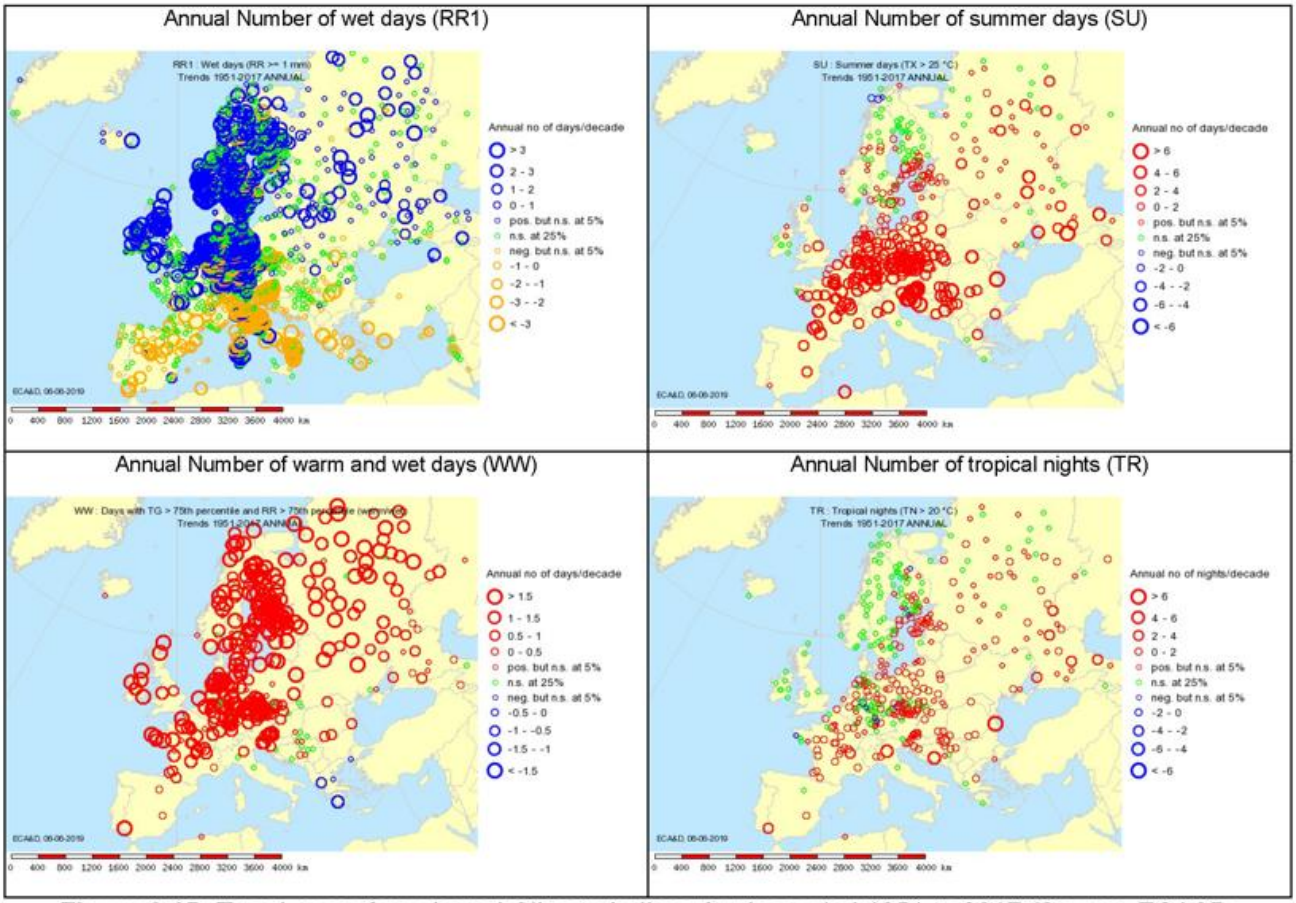

Figure 2.15: Trend maps for selected Climate Indices for the period 1951 to 2017 (Source: ECA&D, http://www.ecad.eu).

2.3. Socio-economic impacts of extreme climate or weather events

From January to October 2017 a severe **drought** occurred in southern Europe (Spain, Italy, and Serbia). MunichRe (2018) estimated the financial loss to 3400 Million €. Dry conditions and heat wave affected most of the agricultural production.

From 15.4. to 9.5.2017 Europe experienced a **cold wave** with frost in central Europe with damages of 3600 Million € (MunichRe 2018). A series of cold spells with low temperatures anomalies (-7°C) and heavy snowfall caused damages at some houses. Severe damages occurred at vineyards, fruit crops, (apples, stone fruits, berries) and vegetables because previous weeks were warm and all the plants were growing and blooming.

Abnormally severe forest fire season in Portugal

(Contribution from IPMA, Instituto Português do Mar e da Atmosfera)

2017 forest fire season was extremely severe and long, with terrific consequences, namely life losses and significant environmental and economic impacts. The accumulated Daily Severity Rating (DSR), obtained from Fire Weather Index (FWI), for 1st of July to 31st of October, was the highest on record (Figure 2.16). Burnt areas exceeded 440 000 ha (ICNF - Portuguese Forest Institute), a new record, even compared to previous extreme 2003 and 2005 fire seasons.

Central regions of mainland Portugal were the most affected by very large fires (> 1000 ha) in several periods namely, 16-21 June (64 casualties and several people were homeless and a financial loss of 180 Million €, after MunichRe, 2018), 16-18 July, 23-26 July, 9-19 August, 23-27 August, 5-9 September and 12-15 October (45 casualties and about 70 wounded and a financial loss of 400 Million €, after MunichRe, 2018). During these periods, the associated meteorological conditions were extremely favourable to fire propagation and very adverse to fire combat, fire weather index (FWI) values were higher than the 90th percentile, in the majority of the regions.

In the particular case of 15th of October, when a burnt area exceeded 200 000 ha, FWI values greater than 99th percentile were recorded due to:

- extremely low soil moisture content;
- a two week period with consecutive hot and dry days following the driest September on record;
- during the day very low humidity values (< 20 %) and wind intensification, with gusts exceeding 50 km/h, in several meteorological stations. The wind intensification was due to the proximity of the hurricane **Ophelia** to the Iberian Peninsula, centred approximately 485 km from Viana do Castelo.

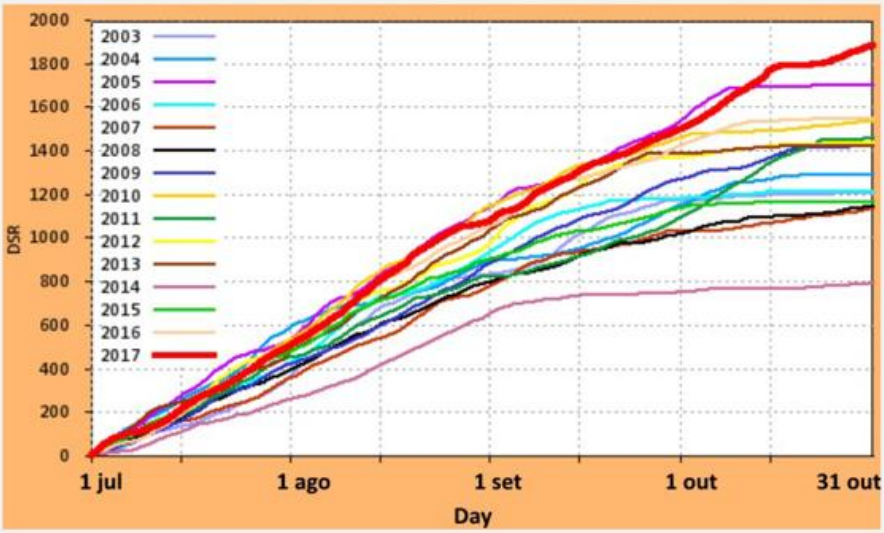

Figure 2.16: Daily severity rate (DSR) average value for mainland Portugal, 1st of July to 31st October from 2003 to 2017 (diagram as provided by IPMA)

Germany was hit by a tornado, severe thunderstorms with hail of up to 8 cm in diameter, heavy rain and wind gusts up to 39 m/s (140 km/h), during 22–23 June. Numerous houses, vehicles,

fruits, vegetables, 500 km^2 of crops and vineyards were damaged and two persons were killed. The damage was estimated to 700 Million € (MunichRe 2018).

Extremely vigorous wildfire in Split, 17-19 July 2017

(Contribution from Meteorological and Hydrological Service of the Republic of Croatia)

An intense heatwave hit Croatia in the first half of July. Extremely high temperatures made the already dry plant cover in Dalmatia even drier, resulting in very high risk of wildfire occurring and spreading. There was almost no precipitation in Dalmatia despite the humid and colder air inflow in mid-July. Driven by the rising anticyclonic ridge from Northwest Europe, strong Bura stormwinds on 15 and 16 July continued to dry out the vegetation. Such weather contributed to the extreme behaviour of the wildfire that broke out near Split on 17 July and was localized on 19 July. Approximately 4300 ha of forest, brush, olive groves and vineyards were burned. The fire front was at times 40 km long and it was one of the biggest wildfires in Croatian history.

The fire was put under control by a joint effort of the firefighters and the military on the afternoon of 18 July, localized and finally extinguished. The damage was substantial, but fortunately there were no human casualties. The authorities declared a state of natural disaster in the Split-Dalmatia County.

Remnants of Hurricane **Ophelia** crossed **Ireland** and the **United Kingdom** with wind speeds up to 49 m/s (175 km/h) on the 16th and 17th of October. Several houses, commercial buildings and 40 schools were damaged with a financial loss of about 90 Million € (MunichRe 2018).

Winter storm **Herwart** hit **Central Europe** on 29th of October with wind speeds up to 40 m/s (145 km/h), heavy rain and flash floods. Houses, roads and railways were damaged. 390,000 customers remained without power. The overall financial loss was estimated to 430 Million €, especially in the forestry (MunichRe 2018).

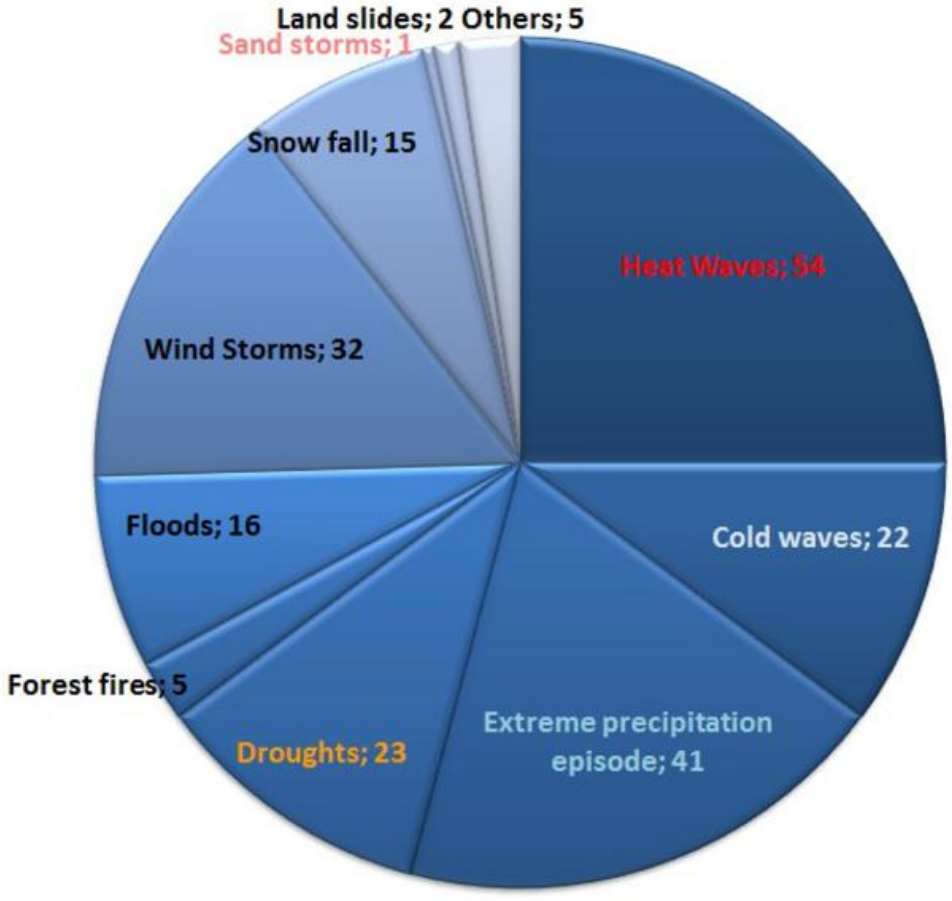

Figure 2.17: Observed extreme weather or climate events in 2017 based on 32 reports from NMHSs (total events reported for 2017: 216).

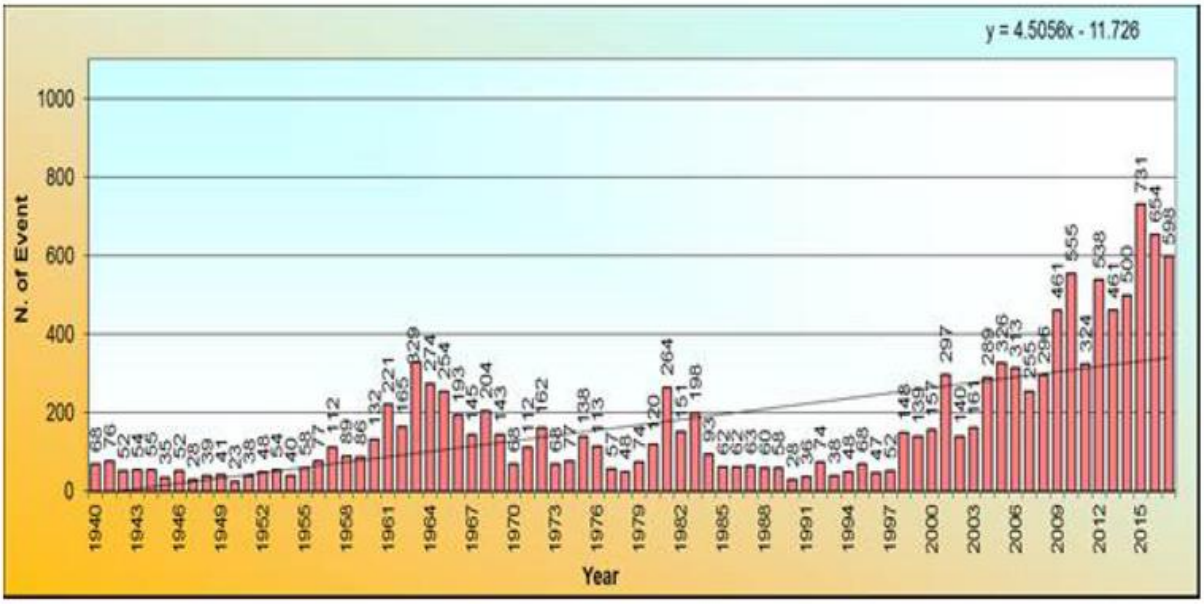

Figure 2.18: Annual count of extreme events per station occurred in Turkey from 1971-2017 (Diagram as provided by the NHMS).

The number of extreme events in 2017 in Turkey reached 598 (Figure 2.18). There is an increasing trend in extreme event occurrences especially during the last two decades (4.0 events/year), possibly partly also due to improved observations and communication means.

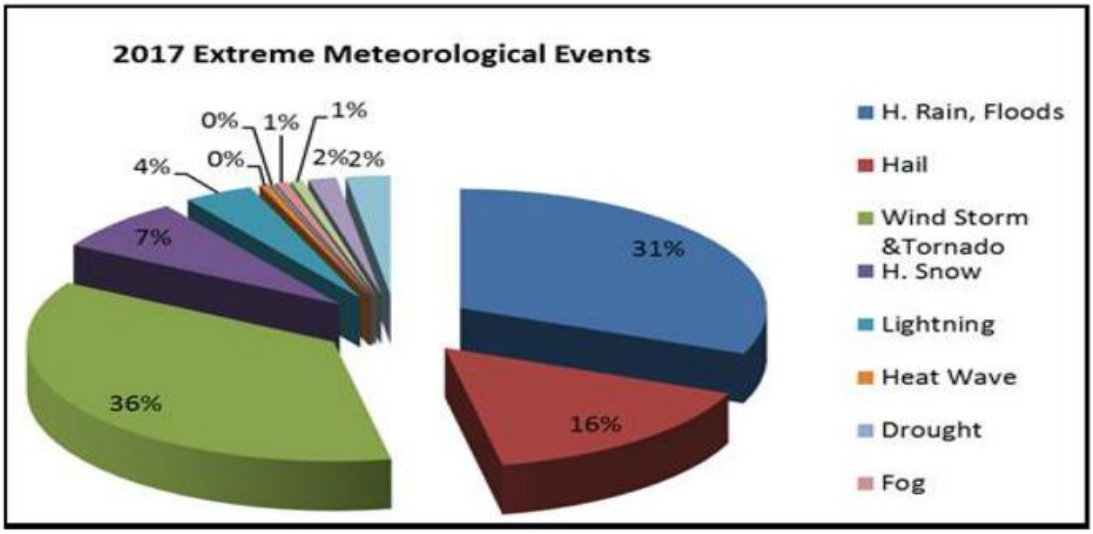

Figure 2.19: Distribution of extreme events occurred in Turkey in 2017 (Diagram as provided by the NHMS).

Most hazardous extreme events recorded in 2017 were wind storms and tornadoes (36%) and heavy rain/floods (31%). The others were hail (16%), heavy snow (7%), lightning (~ 4%), avalanche and frost (~ 1.5%) and heat waves, drought, forest fire and fog (<%1).

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2017 and anomalies related mainly to the normal period 1961-1990 of the following selected climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. Seasonal averages and anomalies of selected climate variables

3.1.1. Sea level pressure and circulation indices

Pressure distribution in **winter 2016/2017** showed a connection between the Azores high and the Russian high. On seasonal average the Icelandic low showed a core pressure below 995 hPa and the Azores high a core pressure above 1025 hPa. The pressure anomalies were above +8 hPa above Central Europe and the zone of below-normal pressure ranged from Greenland and Iceland to the Barents Sea and eastern Europe. This winter the North Atlantic Oscillation (NAO) was not well developed and therefore the East Atlantic/West Russia Pattern (EA/WR) dominated the teleconnections. Several storms affected Europe especially in February 2017. Storm "Urd" crossed Scandinavia during 26-27 December 2016. A mid-Atlantic trough deepened rapidly to a storm (named "Doris" by UK-MetOffice), before crossing Ireland on the 23rd February. This resulted in widespread gales and some disruption.

In **spring 2017** both circulation centres, the Icelandic low and Azores high, were not well distinct. A second low pressure centre was located around the Barents Sea. The Azores and Siberian high were connected with negative anomalies in northern Russia and positive anomalies in central Europe. The northern hemisphere teleconnection indices were small because they had opposite sign in the different months of the season.

Table 3.1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference.

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2016/2017	0.36	0.10	1.10	-0.11	-0.17	1.02
Spring 2017	0.13	0.32	0.39	-0.51	-0.06	0.18
Summer 2017	0.03	1.96	-1.06	-0.99	0.56	0.40
Autumn 2017	0.04	0.77	-1.25	0.23	-1.69	0.04

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

Both circulation centres, the Icelandic low and Azores high, were shifted south in **summer 2017.** The anomalies were deepest between Iceland and Great Britain and reaching Scandinavia and northern Russia resulting in a high East Atlantic Pattern (EA) in all three months. This induced colder and wetter conditions in northern Europe. Austria was hit by several thunderstorms with hail and tornadoes during the summer 2017 and two people died; more than 140 persons were injured. The damage was estimated to more than 22 Mio €.

The circulation centres in **autumn 2017** were well pronounced with a core pressure below 1005 hPa around Iceland and above 1020 hPa around the Azores. Above normal pressure anomalies could be detected in south-western and northern Europe while negative anomalies prevailed from Iceland to south-eastern Europe. The dominant circulation patterns were the East Atlantic/West Russia Pattern (EA/WR) and the Polar/Eurasia Pattern (POL). During October and November several low pressure systems crossed western and northern Europe and also Medicane NUMA (a hurricane like cyclone in the Mediterranean) that circulated several days in the Ionian Sea with heavy precipitation, floods and damages in the surrounding countries, not only in Greece (see 4.1).

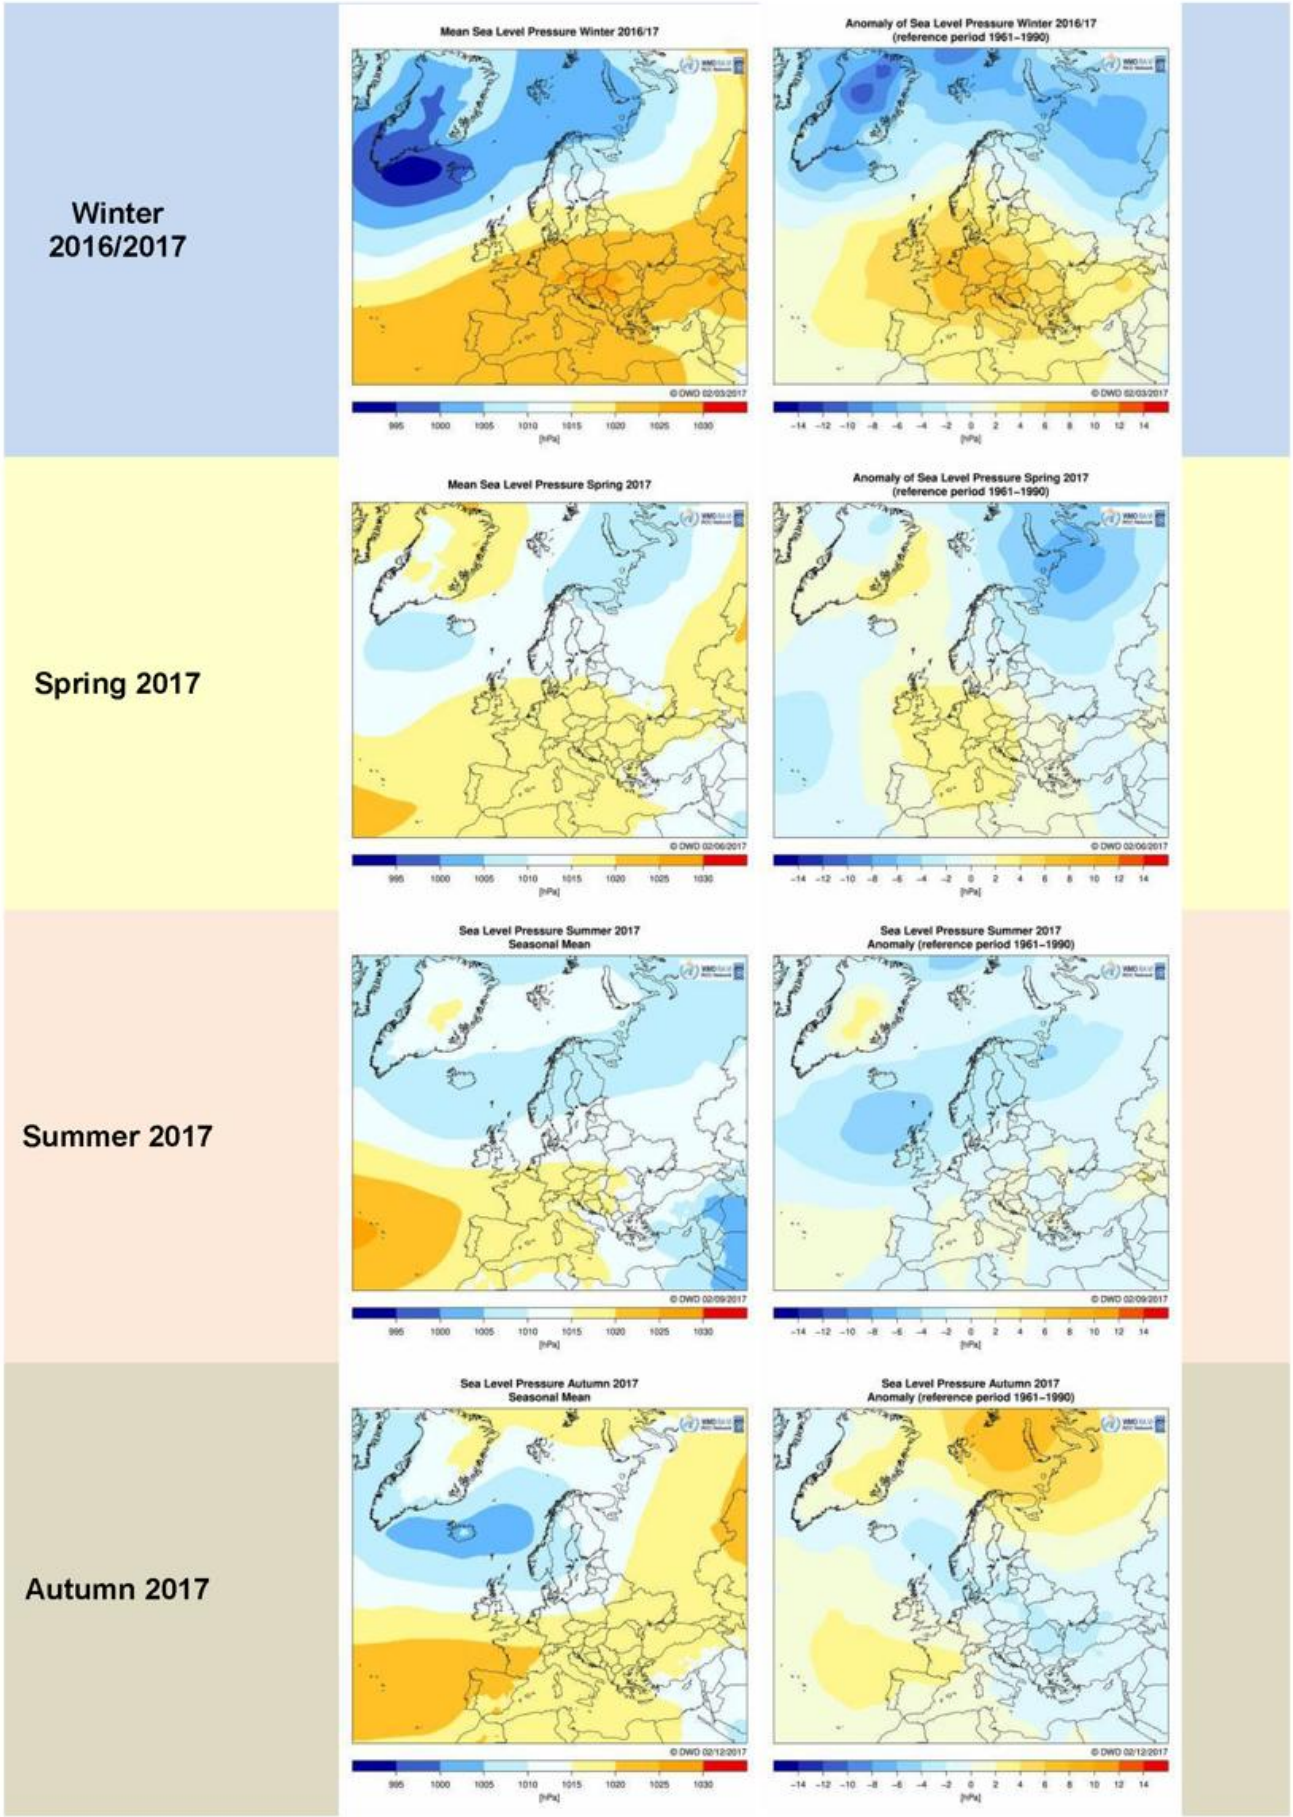

Figure 3.1: Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2016/2017, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.2. Temperature

On average for the whole WMO Region VI and sub-regions the temperature in all seasons in 2016/2017 (except in winter in Mediterranean, Italian and Middle East) was warmer than the normal period 1961-1990. In regional view, however, some differences existed (Tab. 3.2). The annual averages of all sub-regions are very similar and ranged between +1.4 and +1.5°C.

Table 3.2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2017 (reference period: 1961-1990; definitions of the sub-regions see Figure 1.1)

Sub-Region	Winter 2016/2017	Spring 2017	Summer 2017	Autumn 2017	Year 2017
Central and western Europe	0.68	1.99	2.56	0.07	1.35
Nordic and Baltic countries	2.98	0.83	0.65	1.74	1.52
Iberia	0.80	2.51	2.81	0.20	1.49
Mediterranean, Italian and Balkan Peninsula	-0.40	1.74	2.93	0.91	1.44
Eastern Europe	1.66	0.92	0.09	1.74	1.47
Middle East	-0.49	1.19	1.57	2.06	1.42

Temperature anomalies for **winter 2016/17** show lower than normal values in south-eastern Europe and eastern Russia as well as in parts of France and Spain. Northern Scandinavia showed higher than normal values of more than +4°C. The highest positive anomalies occurred in the far North. For example Svalbard Lufthavn reported a temperature anomaly for winter of +7.3°C (+9.3°C in February 2017) and Ny Ålesund +4.9°C. In Porvoo, Finland, the temperature rose to +8.2°C on 14 February, which also was the month's highest temperature in whole Finland.

Some ranks of warm winters based on web-available bulletins by NMHSs are given below (Most countries have not published a rank statistic since the temperature of this winter (2016/17) were for many countries about normal).

Table 3.3: Seasonal rank statistics for winter mean temperature (2016/2017) as provided by the NMHSs.

Country	Rank	Anomaly in °C	Start of time series
Austria	~20 (14 in the mountains)	0.5 (+1.2)	1767
Germany	21	+1.6 (1961-1990)	1881
Norway	8	+3.7 (1961-1990)	1900

The third-warmest **spring 2017** in Switzerland, since measurements started in 1864, was recorded with country wide anomaly of 1.7°C above the normal value 1981–2010. March (the second-warmest since observations began) was 3.3°C, April 0.5°C and May 1.1°C above the normal value. The spring in Spain was extremely warm with an average temperature 1.7 ºC above its normal value. It was the hottest spring since1965, exceeding by 0.1 ºC the highest spring in the series recorded before, the one in 2011. Spring in Spain began with a warm March, with a mean anomaly of +0.9 ºC. April was very warm with an average temperature exceeded by +1.9 ºC its normal value, while May was extremely warm with a mean anomaly of +2.4 ºC.

From Spain, **France** and **Slovenia** 5 heat waves were reported for the **summer 2017**. During summer in **Spain** there were frequent episodes of temperatures higher than normal, both in the

peninsula and in the Balearic and Canary Islands. There were three remarkable heat waves. That from 13th to 21st June, which affected mainly the west, center and northeast of the peninsula; that from 12th to 16th July, when the highest temperatures of the summer were registered and that affected mainly to the south and center of the peninsula; and the one from 2nd to 6th August which affected mainly the south and east of the peninsula and the Balearic Islands. The highest temperatures in principal stations were observed during the first days of the heat wave from 12th to 16th July. In this heat wave it is remarkable the maximum absolute temperature of 46.9 ºC which was observed in Córdoba Airport on 13th. In eight principal stations of the southern half of the peninsula the highest temperature observed exceeded the maximum absolute temperature previously recorded in any summer month. It was the second hottest summer since 1965, only below 2003.

The third-warmest spring in Switzerland was followed by the third-warmest summer since analysis started in 1864. Averaged across the country the summer temperature rose +1.9°C above the normal value 1981–2010. Only the summers of 2015 and the legendary hot summer of 2003 were warmer: the former with +2.3°C, the latter with +3.6°C above the normal value. There were five heat waves in Slovenia during summer, but none of them lasted longer than 8 days.

Summer 2017 in Slovakia, with a country average temperature of 18.5°C, was the 4th warmest summer since 1961 with temperature anomaly +2.7°C compared to 1961-1990 values and +1.7°C compared to 1981-2010 values. Summer temperature at Hurbanovo was the 3rd highest (1901-2017, Figure 3.2).

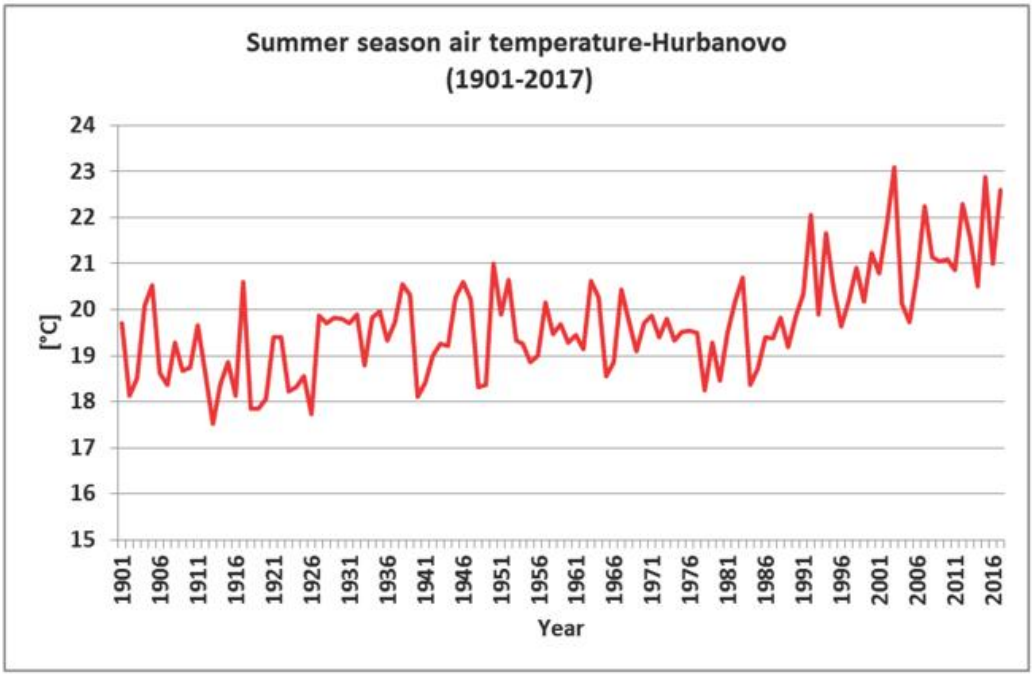

Figure 3.2: Summer temperature at Hurbanovo for 1901-2017

The summer in **Sweden** showed an almost complete absence of really warm spells. The highest temperature in Sweden during the summer was 28.0°C. This is the lowest national maximum temperature for a summer since at least 1922.

Temperatures of **autumn 2017** were normal in most of Europe, around the Mediterranean below normal. In Spain, October was extremely warm, with an average temperature of +2.6 ºC above its normal value. It was the warmest October since the beginning of the analysis in 1965. In Poland the highest autumn temperature occurred at station Rzeszów with 29.1°C on 1.09.2017.

In the Arctic temperatures in autumn were well above normal with anomalies of +5.8°C in Svalbard Lufthavn and 5.7°C in Ny Alesund (Norway).

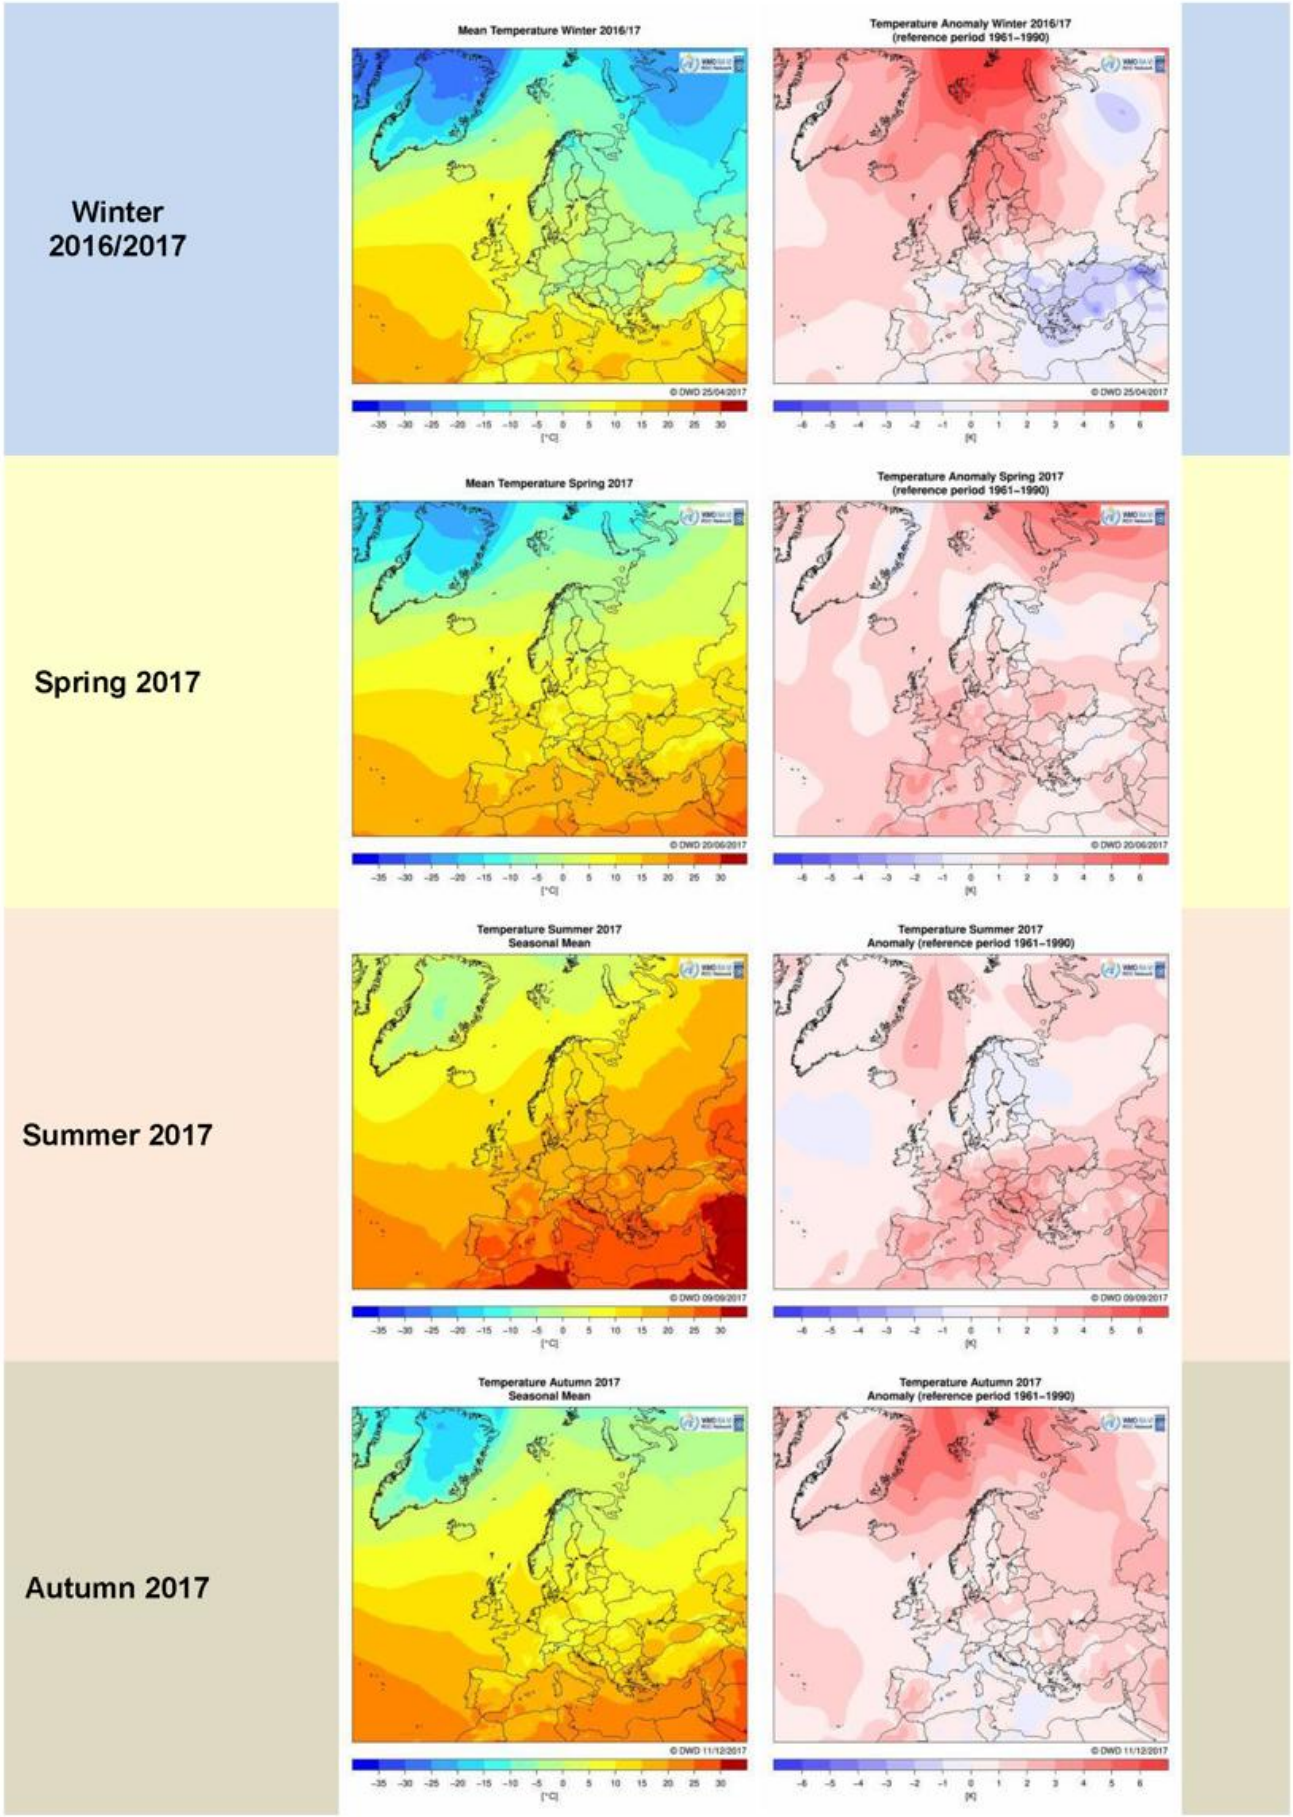

Figure 3.3: Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2016/2017, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.3. Precipitation

Precipitation anomalies in **winter 2016/17** showed lower-than-normal values in many parts of Europe except in eastern Europe, Norway and south-eastern Spain. Therefore the mean snow depth was also less than normal in many mountains although January was very cold in many parts.

Corsica (France) noted the rainiest and snowiest (several episodes) **winter** (DJF) since 1959 that culminated in a flood from 21-23 January with damages on roads and houses.

In mountain regions of **Switzerland** the thin winter snow cover in 2016/17 was at close to record-breaking levels. Davos for example recorded 27 cm, only 1 to 3 cm more than the winters with the least snow up to now: 2006/07, 1995/96 and 1989/90. Arosa registered – on average from December 2016 to February 2017 - only 31 cm of snow, Segl-Maria even as little as 12 cm. At both stations, only one winter with an even thinner winter snow cover had been observed: in Arosa this was the winter 1989/90 with 28 cm and in Segl-Maria the winter 2001/02 with only 7 cm of average snow cover.

In **spring 2017**, western and southern Europe was drier than normal while eastern Europe and Norway were wetter. **Romania** was affected by several floods in May due to storms and convective phenomena almost everywhere on numerous days during the month. On the 6th, such phenomena led to hail occurrence and flooding in Oltenia, which triggered damage to a number of households. The situation was similar in Arad County, where massive rainfalls disturbed the traffic. Rainfalls continued in the same manner until the 14th in more counties, flooding tens of houses, households, communes and county roads. In the latter half of the month, torrential rainfalls accompanied by hail, thunder and squalls again occurred in several counties and in the Capital city Bucharest, flooding tens of localities. Hundreds of households and agricultural lands were flooded and even completely covered by water, crops were destroyed and more county and national roads were blocked after the water outpoured.

Precipitation anomalies in **summer 2017** were highest in Scandinavia, European Russia, and central Europe with partly more than 150%. Greece and western Turkey were wetter than normal due to convection. Southern France, Italy, the Balkans, eastern Turkey and parts of Iberia showed a precipitation deficit.

The **United Kingdom** received 320 mm of rainfall over the summer (1 June – 30 August), 32.8% more than the 241 mm average. This makes this summer the UK's 11 wettest on record. In Germany the start of the summer saw long periods of dry weather, from the end of June onwards there were frequent thunderstorms and intensive heavy rain events. Berlin Airport measured on 29th of June 197 mm/day (low RASMUND). From 24 to 26 July, low ALFRED moved slowly through central Germany (Harz-region, Lower Saxony and Thuringia) with a precipitation amount of 302 mm/72h inducing floods and damages. Greece was also affected by thunderstorms with highest daily precipitation amount of locally up to 99 mm on 29th of August. Local thunderstorms in Turkey induced local heavy precipitation of 98.4 mm/d in August.

In central and eastern Europe **autumn 2017** was wetter than normal, while western and southern Europe was drier than normal.

In **Latvia**, September with an average precipitation amount of 129.4 mm was the 3rd wettest since 1924, while October with an average of 114.3 mm was 6th wettest on record and 1st wettest in the 21st century. Due to high precipitation amount in September and October, autumn with an average precipitation amount of 313.5 mm was the 2nd wettest in the last 94 years, while in western Latvia in some stations it was the wettest autumn. Monthly precipitation in most parts of **Lithuania** amounted in September and October to about 1.5–2.5 of the norms. Autumn became the most humid season in Lithuania since 1961 (amounting to 345 mm, i.e. more than 1.8 of the norms).

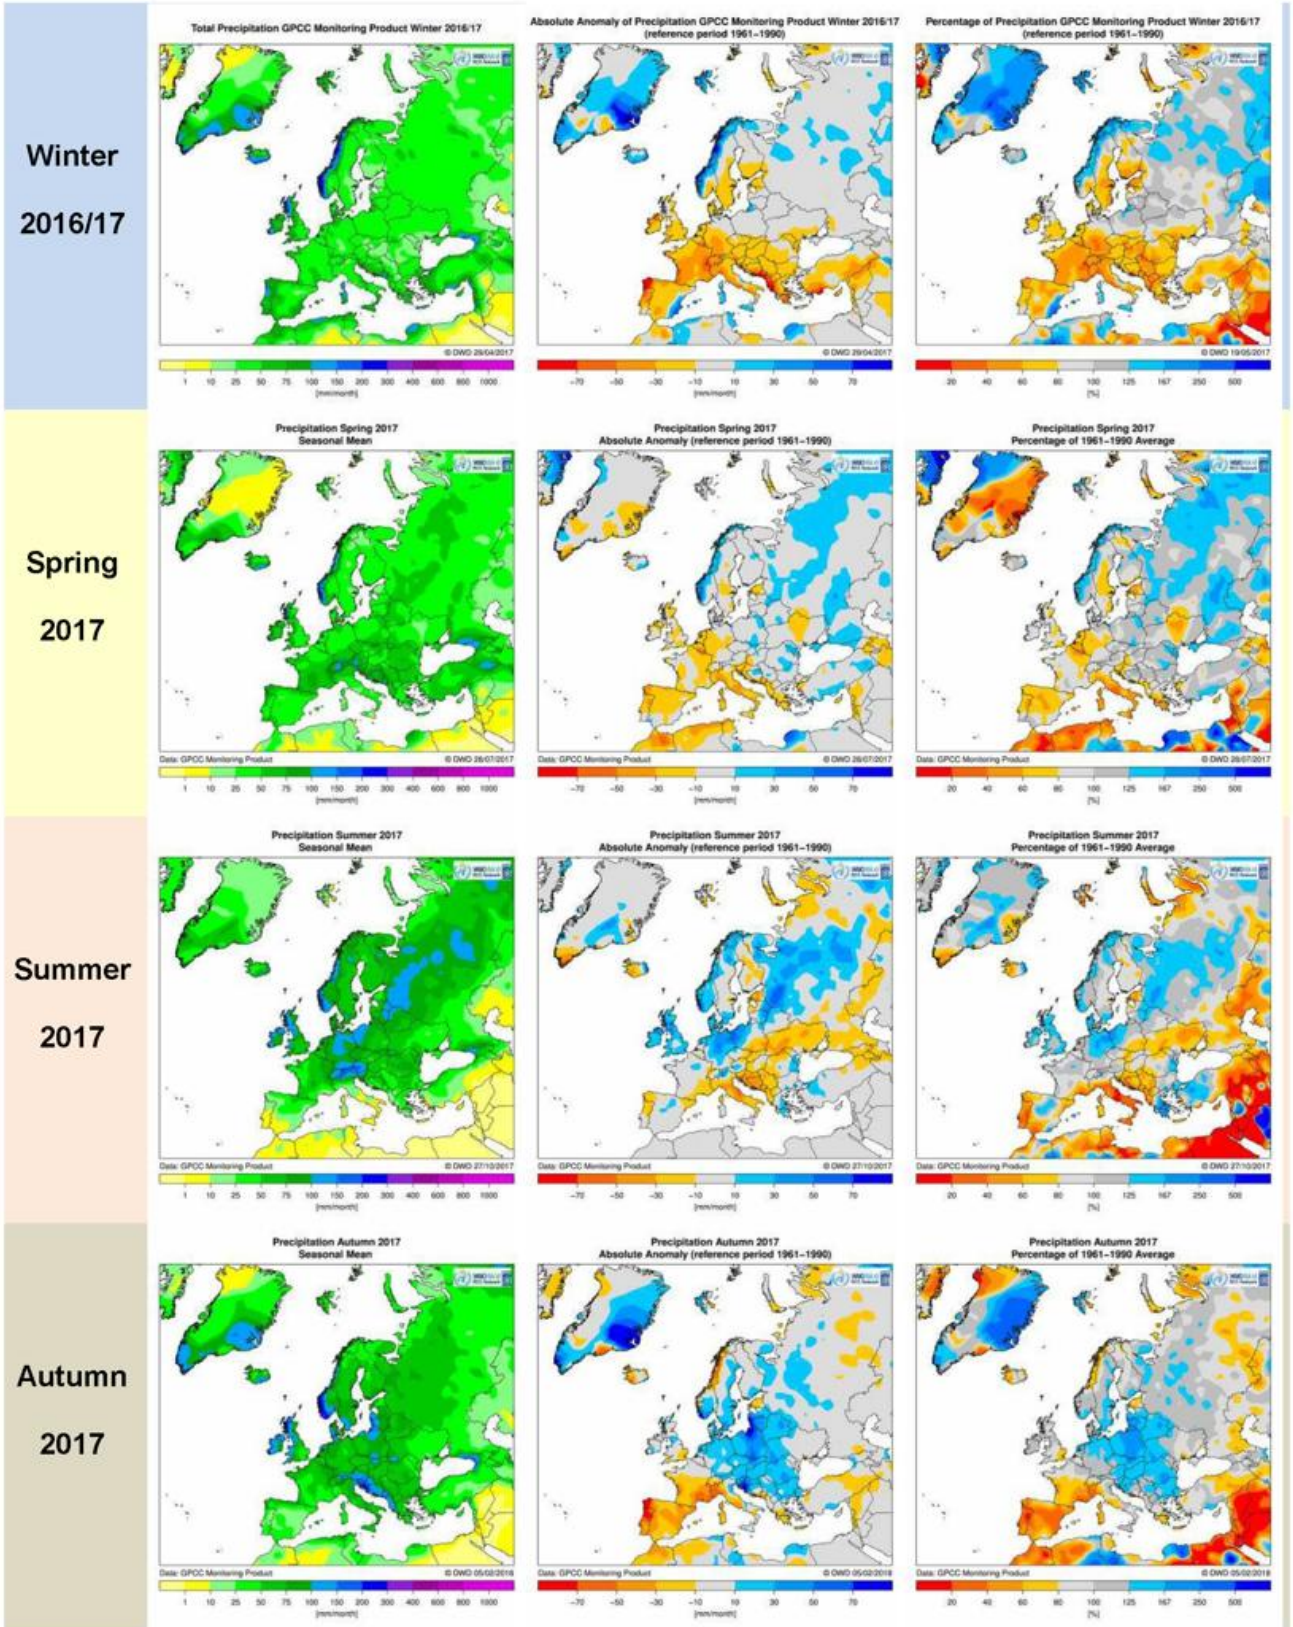

Figure 3.4: Seasonal total precipitation (left, in mm/mon), absolute anomalies (middle, in mm/mon) and relative anomalies (right, in %) in 2016/2017, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.4. Sunshine duration

Many parts of Europe received more than average sunshine in **winter 2016/17**. Only parts of Portugal, the United Kingdom, northern Scandinavia, the Baltic States, Belarus, Ukraine and Russia noted below-normal sunshine. This coincided well with below-normal cloud cover anomalies in most parts Europe. In contrast, the far north showed more clouds and less sunshine than normal in winter 2016/17.

Sunshine duration in winter **Switzerland** amounted to between 110 and 145 percent of normal values 1981–2010 across many parts of the country. In mountain areas the above-average sunny winter of 2016/17 terminated a multi-annual period with mostly below-average sunshine duration. Samedan registered 419 sunshine hours and Davos 409, bringing the winter at these stations up to the second-sunniest since the beginning of homogenous data series in 1959. The sunshine record in December 2016 contributed substantially to this sunshine record. Above-average sunshine was also registered for January 2017. For the winter 2016/17, both meteorological stations registered only a few sunshine hours below the existing record.

In **spring 2017** most of Europe registered above normal sunshine duration. Sunshine deficit was reported for south-eastern and northern Europe.

Southern and Central Europe had positive sunshine duration anomalies in **summer 2017** with up to 125% in the Balkans. Only Scandinavia, the Baltic States, and northern European Russia showed less sunshine and more cloud cover. Due to more radiation several heat waves were observed in southern Europe.

In **autumn 2017** most of Europe registered a sunshine deficit or higher cloud amount which was related to the extreme precipitation. Only south-western and north-western Europe as well as the Caucasus and parts of south-eastern Europe received more sunshine than normal.

In Austria, in this autumn the sun shone 10 % less than on average. Together with the one from 2013 and 2014 this autumn was the dullest in the past 20 years.

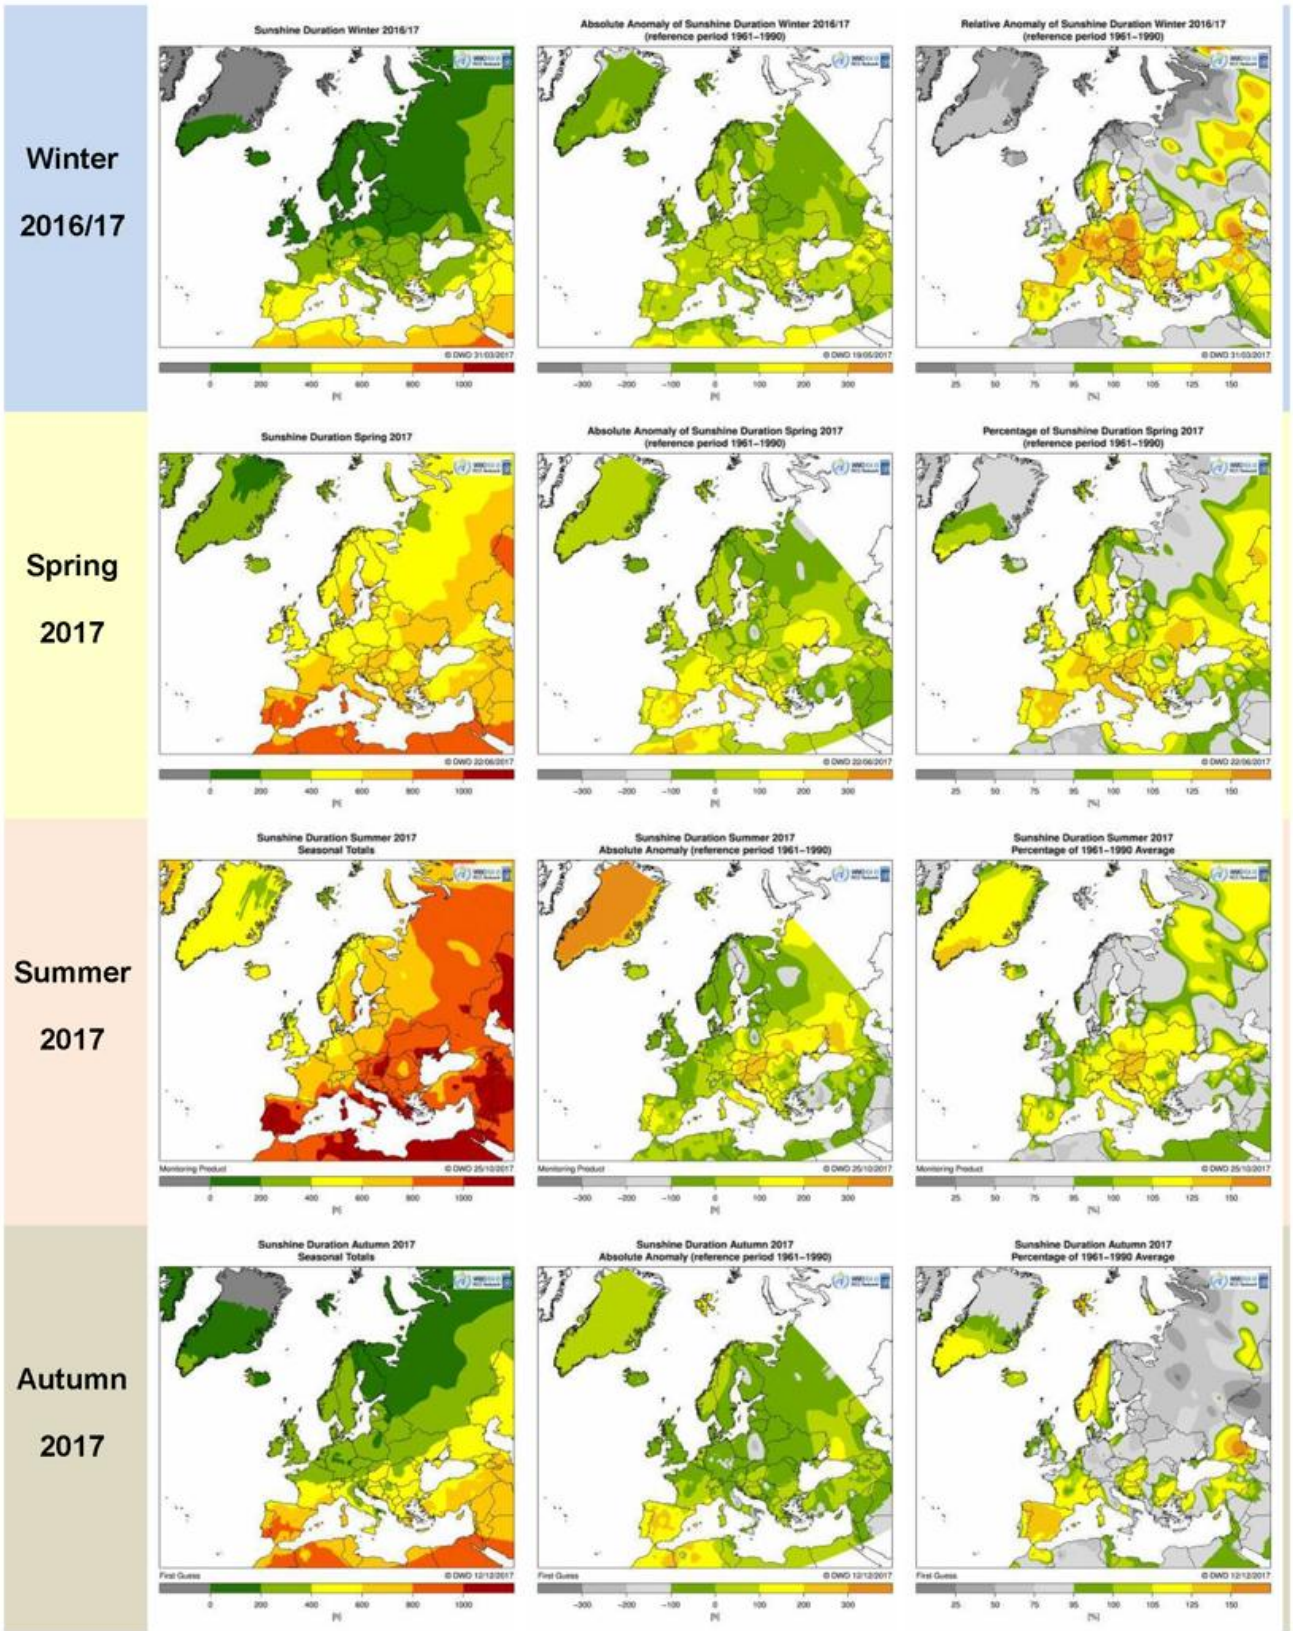

Figure 3.5: Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and percentage of mean (right, in %) in 2016/17, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.5. Drought

Winter 2016/17 precipitation in **Switzerland** totals from December 2016 to February 2017 reached only half of the normal values 1981-2010 in the nationwide average. In western Switzerland and in the Valais only 30% to 50% of the normal precipitation values were recorded. Western Switzerland observed – in certain regions - a winter with the least precipitation in 45 to 55 years. A comparable winter drought period in the Valais dates back 40 years. Little precipitation also means little snow. Some places south of the Alps registered the thinnest snow cover since measurements began 55 years ago.

In **spring 2017** mild drought occurred in southern, western and northern Europe while eastern Europe was mildly wet. Only central Italy showed severe drought. The monthly amount of precipitation of 5.3 mm recorded at Findel Airport (**Luxembourg**) is the second driest value ever recorded in April since 1947. This event can be referred to as exceptional. Very dry weather was observed in **Lithuania** in May (24% of the norm) and the water level of the rivers reached its minimum due to below normal temperature. **Austria** documented a drought in northern parts from May to 20 July with locally massive harvest losses (especially winter wheat, maize, potatoes) of approximately 40% (in Lower Austria). The drought in the **Czech Republic** last from June until August. In southern Moravia even from January to August 2017 when a precipitation amount of only 284 mm (71 % of normal 1981-2010) was registered which was the 2nd lowest in 1961-2017 (affected area: approx. 8 000 km^2).

In **Belgium**, almost the whole country had a rainfall deficit in 2017. Especially the winter and spring were highly dry. For a limited period of time, pumping water as watering the gardens was prohibited in some areas of Belgium. All this caused a lot of damage on field crops. The spatial distribution of the drought index SPI-3 for April-June 2017 shows that the main part of the country was extremely dry.

Spring and summer atmospheric droughts in the **Ukraine** have gradually evolved since April, intensified and spread in May-June and last until first half of September. Precipitation deficiencies in many areas reached 50-70% of the norm. In June the drought was classified as air-soil one of varying intensity. She has led to essential reduction of the harvest of early grain crops and late crops, namely corn, soybeans, sunflower.

Summer 2017 was extremely dry in many parts of southern Europe. Especially Italy suffers from heat, drought and water scarcity (Figure 3.7). Because of the water crisis in Italy, the government in Rome has declared a state of emergency for Lazio (with the capital Rome) and Umbria. Cooler air from north induced heavy storms with hail in northern Italy (e.g. 9th of August on Lake Garda) and tornadoes (e.g. the 10th August in the seaside resort Cavallino northeast of Venice) and reduced partly the drought.

Very dry **autumn 2017** in south-western Europe. Autumn in **Spain** has been the driest in the XXI century. Mean precipitation was only 84 mm, 59% lower than normal. In the Republic of **Moldova** between August 1st and September 20th it was hot with a significant shortage of precipitation, which contributed to the occurrence of a severe, and sometimes very severe, drought and in this period of the year, it is possible on average once every 15 years.

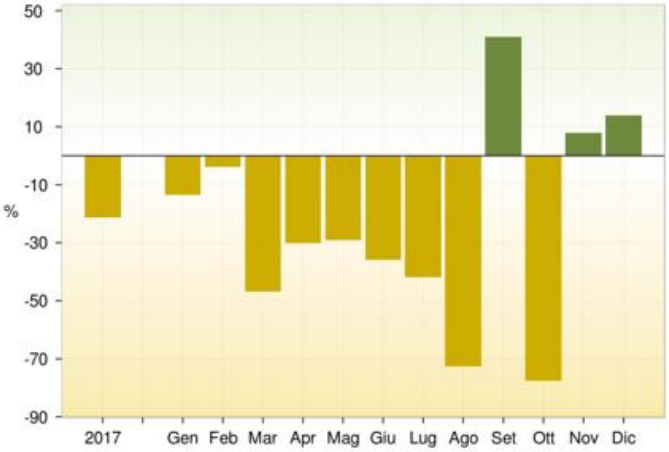

Figure 3.6: Monthly and annual precipitation anomalies for Italy in 2017, expressed as percentage of the normal value 1961-1990 (Diagram as provided by the ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

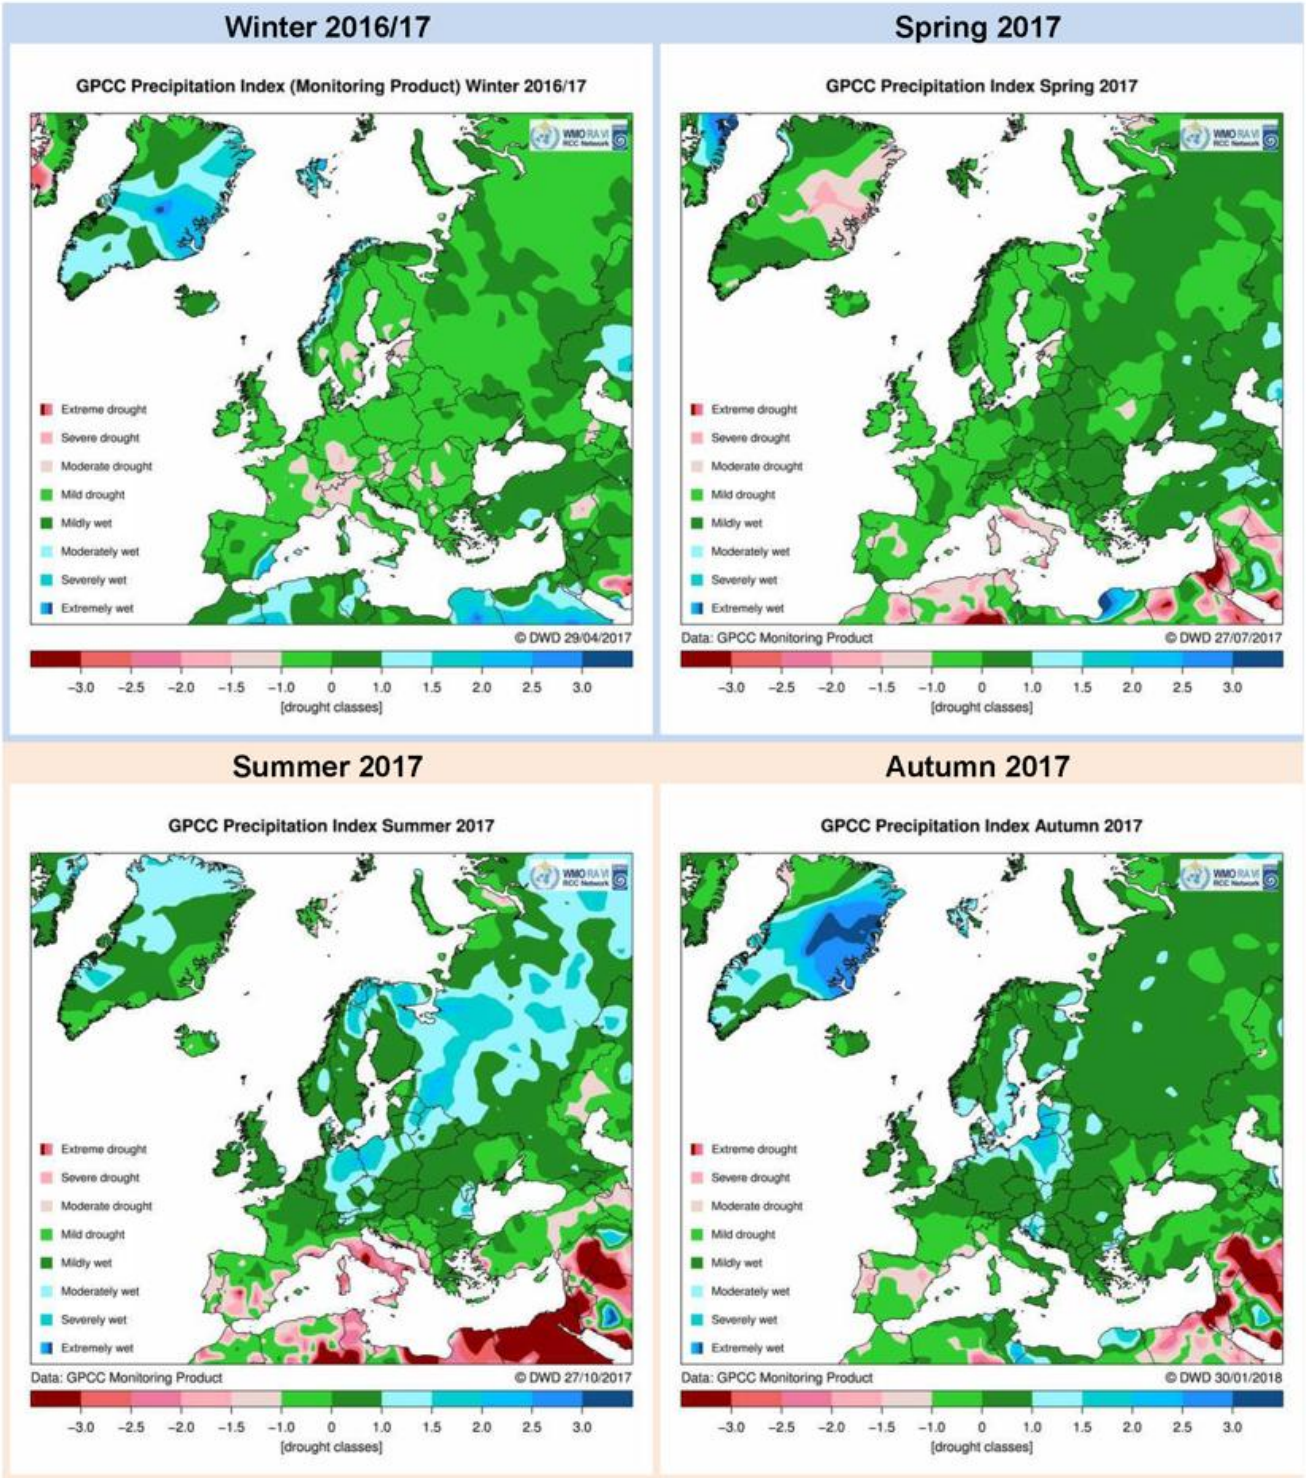

Figure 3.7: Seasonal standardized precipitation index (SPI, in drought classes) in 2016/2017, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2017 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each month as well as monthly overviews of extremes and notable events.

4.1. Sea surface pressure and circulation indices

This chapter about atmospheric circulation provides information on selected northern hemisphere teleconnection indices which are considered to be relevant for WMO RA VI and it discusses influences of circulation patterns upon anomalies and outstanding events. The information is based on the "Monthly Bulletins on the Climate in WMO RA VI" and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4.1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference and the Arctic Oscillation, for January to December 2017.

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2017	1	0.05	-1.15	0.63	0.17	0.96	0.94
2017	2	0.69	0.58	1.14	0.67	-0.38	0.34
2017	3	0.37	1.03	-1.02	-1.02	0.73	1.37
2017	4	1.74	-0.62	0.71	-1.45	-1.37	-0.09
2017	5	-1.72	0.54	1.48	0.95	0.46	-0.73
2017	6	0.35	2.03	0.34	-1.43	-0.11	0.40
2017	7	1.28	1.83	-0.58	0.03	-0.05	0.63
2017	8	-1.53	2.02	-2.93	-1.57	1.83	0.15
2017	9	-0.45	1.58	-2.52	0.46	-1.66	-0.49
2017	10	0.71	0.62	-0.02	0.30	-1.17	0.69
2017	11	-0.14	0.12	-1.21	-0.08	-2.23	-0.08
2017	12	0.73	-0.50	-1.63	-0.48	-1.95	-0.06

Note that all values are standardized with reference to the period1981-2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

The winter storm "Egon" affected from 12–13 January 2017 mainly **France** and **Germany** with wind gusts of up to 40 m/s (145 km/h) and heavy snowfall. Rail and air traffic were affected. Several houses and a cathedral were damaged and one person died. The financial loss was estimated to about 350 Million Euro (MunichRe 2018).

On the 18 January in **Sweden** the mountain top station Stekenjokk recorded a mean wind speed of 47.8 m/s. This is a new Swedish record, but due to the extreme exposure of the station it might be regarded as a singular event. During the 3th and 5th storm "Axel" (in German), with wind gusts of 36 m/s (130 km/h) caused fallen trees and traffic disruption in **Austria**. The majority of damage, like uprooted trees and damaged roofs, was reported in the eastern part of Austria. On the **German** coasts storm "Axel" caused storm surges with rock slide, flooding, fallen trees and heavy snow fall.

Several storms affected Europe in February 2017. From 2nd – 5th in **Portugal** a maximum wind gust of 36 m/s (129.6 km/h) was measured in Guarda. **Spain** reported storms from 1st – 4th of February in many provinces with maximum wind gusts of more than 25 m/s (90 km/h). In **Slovakia** the highest maximum wind speed (gusts: 61.6 m/s or 222 km/h) occurred at Lomnický štít (2634 m a.s.l.) in recorded history (at least from 1951) on 24th of February. In **Ireland** storm "Doris" (named by MetOffice; 23rd Feb) brought the month's highest wind gust of 39 m/s (141 km/h) at Mace Head.

Strong wind in February

(Contribution from Instituto Português do Mar e da Atmosfera, I.P.M.A.)

Between the 1st and 5th of February heavy precipitation and strong wind occurred in the territory of Portugal, especially in the northern and central regions.
Between the 2nd and 5th of February the wind was moderate to strong on the west coast, with wind gusts of 60-80 km/h, and strong to very strong in the highlands with wind gusts of 100-110 km/h. During this period, high and persistent values of wind intensity were recorded in some places in the North and Center regions, with values above 100 km/h (Guarda, Penhas Douradas, Mogadouro, Moimenta da Beira and Vila Real stations).

In the early morning and late afternoon of the 3rd and early morning of the 5th of February there was a persistence of high values of wind intensity at more than 10% of the stations, namely with wind mean values above 40 km/h and gusts above 70 km/h (Figure 4.1). The highest value occurred in Guarda weather station at 04:20 UTC, 129.6 km/h, which exceeded the previous maximum (129.2 km/h on January 23rd, 2009).

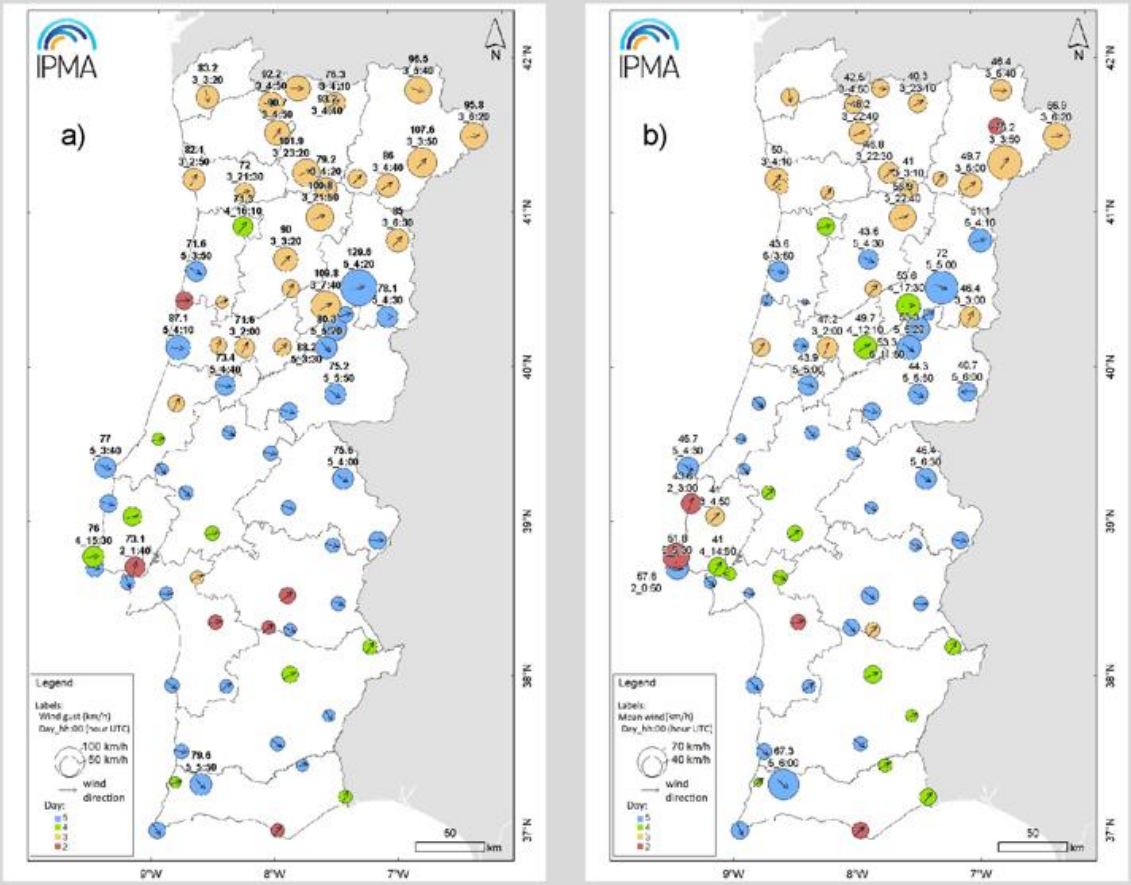

Figure 4.1: Maximum values of instantaneous wind intensity (a) and mean wind (b), respective direction, day and hour of occurrence, in IPMA observation network, 2nd to 5th February, 2017

Europe was affected by several storms in **March 2017**. On March 4, 2017, in **Austria** a heavy Foehn storm on the mountains in Vorarlberg, Tyrol and Salzburg caused numerous storm damages. Numerous trees were uprooted by wind peaks of up to 44 m/s (160 km/h). In Tyrol, railway lines were interrupted by fallen trees. In Salzburg, several ski lifts were closed because of the storm. During the 6th and 7th March storm "**Zeus**" passed **France** with strongest gusts of about 35 m/s in Brittany (tornadoes were also observed and power breakdown). On the coasts, they reached about 40 m/s and even 53 m/s at station Ouessant and 54 m/s at Camaret-sur-Mer, new absolute records. The system moved across the Mediterranean with strongest gusts of about 51 m/s at Saint-Raphaël (near Cannes) and 40 m/s at Calvi (Corsica). Storm "Zeus" was accompanied by heavy precipitation of up to 30 mm/day in south-eastern France, above an elevation of 300 m as snow.

In **April 2017** Europe was still affected by several storms. Especially from 27 to 29.04.2017 low "**Tarek**" affected Europe from southern Spain to Belarus with locally heavy precipitation. In southern **Spain** over 100 mm were accumulated at station Huelva and more than 200 mm in the City of Ceuta (Spanish enclave in Africa). The Alps were also affected by snow and rain. **Switzerland** reported several new records of snow depth for the second half of April. In St. Gallen 35 cm snow were accumulated during 2 days. The maximum precipitation amount in **Germany** also occurred in the Alpine region with 237 mm/month at station Zugspitze. At the end of April the precipitation in south-western **Austria** was also extreme with 256 mm/48hours at station Loiblpass (return period of once in 40 to 50 years) with a monthly total of 340 mm (or 108% of the reference 1981-2010). In **Slovenia**, at station Vogel 626 mm/month and 269 mm/day were registered

On 29 **May 2017**, a hurricane affected Moscow (**Russia**), with wind speed as strong as 29 m/s, caused the greatest number of victims on record: 11 people were killed and 70 were injured. In a few minutes, the wind fell thousands of trees, damaged many cars and roofs of 30 houses, and stopped the operation of above-ground subway and commuter trains.

June 2017 started with some showers in western and Central Europe. Prevailing westerly currents accompanied by thunderstorms, sometimes strong wind gusts and heavy showers reached **France** on the 3rd. The west and the east flank of the Massif Central received a daily rainfall amount of 49.5 mm in Aurillac (Cantal) and 80.2 mm in Coublevie (Isère). During the 3rd the cold front (of low "Heinrich") passed **Germany** with hail and heavy precipitation. An amount of 105.6 mm during several hours at station Ludwigschorgast (Bavaria) causing floods. During the 22nd of June a low pressure trough passed northern **Germany** with showers and thunderstorm. Locally heavy rainfall of 72 mm in Göttingen was measured and 37.8 mm in Potsdam.

Strong thunderstorms from the south-west passed **Switzerland** from the 24th to the 25th of June. At the southern side of the Alps station Lugano measured a rainfall of 81.5 mm within one hour (the last record with 63.8 mm dates back to 12th of September 1994). Until the end of the month several depressions passed the Alps with heavy precipitation. Together with the heavy rainfall at the beginning of the month, the southern side of the Alps and the Engadin received precipitation sums well above the normal 1981-2010. At station Lugano a new June record with a sum of 493.3 mm was registered (measurements started in 1864). At station Crana-Torricella an amount of 33.5 mm was measured during 10 minutes.

In **July 2017** in Austria out of a thunderstorm with heavy rainfall and hail a tornado of the F1 category developed in the vicinity of the airport Vienna-Schwechat with wind peaks up to 50 m/s (180 km/h). Only negligible damage was reported, however, there were some air traffic delays. In addition, hailstones of up to 5.5 cm caused damage to agriculture

In **August 2017** at Osmussaar, (an island) in Northwest Estonia on the 12th a wind gust of 38.2 m/s was measured and in Käravete an F(0) tornado was observed.

At the end of **September 2017**, extremely high air pressure was observed in Sweden. On the 28th, a new Swedish air pressure record was recorded for September with 1044.1 hPa in Lycksele and Åsele in southeast Lapland. Storm „Sebastian" passed Austria in the middle of the month with wind gusts of 31 m/s (110 km/h) causing uprooted trees and unroofed houses.

Ex-Hurricane "**Ophelia**" (named by the US National Hurricane Center) reached on 16th of **October 2017** the British Isles. The strongest winds were around Irish Sea coasts, particularly west Wales, with gusts of 43 m/s (155.6 km/h at Roche's Point, Ireland) with cancelled flights, closed roads and railway lines and disrupted ferry services between Wales and Ireland. On 5th of October 2017, storm "**Xavier**" crossed Germany, with wind gusts up to hurricane force (118 km/h and more) even in the lowlands. In northern Germany heavy rain with locally more than 50 mm/d was noted. In other European countries, such as Netherlands, Poland and the Czech Republic - with the exception of exposed layers - gusts of up to 11 Beaufort (up to 117 km/h) were registered.

During the 29th of October northern Austria was hit by a storm (named "**Herwart**" in Germany and "**Ingolf**" in Scandinavia) with wind gusts of up to 50 m/s (180 km/h) that led to operating delays on some Austrian airports, about 150.000 homes were left without power. The same storm reached also the Czech Republic with wind gusts over 30 m/s in some locations, over 50 m/s in mountain stations (Krkonoše Mountains). The result of "**Herwart**" was a loss of about 20 Million Euro and 3 dead (MunichRe 2018).

Spain reported wind storms from 10-11 November 2017 in many provinces with maximum wind gust of more than 25 m/s (90 km/h). The cyclone "**Ylva**" (named by Met Norway, "Reinhard" in German) affected northern Norway with very strong winds from 22 to 24 November. The strongest wind was recorded at the station Narvik - Fagernesfjellet (Nordland) with a wind speed of 47.5 m/s.

Medicane "Numa" over the Adriatic Sea

(Contribution from Hellenic National Meteorological Service)

On 11 November a cut-off upper low over Tunisia accompanied by a corresponding low pressure center in the sea level pressure field over the Gulf of Syrtis produced widespread thunderstorms across the central Mediterranean region, mainly over Sicily, Malta and north Ionian Sea. On 12 November, the cut-off low moved east northeast and on 13 November affected at first the west Greece and gradually the eastern areas including Attica, Cyclades, Crete, and Dodecanese islands causing locally strong flash flooding (e.g. Symi Island). Also on 13 November a second deep low over the gulf of Genoa (995 hPa surface pressure for 00UTC) pushed polar air towards southern Italy. From 15 November onwards the low widened and moved to the Central Mediterranean. Over the warm Ionian Sea the cold and humid air mass destabilized, under weak vertical wind shear, causing the formation of a Medicane (Mediterranean tropical-like hurricane).

On 15 November major flash floods hit western Attica, after a night of intense rainfall. In particular, flooding hit the towns of Mandra and Nea Peramos. According to the HNMS's radar recordings the 24 hour accumulated precipitation over the wider area of the Mount Pateras (west Attica) during 14 - 15 November was 80 mm approximately (there is no meteorological station in that region). Also the HNMS's radar recorded the intensity of rainfall over west Attica.

The figure below indicates the appearance of a Medicane on 18 November. A whirl of convective cloud and a distinct quasi cloud-free eye is obvious (Figure 4.2). However by the evening of 18 November the Medicane had dissipated.

Figure 4.2: A well-defined eye structure of Medicane over the north Ionian Sea on November 18, 12:00 UTC (Terra MODIS and Suomi NPP VIIRS true-color RGB, source: http://cimss.ssec.wisc.edu/goes/blog/archives/26136).

Several storms affected Europe in December 2017. In western **Norway** on 7 and 8 December storm **Aina** (named by Met Norway, Walter in German) came with a mean wind speed of 33.1 m/s, at Folgefonna Ski Center (Jondal, Hordaland). The station also recorded a wind gust of 40.2 m/s. On 25 December wind speed in Stavropol (**Russia**) reached 30 m/s. As result, trees were fallen, a gas pipeline and cars were damaged, and interruption of power supply was recorded. Storm Dylan on 31st December brought strong winds, and trees downed in the South West of the **United Kingdom** with travel disruption. There were fallen trees also across Northern Ireland. The month's highest gust in **Ireland** was 34 m/s (124 km/h) reported at Malin Head, Co Donegal on the 31st Dec.

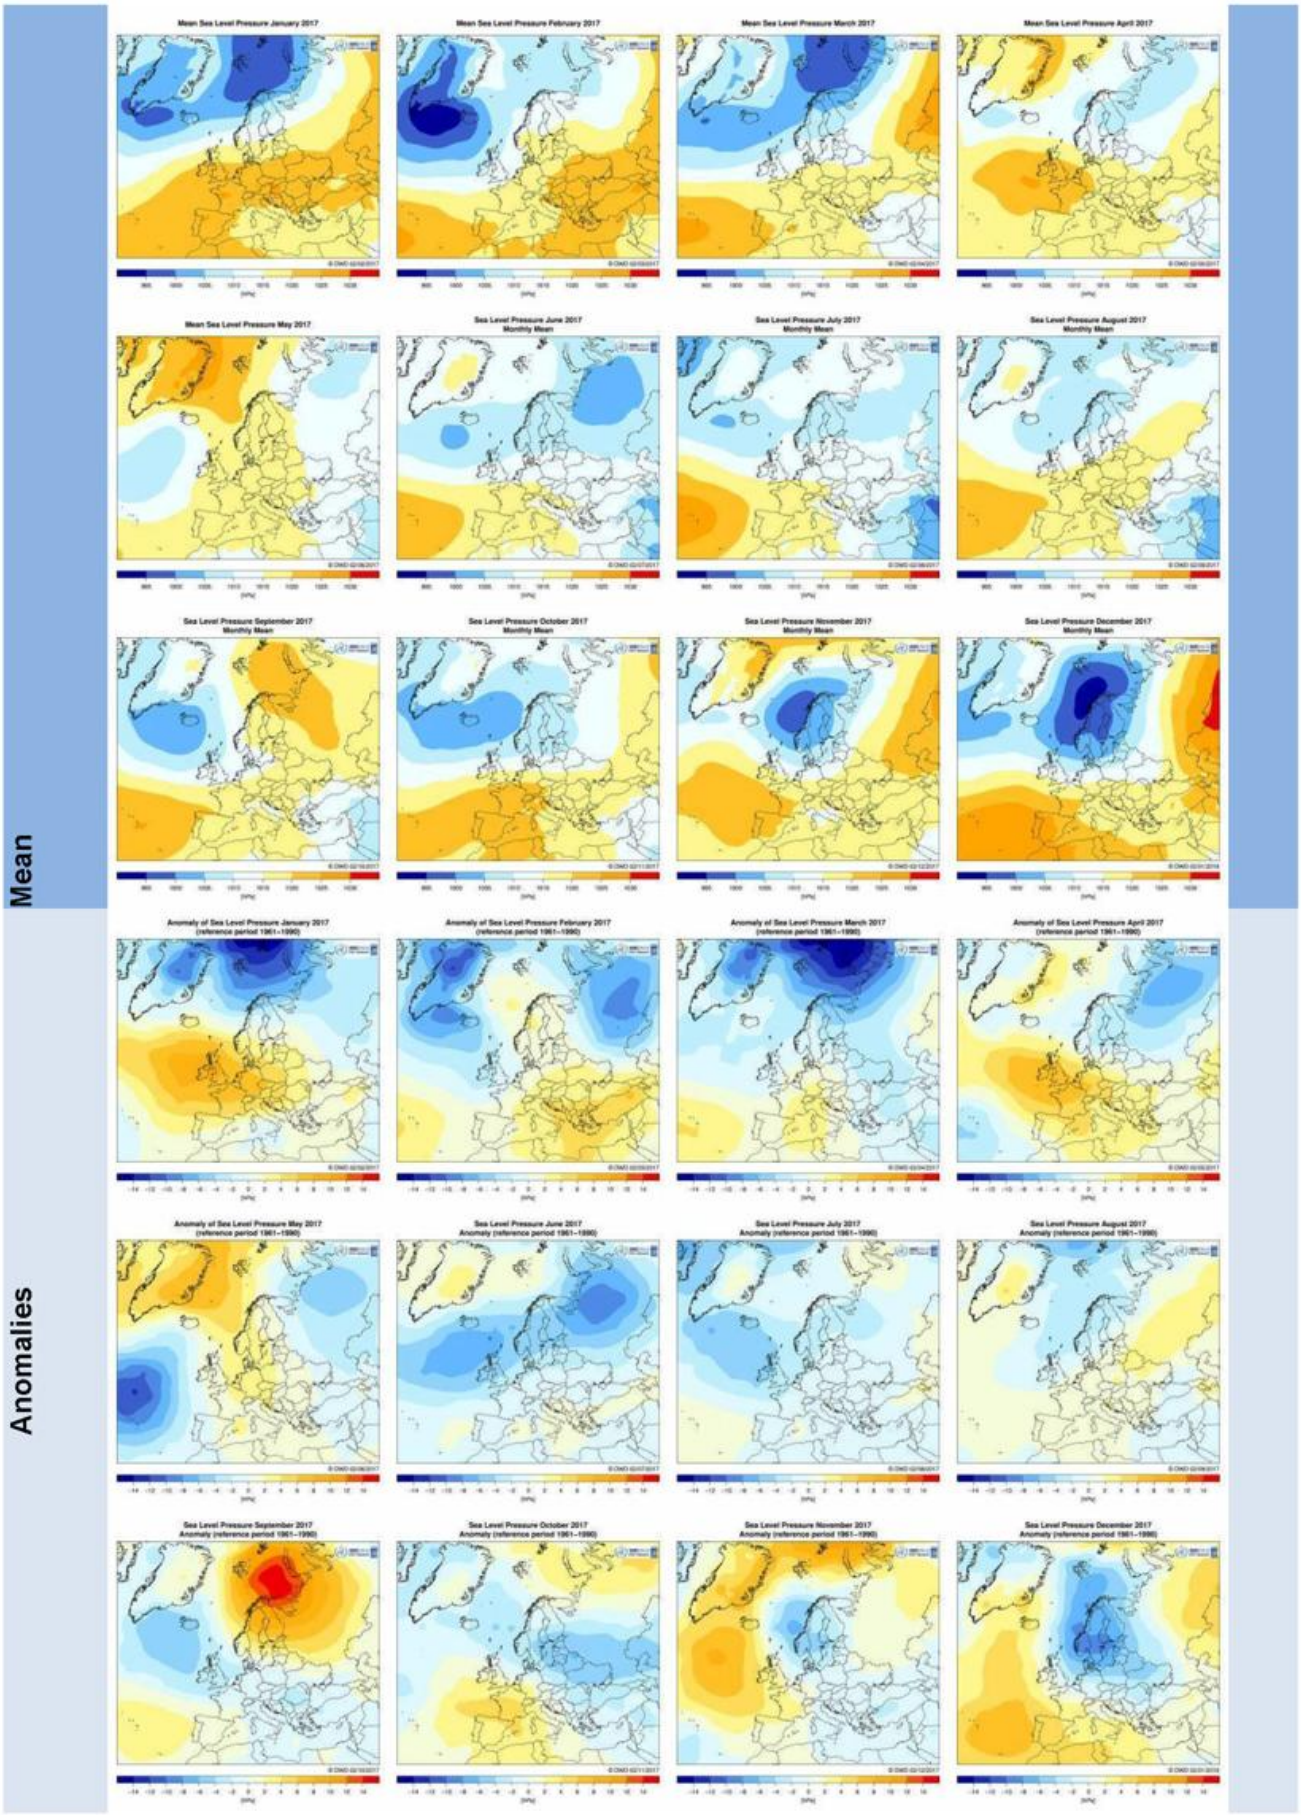

Figure 4.3: Mean and anomalies of sea level pressure in hPa for each month of the year 2017. (First row January, February, March, April; reference period 1961-1990).

4.2. Temperature

In most of the months and sub-regions it was warmer than normal as can be seen from Table 4.2. The Nordic und Baltic Countries had positive anomalies throughout the whole year 2017 and in eastern Europe in March and December anomalies above +4°C occurred.

Table 4.2: Monthly and annual area average temperature anomalies in °C for each sub-region in the year 2017 (reference period: 1961-1990; definitions of the sub-regions see Figure 1.1).

Region	Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sep.	Oct.	Nov.	Dec.
Central and western Europe	1.35	-1.25	2.26	3.38	0.61	1.99	2.76	2.25	2.68	-0.07	-0.39	0.68	1.34
Nordic and Baltic Countries	1.52	2.30	3.05	2.18	0.14	0.17	0.32	0.60	1.02	1.86	1.35	2.03	3.28
Iberia	1.49	-0.42	1.72	1.79	2.57	3.17	4.08	3.07	1.27	-0.64	0.76	0.49	0.06
Mediterranean	1.44	-2.60	2.03	3.03	0.85	1.34	3.02	3.36	2.42	1.70	0.58	0.45	1.07
Eastern Europe	1.47	2.00	2.54	4.54	-0.26	-1.51	-0.91	-0.17	1.36	3.40	-0.21	2.01	4.80
Middle East	1.42	0.41	-0.15	2.21	0.58	0.77	1.18	1.46	2.07	3.39	1.38	1.40	2.34

In January 2017 a cold wave occurred in central and southern Europe. **Spain** reported a cold wave from 15 provinces with a monthly minimum temperature of -4.0°C and a deviation from normal of -2.5°C. The most significant cold spell of the year occurred from 18th to 20th of January, due to an invasion of a mass continental cold air that affected the Iberian Peninsula and the Balearic Islands, with the lowest temperatures of the year. The coldest temperatures recorded in 2017 at principal stations were observed in Puerto de Navacerrada with -13.8ºC on 18th January, Molina de Aragón with -13.4ºC on the same day, Salamanca Airport on 19th with -10.9ºC and Albacete Air Base with -10.2ºC on 18th.

The first cold wave encompassed **Serbia** from 6 - 12 January 2017. Cold wave first affected Vojvodina and mountain regions on January 6, spreading to the entire country on January 7 and lasting until January 12, 2017. During this cold wave, the departure of the minimum daily air temperature from the mean minimum daily air temperature reached -20.4°C in Leskovac. The second less intensive cold wave was registered from 20 to 24 January 2017 in most of Serbia. The third cold wave was recorded in a period from 27 to 31 January 2017 in Pozega and others.

Greece experienced a cold wave during 7-12 January 2017 with low minimum temperatures (Florina Tmin=-22.7°C on 11th January). Heavy snowfall caused huge problems in transportation; hundreds of vehicles were trapped in highways; public transportation in Thessaloniki collapsed and flights were suspended. Migrants in Greece suffered from very low temperatures and were housed in commercial buildings and ships; one migrant died due to harsh weather conditions.

Minimum temperatures in **Bulgaria** in January 2017 in some parts of western Bulgaria were close to the absolute minimum possible at least once in 50 years (-26°C in Kyustendil and -27°C in Pernik). Seven-day cold spell gripped the most part of Bulgaria in the period 6-13.01.2017 and was caused by the advection of very cold air masses from northern Russia related to the amplification of a ridge over the eastern parts of North Atlantic and a trough downstream which thereafter formed a cut-off low over south-eastern regions of Europe. In the Republic of **Moldova** January 7-9 was extremely cold. The average daily air temperature in these days was -10..-16ºC, which is 8-13ºC below the norm and it is observed in January on average once in 10-20 years.

The mean temperature in **Norway** was +3.9°C above normal, the 12th mildest January month since 1900. A long lasting Foehn wind caused the daily mean temperature at Sunndalsøra to become

13.8 °C, on 25 January. This is equivalent to the daily normal for 4 July, and is probably the highest daily mean temperature ever recorded by a Norwegian weather station in January.

In February 2017 only in the south-eastern part of the RA VI region negative temperature anomalies occurred. According to the temperature anomaly map all other regions showed positive temperature anomalies with its maximum in the north. This is a drastic picture but the rank statistics show that it was in many countries only the 9th warmest year. An overview of the temperature anomalies is shown in the following table.

Table 4.3: Rank statistics, monthly average temperature and anomalies (in °C) from several countries of the RA VI for February 2017.

Country (station)	Monthly average temperature (°C)	Anomaly (°C)	reference period	rank
Austria		+2.9	1981-2010	15th (since 1768)
Belgium (Uccle)	6.1	+2.4	1981-2010	
Denmark	1.9	+1.9	1961-1990	
France		+2.5	1981-2010	10th (since 1900)
Germany	2.9	+2.5	1961-1990	24th (since 1901)
Iceland (Reykjavík)	2.8	+2.5	1961-1990	
Netherlands	4.9	+1.7	1981-2010	
Norway		+2.7	1961-1990	
Portugal	11.05	+1.07	1971-2000	9th (since 1931)
Spain	10.2	+1.6	1981-2010	8th (since 1965)
Svalbard	-6.9	+9.3	1961-1990	
Switzerland		+2.7	1981-2010	
United Kingdom	5.3	+1.6	1981-2010	9th (since 1910)

In **Denmark** the temperature anomaly was +1.9°C above the reference period of 1961-90 but the record was found in the year 1990 with an anomaly of +5.5°C. In **Switzerland** several stations reported new daily maximum temperature records. In **Norway** 12 stations observed new daily maximum temperature records. Extreme monthly temperature anomalies were registered in the Arctic e.g. at Svalbard Lufthavn with a monthly temperature of -6.9°C (or +9.3°C above the normal period 1961 - 1990).

Several stations in **Norway** measured 20 °C or more on 26 March 2017. This is the earliest date with such high temperatures. In Vestfold the record from 26 March 2012 was hit. Together with 2012, March 2017 (8.5 °C) was the warmest March since the beginning of station records in **Luxembourg** in 1947. The March temperature in Germany, with 7.2 °C, was +2.9 °C above the long-term average (reference period 1981-2010). It was therefore the warmest March since the beginning of the analyses in 1881. The month was warmer than normal everywhere - on the coasts locally less than +2 °C (Helgoland +1.6 °C) and isolated in the Alps more than +4 °C (Oberstdorf +4.1 °C).The warmest March of the 251-year observation history in **Austria** was noted with an anomaly of +3.5°C above the long-term average. In second place is March 1994 with a deviation of +3.4°C. In **Switzerland** temperature deviation in March reached +4.1°C and therefore the second rank after March 1994 with +4.3°C. At several stations new records were set since the beginning of measurements.

April 2017 was warm over western and cold over eastern Europe. The first half was warmer than normal in many parts of Europe, the second half much colder except of Iberia and the United Kingdom. At many stations new minimum temperature records were set e.g. in Switzerland, Germany and Austria. In **Austria**, after the warmest March in measurement history and a very mild start of April, the apple blossom started at the beginning of the second week in April. This was the 3rd earliest beginning of the apple blossom since documentation began in 1943. In the midst of April cold air from the north reached **Central Europe** with ground frost that caused widespread frost damage in many fruit cultures. Many farmers tried to protect their fruits by sprinkling water on the trees against the frost. The agricultural damage in Austria summed up to about 45 million Euros. In **Switzerland** it was one of the earliest fruit-tree flowering in the measurement series.

Severe night frosts on 20 and 21 April, however, resulted in a lot of ruin. Substantial damage was caused above all to flowering fruit trees and budding vines. The frost period in **Slovenia** during 21 and 22 April caused considerable damage in agriculture. The fourth cold wave in **Serbia** of 2017 lasted from 18 to 22 April, with the longest duration, of 6 days, between 20-25 April, in Sjenica.

Severe thunderstorms, accompanied by torrential precipitation or hail events, hit many regions in West and Central parts of **Bulgaria** on 15 and 16 April. In some places, a hail precipitation with size about eggs was registered. On 20 April a new snow covers up to 10 cm was observed in non-mountainous parts in North Bulgaria. Low temperatures, snowfall or frost caused considerable damages to the fruit crops.

Spring-like temperatures were recorded during the first half of April in **Finland** with highest temperature (14.4°C) at station Hattula on 10 April. The second half was much colder with snowfall and graupels of 1 to 2 cm in size. In **Estonia** it was the fourth coldest April since 1961 with 3.0°C (together with April 1974 and 1971). In **Russia** in the region around Smolensk minimum temperature falls down to -15°C.

May 2017 was warm in south-western and cold in north-eastern Europe. The highest maximum temperature in **Norway**, 31.8 °C, was recorded on 27 May at Sigdal – Nedre Eggedal (Buskerud). This was a record high temperature for May in Norway and also the highest temperature of the year. In **Sweden** the highest temperature for the year was recorded at Oskarshamn with 30.1°C on 28 May. This is only the third time during the last 100 years that the highest temperature in the nation has been reported in the month of May. From the 9th until 12th of May **Latvia** was affected by a cold wave, when 39 new minimum air temperature records were set. In 8 observation stations new latest snowing records were set (Observations started in 1895) leading to a reduction in harvest of fruits and berries due to late frosts (Figure 4.4).

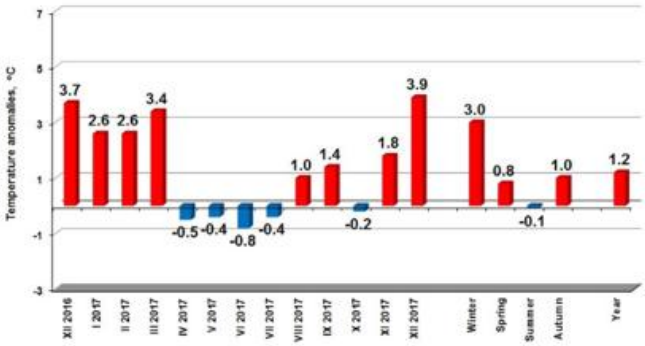

Figure 4.4: Latvian monthly, seasonal and annual mean air temperature for 2017

The weather in **Lithuania** became suddenly cold on May 8: maximum daytime temperature rose merely to 8–13 ºC, and on May 9 at night and in the morning a snowfall was observed in many regions. This extraordinary cooling with winter-related phenomena, such as wet snow-stick, snow cover and even outbreaks of frost, lasted for 6 days. During this period, even the maximum daytime air temperature ranged merely from 5 to 10 ºC, and only on May 13 it jumped locally to above 15 ºC. Mean daily temperature of those six days were typical for the end of March and the beginning of April and did not reach 8 ºC, and on some days even 5 ºC! On May 9–14 many meteorological stations observed morning frost during active plant vegetation. Air temperature dropped to -0.1...-5.5 ºC, and on the soil surface to -1...-6 ºC, on the coldest nights of May 11–12 it fell locally to -7...-8 °C at 2 cm height above the ground. A considerable damage was done to field crops, fruit trees and other plants (Figure 4.5).

Figure 4.5: Unusual snow cover during cold air intrusion on 9-11 of May, 2017 in Lithuania (Photo: from Telsiai meteorological station, provided by the LHMS)

The maximum air temperatures, recorded at **Luxembourg**/Findel-Airport on May 28, 2017 (31.5 °C) and on May 29, 2017 (31.6 °C), exceeded the existing absolute record from May 2009 (30.4°C) on two subsequent days. A heat wave during 12-13 May occurred in the central and southern parts of **Greece**. Many stations over south-eastern mainland recorded temperature records e.g. Argos measured on May 13th, 2017 Tmax = 40.6°C while its monthly average (1981-2017) is 27.0°C.

June 2017 was warm in south-western and cold in north-eastern Europe. From 17 to 21 June **United Kingdom's** temperatures exceeded 28 °C widely across parts of England, with some locations reaching 30 to 32 °C. On 21 June Heathrow (Greater London) recorded 34.5 °C, the UK's highest June temperature since 1976. The heat resulted in some speed restrictions on rail lines to avoid buckling, and there was an increased risk of high air pollution for congested areas such as the East Midlands. The daily maximum air temperature at **Luxembourg**/Findel-Airport of 35.4 °C, recorded on June 22, 2017 is the highest value ever recorded in June since 1947. June 2017 (19.1 °C) is the third-warmest June in station history. With a mean temperature of 21.2°C (2.8°C above normal) June was the 2nd warmest for France with a lot of temperature records being broken.

June was the 3rd warmest for **Serbia**, 2nd warmest for Novi Sad, Zrenjanin and Cuprija. A severe heat wave occurred from 20.06 to 2.07.2017 in **Bulgaria** with maximum temperature up to 42.5°C in Sandanski and 43.6°C in Ruse. The Heat wave in **Greece** persisted between 29 June and 3 July 2017. Most regions of Greece experienced high temperatures; the daily maximum temperatures on June 30, 2017 exceeded 40 °C in many parts especially in July. On 1st July Larissa (airport) reported a maximum daily temperature of 43.2 °C

The heat wave from 12th to 16th **July 2017** in Spain is remarkable as the absolute maximum temperature of 46.9 ºC which was observed in Córdoba Airport on 13th July 2017 turned out the 4th warmest for **Serbia** with two heat waves and record-breaking numbers of tropical nights. **Cyprus** recorded 5 heat waves and July 2017 was the warmest month recorded for at least the last 30 years. Specifically the mean provisional daily maximum temperatures of Athalassa, Prodromos, Pafos Airport, Larnaka Airport and Paralimni are the highest temperatures ever recorded for the last 30 years. From 30 July - 5 August a heat wave was observed in the **Czech Republic** with a maximum temperature 38.3 °C, such an event occurred once per five years, recently more severe heat waves were recorded in 2015, 2013, 2010. The heat wave in the **Greece** mainland last from 11 to 13 July: Maximum daily temperatures were about 40 - 41 °C**July was the warmest July ever recorded in Israel**

(Contribution from Israel Meteorological Service IMS)

Alongside with July 2012 (Figure 4) July 2017 was much warmer than normal - The average daily temperature was 2-2.5°C above normal and in most stations it ranks as the warmest on record alongside July 2012 (figure 4). If we compare July 2017 to the months of August in the past then only August 2010 and August 2015 were warmer.

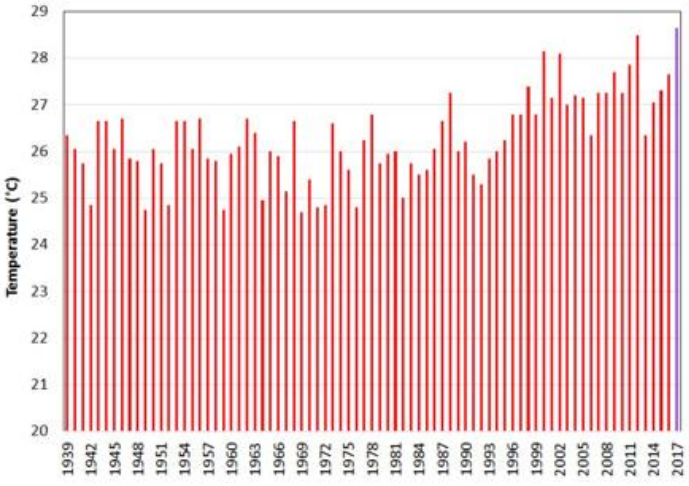

Figure 4.6: Average daily temperature (in °C) in Beit Jimal (Judean Foothills) in July 1939-2017 (Source: Israel Meteorological Service)

During the month there were three heat waves, two of them prolonged ones. The first heat wave of the month was the shorter one (July 1-4th) with temperatures reaching 40-42°C in the Negev, 42-43°C in the northern Valleys and 44-46°C in the Jordan Valley and the Arava. On July 3rd, 47.1°C were measured in Hazeva (Arava) and 46.9°C in Gilgal (the Jordan Valley). The other two heat waves were prolonged ones (on July 10-17th and on July 21-27th) yet the temperatures were not as extreme as in the first one.

The highest temperature in **Finland** in 2017 (27.6 °C in Utsjoki on 28 July) was measured in the northernmost part of the country in Utsjoki and has been this low only twice before since the 1960s (1962 and 1976).

In **Switzerland** in many areas it was one of the ten warmest August 2017 months since observations started in 1864. The warm temperatures prevailed even at night. Some meteorological stations registered the highest August minimum temperatures since measurements began: In Lugano the temperature on 5 August did not fall below 23.5°C, in Neuchâtel on 4 August not below 23°C. In Geneva on 4 August and in Basel on 3 August the minimum was not below 21.8°C respectively. On 5 August Locarno-Monti registered the second-highest August minimum with 23.9°C. All five measurement series span more than 100 years.

In **Serbia** several temperature records were broken, for example: Banatski Karlovac observed air temperature of 40.1°C thereby breaking the previous record of 39.8°C set on August 22, 2000. On August 6, Zrenjanin observed air temperature of 40.4°C besting the previous record of 39.6°C set on August 24, 2012. Absolute maximum air temperature anomalies in **Croatia** for August 2017 were above the corresponding average (1961 - 1990) at the all stations considered and were within the range from 3.5°C to 8.2°C. The historical comparison reveals that in August 2017 13 out of 27 stations exceeded or was on par with the previous maximum air temperature records of the available data series. The highest maximum temperature with 42.3°C was measured at station Knin. **Bulgaria** observed a heat wave in the south during the period 30.07-13.08.2017 (40.8°C in Sandanski) and in the north from 30.07 to 07.08.2017 (40°C in Vidin).

September 2017 was warm over most of eastern Europe and cold in Central Europe. On September 18, station Serres (**Greece**) reported daily maximum temperature of 39.9 °C while its normal monthly value is about 28.0 °C. Furthermore during 10 consecutive days (11-20 September), the maximum temperatures were above 34.0 °C. Also, station's mean monthly maximum temperature was 31.2 °C, which is the second highest mean monthly value in September since 1961 (previous mean monthly record of maximum temperature was 1994 with a value of 33.3 °C). On September 18, Tithorea station located in central mainland of Greece reported daily maximum temperature of 41.0°C.

It was the warmest October 2017 of the last 87 years in mainland **Portugal** and also the highest average maximum temperature was recorded with 27.11 °C or +5.88° C above the normal; extreme temperature values (38.5°C at station Alvega during the 6th) for the month of October were exceeded, especially on the 15th (the hottest day of the month). At the same time **Spain** measured a maximum temperature of 35.8 °C at station Badajoz/aeropuerto. The highest temperatures between were registered in Canary Islands (Spain) during the episode of high temperatures in mid of the month, highlighting the 38.7 °C in Fuerteventura/airport and 38.6°C in Tenerife South/airport measured on day 14. In the extreme north temperature anomalies were also extreme. In the Norwegian arctic Jan Mayen was the mildest station with a mean temperature of 4.7 °C (+4.6 °C above the normal). Svalbard airport had a mean temperature of 0.5 °C (+6.0 °C above the normal).

In November 2017 central and eastern Europe was warmer than normal while the temperature anomalies in southern Europe were normal or below the reference period of 1961-1990. In most parts of **Finland**, November was 1-3 °C warmer than usual. **European Russia** was also warm, particularly in the northeast of the Region, where mean monthly air temperature anomalies exceeded +5°C.

Temperature anomalies in December 2017 were above normal in eastern Europe and below normal in southern Europe. Throughout December, abnormally warm weather was recorded over **European Russia**. From one ten-day period to the other, both the value of positive ten-day anomalies and the area of the warm source were increasing. Record-breaking maximum temperatures were registered in central European Russia, the Black Earth Zone, northern Caucasia, the Crimea and the Volga Region. On 17 December, the absolute air temperature record for the entire period of observations was registered in Moscow: air temperature in the morning was +8°C.

At the beginning of December Alexandroupolis (**Greece**) recorded during 4 consecutive days daily maximum temperature equal or above 18.0 °C while its monthly normal value (1971-2000) is about 10.0 °C. Furthermore, station's mean monthly maximum temperature was 13.5 °C.

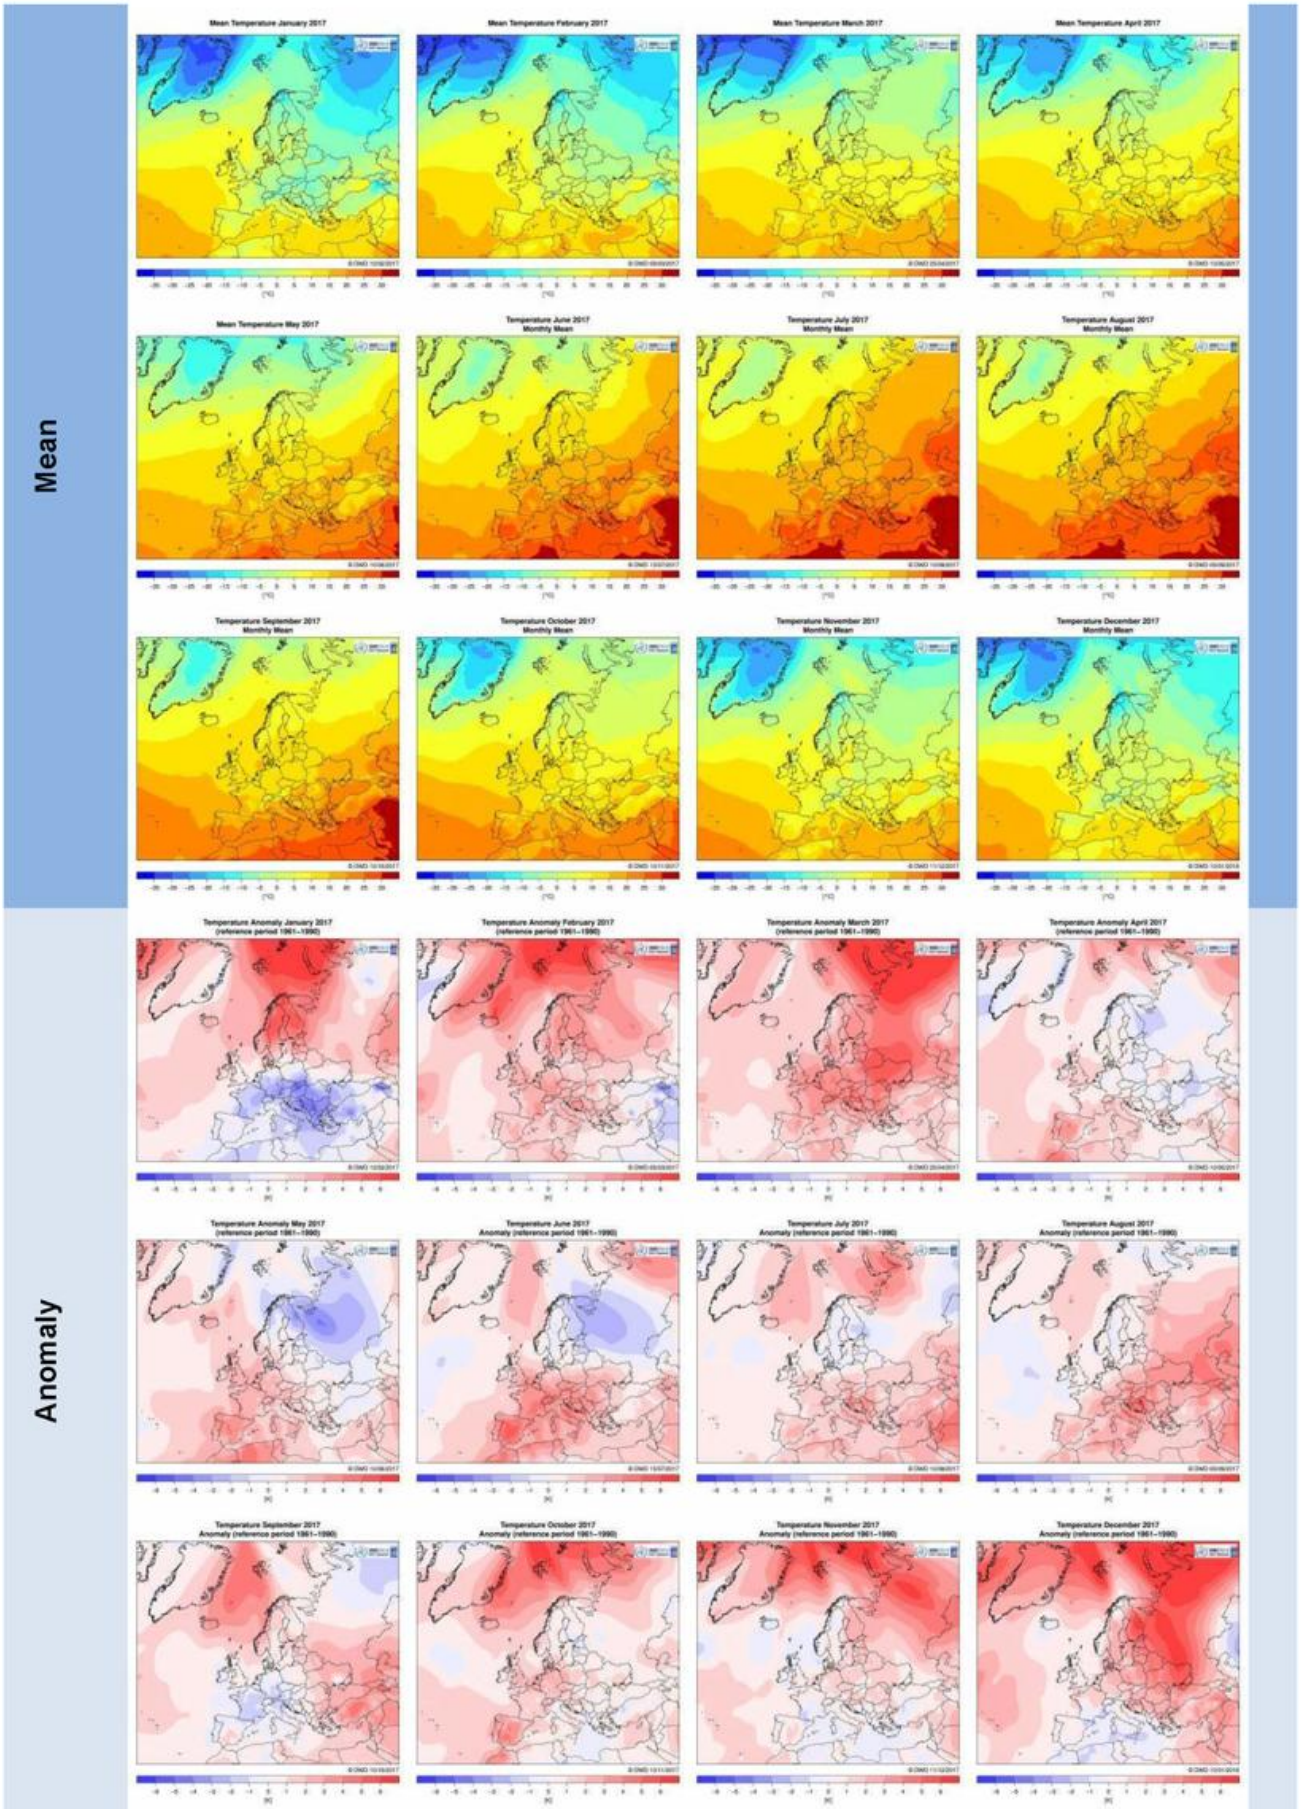

Figure 4.7: Mean and anomalies of temperature (in °C) for each month of the year 2017. (First row January, February, March, April, …; reference period: 1961-1990).

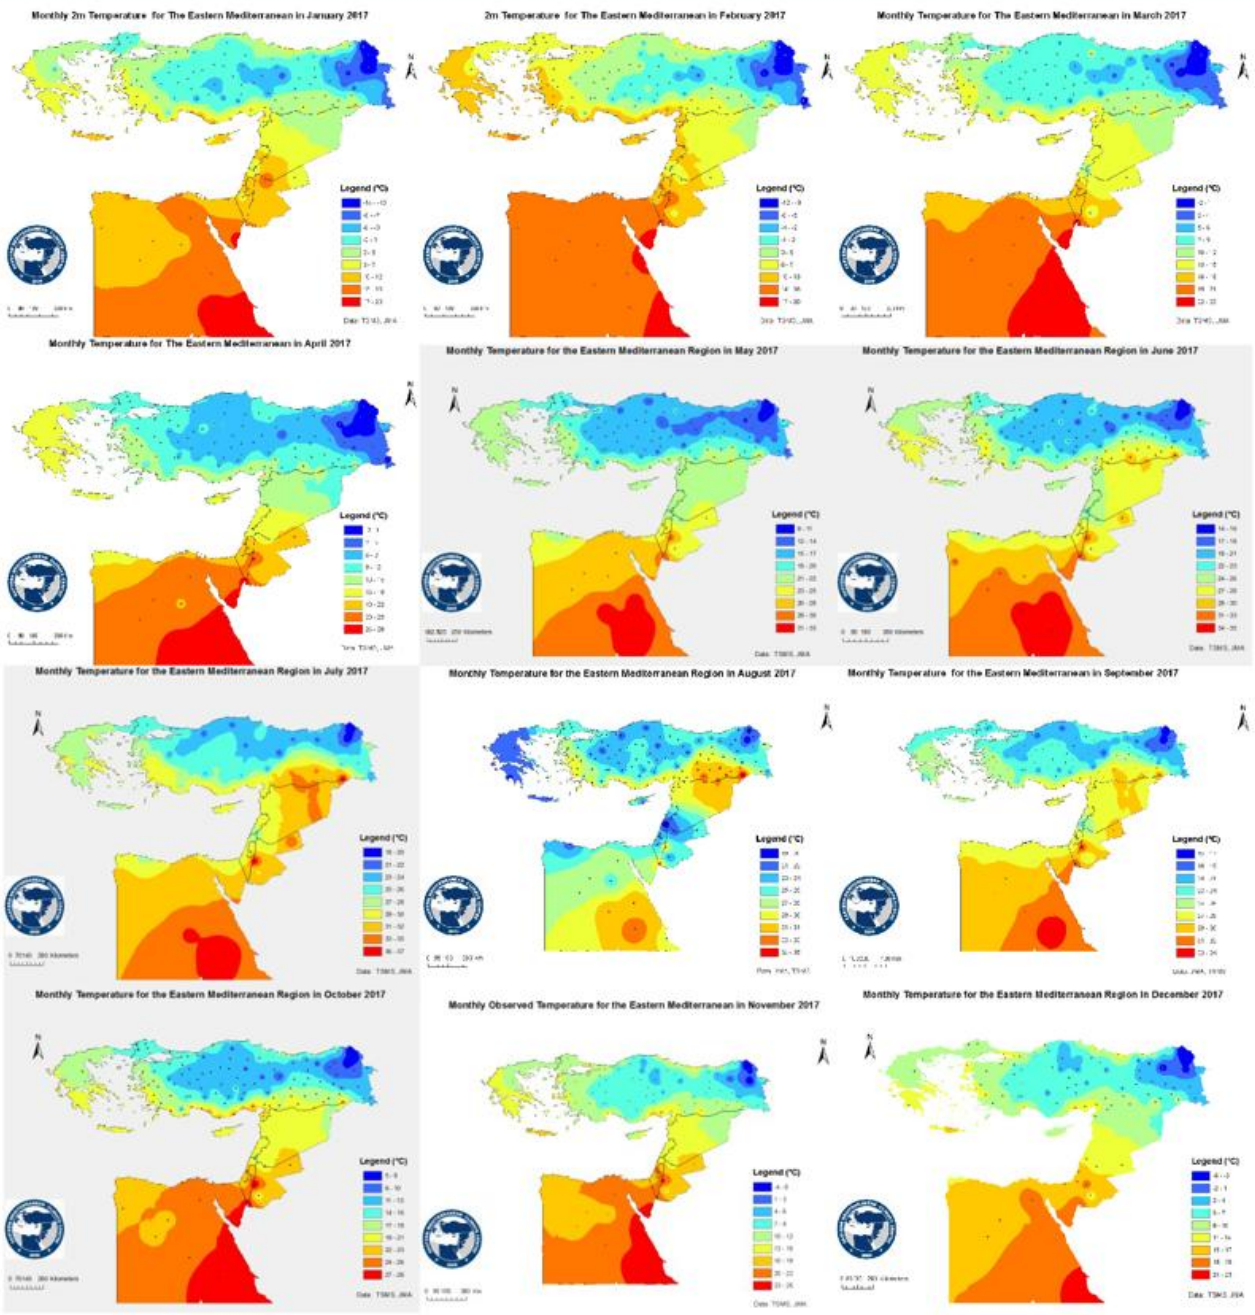

Figure 4.8: Monthly mean temperature (°C) for the eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC http://www.emcc.mgm.gov.tr/prediction.aspx; first row January, February, March, …).

4.3. Precipitation

One of the heaviest rainfalls in **Spain** this year occurred from 18th to 22nd **January 2017** and affected Baleares, Valencia Region, Murcia, Almeria, south and northeast Catalonia, Southeast Aragón and east Castilla-La Mancha, which in many places were snow precipitations. In the far northeast of Alicante and in the north area of Mallorca the accumulated precipitation during this event was more than 250 mm (117 mm/24h recorded in Castellón de la Plana / Almazora on January 19th).

From 27th to 29th January on **Cyprus** snow was observed at mountainous and semi-mountainous areas and reached locally 10 cm and at the highest peak-Olympos 15 cm. Last time of snowfall in Akaki on the 1st January (Nicosia district) was in 1952. January was not only very cold but also a very snowy month in **Bulgaria** with positive precipitation anomalies, especially in East Bulgaria (257% in Omurtag, North-East Bulgaria; 287% in Sredets, South-East Bulgaria). The snow cover reached 1m in Isperih, North-East Bulgaria. Wet conditions dominated in most parts of **Greece** during the second half of January. The precipitation amounts for January were 140 -260 % above climatological normals (1971-2000) for the greatest part of Greece.

From 1th to 6th **February 2017** in **Spain** a heavy precipitation event mainly affected the northern half of the peninsula which accumulated more than 200 mm in some areas of Galicia, and, in the same month, the one from 11th to 13th that affected to the west of the peninsula and were more intensive over the Central System (137 mm/24h recorded in Puerto de Navacerrada on February 12).

Floods on February the 11th in eastern Algarve

(Contribution from Instituto Português do Mar e da Atmosfera, I.P.M.A.)

On February the 11th, strong precipitation occurred in eastern Algarve, especially in the municipality of Vila Real de Santo António. The strong and persistent precipitation and hail caused several floods in this region. The daily precipitation value on this day (00-24UTC) was 98.1 mm, however it was between 14 UTC and 20 UTC that the highest precipitation values occurred and in 1h (18 and 19 UTC) 57.8 mm was observed. Figure 4.9 shows the accumulated precipitation values (mm) in 24 hours, on February 11th, 2017 estimated by a combined method radar/udometer.

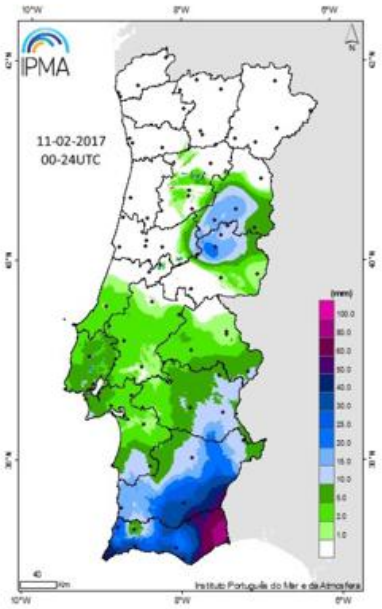

Figure 4.9: Daily precipitation (mm), on 11th of February, 2017, estimated by the combined method radar/udometer.

In **March 2017,** a remarkable precipitation episode in **Spain** from 12th to 13th affected the southeast of the peninsula, with more than 120 mm/month in some areas.

At the beginning of March, in **Lithuania** a 2–13 cm snow cover formed again in many regions, it melted by the middle of the month. The precipitation amount in **Norway** was 130% of the norm. The highest relative amounts could be found in northern Norway, from just over 200 to almost 400% of the normal. Some stations in eastern Norway got less than 50% of normal rainfall. In most countries of the RA VI the precipitation amount in March was around normal without extreme events.

In **April 2017**, the episode from 25 to 29 that affected mostly of **Spain**, with intense rainfall on 27 and 28 in the area of Huelva, Ceuta, southern Cádiz and Málaga with new daily records set in Ceuta on April 28 with 184 mm.

The southern part of Lower **Austria** and Obersteiermark (state of Styria) was affected by heavy snow fall during 19th and 20th of April with more than 750 vehicles caught in traffic jam for hours (even the whole night), temporary more than 25.000 homes were without power.

April was (according to the reference period 1961-1990) exceptionally wet especially in the middle and northeastern part of **Slovakia**. Maximum precipitation amount 425.7 mm that is 432.6% of normal and was measured at Lomnický štít (mountain meteorological station). According to the long time series (historical measurements) since 1901, and individual station precipitation totals in north parts of Slovakia April 2017 was from 1st to 3rd wettest since 1901. The consequence was a flood during 28.4. - 2.5.2017 within the tributaries of the upper Váh and the upper Hron river basins (less than 500 km^2).

In the Republic of **Moldova** very difficult meteorological conditions were observed on most of the territory on April 20-21 in connection with a cyclone - rain, snow, sleet, deposition of wet snow on wires and trees, a strong gusty wind, and frost, which led to disastrous consequences for the country's economy. Amount of precipitations in the form of rain and snow, on 20-21 April, in the central and southern regions reached 35-82 mm (100-230% of the norm for the month), which in some areas in April is observed for the first time for the entire period of observations. For the first time a country wide snow cover in late April was observed. Its maximum height on meteorological sites, on April 21, in northern regions reached 5-14 cm, in the central and southern regions – mostly 20-40 cm. However, in some areas its height reached 47-57 cm, which in the winter season in these places is observed for the first time for the entire period of observations. Similar happened in **Romania** where hundreds of localities were left without electricity; traffic was disturbed along roads and railroads because of the snowfalls and frost damage were registered in many fruit cultures. In most regions of **Lithuania**, April 16 saw a snow cover of 1–5 cm, locally 9–12 cm deep, which thawed during the day.

May 2017 was characterized in **Romania** by storms and convective phenomena almost everywhere on numerous days during the month although on the average, 79 mm of water fell across the country or 19% more than the climatological normal. On the 6th, such phenomena led to hail occurrence and flooding in Oltenia, which triggered damage to a number of houses. Similar happened in different regions of Romania until the end of the month with flooding and damages at houses and crops due to heavy rain and hail. A flash flood reached the capital city of **Hungary**, Budapest on 23rd of May. One hour rainfall exceeded 44 mm and the daily mean precipitation was 55.2 mm. The mean May precipitation is 59.6 mm, thus diurnal rainfall amount almost reached the monthly average. In the afternoon of the 5th May many regions in West **Bulgaria** were hit by severe thunderstorms with strong winds, hail and short heavy precipitation. More than 20 houses were flooded in village Lilyache, Vratsa district. Many roads were blocked by broken trees. Severe convective storm with giant hailstones on 15th of May in the region of Lyubimets and Svilengrad caused significant damages on buildings, vehicles and agricultural crops. Several hailstorm destroyed agricultural crops in **Greece** in May.

In **Sweden** there was an unusually late peak of the snow cover in the northern mountains with a maximum value of 205 cm at Katterjåkk on 2nd May. Snow fall also in **Latvia** from 9th - 11th May, an unprecedented event (historical record): At 8 observation stations new latest snowing records were set (Observations started in 1895).

In **Slovenia**, during the 6th of June 2017 a new daily precipitation record was set at station Vojsko with 200 mm/24h. Between the 1st and 6th of June a series of severe thunderstorms, accompanied by heavy rainfall and hail were registered in many regions in West and Central **Bulgaria**. In some towns and rural areas, they caused local floods and damages on vegetable and fruit crops.

On June 13th, between 17:30h and 22:30h, southern **France** (Haute-Loire) was struck by exceptionally intense and localized rainstorms. Between 20h and 21h, the accumulations exceeded locally 150 mm and up to 300 mm in 4 hours (after radar images). At station Landos-Charbon 226 mm were measured during the episode, 122.7 mm in 1 hour (between 20 and 21h) and 21.5 mm in 6 minutes.

Severe thunderstorms during the 22nd and 23rd with hail of up to 8 cm in diameter, heavy rain and gusts of up to 39 m/s (140 km/h) in western and northern **Germany** caused damages of about 640 Million Euro and two deaths. Numerous houses and vehicles were damaged and delays in air and rail traffic occurred. The affected agricultural area was 500 km^2 with damages in crops, fruits, vegetables and vineyards (MunichRe 2018). A rain band moved from southern **Germany** to the north during the 29th and converged with thunderstorms coming from Poland leading to heavy and

long lasting rainfall. The highest daily totals of 197 mm were measured at the airport Berlin-Tegel (return period of 100 years) and also 73.5 mm in Potsdam. The highest daily total in the history was below 90 mm, measured at a surrounding station near to Berlin. The enormous amounts of water led to flooding and the fire brigades in the capital reported 1830 weather-related missions during this exceptional event.

From 28 - 29 of June an extreme precipitation episode was observed in the **Czech Republic** with more than 100 mm in 2 days, such an event occurred once per five years. In **Austria** thunderstorms with heavy precipitation and hail caused more than 4 Million Euro agricultural damage. In **Lithuania** on 29th of June very severe storm in southeastern regions occurred with very heavy rain (50–65.6 mm/12 hours). From 30 June to 1 July, heavy thundershower (65 mm) accompanied by hail as large as 3-8 mm and strong wind took place in Moscow (**Russia**). Railroad bed in the Moscow Central Circle and motor roads were inundated, 1200 trees were fallen, roofs of nearly 100 houses and nearly 100 cars were damaged. Two people were killed.

High precipitation amounts were measured from Ireland to northern European Russia in **July 2017**. Severe convective storms, associated with hail and strong winds hit northwestern and northcentral parts of **Bulgaria** on 3rd of July. In some meteorological stations more than 4 hail-fall events were registered in the time interval 00:00-05:45 local time (LT). In Mezdra and Levski the giant hail stones with size up to 8 cm were observed. Several locally disastrous rainfalls (>80 mm/12 h) occurred in **Lithuania** on July 1st and 11th. The thunderstorms also affected **Belarus** with 57 mm at Novogrudak on the 13th. During 25th and 26th widespread thunderstorms occurred in **Belarus** with local precipitation amounts of 77.5 mm in Minsk or 103.7 mm (16:00 - 03:00 on 26th) in Samohvalovichi with local floods and damages on houses and infrastructures.

Especially central and eastern **Germany** was affected by continuous rainfall from 24th to 27th with more than 100 mm/day at several stations. The several days lasting rainfall caused flooding and landslides. For example, in Goslar and Wolfenbüttel entire streets were flooded - residents had to be evacuated. Flooded railway lines were blocked and softened dikes secured with sandbags.

On the 27th a severe thunderstorm with wind speeds of up to 28 m/s (100 km/h), hail of up to 9 cm in diameter, heavy rain and flash floods occurred in **Turkey.** More than 90 houses, 150,000 vehicles and 4 planes were damaged. Streets and metro stations were flooded. The overall damage loss was estimated to 500 Million Euro (MunichRe 2018).

On the evening of 1st and in the night to the 2nd **August 2017**, violent thunderstorms erupted in **Switzerland** north of the Alps, accompanied by hail and strong wind gusts. At the northern edge of Switzerland wind gusts attained 25-38 m/s (90 to 135 km/h), locally even up to 53 m/s (190 km/h) brought a new Swiss rain record. At the station of Eschenz a ten-minute total of 36.1 mm fell between 02.40 and 02.50. The previous ten-minute record amounted to 33.6 mm, collected on 29 August 2003 in Locarno-Monti. A comparable ten-minute total of 33.5 mm was registered on 25 June 2017 at the Ticino observation site Crana-Torricella. The previous highest ten-minute total north of the Alps amounted to 32.8 mm, collected on 2nd May 2013 in Schaffhausen.

Heavy thunderstorms in **Austria** caused mudslides with a damage loss of more than 20 million Euro on the road system. Trees were brought down, power outages of 80.000 homes and travel disruption. On the night of 19 August a storms over the northern part of Upper Austria damaged a marquee and killed two people and at least 140 people were seriously injured.

An extreme precipitation episode was observed in southeastern **Estonia** with 84.7 mm (98% of the month's normal) in Räpina and 78.8 mm (94% of the month's normal) in Mehikoorma during 24 hours on the 24th. The heavy precipitation caused floods and washed away roads. This extreme precipitation also affected southeastern part of **Latvia** from 22nd - 24th August causing in the next hours a flash flood in the region that was one of the biggest flash flood events in Latvia on the record. 20 000 ha of agricultural lands were flooded and 17 roads were washed out.

Torrential precipitation in **Bulgaria** with duration of more than 30 hours caused local floods in southeastern parts of Burgas district in **September 2017**. More than 10 villages were flooded. In Gramatikovo the 24-hours precipitation amount of 198 mm was measured on 27th, which was 4 times over the monthly normal. September was (according to the reference period (1961-1990) significantly above-normal in most of **Slovakia**, exceptionally wet in the northern part (Orava,

Kysuce region) and locally in south of Slovakia. Minimum percentage of normal value compared to 1961-1990 was 134.8% at Milhostov (southeastern part), maximum 294.6% at Hurbanovo (southern part of west Slovakia) that was the 4th wettest monthly precipitation total since 1901. According to the long time series (historical measurements) since 1901, and individual station precipitation totals in north parts of Slovakia (Tvrdošín, Dolný Kubín, Čadca) September 2017 was the wettest since 1901.

Precipitation amounts in **Croatia** were within the range of 110% - 470% of the average for this month. In September 2017, the maximum daily precipitation amount observed at 7 a.m. (CET) at the main meteorological station Zadar was 213.4 mm (12th), less than the highest daily precipitation amount on record for Zadar (352.2 mm, 11 September 1986). On 11 September 2017, rain shower started at 4:57 a.m. and lasted till noon, and then rain was recorded till 4:52 p.m. The maximum 10-minute precipitation amount for this day was 18.9 mm while the total precipitation amount during the period in question was 283.4 mm. Such amounts caused torrential floods that led to substantial property damage and declaration of state of natural disaster in the wider Zadar area. Roads, cellars, shopping centres and the hospital in Zadar were flooded, and there was a power outage in parts of the city.

Very wet from north-western to southeastern Europe in **October 2017**. The rainiest month in **Bulgaria** was October with average precipitation of about 2.5-3 times more than monthly normal (692% in Karnobat, Burgas district). A 20-hours heavy precipitation led to overflowing dams and rivers, local floods, great damages on infrastructure and 4 victims. In Karnobat the 24-hours precipitation amount of 178 mm was measured on 25th of October (460% of monthly normal). At three weather stations in **Romania**, Bucharest Băneasa, Videle (631%) and Omu Peak (207 mm), the absolute monthly maximum precipitation amounts in a month of October were exceeded. Monthly precipitation in most parts of **Lithuania** amounted to 80–125 mm (1.5–2 norms), and in some southern and most western regions to 130–260 mm (2.3–2.8 norms), locally to 277 mm (even 3 monthly norms!).

Norway was affected by two heavy precipitation events, the one from 30 September - 2 October and only 100 km eastwards the second one from 20 - 22 October 2017. During the three days of the first event 10 stations reported a total precipitation of more than 200 mm/3d and even two of them more than 280 mm/3d. New precipitation records were set for 1, 2 and 3 days at a number of stations. The highest values were observed at Senumstad with 173.1 mm in a 24-hour period (88% of October monthly normals), 236.7 mm in two days, and 281.8 mm in 3 days. For some water courses this was the largest flood ever recorded in southern Norway. In the areas most affected, both observed rainfall and flood levels exceed 100 years of return periods. The rain induced flooding and landslides. Over 40 roads were closed, several houses were destroyed, tens of thousands of people were evacuated 2000 damages have been reported and the overall losses were estimated to several 10th of millions € (hundred millions of Norwegian Kroner, NOK).

On the 20th of October 2017 a front passed southern **Norway** while a low west of Ireland (storm **Brian**) passed during the 21st Ireland and United Kingdom and moved towards Norway with plenty of rain. In southern Norway during the following days the maximum precipitation amount was registered in Bøylefoss with 192 mm/3 days (return period of 50 years) or 103.8 mm/24h at Eikeland (return period of 50 years). The high precipitation amount caused local floods but the damage and the impact was much smaller than of the event 3 weeks ago. Some roads were closed for a shorter or longer period. For this period a Climate Watch Advisory on above-normal precipitation was issued on 13th of October 2017 for Ireland, United Kingdom and Norway and terminated on 29th of October 2017 after precipitation in these countries had normalized.

High precipitation due to cyclone “Numa” in the Central Mediterranean in **November 2017**. The **Greek** station Kerkyra (airport), located in the north Ionian Sea, reported a total monthly precipitation of 439.0 mm, while its monthly normal value (1971-2000) is 182.0 mm. Also, the station reported its second wettest November since 1955 (previous record of monthly total precipitation was 446.0 mm on November 2000). Moreover on 11th November the station recorded daily (24-hour) precipitation of 94.0 mm. Station Elefsis (airport, Greece), located in west Attica, reported total monthly precipitation of 194.0 mm while its monthly normal value (1971-2000) is about 64.0 mm. Moreover, the 4-day total precipitation measured between 14 and 17 November was also high (108.9mm). Heavy rainfall hit Symi island (Greece) on 13th, causing flash floods and

major problems in infrastructures, such as power and water supply. Greek authorities declared a state of emergency on the island of Symi. On 15th of November, a sudden flash flood over western Attica (Greece) caused 23 fatalities. The flooding came after a severe overnight storm. Roads were turned into muddy rivers and dozens of people were trapped inside their flooded homes. Cars, trucks, and buses were trapped in an inundated underpass in the highway between Athens and Corinth. A state of emergency has been declared in the west Attica region.

On 10/11 **December 2017** the lowest altitude levels south of the **Swiss** Alps received a snow cover of a few centimetres. Meanwhile, in the low areas of the Central Valais record snow totals were measured. Sion registered an extreme value of 60 cm within one day. This is far above the previous maximum value of 43 cm, collected in November 1971. Even the previous highest 2-day totals only amounted to scarcely above 50 cm in Sion. Shortly after mid-month over 170 % of the normal snow totals were registered in many parts of the Alps. In the entire Alpine region of Switzerland conditions for the seasonal ski tourism were ideal.

Heavy precipitation with snow melting affected **Belarus** on 10th with 35-39 mm in 4 hours.

From 4th to 7th December, a strong western and southwest wind (storm **Aina,** named by Met Norway) brought warm and humid air masses to the southern part of western Norway with a lot of precipitation over several days. The strongest wind associated with Aina was measured at Folgefonna with 33 m/s (10 minutes average), and the most powerful windgust was 44.2 m/s. Most precipitation was observed at Gullfjellet, where the 3 days totals were 284.6 mm. Such amounts resulted in floods, landslides and damages at houses and ships. Storm **Birk** (named by Met Norway, Diethelm in German) affected south-western **Norway** with heavy precipitation from 22nd - 24th of December 2017. The largest daily amount during this event was 127.5 mm on Gullfjellet (Bergen) on 23 December and more than 200 mm in 3 days. This amount of precipitation resulted in floods and landslides.

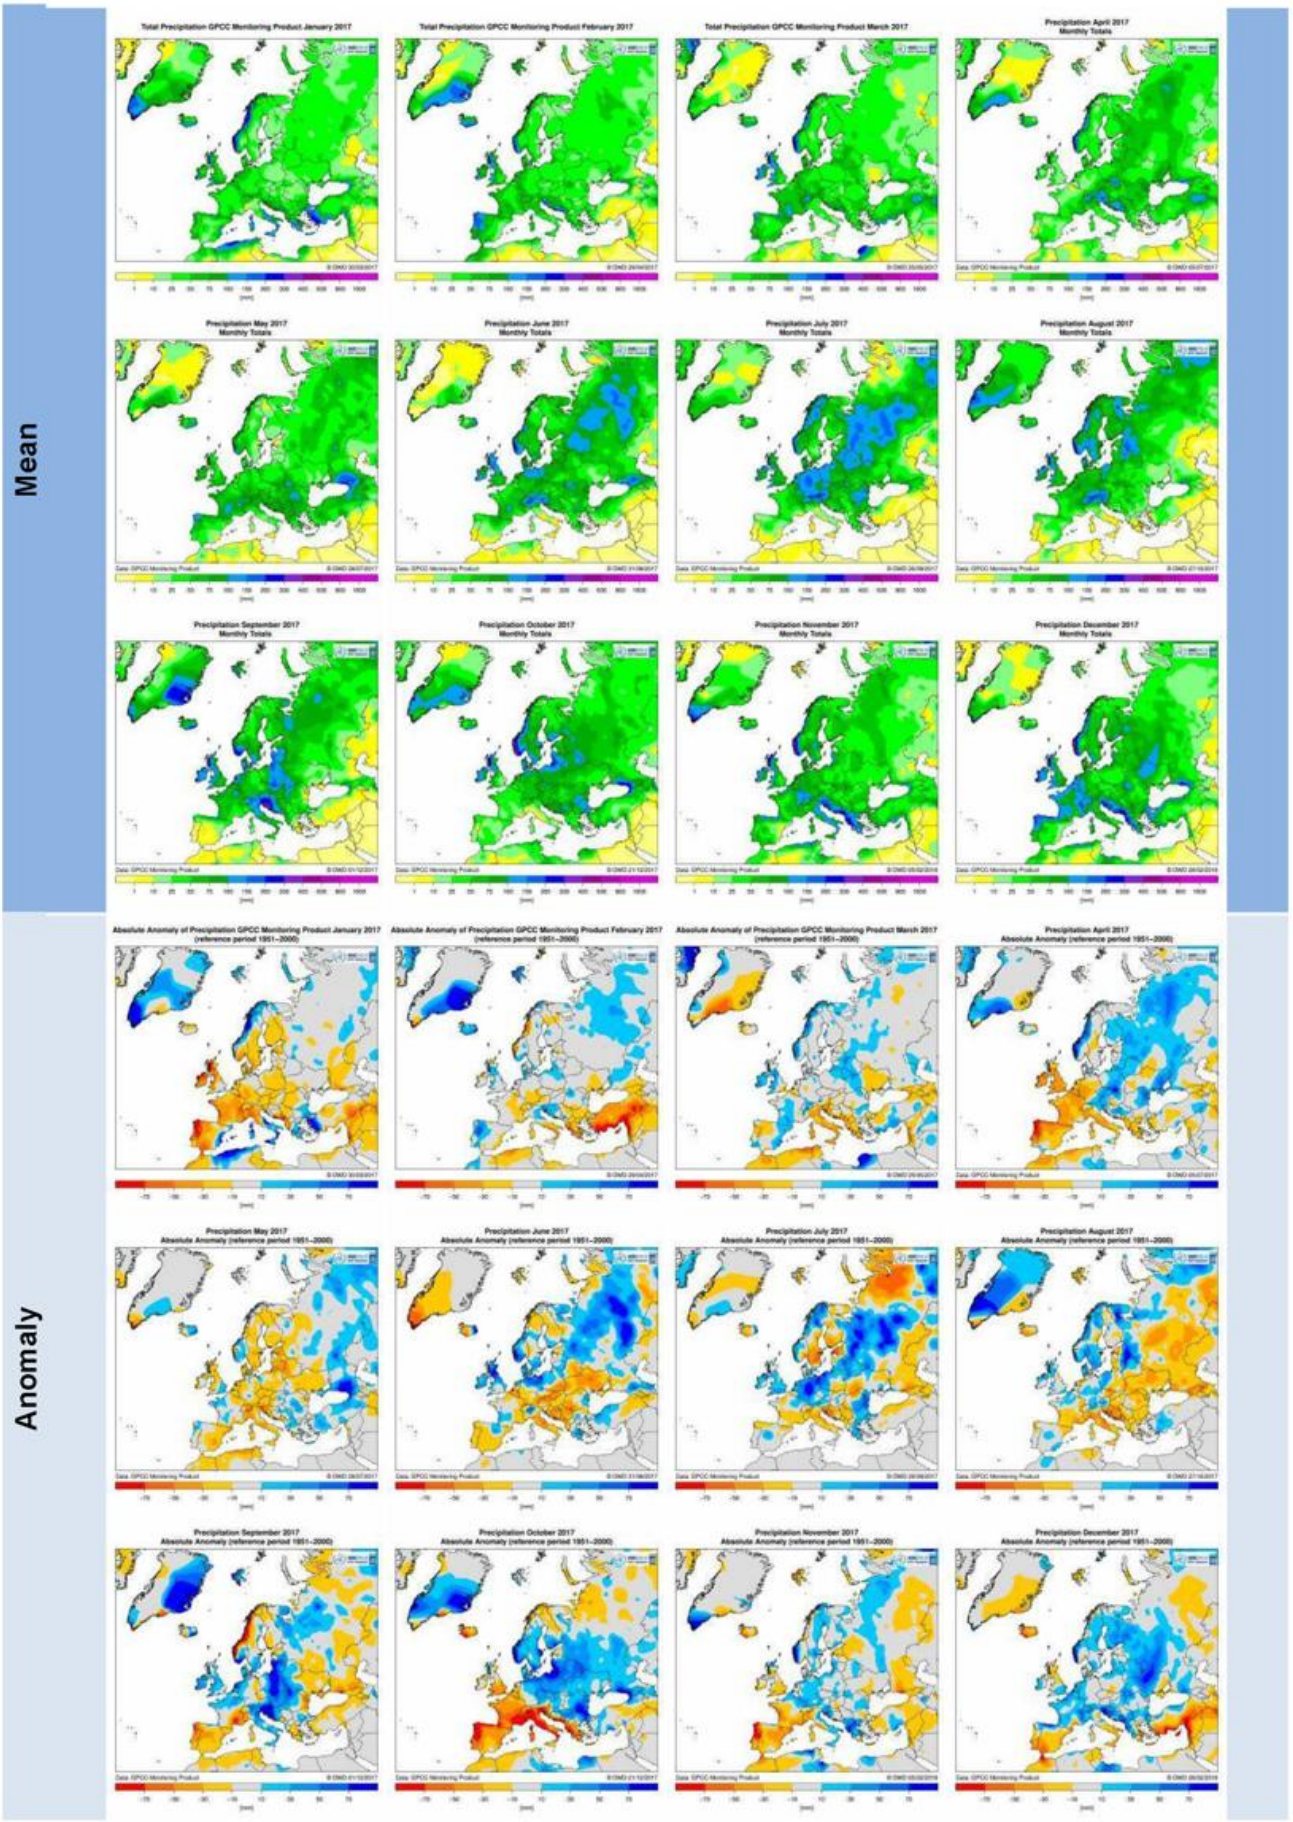

Figure 4.10: Mean and anomalies of precipitation (in mm/month) for each month of the year 2017. (First row January, February, March, April, … ; reference period 1961-1990).

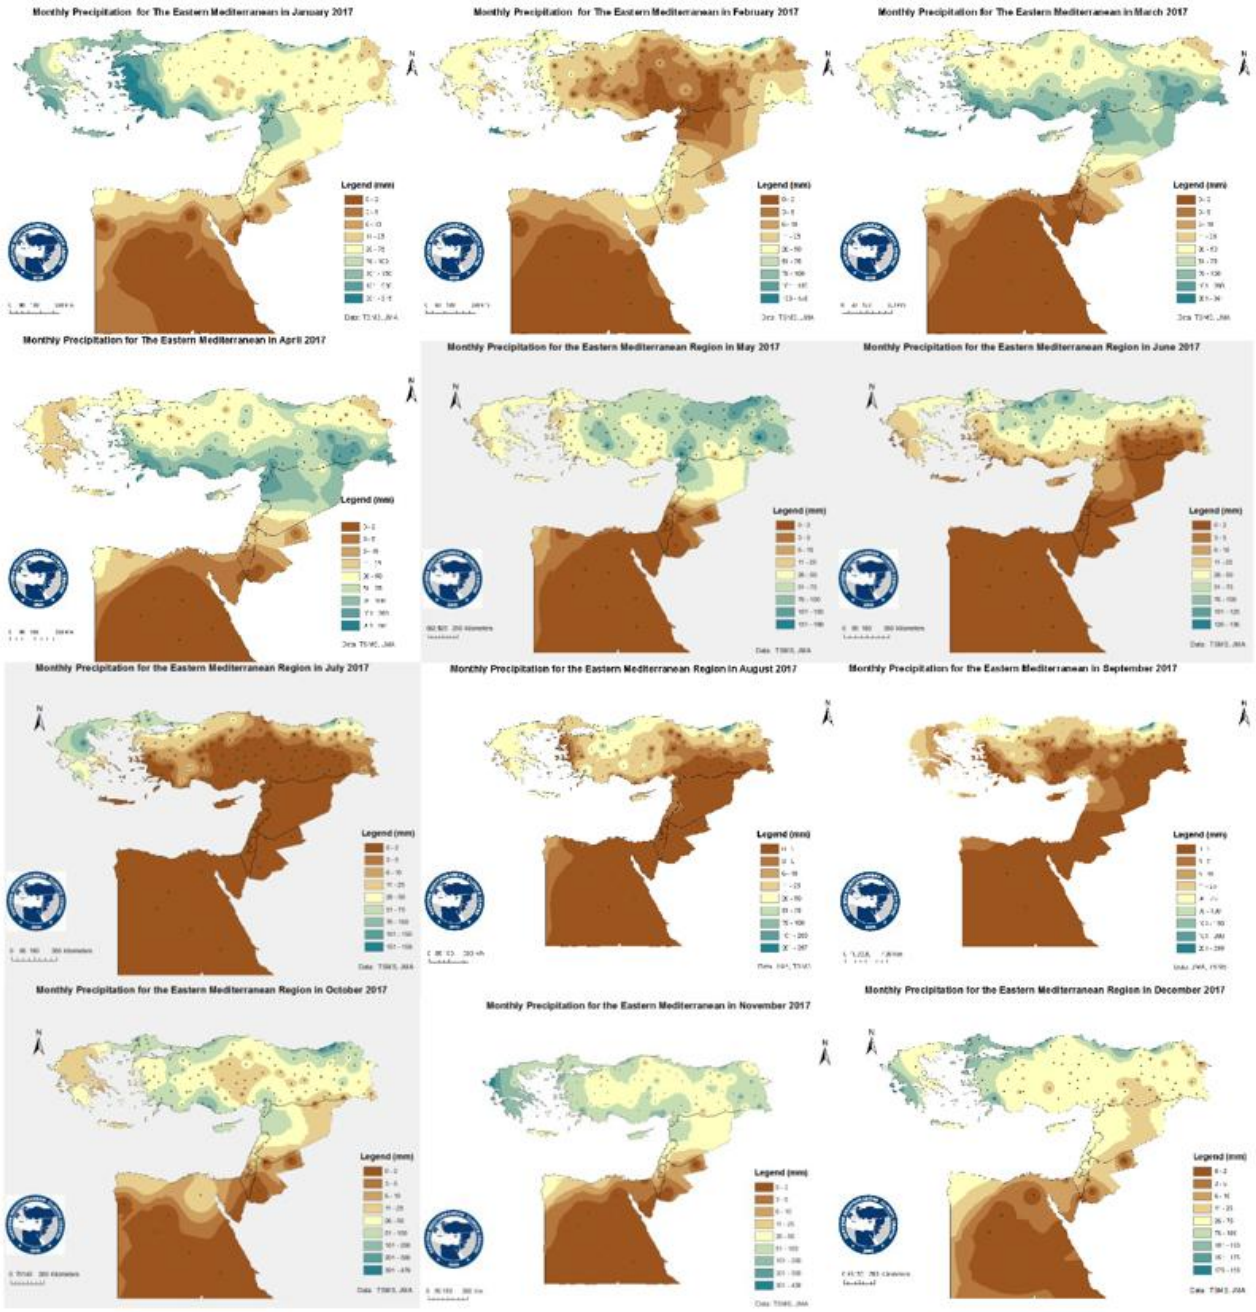

Figure 4.11: Monthly precipitation totals (mm) for the eastern Mediterranean region as provided by the Eastern Mediterranean Climate Center (EMCC http://www.emcc.mgm.gov.tr/prediction.aspx; first row January, February, March, …).

4.4. Sunshine duration

Monthly sunshine duration in January 2017 in Central Europe was well above normal. In **Slovakia** 6 out of 14 stations measured their highest sunshine duration in this January with more than 200%. In Hurbanovo 119.7 hours or 193% of the normal (1961-1990) was registered (Figure 4.12). In **Germany** most stations reported more sunshine than usual and January became the fourth sunniest since 1951 with 143% from the normal, at some stations even more than 200%.

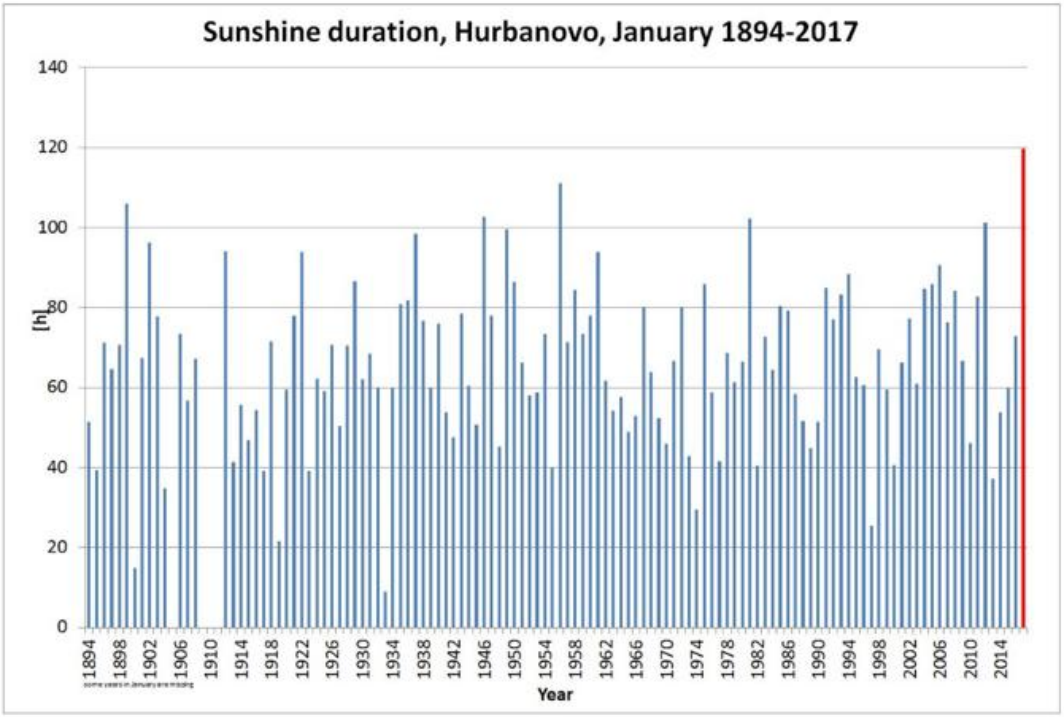

Figure 4.12: Monthly sunshine duration at station Hurbanovo for January 1894-2017 (Source: Slovak Hydrometeorological Institute)

Sunshine duration in March 2017 in **Serbia** ranged from 115% in Leskovac up to 148% in Pozega relative to the normal for the 1981-2010 base period. The insolation ranged from 157.9 hours at Kopaonik to 197.9 hours in Banatski Karlovac.

Sunshine duration for April 2017 in **Spain** was higher than normal (reference period 1981-2010) in all Spanish regions. The relative positive anomalies of sun hours exceeded 50% in a large part of the northern third of the peninsula, rising above 70% in the northeast of Galicia. The maximum sunshine value was observed in Izaña with 339 hours, followed by Zaragoza/Airport with 331 hours and Salamanca/Airport with 329 hours.

In June 2017 sunshine duration was above average in whole **Slovenia**. Most sunshine hours were registered on the coast, in Portorož the sun shone for 323 hours. For the summer months, it is characteristic that in the mountains there is less sunshine than in the lowlands, in Kredarica the sun shone only 225 hours. In Ljubljana, the sun shone 274 hours, which is 15% above the long-term average.

The sunshine deficit in **France** in July 2017 was generally greater than 10% in the western half of the country as well as in the east and often reached 20 to 30% in the south. The sun shone only 140 hours in Brest (Finistère) and 173 hours in Le Mans (Sarthe).

Most measuring stations in **Slovenia** reported in August 2017 a surplus of sunshine between 20% and 30% above the long-term average. A smaller surplus, between 10 and 20%, was in Pomurje, on the coast, in Godnje. Most sunshine hours were measured at the airport in Portorož (352 hours).

The sunshine duration in **Germany** for September 2017 with 121 hours was 18% below the long-term average of 148 hours. Stations on the Baltic Sea exceeded the normal values (Waren 102%).

Sunshine deficit with values below 60% occurred in the mountains (Braunlage 52%). The sun shone from 67 hours on the Kahler Asten to 162 hours in Rostock-Warnemünde.

Around mid-**October 2017** the weather in **Switzerland** was dominated for ten days by high-pressure zones. The autumn sun shone frequently from a cloudless bright blue sky. In the lower areas, daily maximum temperature rose in many parts to between 22 and 25°C. The persistent fair weather brought the Plateau and southern Switzerland the sunniest October, regionally, in the homogenous observation series spanning at least 50 years. At other stations with homogenous observation series of at least 50 years it was the second- or third-sunniest October. In **Spain** sunshine duration was higher than normal (reference period 1981-2010). The relative anomalies of sunshine surpassed 30% in central Spain and were especially significant, above 50% in north-western; reaching over 70% in some points of the provinces of A Coruña and Lugo. The maximum value of insolation was observed in Seville Airport with 289 hours, followed by Huelva Ronda Este with 286 hours and Ciudad Real with 285 hours.

In **November 2017** sunshine duration in **Spain** was more than 10% higher than the normal value (reference period 1981-2010) throughout the Peninsula. The relative anomalies of sunshine exceeded 30% in a large part of the peninsular territory and values higher than 50% were reached in some places in central Spain. The maximum value of sunshine was observed in Castellón Almassora with 246 hours.

December 2017 was dull in the Netherlands. Only 32 hours of sunshine on average over the country instead of 49 hours as in the long-term average. In the west the sun shone the least with only 16 hours. The sunniest station was Terschelling with 47 hours. In De Bilt the sun was shining only 25 hours and on 15 days the sun was not visible.

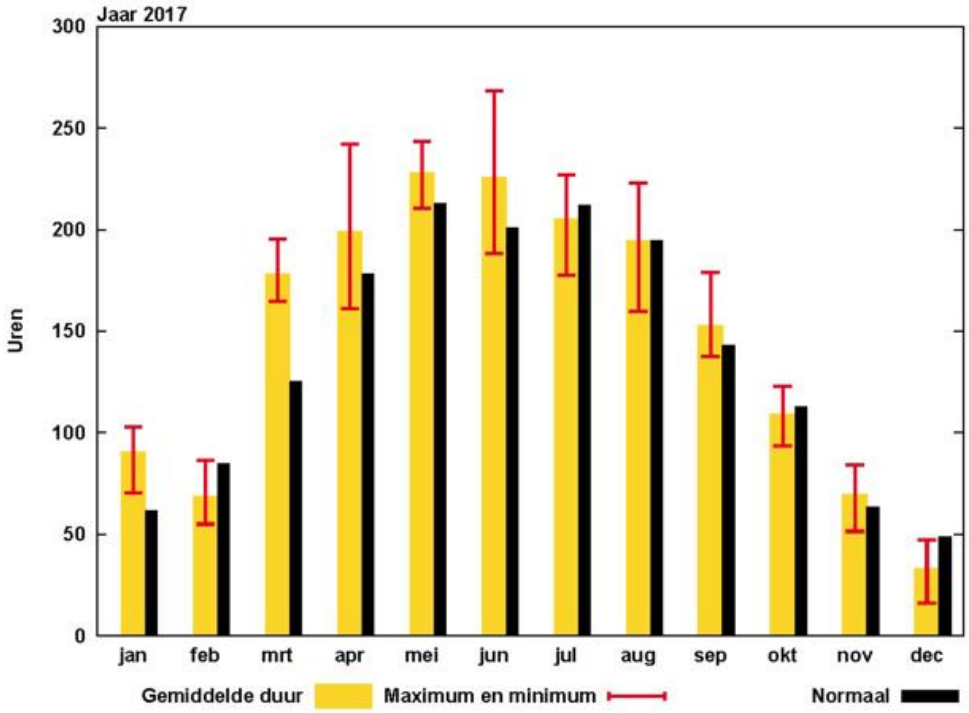

Figure 4.13: Annual cycle of sunshine duration (in hours) for the Netherlands in comparison to the normal values (black bar; source: Koninklijk Nederlands Meteorologisch Instituut, KNMI)

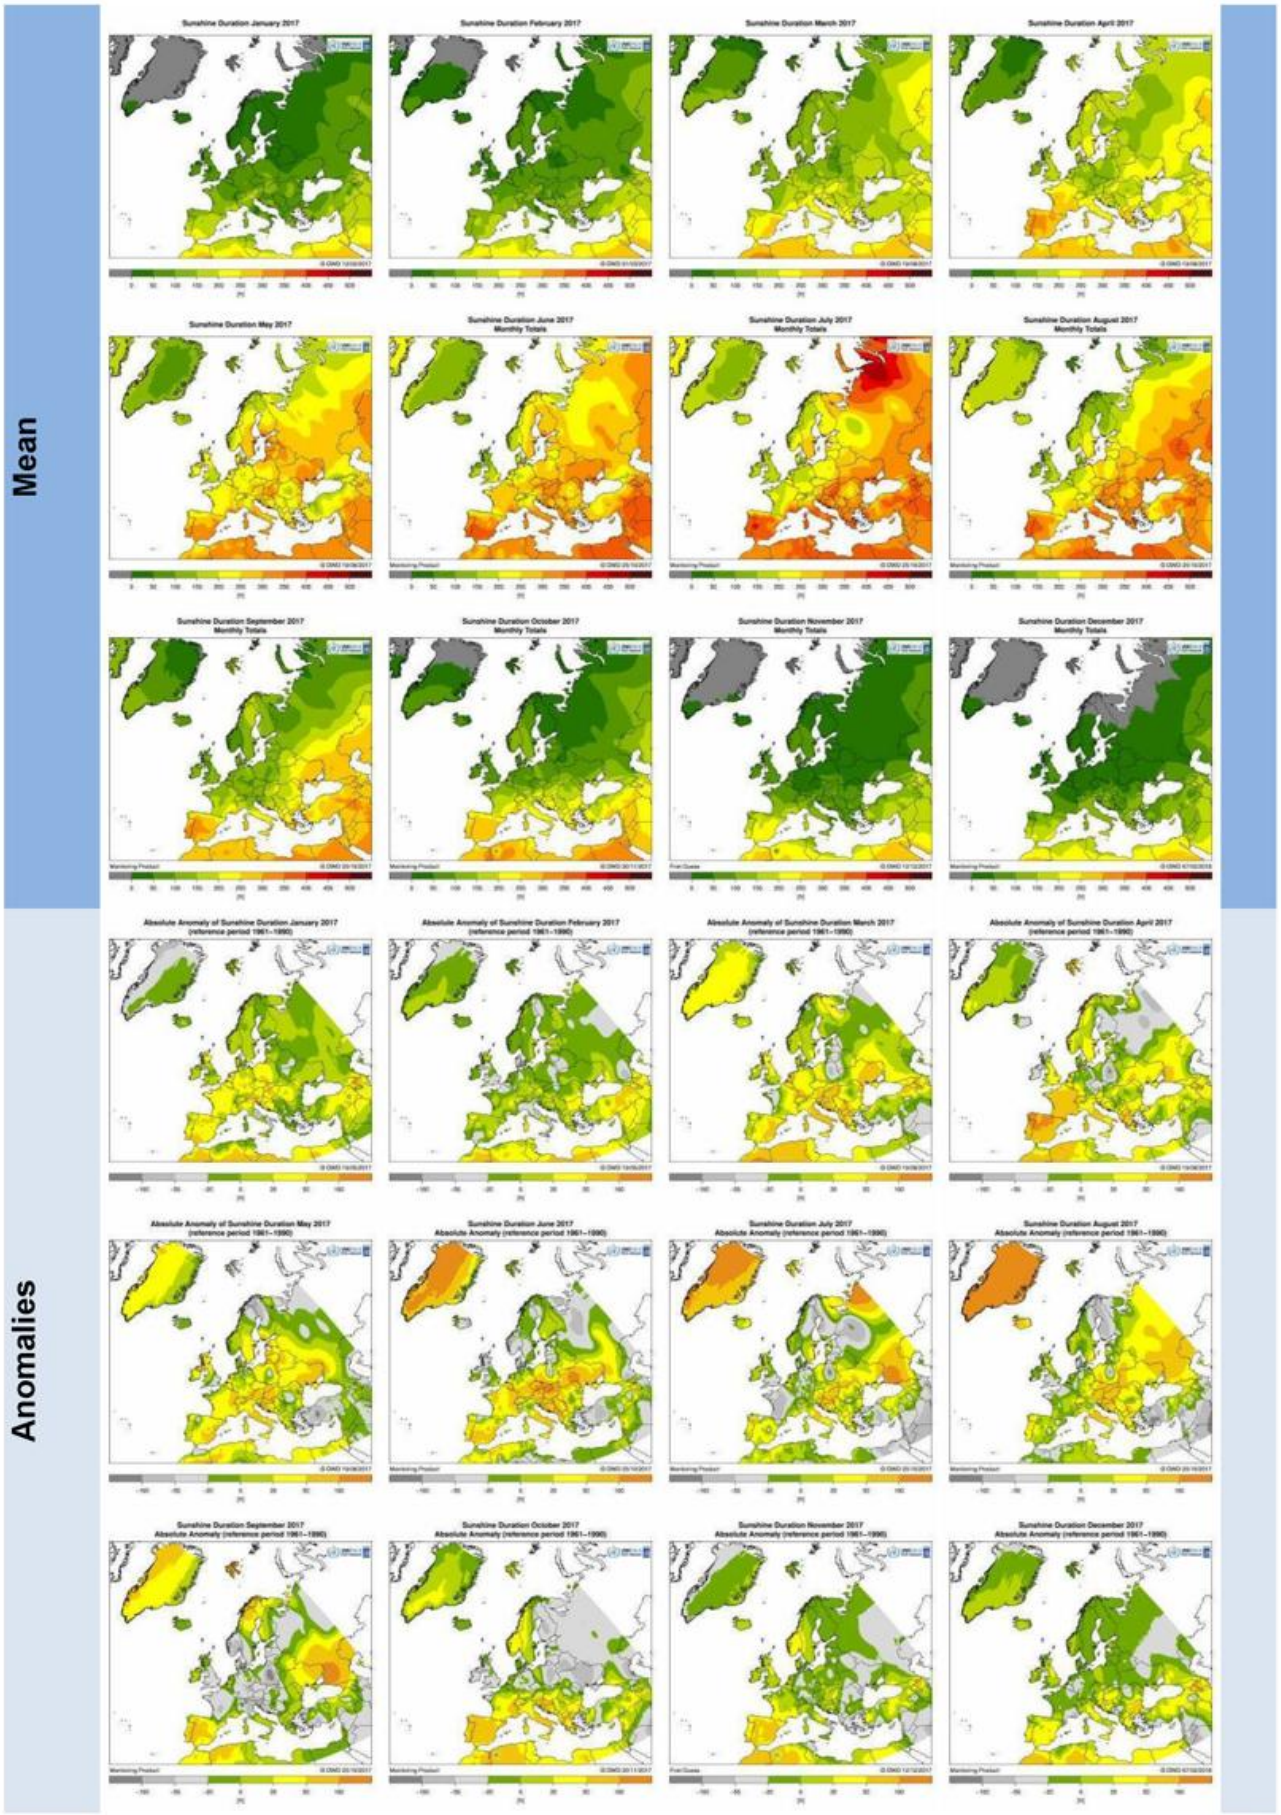

Figure 4.14: Mean of sunshine duration (in hours) and anomalies (in hours) for each month of the year 2017. (First row January, February, March, April, … ; reference period 1961-1990).

4.5. Maps of monthly climate extremes and events

The following maps are based on different data (as noted in the legends in parentheses), and is meant to summarize weather conditions in each month of the year 2017.

In January 2017 Scandinavia was down to +5°C warmer than normal and the numbers of warm days were above normal. Central and southern Europe showed more cold days than usual. The areas at the Norwegian and Greenland coasts were affected by strong wind gusts (storm "Axel", "Doris", "Egon") and also the Bretagne, the Gulf of Lions and the coast of the Adriatic Sea. Most of Europe was wetter than usual.

In February 2017 more warm days than normal could be found in Europe in combination with more precipitation and storms on the coasts of western Europe.

Warmer days in March 2017 occurred almost everywhere in Europe with strong wind gusts at the Atlantic and Mediterranean coasts. In most parts of Europe the very wet days were abnormally high.

In nearly the whole of Europe April 2017 had more warmer-than-normal-days in combination with very wet days; only in northern and southeastern Europe cold days were more usual.

In May 2017 more than usual warm and wet days were registered except in northeastern Europe where some cold days occurred.

June 2017 was wet and warm in many parts except in northeastern Europe where some cold days occurred. It was also drier than normal in southern Iberia.

As several month before July 2017 became warmer than normal in the southern and western part of Europe while the North had more cold days and East Europe had more wetter days as usual.

Europe had more warm days in August 2017 with thunderstorms in France and Iberia. Sweden had more wet days and locally some colder days. Eastern and northern Europe had in many parts a precipitation surplus.

In September 2017 the Mediterranean coasts were affected by wind gusts from thunderstorms and with more cold days. The rest of Europe has above normal wet and warm days.

Central, northern and western Europe showed in October 2017 more warm days than usual and strong wind gusts because Ex-Hurricane "**Ophelia**" and other storms crossed these areas. Eastern Europe noted a higher number of very wet days. The Gulf of Lions and the Aegean Sea were affected by thunderstorms with strong wind gusts.

During November 2017 western parts of Europe showed a higher number of warm and wet days. Norway, the UK, Denmark, the Bretagne and in the Gulf of Lions were affected by strong wind gusts in November. Central, northern and eastern Europe showed more wet days than normal

December 2017 showed in the northern part of Europe more warm days than normal, but in the south more cold days. Eastern Europe was wetter than normal. Several cyclones with strong wind gusts passed over Scandinavia, the UK, Central Europe up to Greece.

The Monthly Event Map contains information about the extreme anomalies of temperature, precipitation and wind gusts. Points are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (>=32 m/s) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

Legend of Figure 4.10:

- Anomaly of very wet days > 0 (ECAD)
- Wind gusts (≥ 32 m/s) (SYNOP)
- Anomaly of warm days > 0 (ECAD)
- Anomaly of cold days > 0 (ECAD)
- Anomaly of TG ≤ -4K (CLIMAT and ship obs.)
- Anomaly of TG ≥ 4K (CLIMAT and ship obs.)
- Aridity index < -1.5 modified SPI (GPCC)
- RR ≥ 150% of climatology (GPCC)

Based on climatology 1961-1990 (GPCC climatology: 1951-2000)

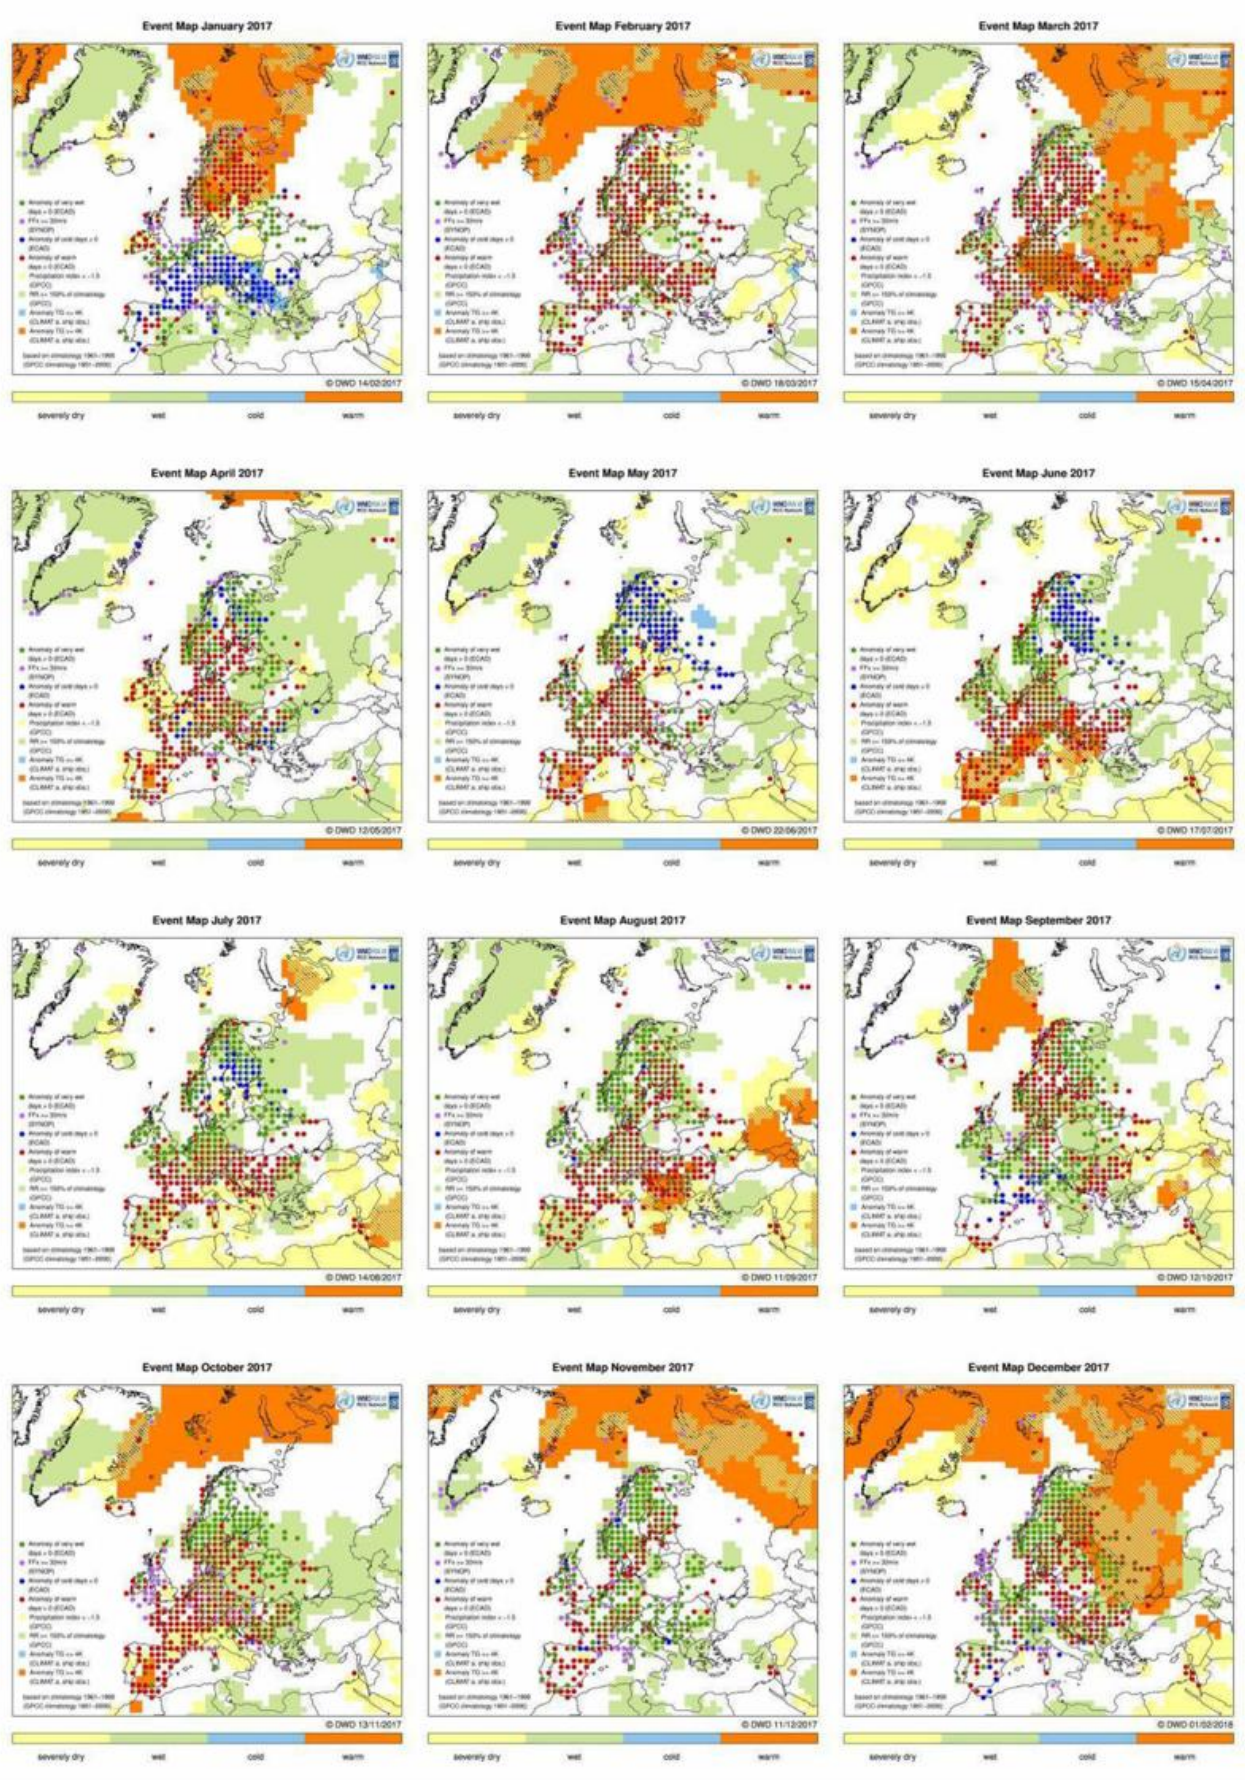

Figure 4.15: Maps of Climate Extremes for each month of the year 2017 (First row January, February, March…).

5. Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the National Meteorological and Hydrological Services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 sub-regions defined above (Figure 1.1**Fehler! Verweisquelle konnte nicht gefunden werden.**). An overview of contributing countries, time series' lengths and area representativeness can be found in Table 5.1. Most are temperature time series. Each sub-region is at least represented by one country. Time series of precipitation totals are fewer but each sub-region is represented by at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by 4 countries, belonging to different sub-regions.

After this, we present examples of the temporal development of other temperature-related phenomena, such as the sea surface temperature in the North Sea and sea level anomalies at the Polish station Władysławowo.

Table 5.1: Availability of the long-term records (start year) of temperature, precipitation and sunshine duration from some participant countries.

Sub-region	Country	Temperature		Precipitation		Sunshine Duration	
		Spatial Mean	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station
Central and Western Europe	Austria	1768					
	Belgium		1833		1833		
	France	1900		1959			
	Germany	1881		1881		1951

Italy

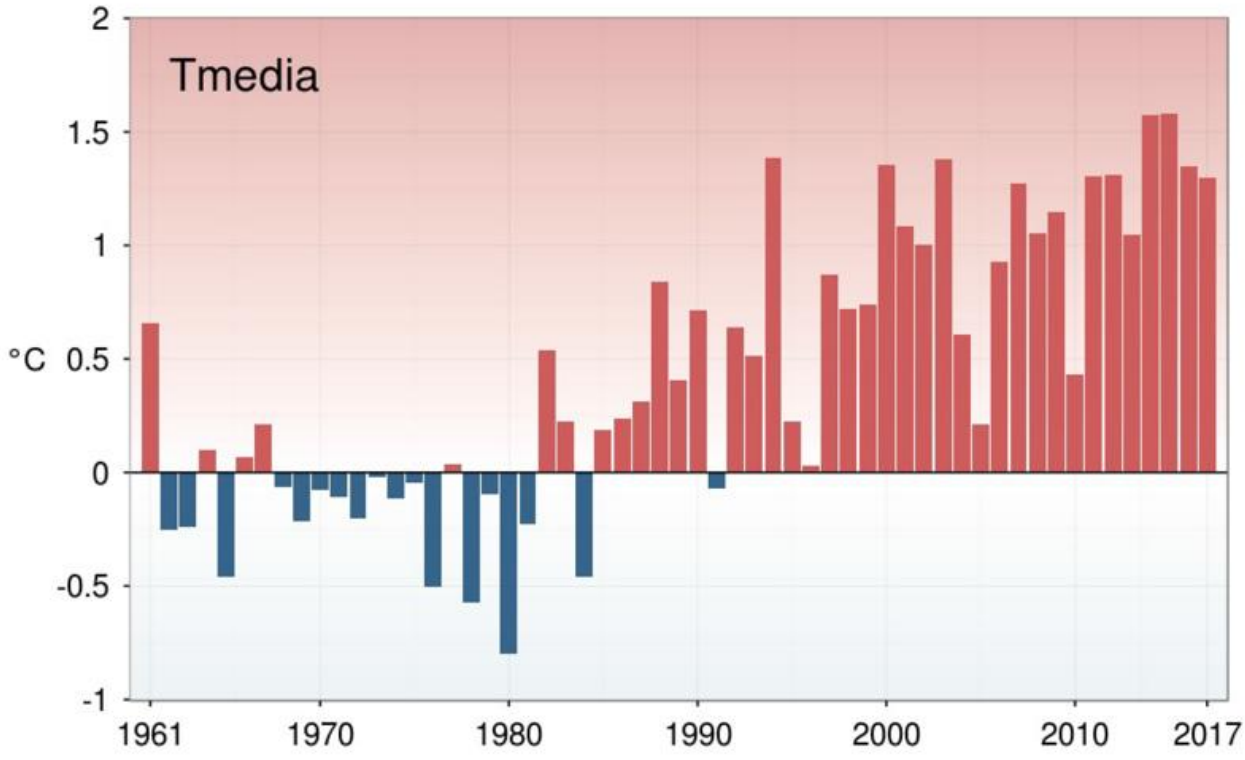

Figure 5.21: Time series of annual temperature anomalies for Italy for the period 1961-2017 (reference period 1961-1990; diagram as provided by ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

Mediterranean, Italian and Balkan Peninsula – annual temperature series

Slovenia

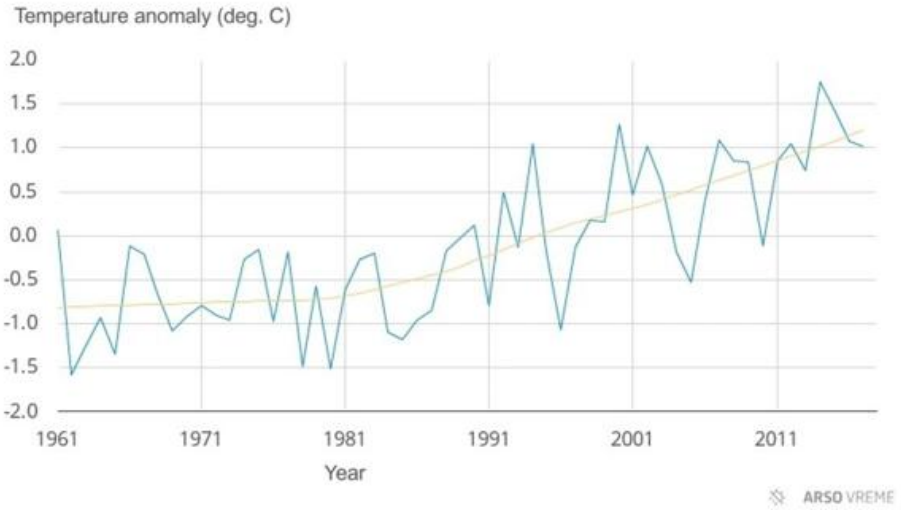

Figure 5.22: Time series of annual temperature anomalies for Slovenia for the period 1961-2017 (reference period 1961-1990; diagram as provided by the NHMS)

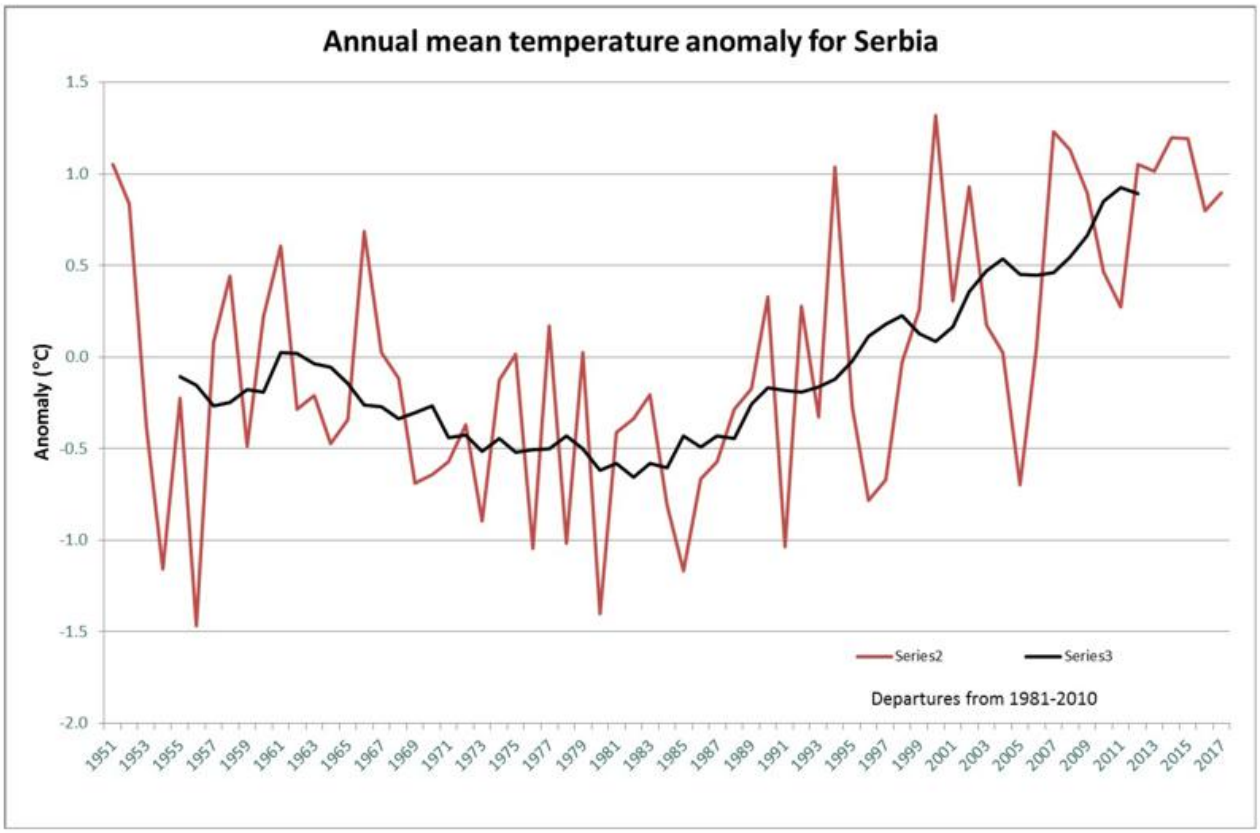

Serbia

Figure 5.23: Time series of annual temperature anomalies for Serbia for the period 1951-2017 (reference period 1981-2010; diagram as provided by the NHMS)

Mediterranean, Italian and Balkan Peninsula – annual temperature series

Turkey

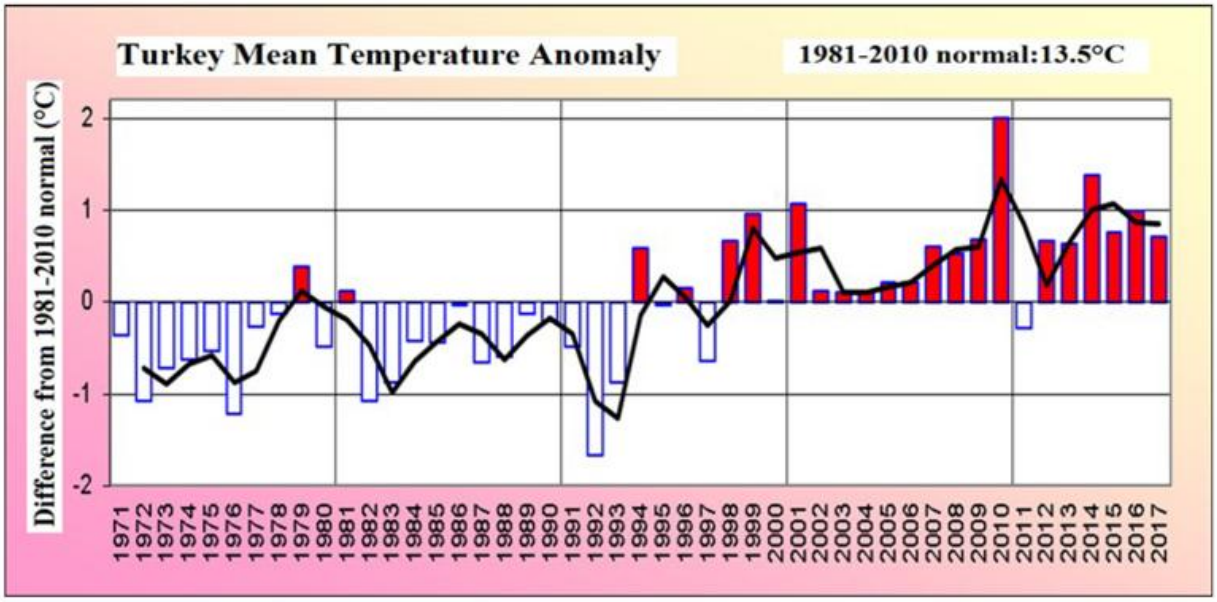

Figure 5.24: Time series of annual temperature anomalies for Turkey for the period 1971-2017 (reference period 1981-2010; diagram as provided by the NHMS)

Eastern Europe – annual temperature series

Belarus, European Russia, Moldova, Ukraine

Belarus

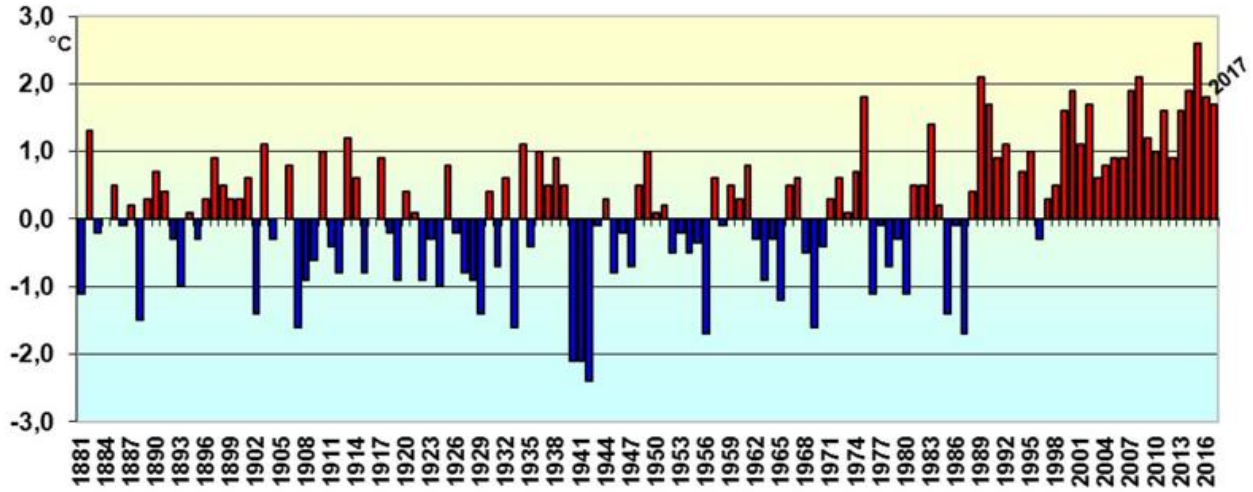

Figure 5.25: Time series of annual temperature anomalies for the Republic of Belarus for the period 1881-2017 (reference period 1961-1990; diagram as provided by the NHMS)

European Russia

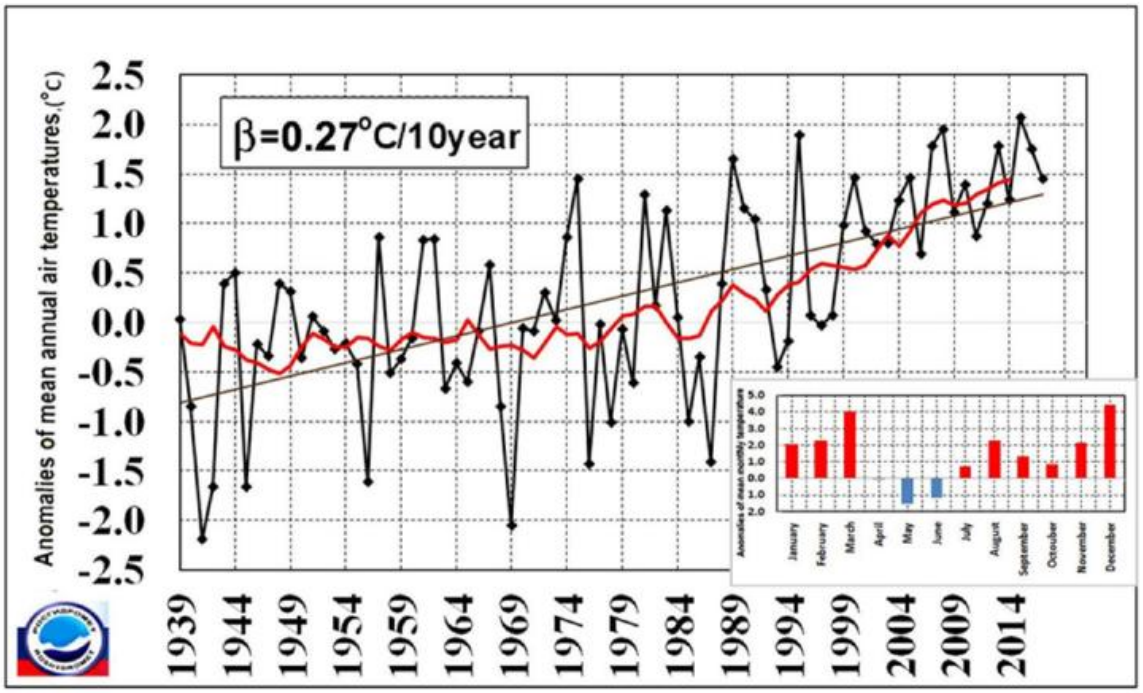

Figure 5.26: Time series of annual temperature anomalies for European Russia for the period 1939-2017 (reference period 1961-1990; diagram as provided by the NHMS)

Eastern Europe – annual temperature series

Moldova

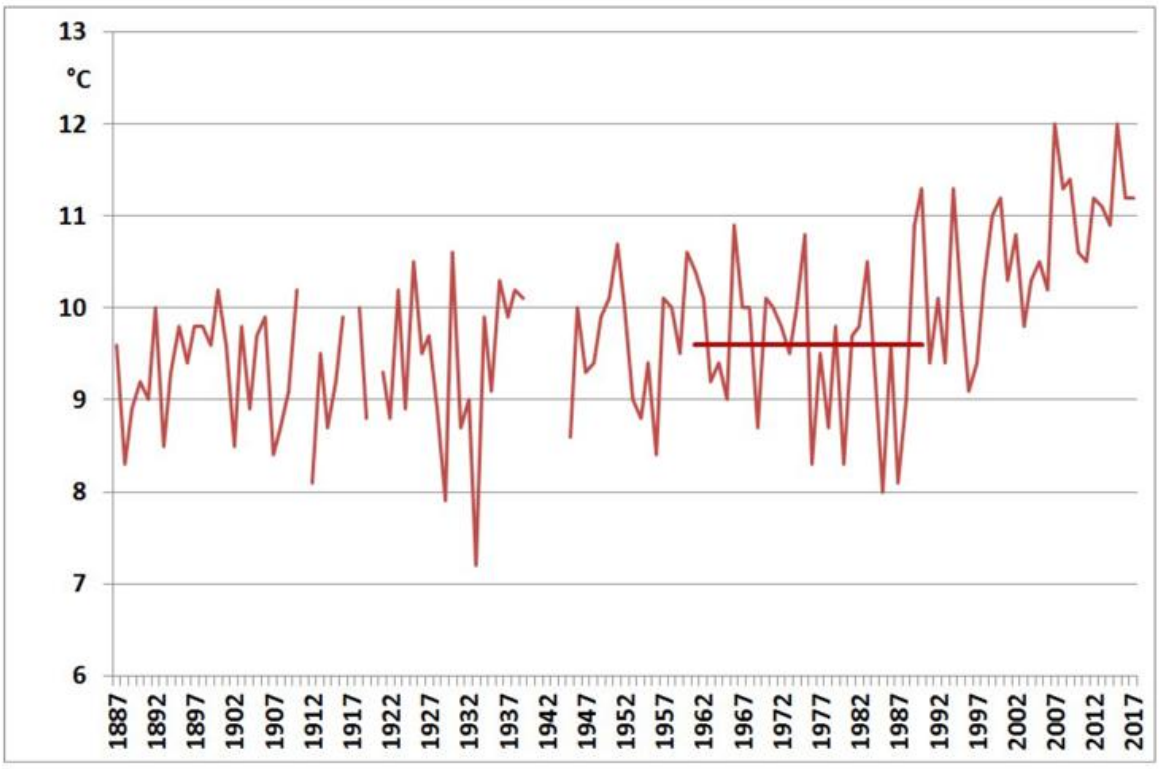

Figure 5.27: Time series of annual temperature for station Chisinau, Moldova for the period 1887-2017 (diagram as provided by the NHMS)

Ukraine

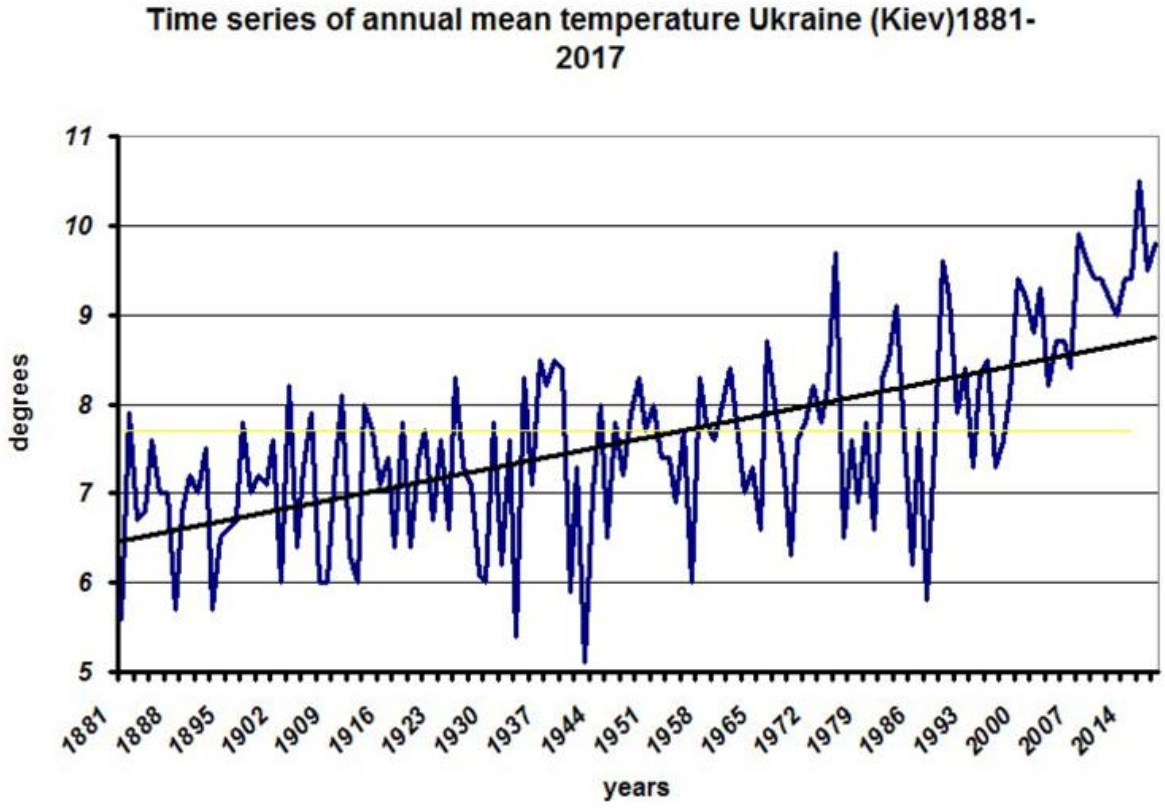

Figure 5.28: Time series of annual temperature for Kiev (Ukraine) for the period 1881-2017 (Diagram as provided by the NHMS)

Middle East – annual temperature series

Georgia, Israel

Georgia

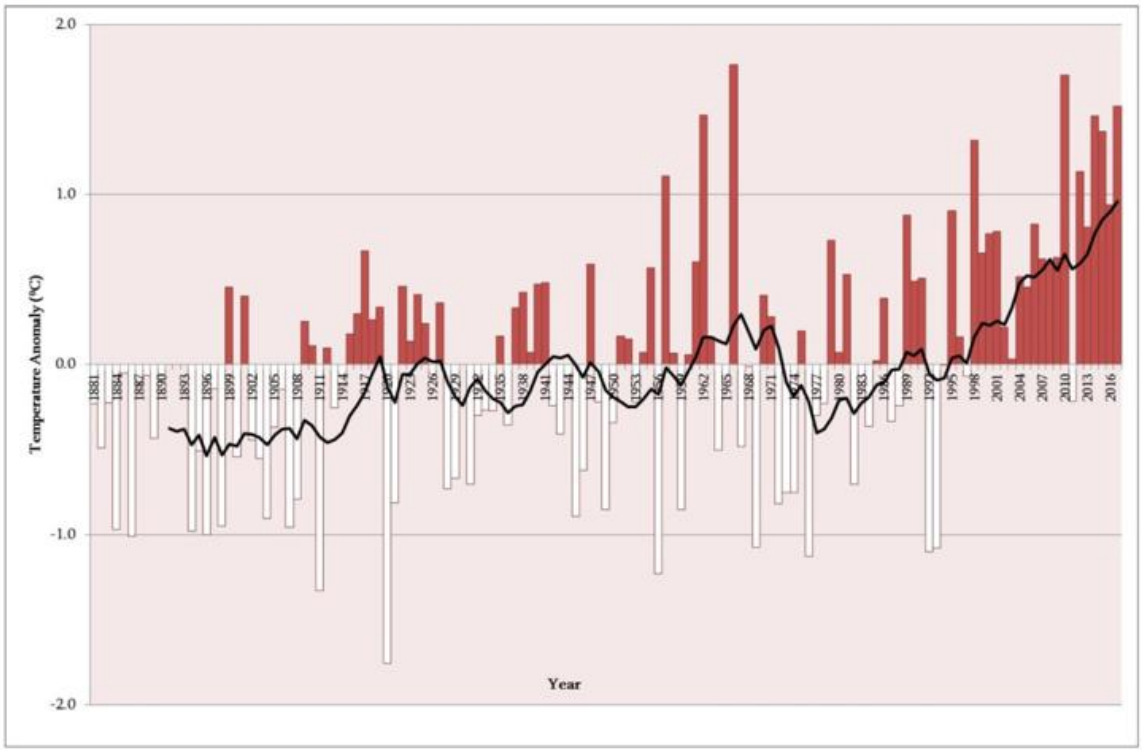

Figure 5.29: Time series of annual temperature anomalies and 11-yr moving averages for Tbilisi (Georgia) for the period 1881-2017(reference period 1961-1990; diagram as provided by the NHMS)

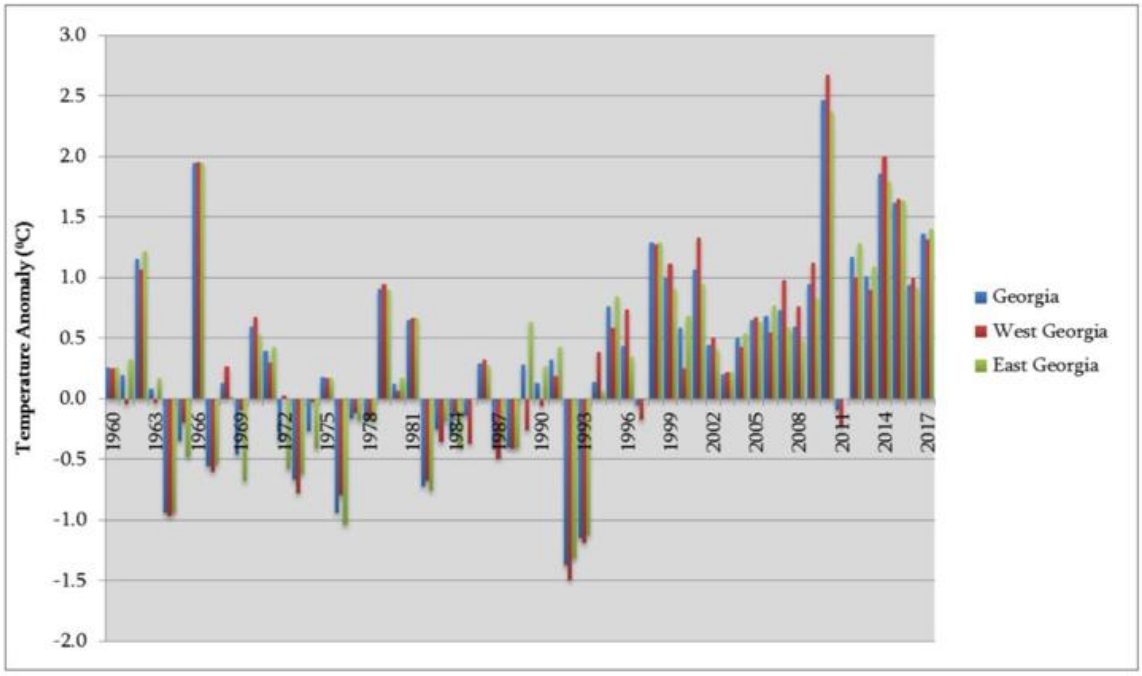

Figure 5.30: Time series of annual temperature anomalies for Georgia for the period 1960-2017 (reference period 1961-1990; diagram as provided by the NHMS)

Middle East – annual temperature series

Israel

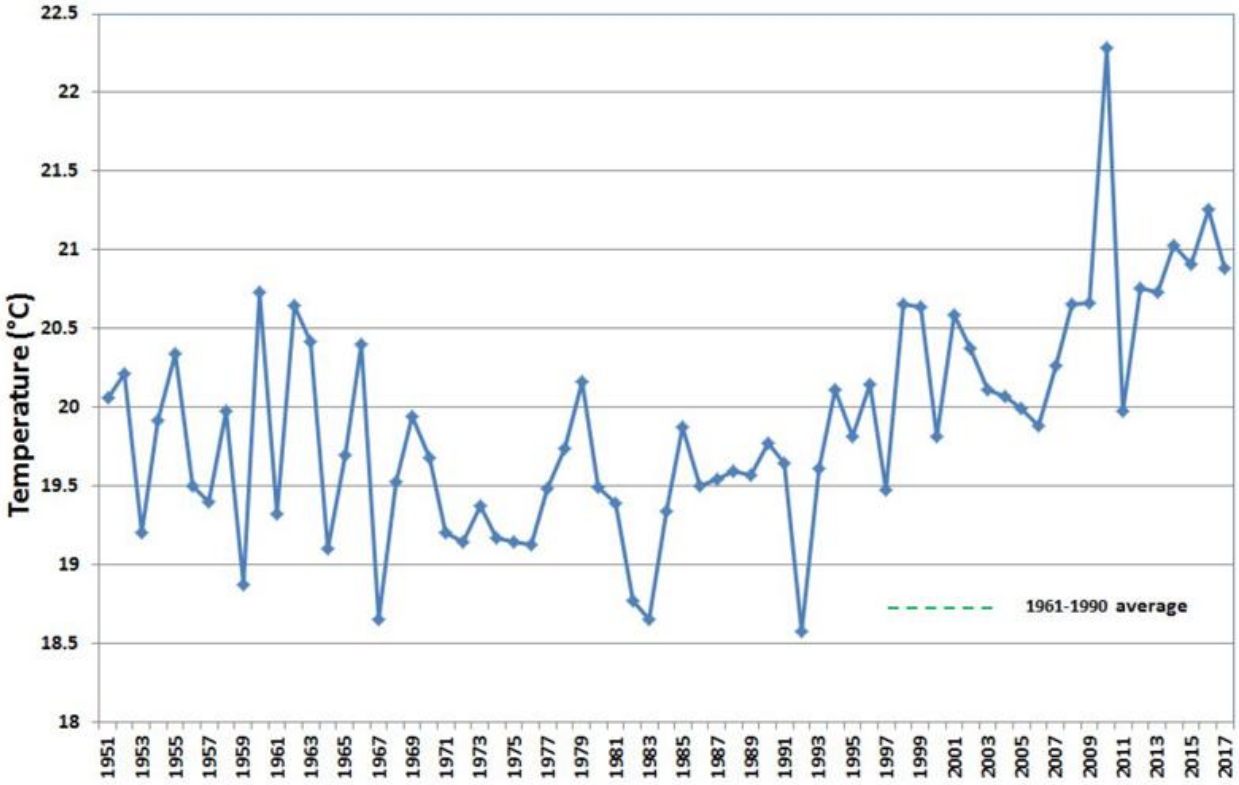

Figure 5.31: Time series of annual temperature for Israel (based on five stations) for the period 1951-2017 (diagram as provided by the NHMS)

5.2. Precipitation

Central and Western Europe - precipitation totals and anomalies

Belgium, France, Germany, Hungary, Netherlands, Switzerland, United Kingdom

Belgium

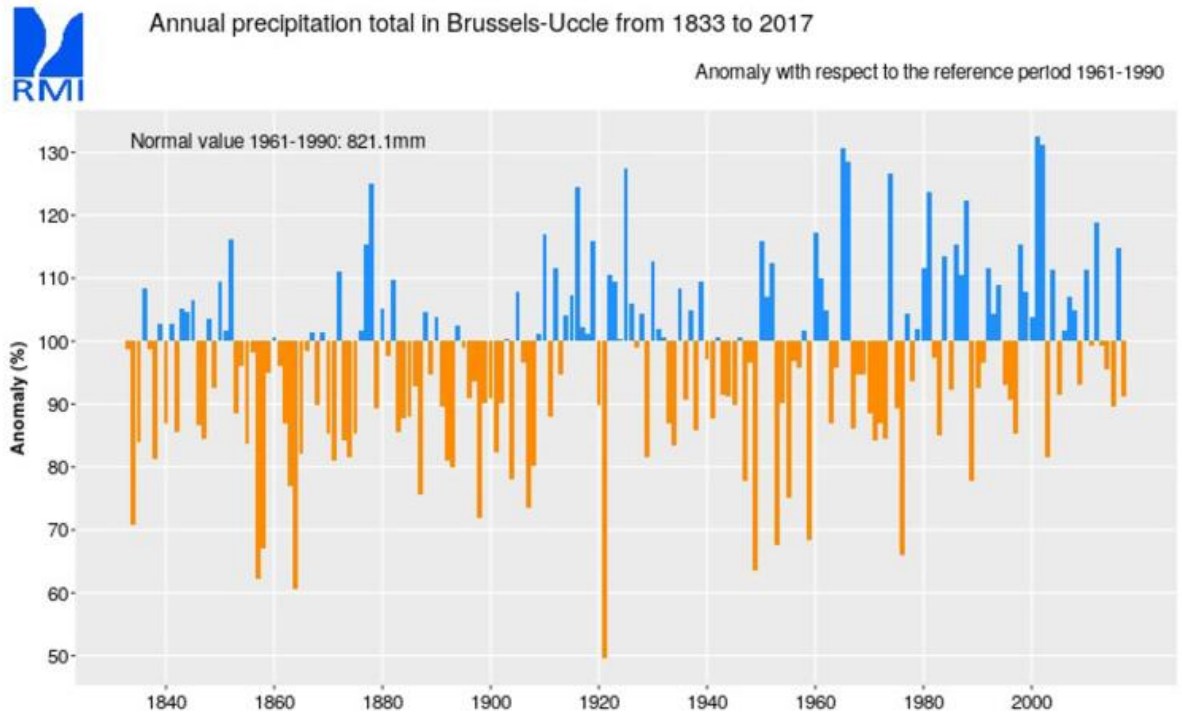

Figure 5.32: Time series of annual precipitation anomalies in relation to the long term mean (1961-1990) for Belgium (station Uccle) for the period 1833-2017 (Diagram as provided by the NHMS)

France

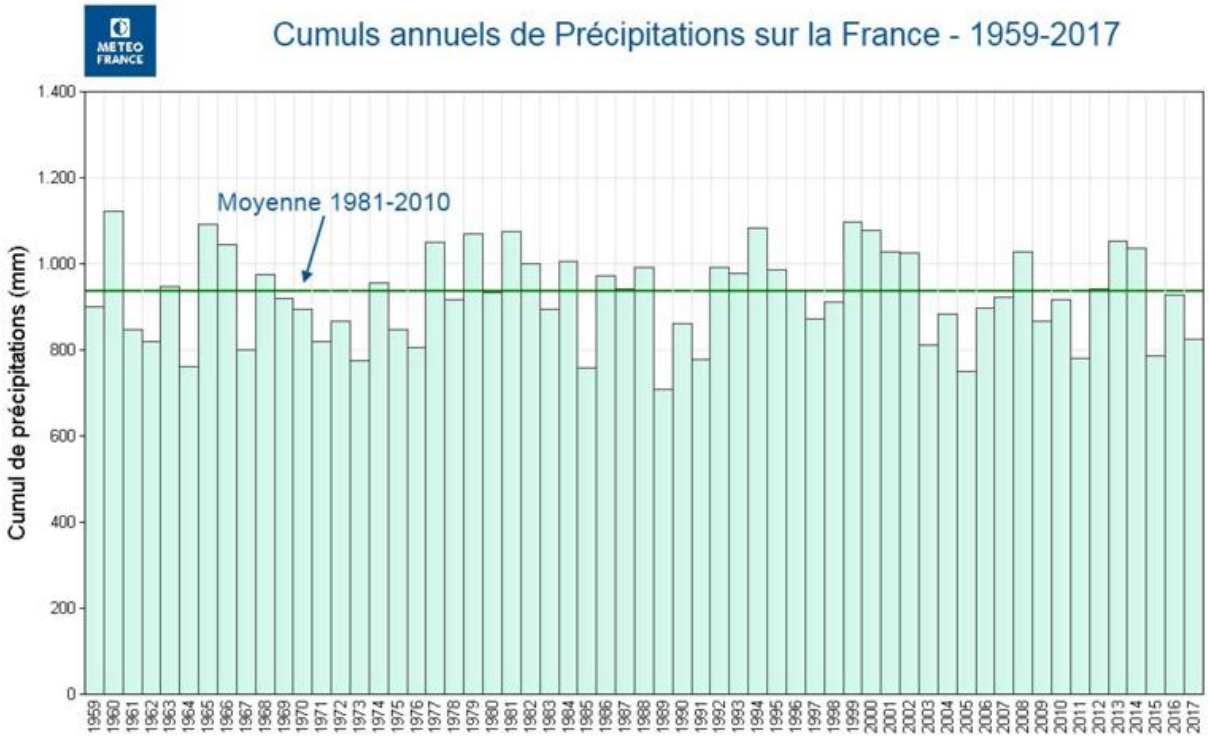

Figure 5.33: Time series of annual precipitation totals in mm/year for France for the period 1959-2017 (green line: long term mean 1981-2010; Diagram as provided by the NHMS)

Germany

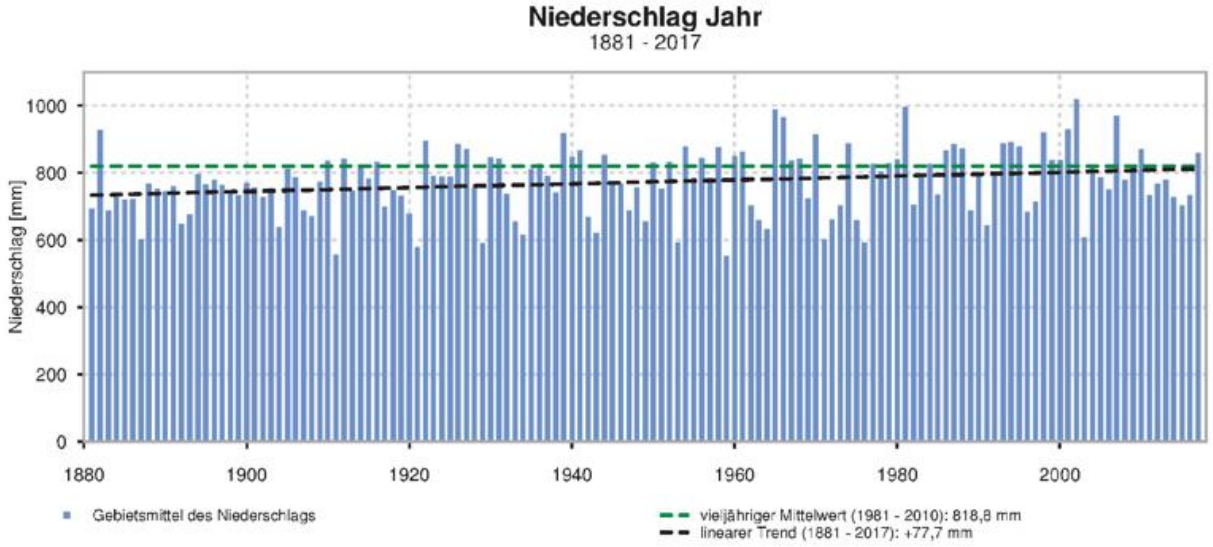

Figure 5.34: Time series of annual precipitation totals in mm/year for Germany for the period 1881-2017 (green line: long term mean; Diagram as provided by the NHMS)

Central and Western Europe - precipitation totals and anomalies

Hungary

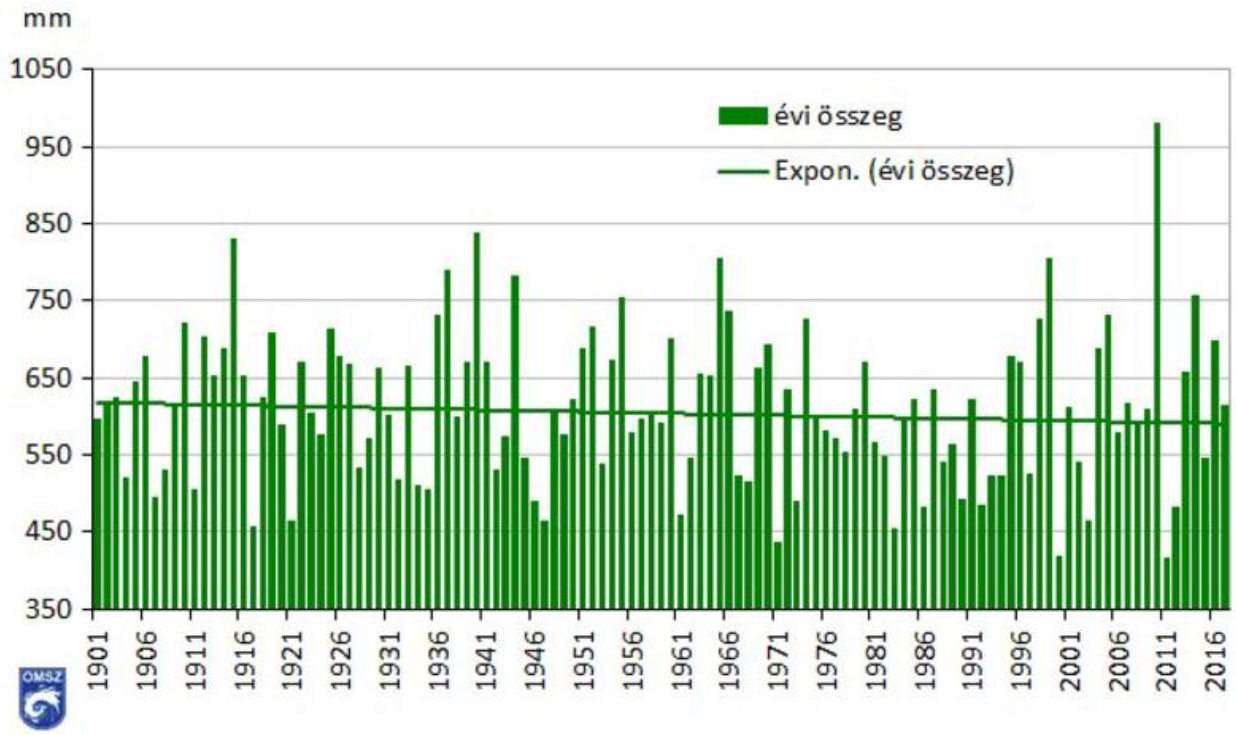

Figure 5.35: Time series of annual precipitation totals in mm/year for Hungary for the period 1901-2017 (Diagram as provided by the NHMS)

The Netherlands

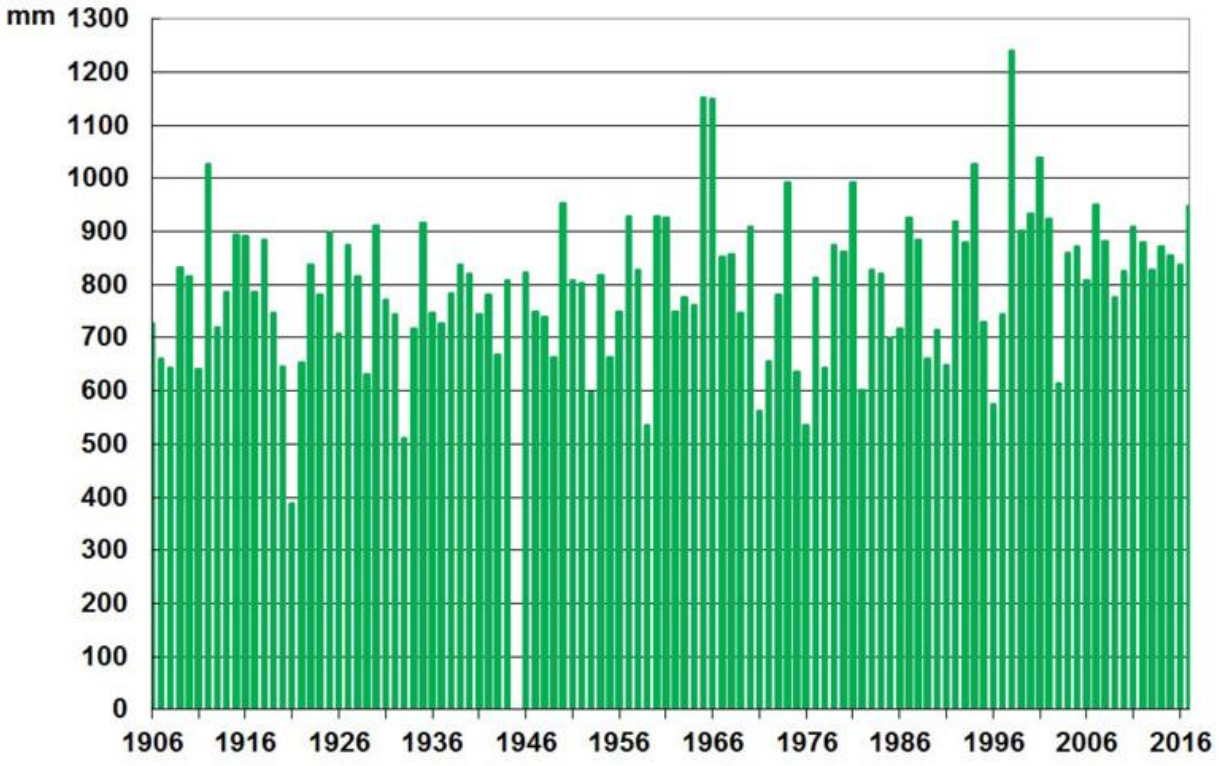

Figure 5.36: Time series of annual precipitation totals in mm/year for the Netherlands (station De Bilt) for the period 1906-2017 (Data as provided by the KNMI)

Central and Western Europe - precipitation totals and anomalies

Switzerland

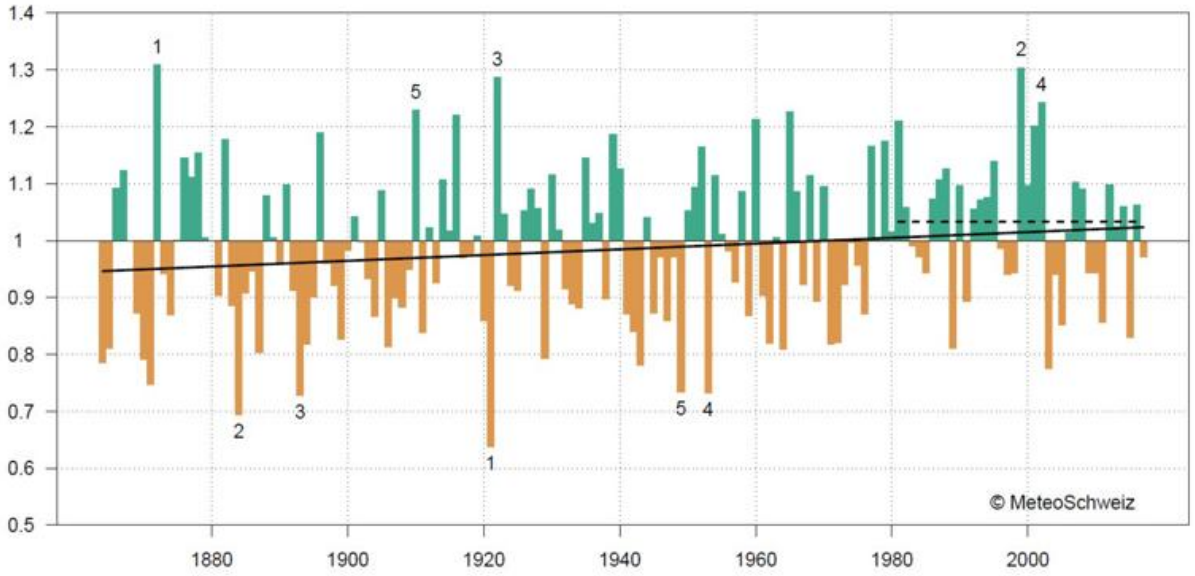

Figure 5.37: Time series of annual precipitation anomalies in relation to the mean of 1961-1990 for Switzerland for the period 1864–2017. Color bars represent anomalies in respect to the long-term mean 1961–1990 and green indicates positive and bronze negative anomalies. The black line represents the linear significant trend (5.0%/100y). The black dashed line represents the mean 1981–2010. (Diagram as provided by the NHMS)

United Kingdom

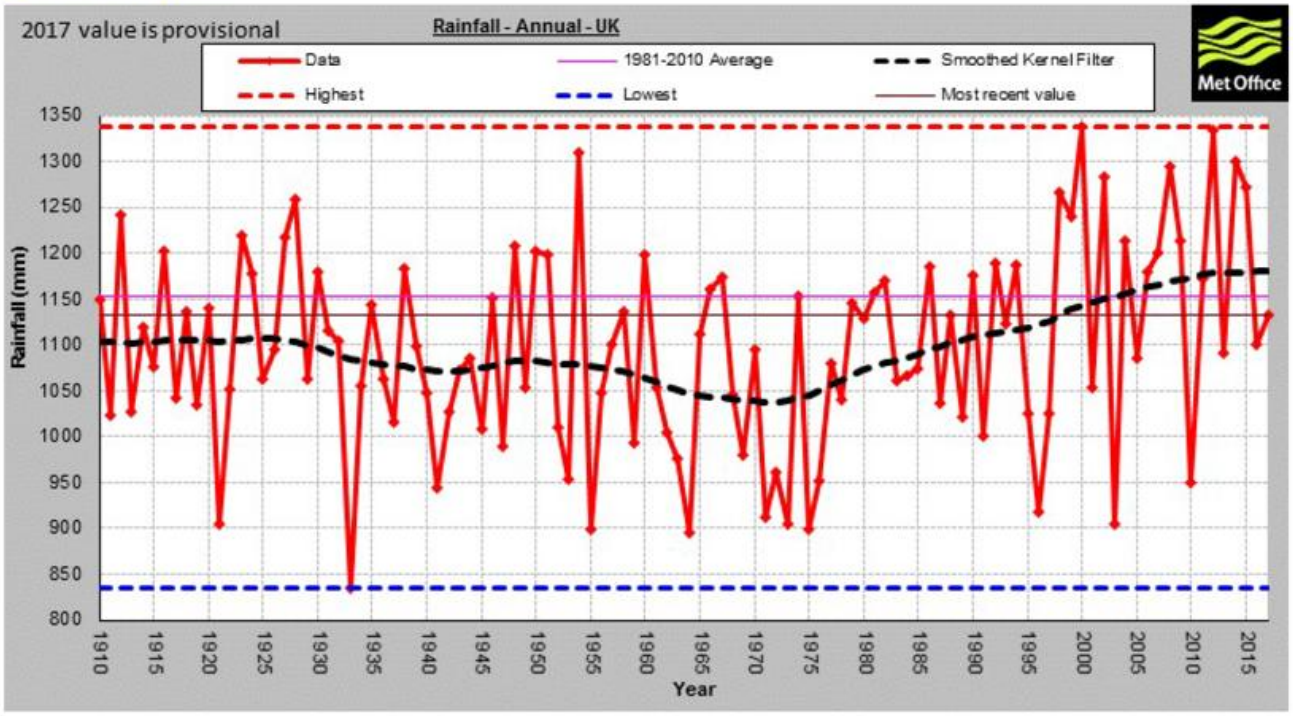

Figure 5.38: Time series of annual precipitation totals in mm/year for the United Kingdom for the period 1910-2017 (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Denmark, Finland, Latvia, Norway, Sweden

Denmark

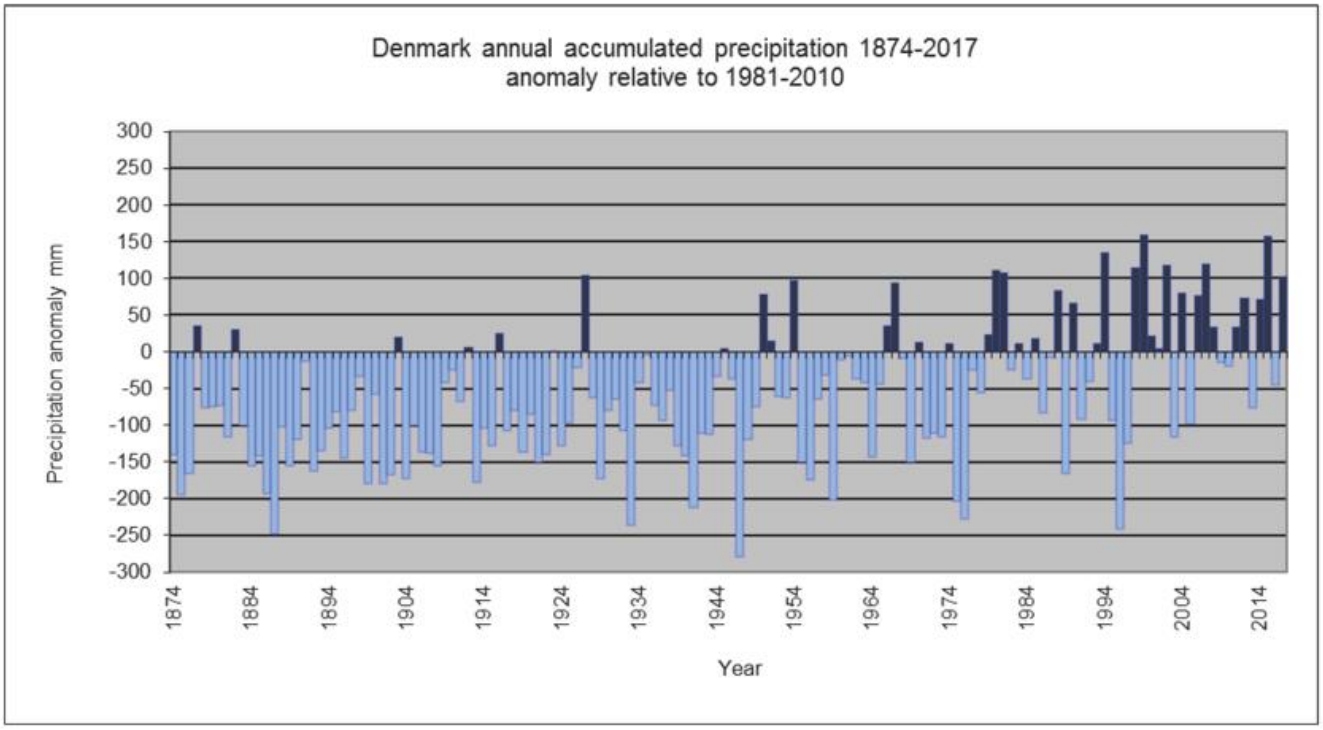

Figure 5.39: Time series of annual precipitation totals in mm/year for Denmark: anomaly relative to 1981-2010 (Diagram as provided by the NHMS)

Estonia

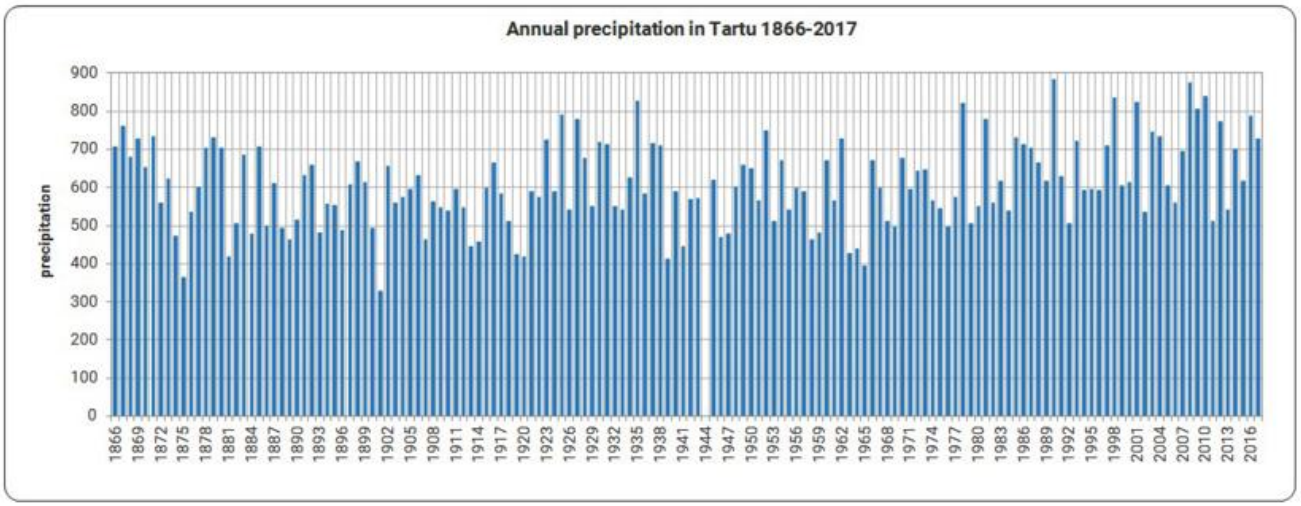

Figure 5.40: Time series of annual precipitation totals in mm/year at station Tartu, Estonia (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Finland

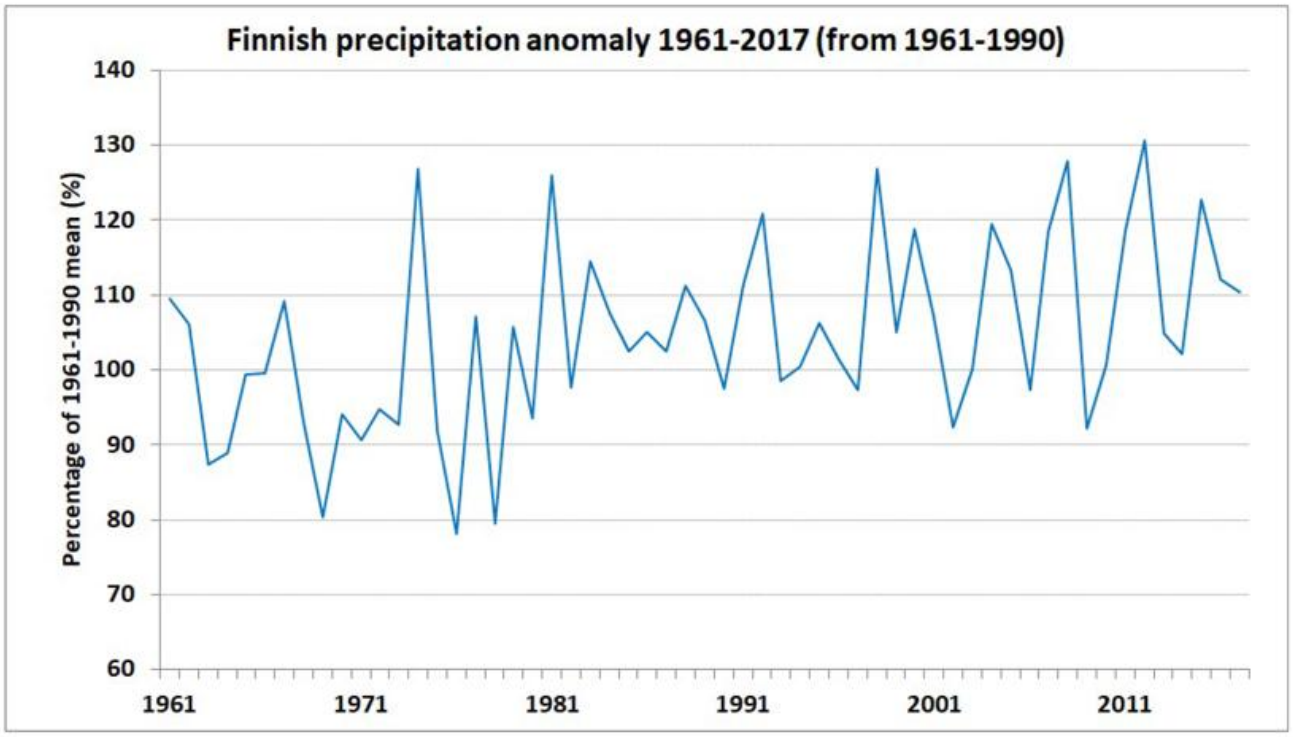

Figure 5.41: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Finland (Diagram as provided by the NHMS)

Latvia

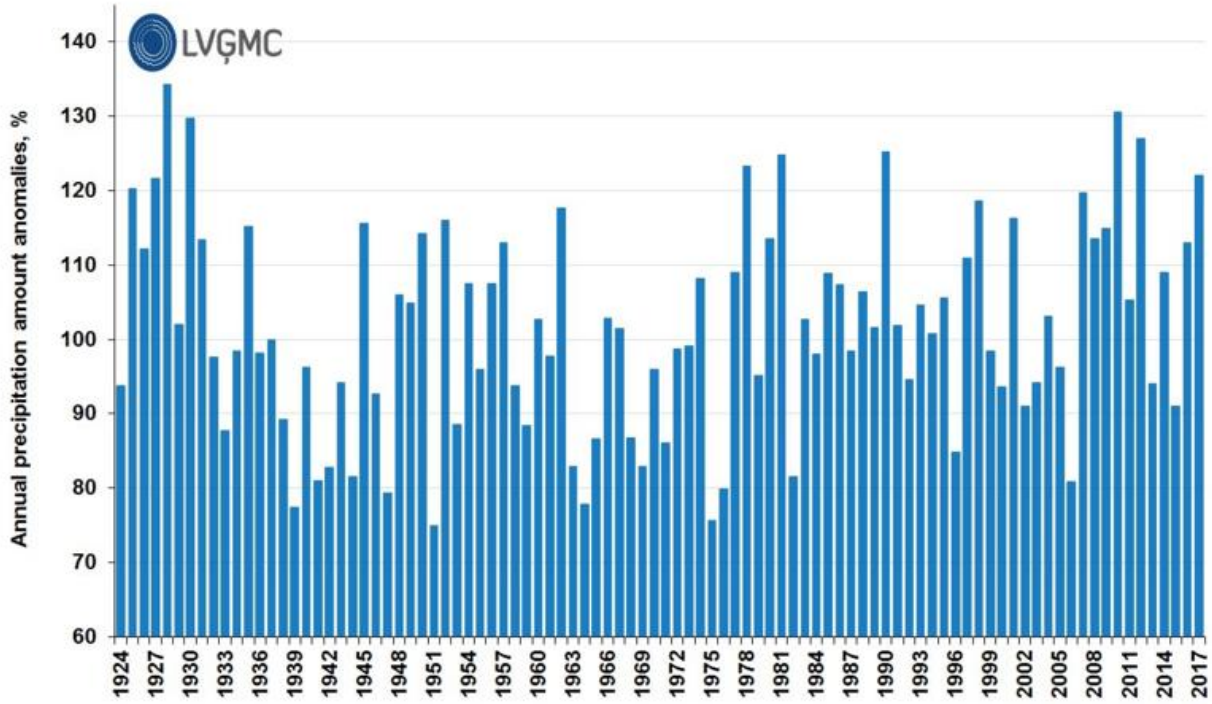

Figure 5.42: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Latvia (Diagram as provided by the NHMS)

Nordic and Baltic Countries - precipitation totals and anomalies

Norway

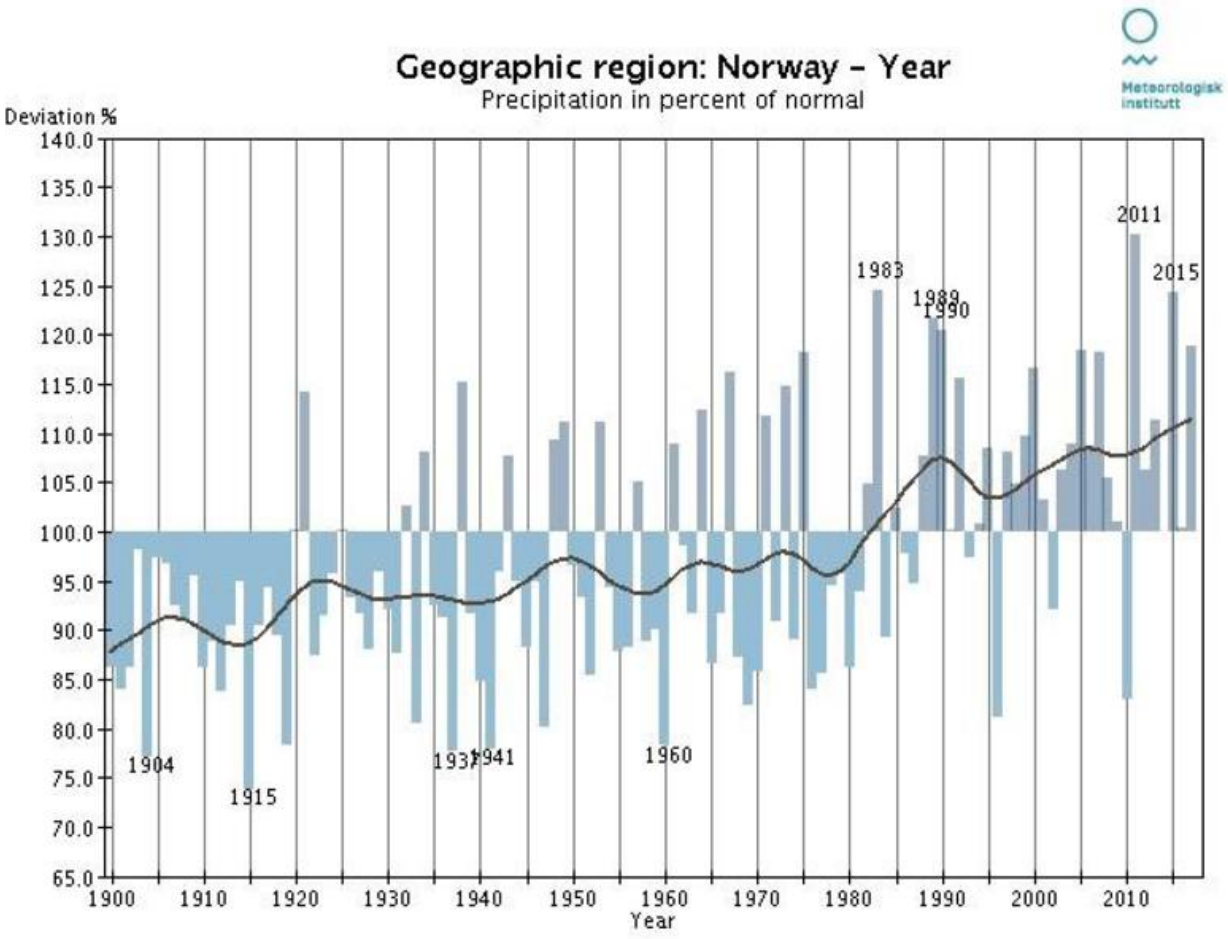

Figure 5.43: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Norway (Diagram as provided by the NHMS)

Sweden

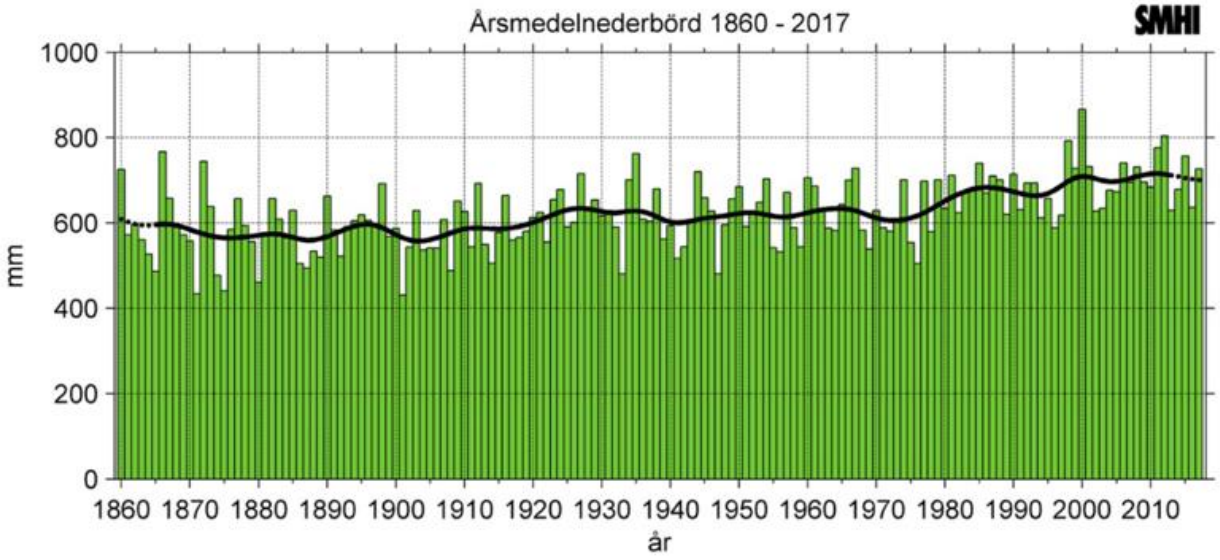

Figure 5.44: Time series of annual precipitation totals in mm/year for Sweden (Diagram as provided by the NHMS)

Iberia - precipitation anomalies

Portugal, Spain

Portugal

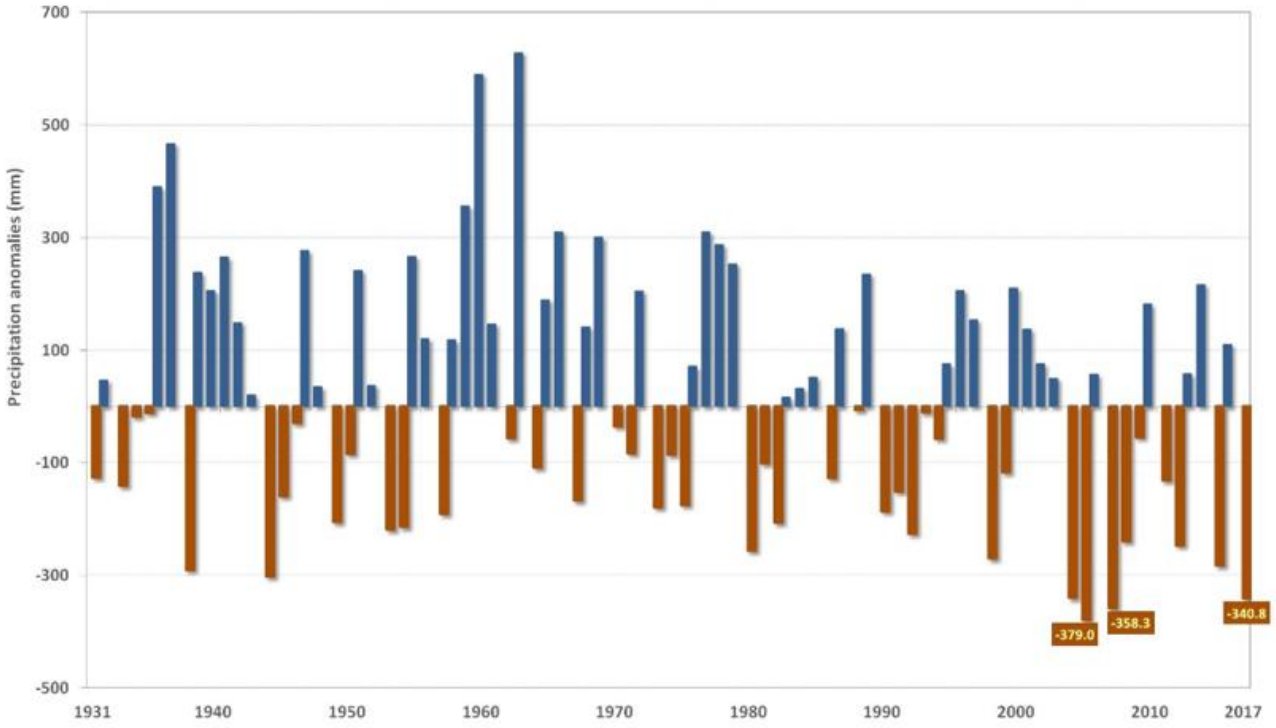

Figure 5.45: Time series of annual precipitation totals in mm/year (deviations from the mean of 1971-2000) for Portugal (Diagram as provided by the NHMS)

Spain

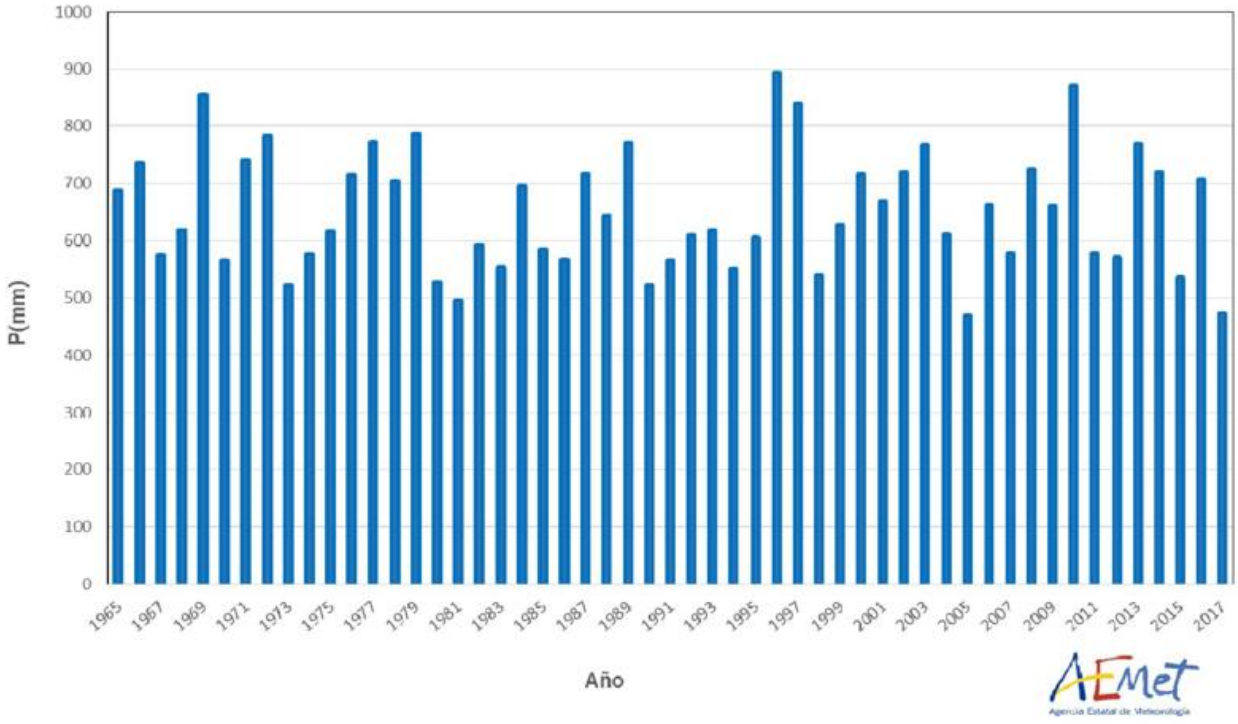

Figure 5.46: Time series of annual precipitation totals in mm/year for Spain (Diagram as provided by the NHMS)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Croatia, Italy, Slovenia, Turkey

Croatia

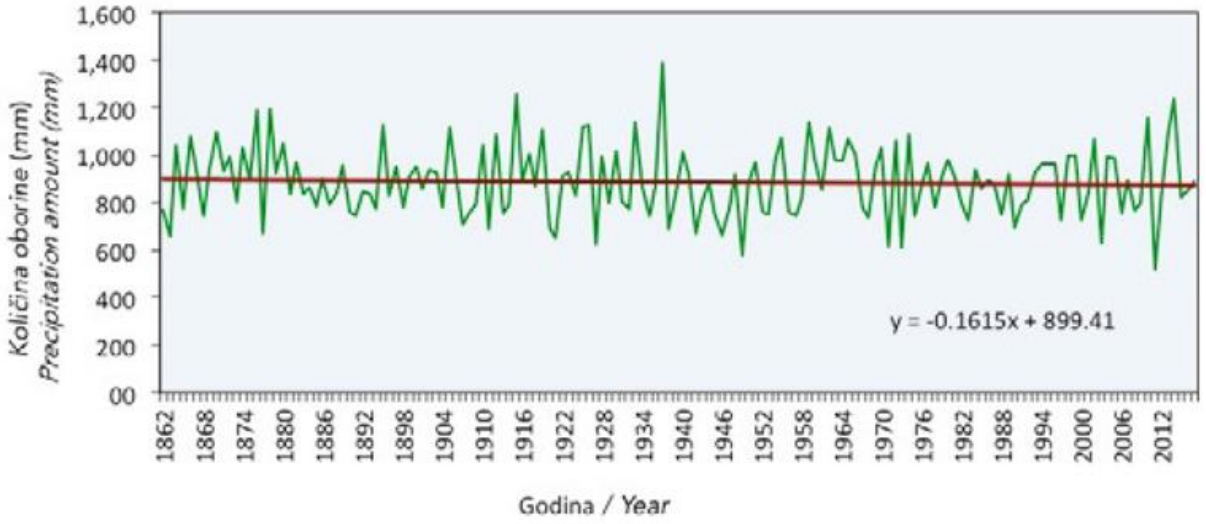

Figure 5.47: Time series of annual precipitation totals in mm/year for Zagreb Grič (Croatia) (Diagram as provided by the NHMS)

Italy

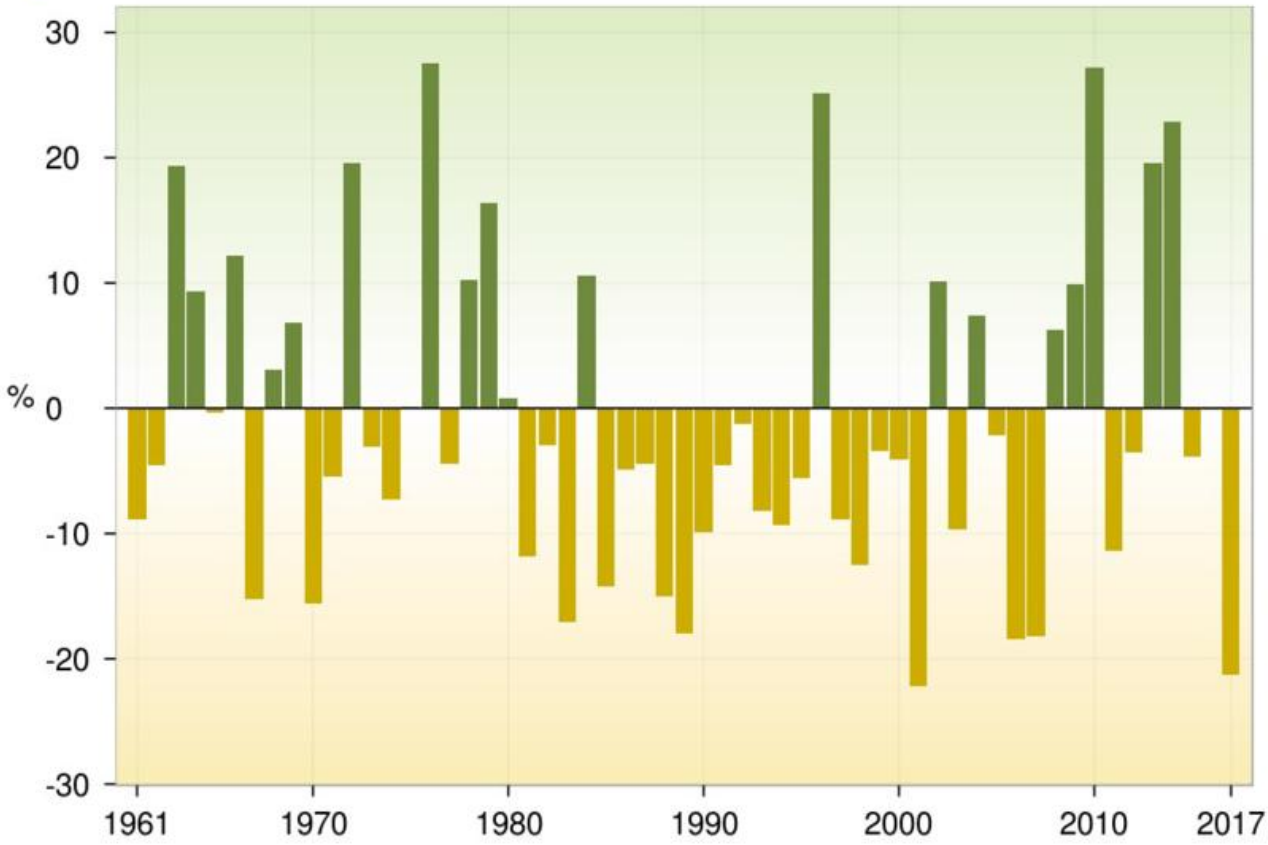

Figure 5.48: Time series of annual precipitation anomalies for 1961 to 2017 in relation to the mean of 1961-90 for Italy (diagram as provided by ISPRA – Istituto Superiore per la Protezione e la Ricerca Ambientale)

Mediterranean, Italian and Balkan Peninsula - precipitation anomalies

Slovenia

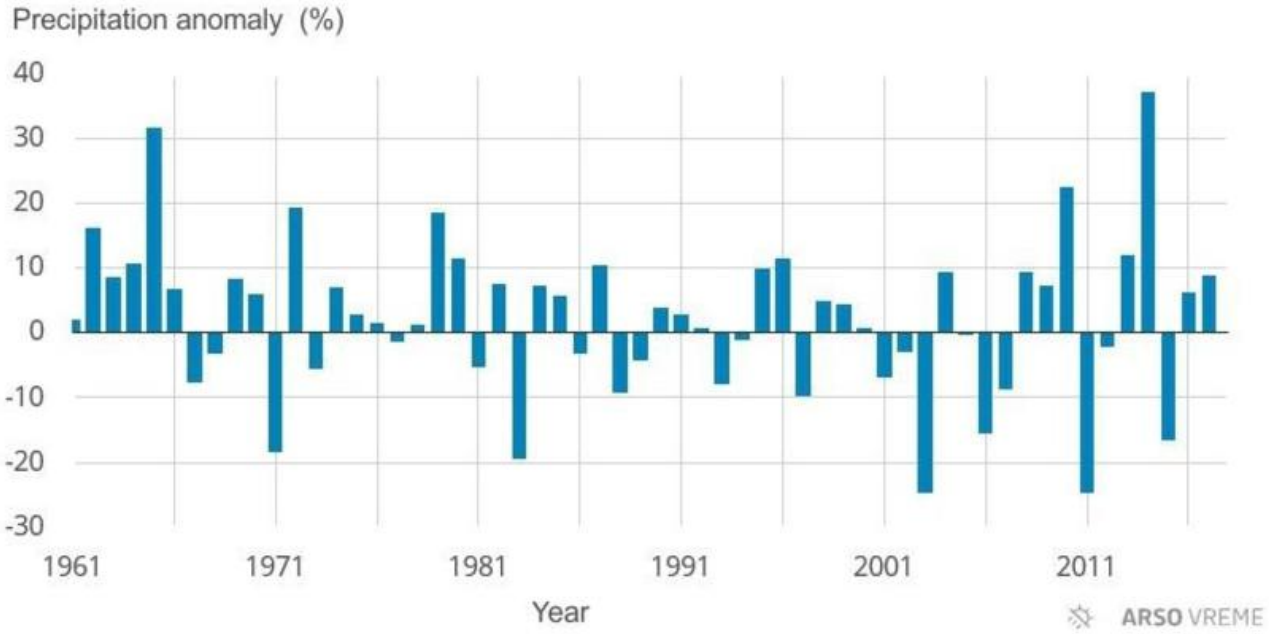

Figure 5.49: Time series of annual precipitation totals in mm/year for Slovenia 1961-2017 (diagram as provided by the NHMS)

Turkey

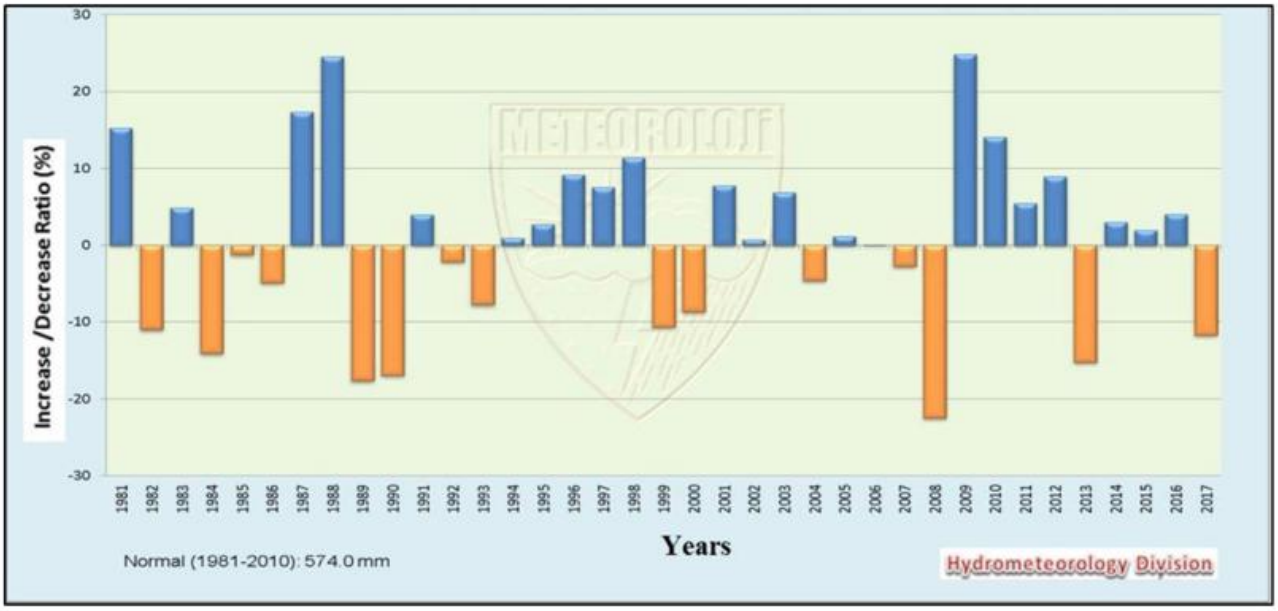

Figure 5.50: Time series of annual precipitation anomalies in relation to the mean of 1981-2010 for Turkey (Diagram as provided by the NHMS)

Eastern Europe - precipitation anomalies

Belarus, European Russia, Ukraine

Belarus

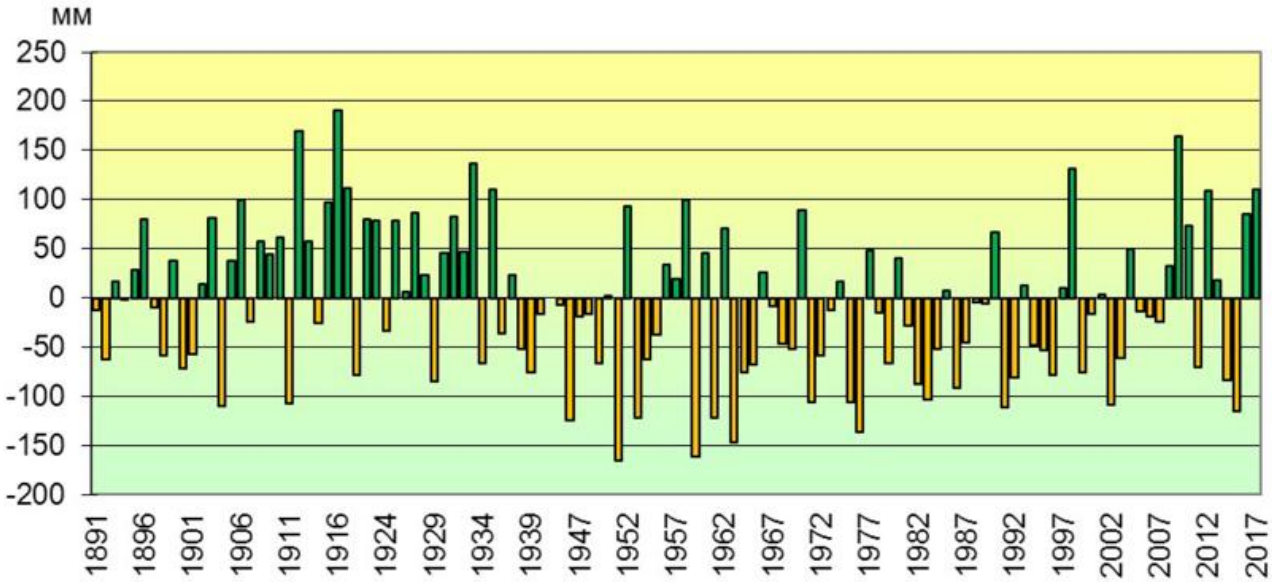

Figure 5.51: Anomalies of annual precipitation totals for Belarus 1891-2017 (base period: 1961-1990; Diagram as provided by the NHMS)

European Russia

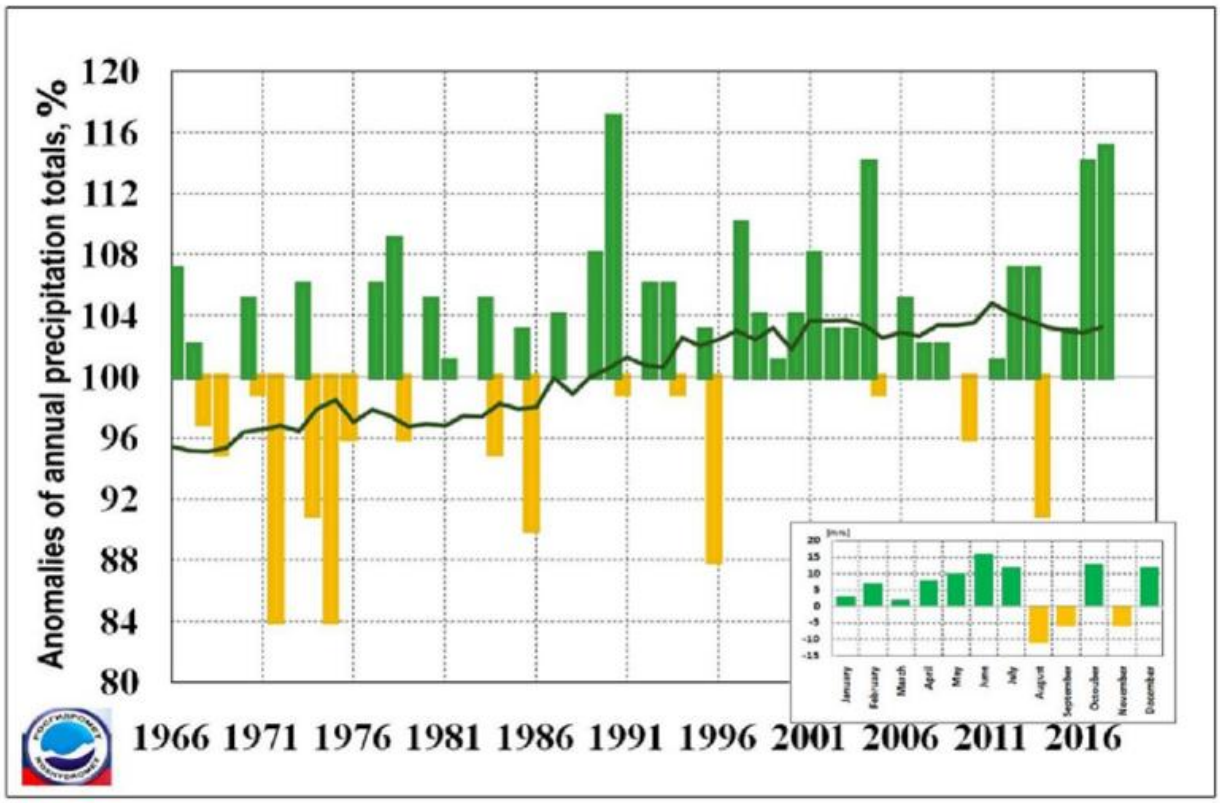

Figure 5.52: Time series of annual precipitation totals in relation to the mean of 1961-1990 for European Russia (Diagram as provided by the NHMS)

Eastern Europe - precipitation anomalies

Ukraine

Time series of annual precipitation totals for Kiev, Ukraine (1891-2017)

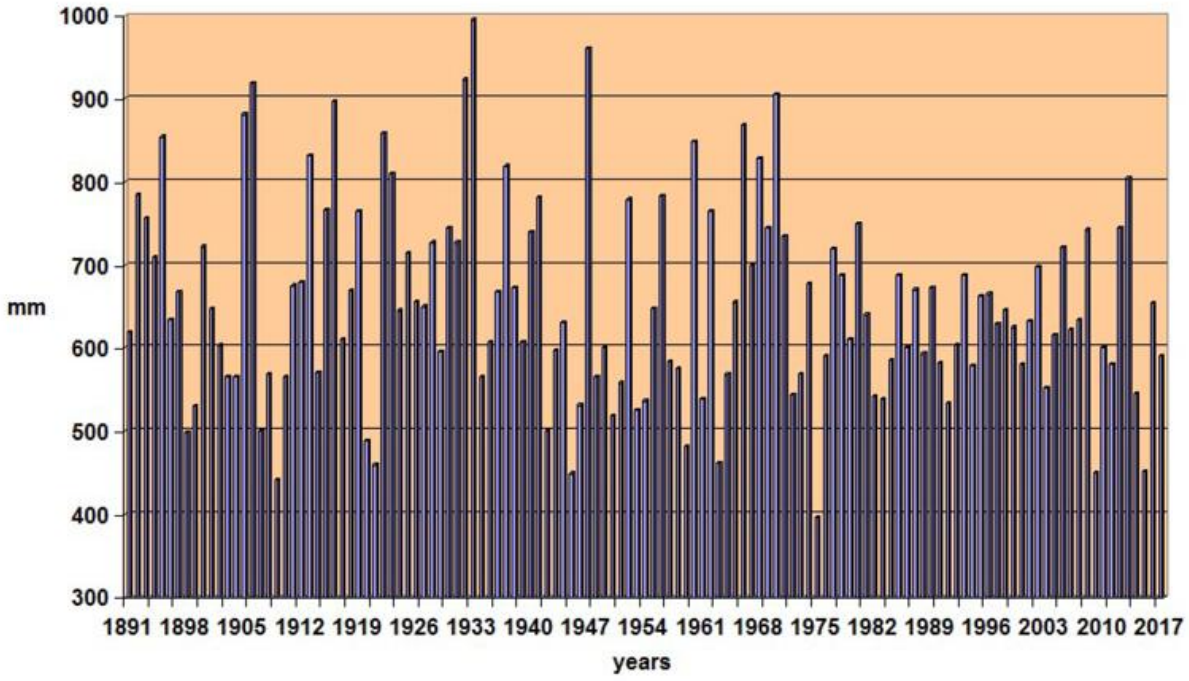

Figure 5.53: Time series of annual precipitation totals for Kiev (Ukraine)
(Diagram as provided by the NHMS)

Middle East - precipitation anomalies

Georgia, Israel

Georgia

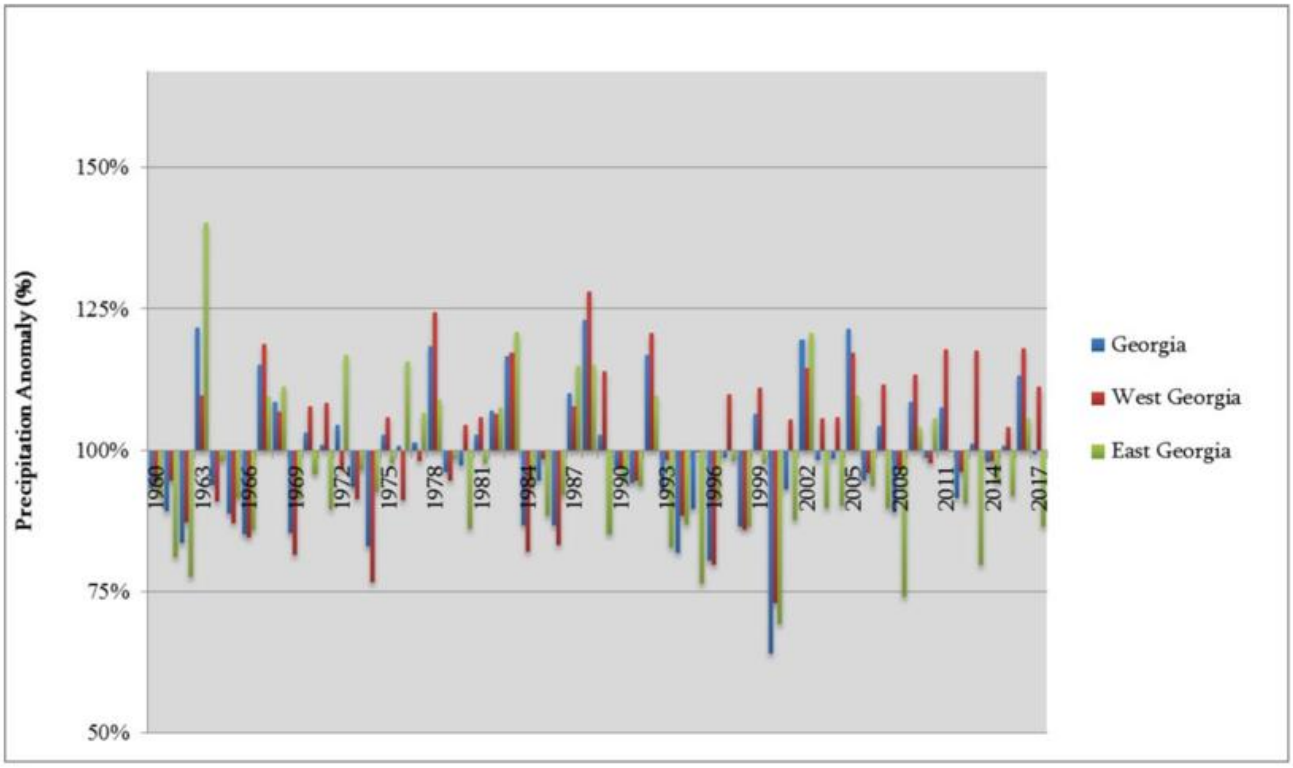

Figure 5.54: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Georgia (Diagram as provided by the NHMS)

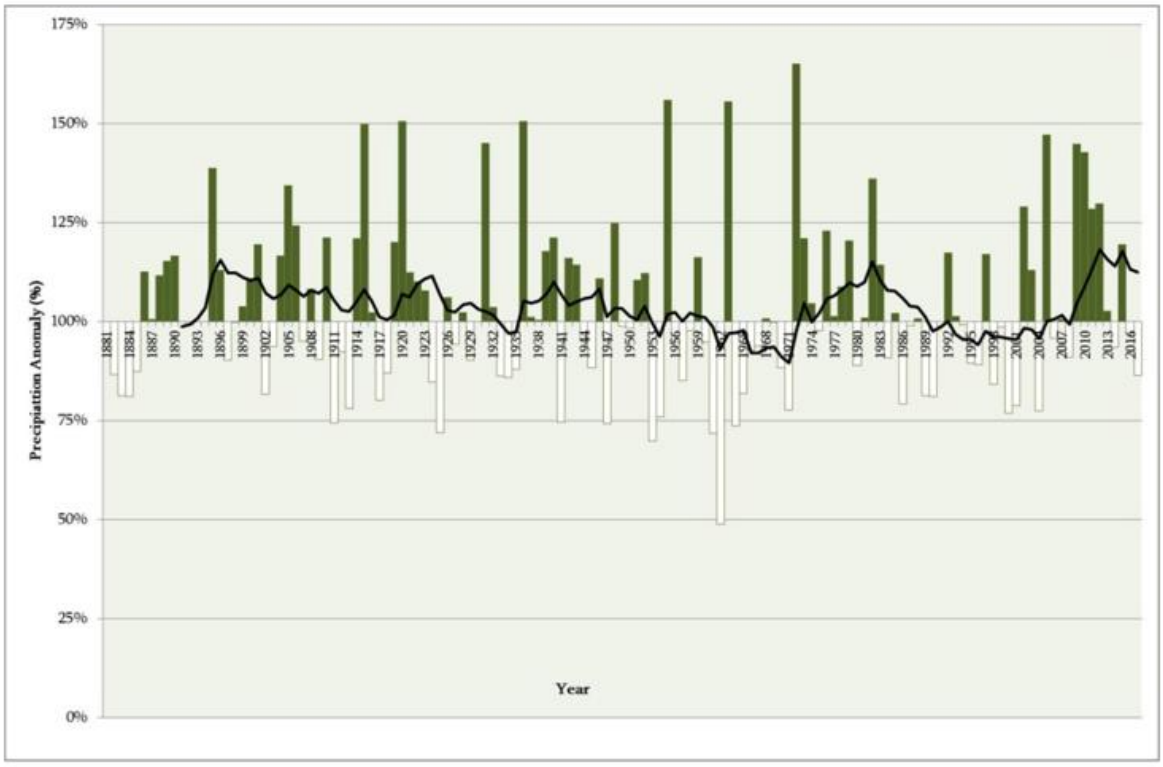

Figure 5.55: Time series of annual precipitation totals in relation to the mean of 1961-1990 for Tbilisi, Georgia (Diagram as provided by the NHMS)

Middle East - precipitation anomalies

Israel

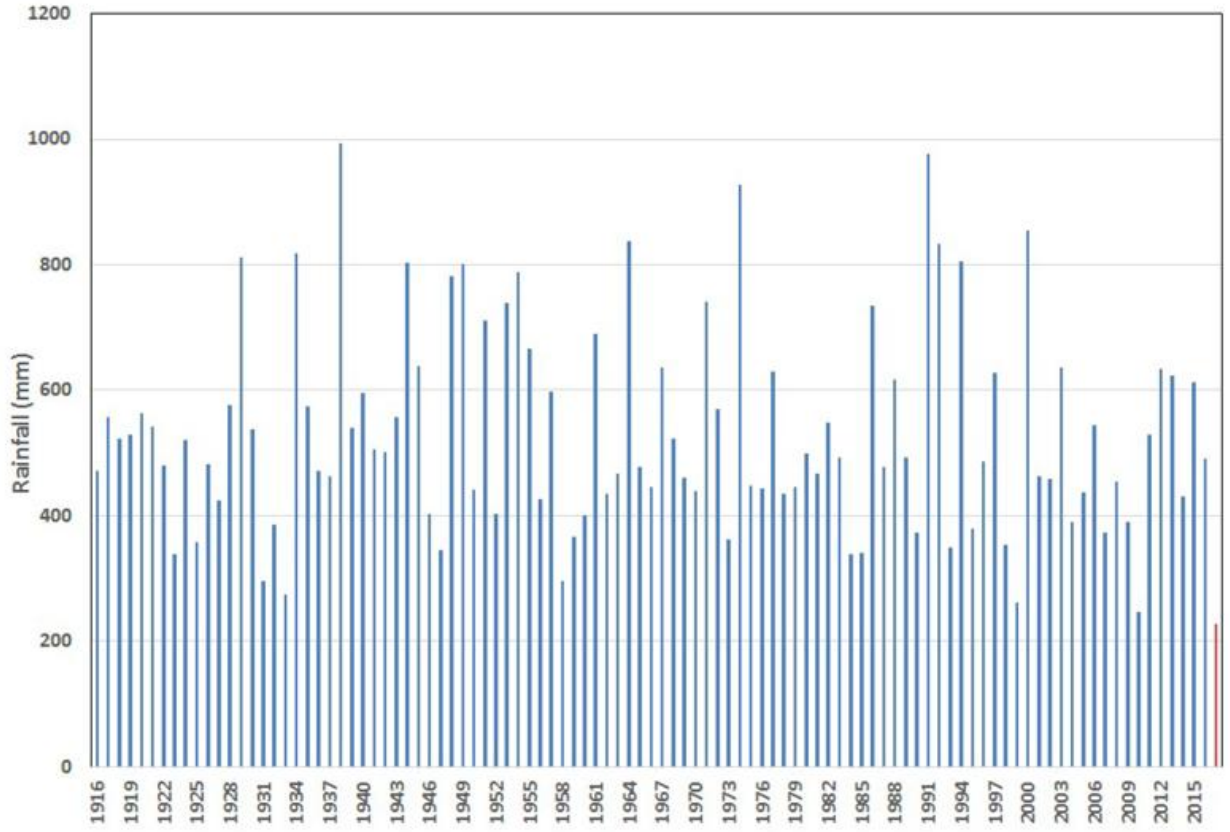

Figure 5.56: Yearly rainfall amounts (mm) in Miqwe Yisrael (Central Coastal Plain) 1916-2017 (diagram as provided by the NHMS)

5.3. Sunshine duration

Central and Western Europe - sunshine duration anomalies

Germany, Switzerland, United Kingdom

Germany

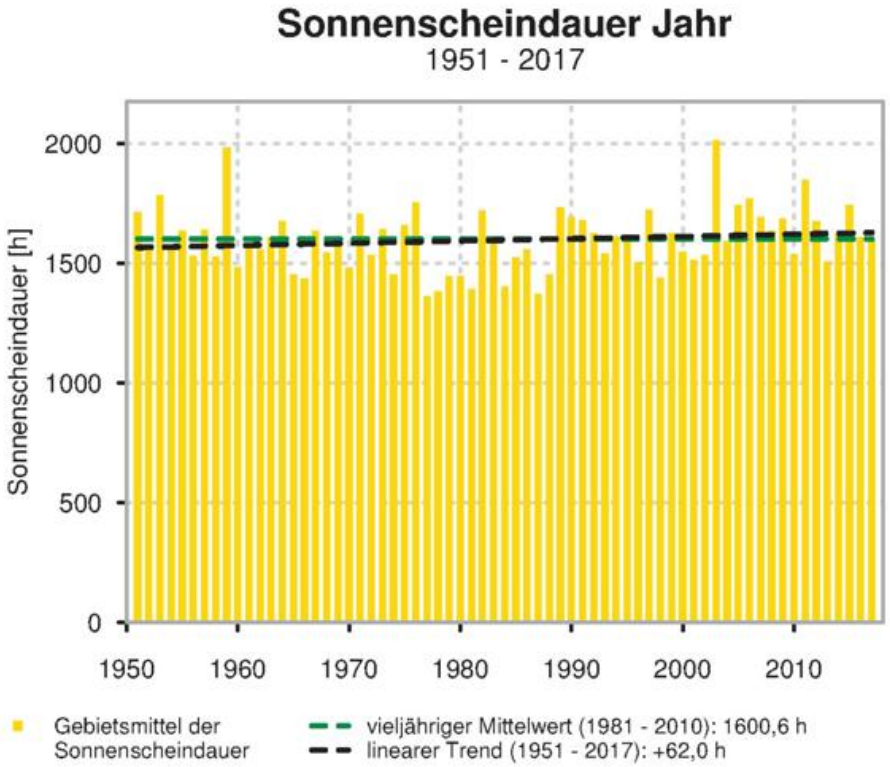

Figure 5.57: Time series of annual sum of the sunshine duration in hours for Germany (green line: long term mean; diagram as provided by the NHMS)

Switzerland

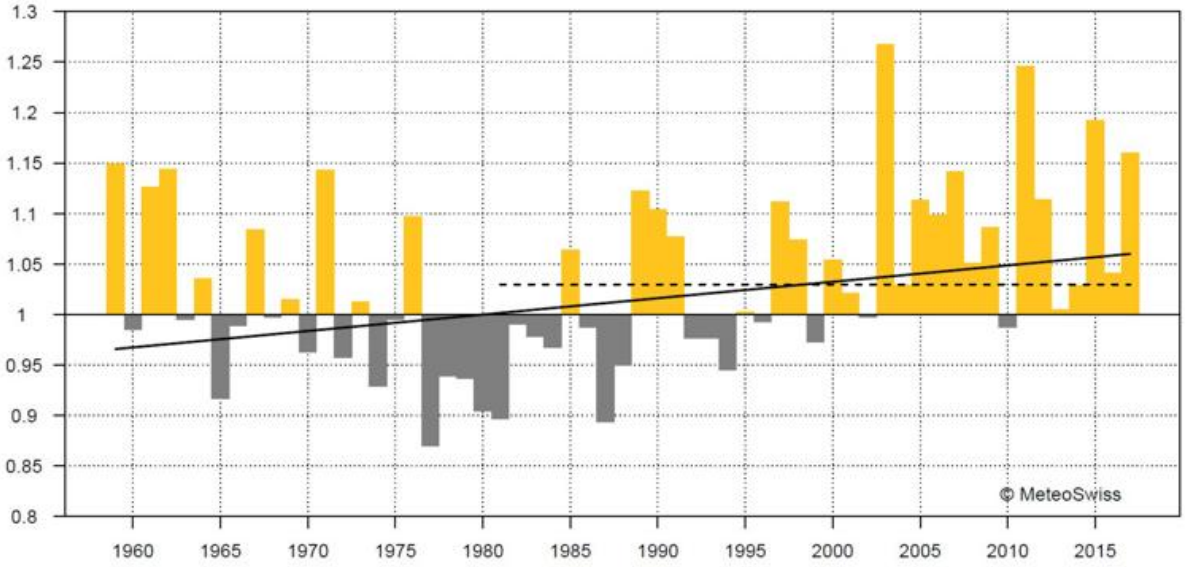

Figure 5.58: Time series of the yearly sunshine duration [ratio] for Switzerland 1959–2017. Color bars represent anomalies in respect to the long-term mean 1961–1990 and yellow indicates positive and grey negative anomalies. The black line represents the linear significant trend (1.48 %/10y). The black dashed line represents the mean 1981–2010 (diagram as provided by MeteoSwiss).

Central and Western Europe - sunshine duration anomalies

United Kingdom

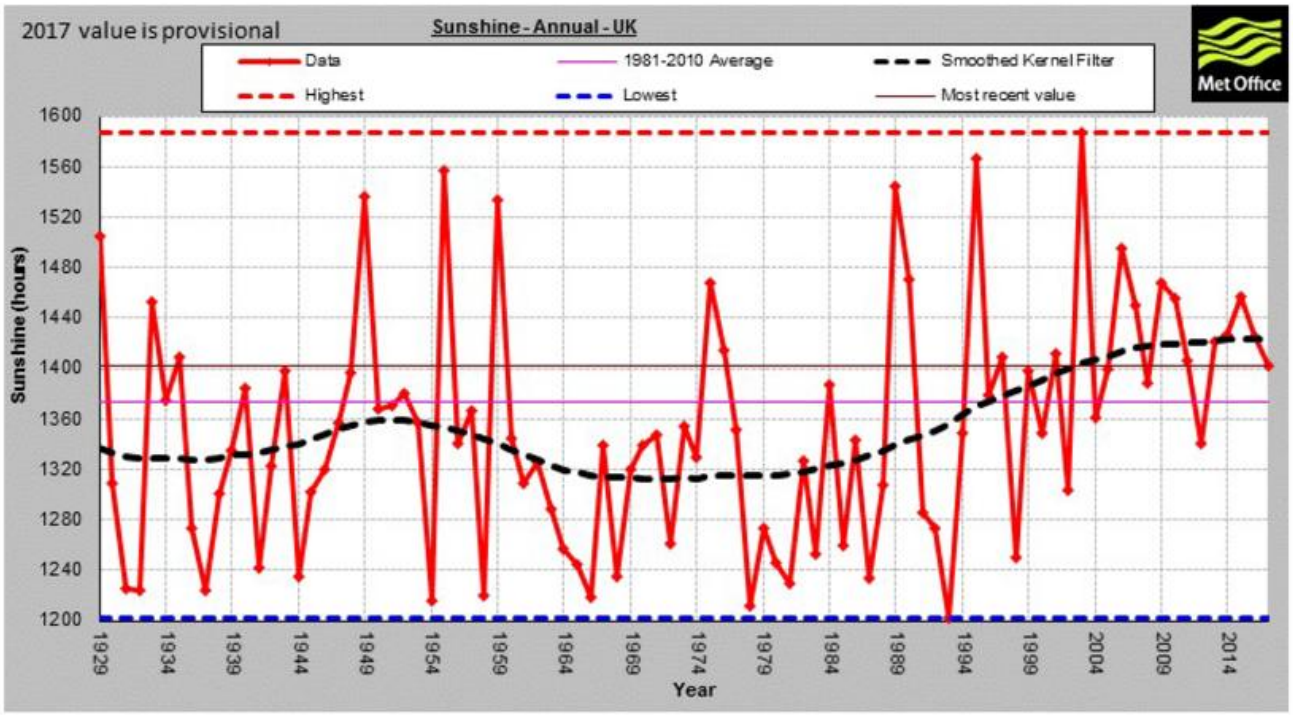

Figure 5.59: Time series of annual sum of the sunshine duration in hours for United Kingdom (Diagram as provided by the NHMS)

Nordic and Baltic Countries - sunshine duration

Denmark

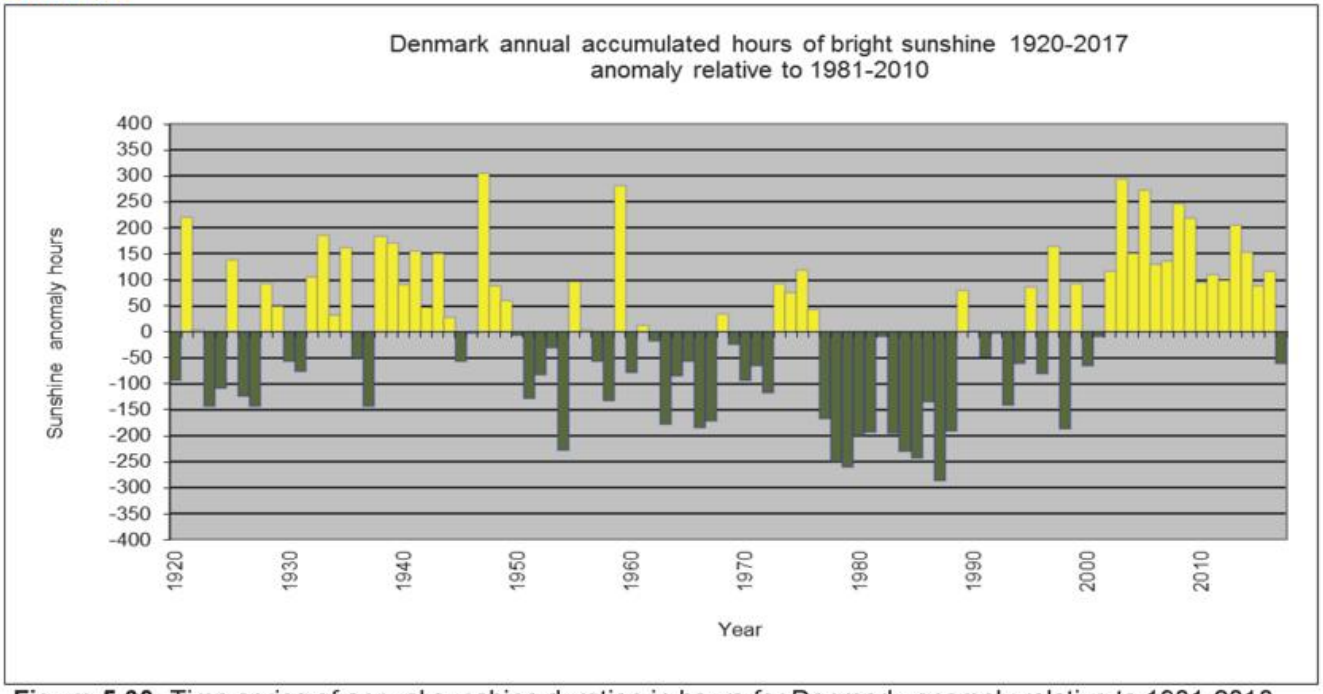

Figure 5.60: Time series of annual sunshine duration in hours for Denmark: anomaly relative to 1981-2010. The values are calculated national average based on a number of selected stations. (Diagram as provided by the NHMS)

Note: *OBS! DMI has since 2002 observed the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. I should also be noted that all values before 2002 are adjusted ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990.*
http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf
Data up to 2016 are published in DMI report series, No. 17-02 John Cappelen (ed) (2017): Denmark - DMI Historical Climate Data Collection 1768-2016.
http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2017/DMIRep17-02.pdf (report)
http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2017/DMIRep17-02.zip (data)

Estonia

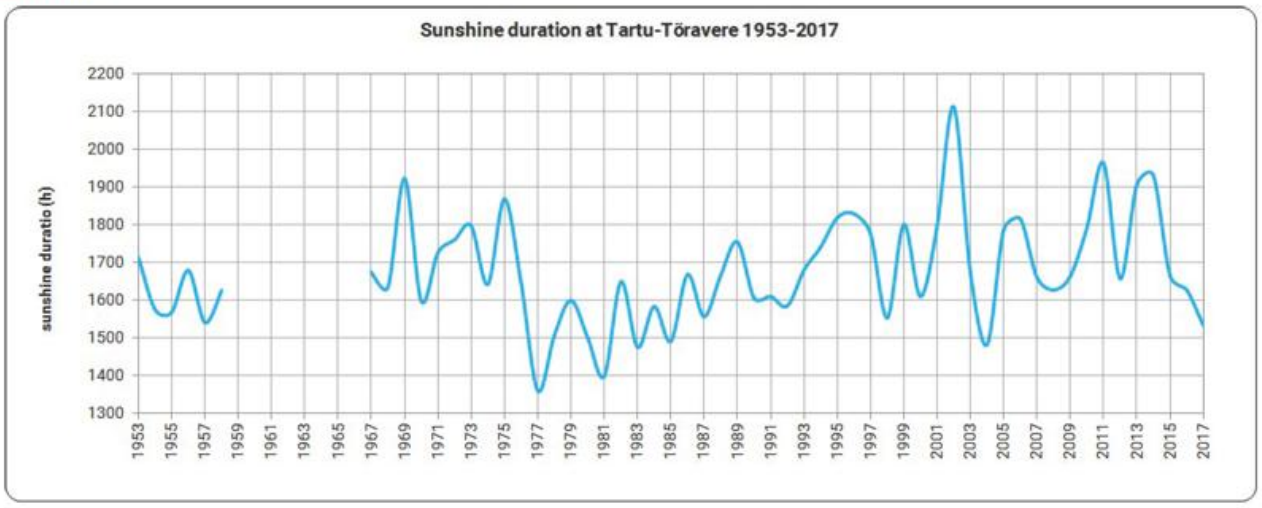

Figure 5.61: Time series of annual sunshine duration in hours for Estonia (station Tartu-Töravere, diagram as provided by the NHMS)

Eastern Europe - sunshine duration

European Russia

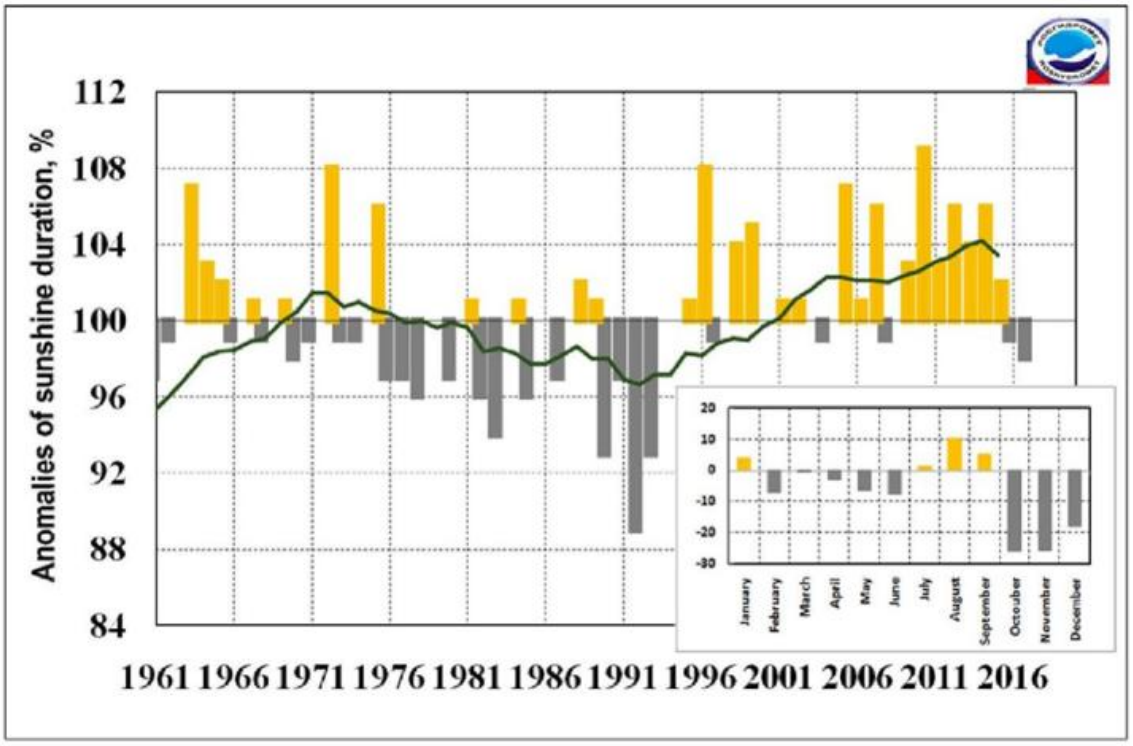

Figure 5.62: Time series of annual sunshine duration in relation to the mean of 1981-2010 for European Russia (Insets show the anomalies of monthly sunshine duration in 2017; Diagram as provided by the NHMS)

6. Annex: Monthly and annual tables

Table 6.1: Statistical values of **annual** mean temperature and total precipitation and their deviations from the long term mean (1961-1990, CLIMAT Data) for several stations of the RA VI region.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 50 Members) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official Websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Global Climate and the State of the Climate published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ among the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the Webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes 4 parts: the annual, seasonal and monthly survey of the climate state in 2018 as well as contributions of the NMHSs to the long-term variability of selected parameters up to 2018 (section 5).

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collecting Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), operated by the Deutscher Wetterdienst
- Sunshine: Meteosat Satellite data (new in 2018).
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

The following sub-regions are used in this bulletin:

Central and western Europe (14 countries): *Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, and United Kingdom*

Nordic and Baltic Region (9 countries/territories): *Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, and Sweden*

Iberia (2 countries): *Portugal, and Spain*

Mediterranean, Italian and Balkan Peninsula (12 countries): *Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Montenegro, North Macedonia, Serbia, Slovenia, and Turkey*

Eastern Europe (5 countries): *Belarus, European Russia, Moldova, Romania, and Ukraine*

Middle East (9 countries): *Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, and Western Kazakhstan*

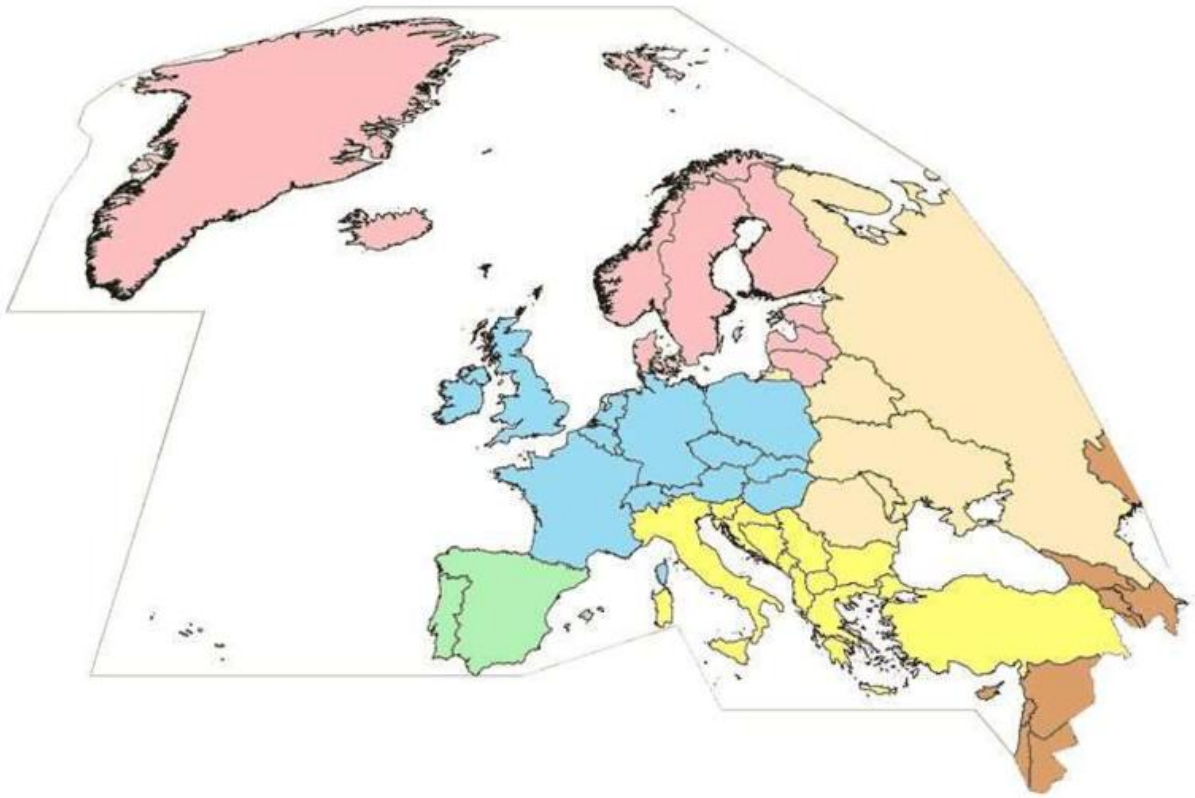

Figure 1-1: Definitions of the 6 sub-regions used in this bulletin.

Box 1 | The climate in 2018 - overview

Anomalies

Temperature

- Warmer-than-normal conditions over the entire RA VI region with an annual mean temperature of +1.25°C above normal for Europe as a whole and largest anomalies occurring over the Arctic region, Central Europe, Finland and the Eastern Mediterranean region with annual mean temperatures of +2°C above normal (w.r.t. 1961-1990), all seasons were warmer than normal

Precipitation

- Drier-than-normal conditions over large parts of the RA VI especially over central and northern Europe with annual precipitation amounts lower than the 10th percentile (w.r.t. 1951-2010) due to an extended period of drought caused by blocked weather patterns

Sunshine Duration

- Sunnier-than-normal conditions over large parts of the RA VI region with anomalies of 105 - 125% (corresponding to 200 -500 hours)

Events:

- several cold spells during February and March in central, northern and eastern Europe making these two months the only ones in 2018 with below-normal temperatures
- Parts of southern Europe experienced a very wet spring with precipitation sums exceptionally above average (> 90th percentile)
- Intense warm period from spring till end of summer over most of the RA VI region, especially over central Europe with temperature anomalies between +2°C and +4°C for the spring and summer season and many new country records set on the monthly scale

2. Annual survey

The climate of 2018 was characterised by a broad range of spatial and temporal anomalies outlined in Box 1 and Figure 2-5. This section presents an overview of the spatial patterns of mean annual climate conditions in 2018 and anomalies related mainly to the normal period 1961-1990 of the selected climate variables: sea level pressure, surface air temperature, precipitation, sunshine duration and snow. Sub-section 2.1.4 reveals climate extremes for individual countries. Long-term trends in temperature and precipitation indices are presented in section 2.2. Section 3 and 4 present the seasonal and monthly patterns and statistics for selected climate variables including also reports from individual countries. More insight into the long-term variability of temperature, precipitation and sunshine duration for the individual countries are given in section 5.

2.1. *Annual averages and anomalies of selected essential climate variables*

2.1.1. Sea level pressure

Generally, mean annual sea level pressure distribution in 2018 over the WMO Region VI was dominated on one hand by low pressure in the polar region with the minimum pressure extending from southern Greenland to Iceland. On the other hand, there was a high pressure belt with maximum pressure in the area of the Azores (Azores High) extending further across southern and central Europe till Russia.

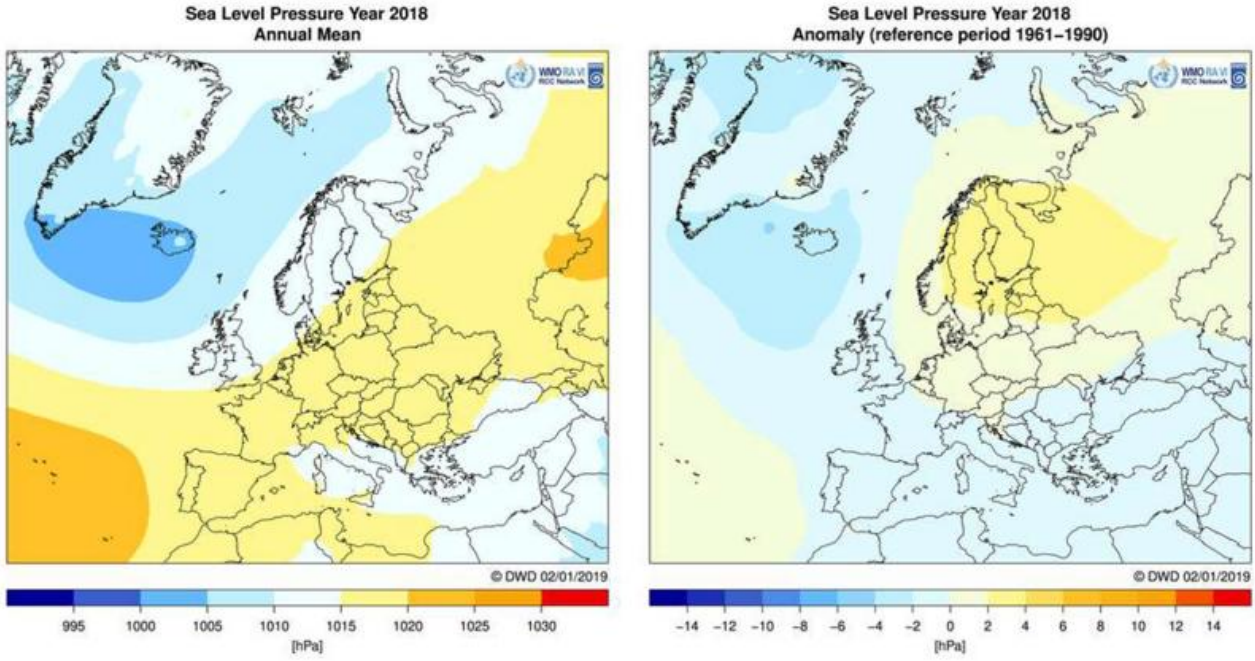

Figure 2-1: Annual mean of sea level pressure (left) and anomalies (right) in hPa for the year 2018 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

The mean sea surface pressure in 2018 differs to some extent from the long-term mean with a reduced pressure in the polar regions and over southern parts of Europe and the Mediterranean Sea

with anomalies generally between 0 to -2hPa as can be seen from Figure 2-1 (right; normal period 1961-1990). Higher-than-normal pressure occurred especially over Central, Northern and Eastern Europe with largest anomalies of +2 to +4hPa over Scandinavia and North-eastern Russia.

2.1.2. Temperature

In 2018, mean annual temperatures were higher than normal (w.r.t. 1961-1990) over the whole RA VI region. Temperature anomalies varied mostly between +1°C and +3°C. Over the European continent largest anomalies occurred over central Europe and eastern Europe as well as over Finland, Turkey and the Middle East with anomalies between +2 to +3°C. Even larger anomalies with values greater than +3°C occurred over the arctic region. These are also documented by several arctic stations located for example on the Norwegian Svalbard archipelago in the Arctic Ocean (see Table 2-1). Largest anomalies were recorded at Svalbard airport with a mean annual temperature of -1.8 °C which is 4.9 °C above the normal and at Hopen with a mean annual temperature of -1.4 °C, which is 5.0 °C above the normal. With these anomalies the year 2018 finished 3rd warmest for Svalbard airport (only 2016 and 2006 were warmer) and 4th warmest for Hopen (2016, 2012 and 2006 were warmer). End of 2018 Svalbard airport had seen 97 consecutive months with above-normal temperatures. Ny-Ålesund and Jan Mayen even recorded the second warmest year since the measurements started in 1972 and 1921, respectively, surpassed only by 2016.

For the European region as a whole, 2018 was one of the two warmest years since at least 1950 considering the E-OBS (Haylock et al. 2008; van der Schrier et al. 2013; Figure 2-3) and the Global Historical Climate Network (GHCN) v3.3.0 datasets (Menne et al. 2012; Bissolli 2019) with an overall anomaly (with respect to the base period 1981-2010) of +1.25°C (E-OBS) and +1.1°C (GHCN). Many countries reported new records (Table 2-2). In Germany, anomalies of +3°C and more with respect to the long-term mean were registered for six months. All seasons were warmer than normal which contributed to 2018 finishing as warmest year since beginning of the measurements in 1881 with an anomaly of +2.2°C w.r.t 1961-1990 (+1.6°C w.r.t. 1981-2010). Besides Germany, also Austria, Czech Republic, France, Hungary, Italy, Luxembourg, Poland, Serbia and Switzerland reported 2018 as their warmest year on record (**Table 2-2**). For many other countries, 2018 finished among the five warmest years on record (see **Table 2-2**).

Globally, 2018 was the fourth warmest year on record (WMO 2019; Blunden and Arndt 2019) with an average global temperature 0.30°–0.40°C above the 1981–2010 average according to four independently constructed in-situ analyses (Sánchez-Lugo et al. 2019) and approximately 1°C above pre-industrial levels (WMO 2019). The 2018 Arctic land surface temperature was 1.2°C above the 1981–2010 average, tying for third highest in the 118-year record, following 2016 and 2017.

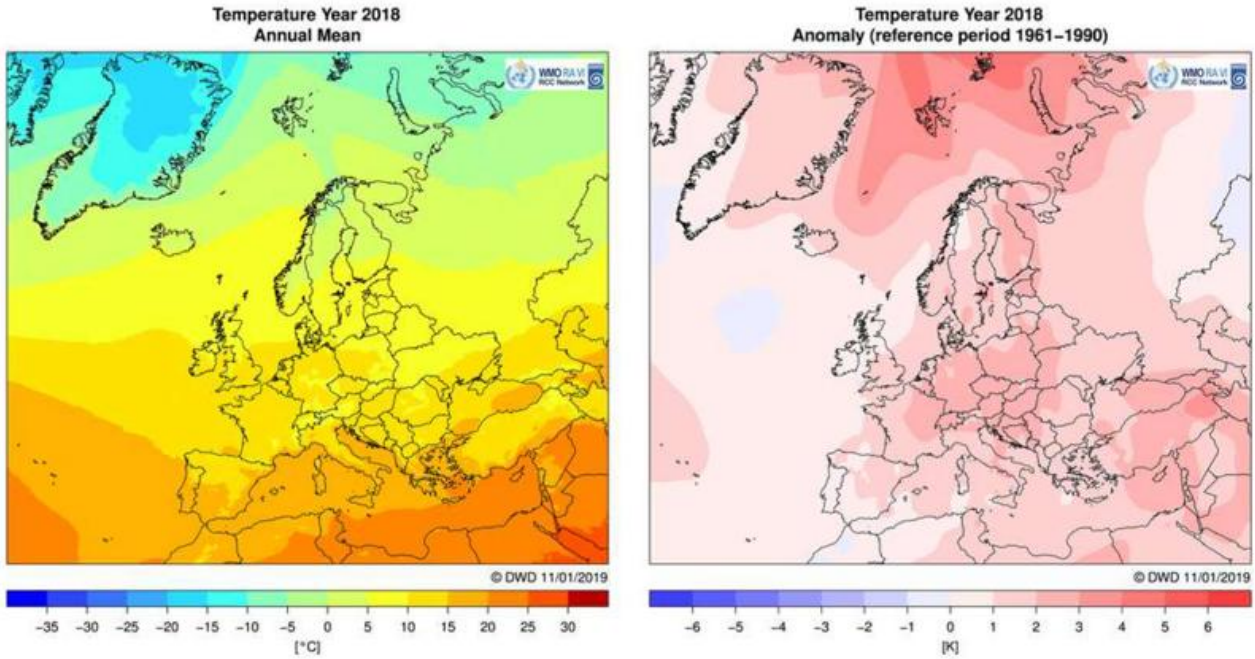

Figure 2-2: Mean annual temperature in °C (left) and anomalies (right) for 2018 (reference period 1961-1990, source: http://www.dwd.de/rcc-cm).

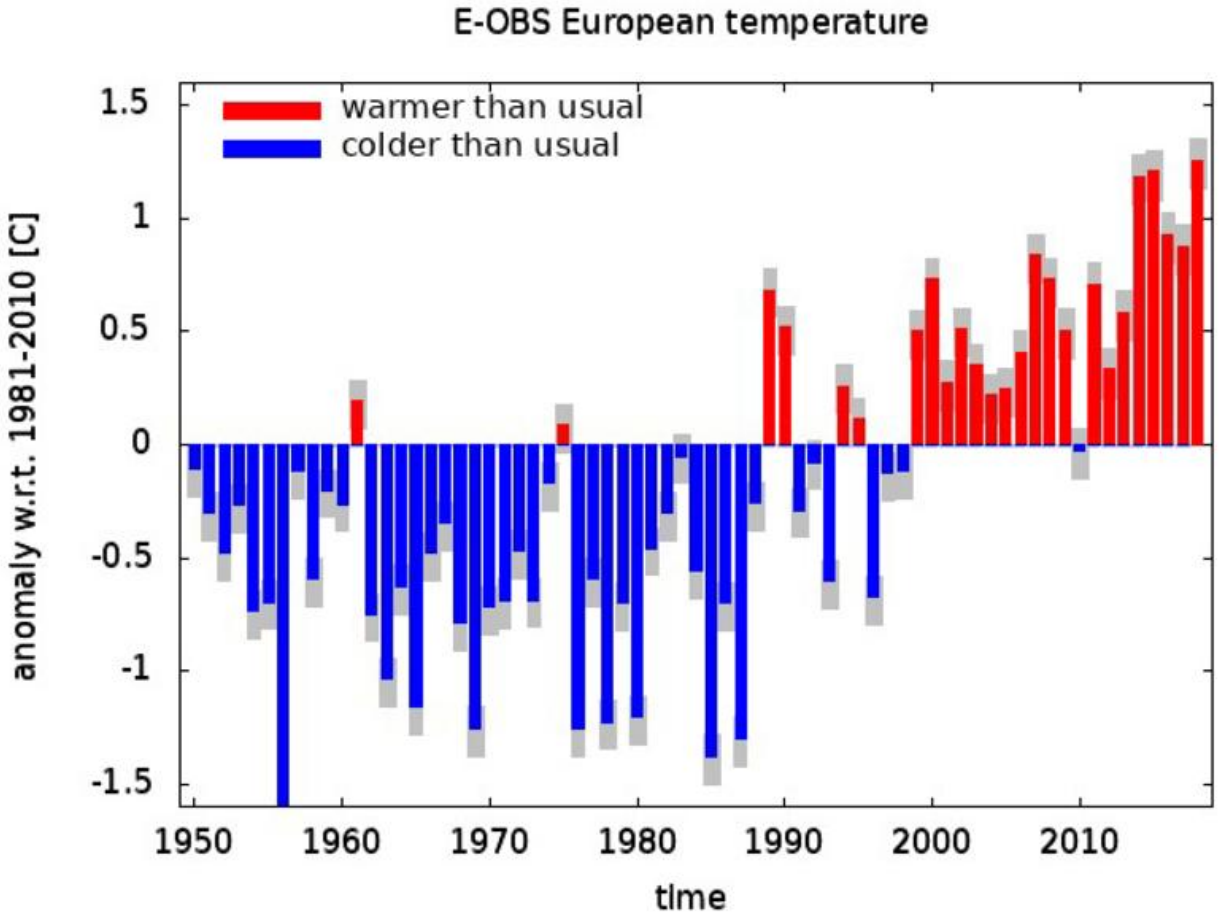

Figure 2-3: Annual temperature anomalies 1950-2018 for Europe (land area; 34°N-71°N and 25°W-40°E, reference period 1981–2010; based on the E-OBS dataset). (Source: Royal National Meteorological Institute Netherlands, KNMI).

Table 2-1 Rank statistics and anomalies of annual temperature in 2018 for the Arctic stations as reported by the Norwegian Meteorological Institute..

Station name	Rank of annual temperature in 2018	Mean annual temperature in 2018	Anomaly in °C	start of time series
Svalbard airport	3	-1.8 °C	+ 4.9 °C	1975
Hopen (Svalbard)	4	-1.4 °C	+5,0 °C	1945
Ny-Ålesund (Svalbard)	2	-2.1 °C	+4.3 °C	1972
Bjørnøya (Svalbard)	3	1.0 °C	+3.4 °C	1910
Jan Mayen	2	2,0 °C	+3,4 °C	1921

Table 2-2: Rank statistics and anomalies of annual temperature in 2018 from some participant countries as reported by the National Meteorological and Hydrological Services (NMHSs) including countries with rankings among the top 5 (*ranks 1–5*) since start of the to time series. Information about all-time temperature records as provided by the individual NMHSs can be found here: https://rcccm.dwd.de/DWD-RCCCM/EN/products/significant/records/download_tabelle.html?nn=500100?

Country	Rank	Annual Anomaly [°C] (1961-1990)	Annual Anomaly [°C] 1981-2010	start of time series

[1] Anomaly value refers to reference period 1960-2018

2.1.3. Precipitation

Precipitation patterns in 2018 show near-normal conditions over large parts of the RA VI region. Exceptionally dry conditions (< 10th percentile) were observed, however, over central Europe, the Baltic region, southern Finland and Sweden as well as over the European part of Russia and Kazakhstan with precipitation totals 60% - 80% of normal, and even below 60% in Latvia and Estonia. Most of the Mediterranean region, however, received above-normal precipitation (100%-167%), with parts of Spain, Sardinia, the Balkan peninsula, Turkey and Syria receiving exceptionally above average amounts (>90th percentile).

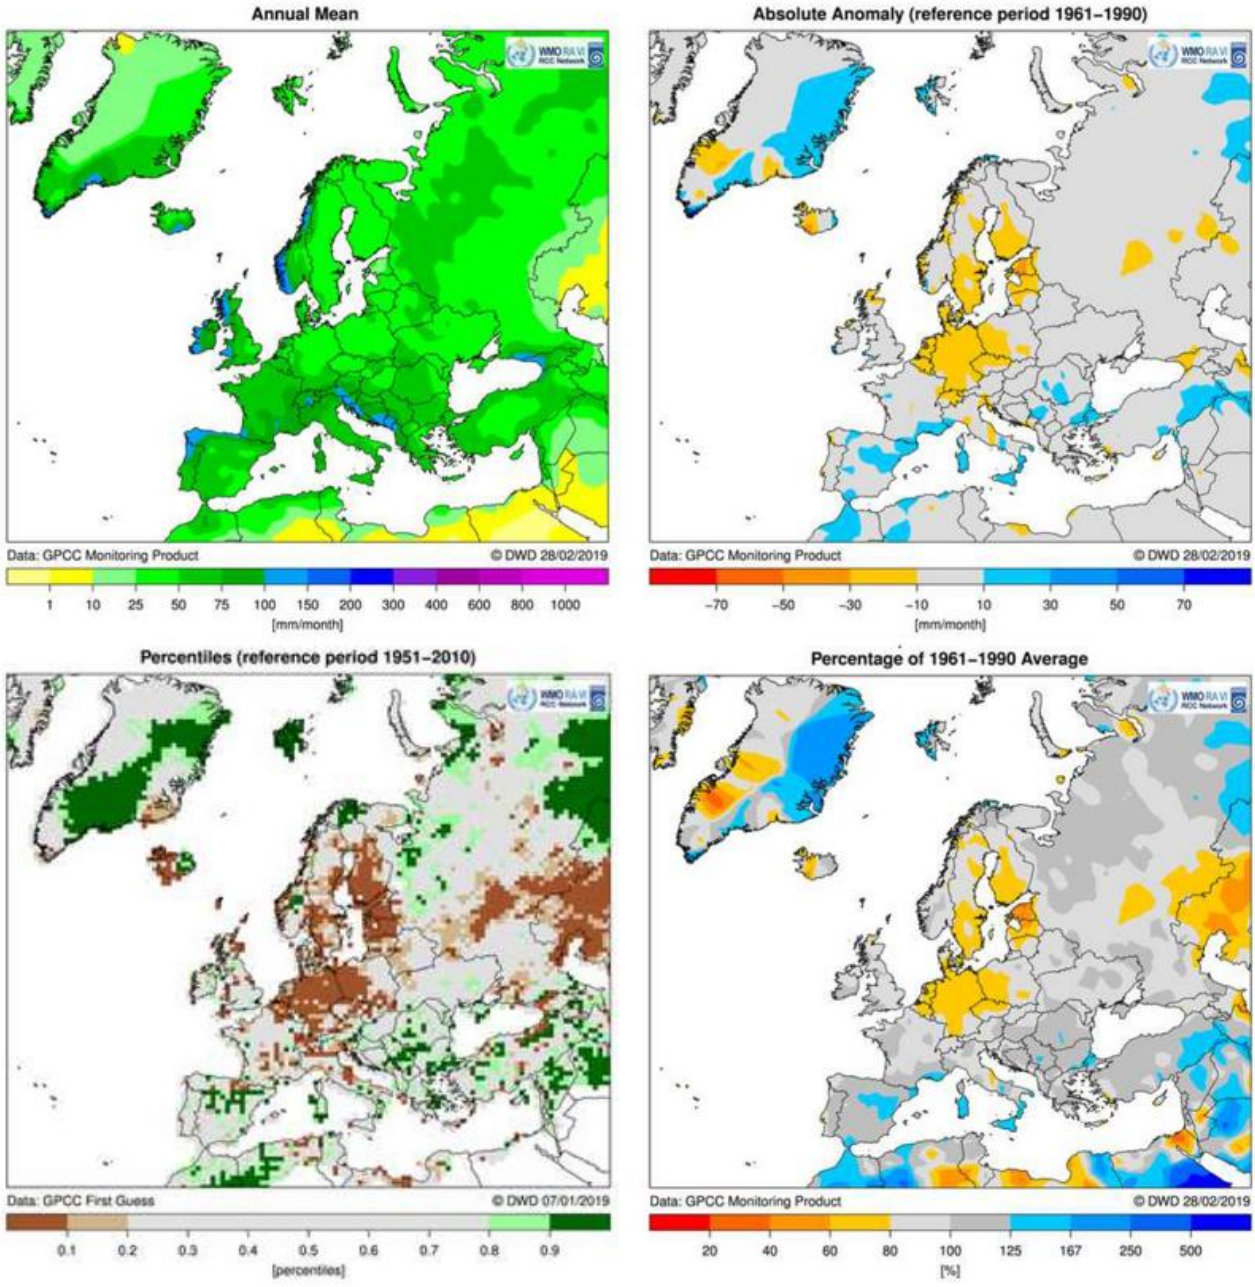

Figure 2-4: Total precipitation (left, top), anomalies (right, top) in mm/month, percentiles (left, bottom) and percentage of precipitation in % (right, bottom, reference period 1951-2010) for 2018 (reference period 1961-1990; source: http://www.dwd.de/rcc-cm).

2.1.4. Annual extreme values of temperature and precipitation

In this section, an overview is given for the temperature spread and the extreme precipitation for each country. Absolute annual extreme values for 2018 of temperature (minimum and maximum), maximum of total daily precipitation and maximum of total 5 consecutive days with precipitation for each country in the WMO Region VI are given in Figure 2-5.

The spatial pattern of extreme temperature corresponds roughly to those of the temperature anomalies of 2018. The highest maximum temperatures (above 40°C) occurred primarily in sub-regions Middle East, Iberia and Mediterranean, Italian and Balkan Peninsula. For most countries maximum temperatures are above 30°C except for Iceland (IS: 24.7°C) and Faroe Islands (FO: 16.6°C). The lowest recorded minimum temperatures occurred in Italy (IT: -48.9°C), Norway (NO: −42.0°C) and Sweden (SE: −40.4°C).

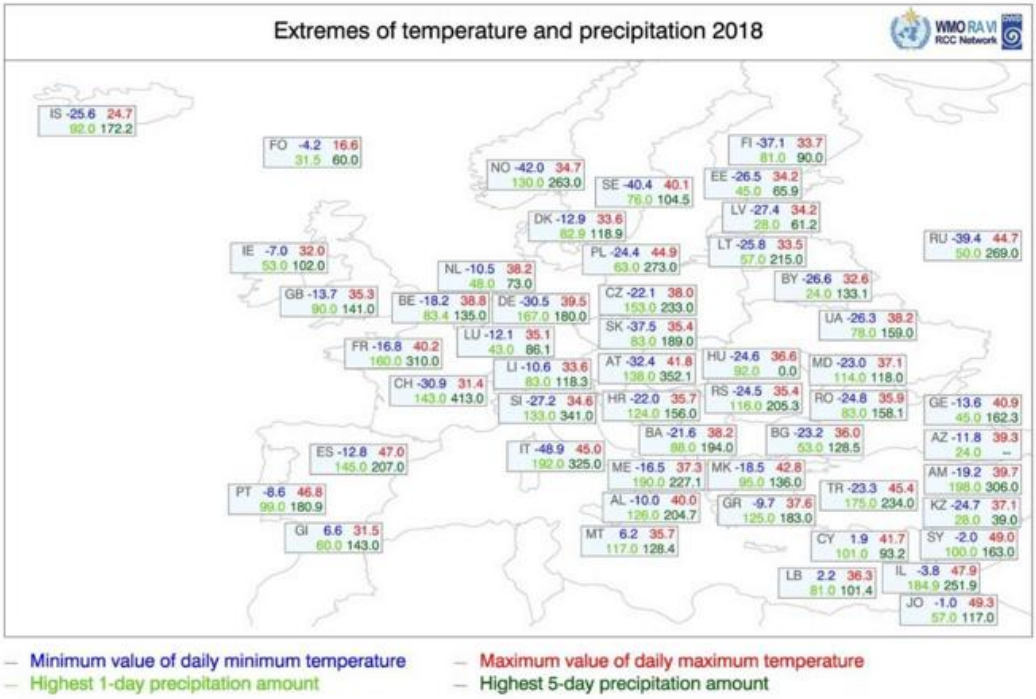

Figure 2-5: Annual extreme values for each country in 2018: first row: ISO 3166 country code (https://en.wikipedia.org/wiki/List_of_ISO_3166_country_codes), lowest daily minimum temperature (in °C, blue) and highest daily maximum temperature (in °C, red); second row: maximum daily precipitation totals (in mm, light green) and maximum 5-daily consecutive precipitation totals (in mm, dark green).

Note: Data (by order or priority) from reports of NMHSs, GPCC, ECA&D or SYNOP; the countries are represented by their ISO 3166 country codes. (Source: http://www.dwd.de/rcc-cm)

The one-day precipitation totals of more than 150 mm for individual countries are documented in several sub-regions; the highest value occurred in Armenia (AM) with 198mm. Highest total precipitation on 5 consecutive days (above 300 mm) was measured in Armenia (AM, 306mm), Italy (IT, 325mm), Slovenia (SI, 341mm), Austria (AT, 352.1mm) and Switzerland (CH, 413mm).

2.1.5. Sunshine duration

Most parts of the RA VI region experienced a surplus of sunshine hours in 2018 (see Figure 2-6). Especially in Central, Northern and Eastern Europe it was exceptionally more sunny than normal (> 90th percentile) with 200 to 500 hours (in relative terms up to 125%) more sunshine hours. Over the Iberian Peninsula, Italy and in the Middle East it was less sunny than normal with deficits mostly in the range of up to 200 hours which corresponds to deficits of up to 25% in relative terms.

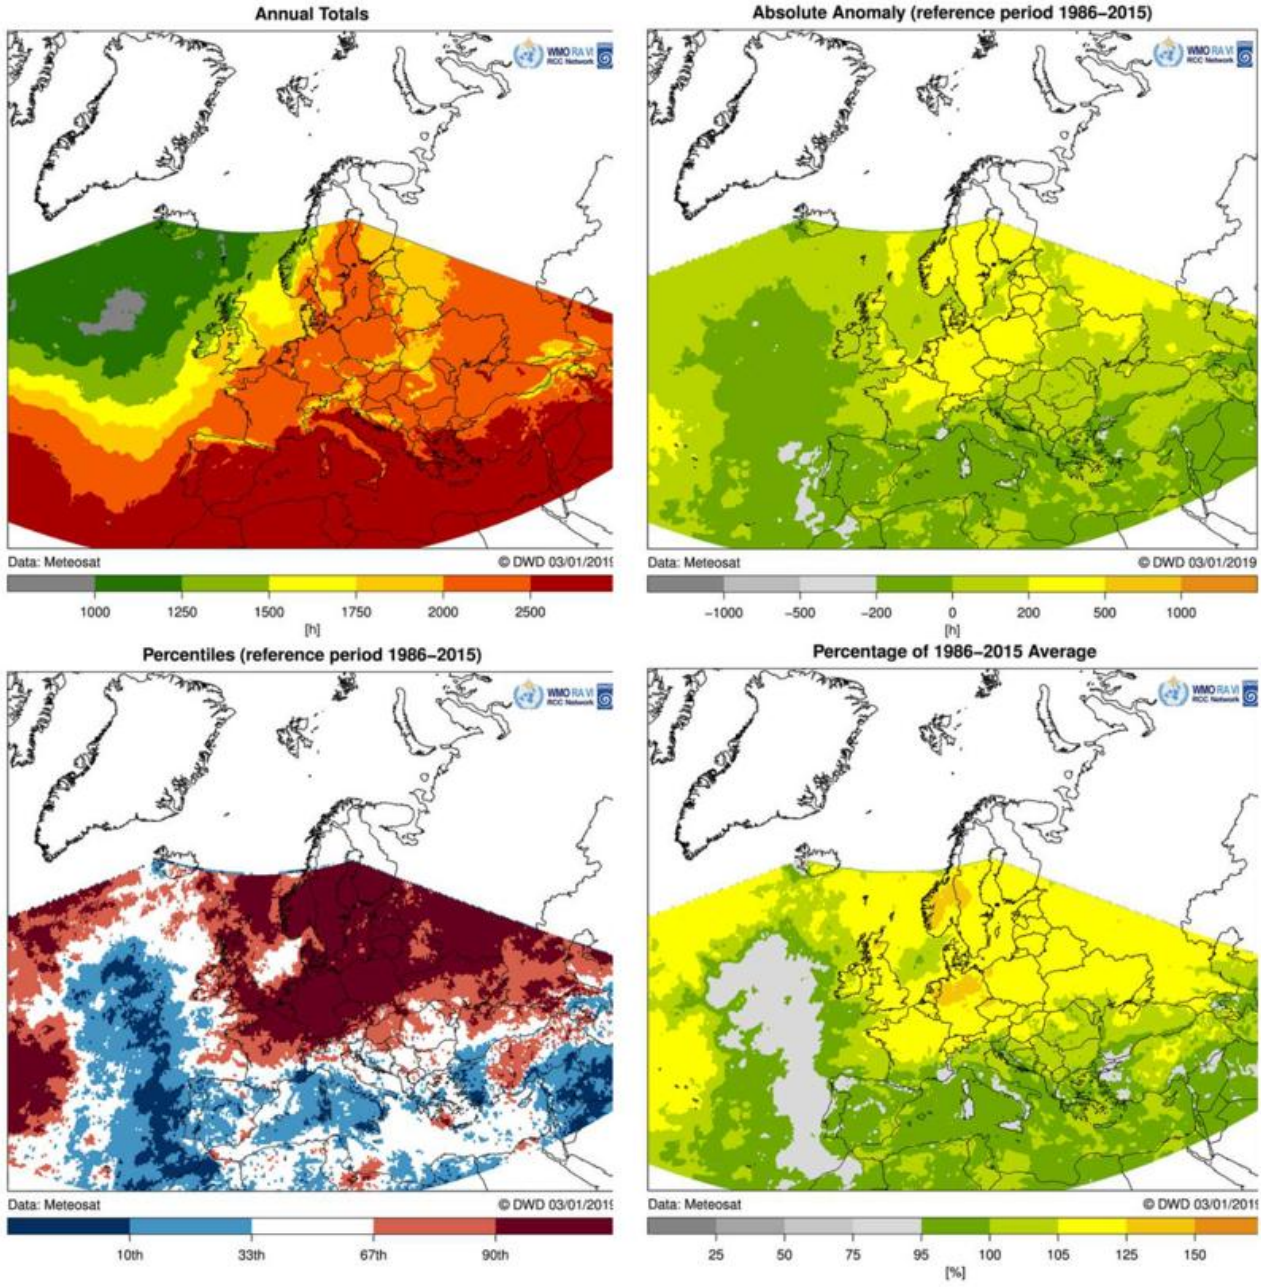

Figure 2-6: Annual sum of sunshine duration (upper left) as well as absolute anomalies (upper right), percentiles (lower left) and percentages of the long-term mean (lower right) with respect to the reference period 1986-2015 for the year 2018. (Source: http://www.dwd.de/rcc-cm).

In Denmark, 2018 was the sunniest year on record with 1905 hours (compared to 1574 hours on average, reference period 1981-2010), thus over 300 hours more (appr. 21% more). In Germany, 2018 was the sunniest year since 1951 with a surplus of 471 (415) hours or 30.5% (26%) with respect

to the 1981-2010 (1961-1990) mean. Several Swedish stations reported new records for annual sunshine duration. The absolute Swedish record for sunshine was also beaten when Svenska Högarna registered 2407 sun hours in 2018. Second place Hoburg came with 2365 hours. In 2015, 2343 hours of sunshine were registered at Hoburg on Gotland. In the Netherlands, with a spatial mean of 2090 sunshine hours, the number of sunshine hours was very close to those in 2003, which is the most sunny year so far with 2099 sunshine hours. In Luxembourg, the year 2018 was also sunnier than average and finished third sunniest on record (after 1959 and 2003). In the UK, the sunshine total for 2018 was 1581 hours, which is 115% of the 1981-2010 average making this the second sunniest year for the UK in a series from 1929, with only 2003 sunnier. East Anglia had its sunniest year on record. In Iceland on the contrary, there was exceptionally little sunshine in the southwest part of the country. The number of sunshine hours in Reykjavik was 1162.8 during 2018, 106 below the 1961 to 1990 mean and lowest number since 1992.

2.1.6. Drought situation

Many countries experience exceptional weather conditions in 2018, with record-breaking warmth and precipitation deficits. As a consequence, prolonged drought periods classified as exceptional or even unprecedented, were observed over several parts of the RA VI region during 2018, especially over Central Europe where the drought period lasted longest, generally from April to November (Germany, Poland, Switzerland, Austria). Drought periods of up to 3 months were observed over Scandinavia and the Baltic countries, Ireland, Belgium and on the Balkan peninsula (e.g. Slovenia, Bulgaria) from May/June to July/August and from August to October over Bulgaria.

In Germany, due an extremely dry period from February to November, the total annual rainfall reached with 586mm only 72% (1981-2010) or 74% (1961-1990) respectively of the long-term average, which corresponds to a deficit of 232 and 202 mm respectively. For Germany, 2018 ended up as the 4th driest year since 1881. In Poland, unprecedented drought conditions lasting from mid-April to early September affected the entire country and at least 15% of arable land resulting in a yield reduction of at least 20% compared to those obtained under average weather conditions. The total annual rainfall reached only 82% of the climate norm (1981-2010). For Latvia, 2018 was even the driest year since 1924. The total annual rainfall in Latvia was 472.7 mm, 32% below the annual norm of 692.3 mm, outperforming the previous record of 484.3 mm in 1964. For Estonia the annual precipitation amount was 506 mm, only 75% of the annual norm (672 mm) – which corresponds to the 4th place in the list of driest years since 1961. Annual sum of precipitation in Lithuania totalled 564 mm and was lower (81 %) than the climatic norm (1981-2010 average of 694 mm).

When looking at the Global Precipitation Climatology Centre Drought Index (GPCC-DI, Ziese et al. 2014) as a metric for characterizing meteorological drought, the values for the year as a whole range mostly between -1 and +1 (see Figure 2-8). The regions with largest precipitation deficits (for example central Europe and Baltic countries, see also 2.1.3) appear here with values between 0 and -1 indicating mild drought conditions on annual average. Over parts of Kazakhstan and Estonia the drought situation is even classified as moderate drought with values up to -1.5. Many countries reported national or local low records of annual precipitation. In Sweden, Stockholm had its driest year since 1892 with only 345 mm. Växjö in Småland and Karlshamn in Blekinge received 414 mm and 402 mm in 2018, which are the lowest amounts since 1886 and 1874 respectively.

Box 2 | Contributions by NMHs - drought

Persistent dryness of top soils over the north-eastern part of France from August to November 2018 (Contribution provided by Météo France)

From August to October, the surface soils have dried up all over France, particularly over a large north-eastern quarter which has suffered an exceptional rainfall deficit since the end of the summer. Despite the passage of several disturbances over France since the end of October, the soils have remained extremely dry from Limousin and northern Auvergne - Rhône-Alpes to Franche-Comté and the Great East. Soil dryness, which has been a record since October in Alsace, Lorraine and Franche-Comté, continued in these regions until late autumn.

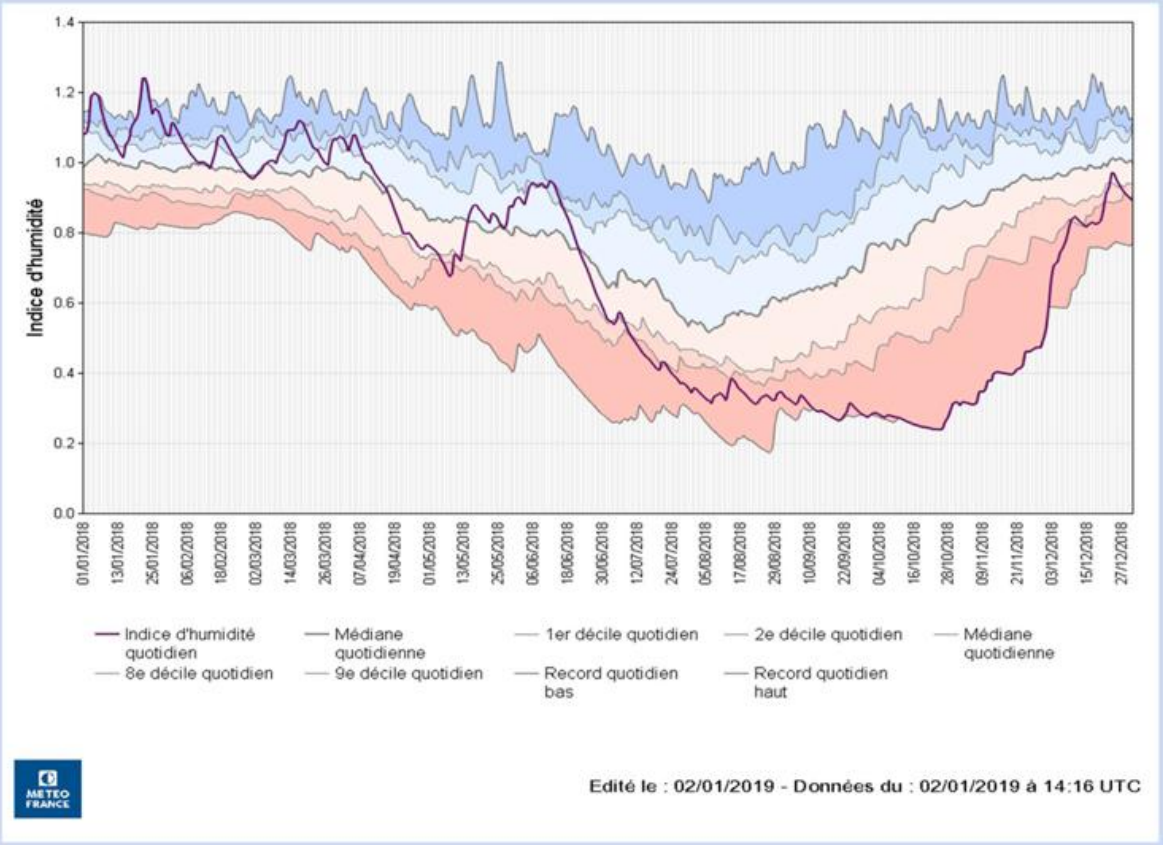

Figure 2-7: Aggregated soil moisture index for the period from 1 January until 31 December 2018 for the region Franche-Compté

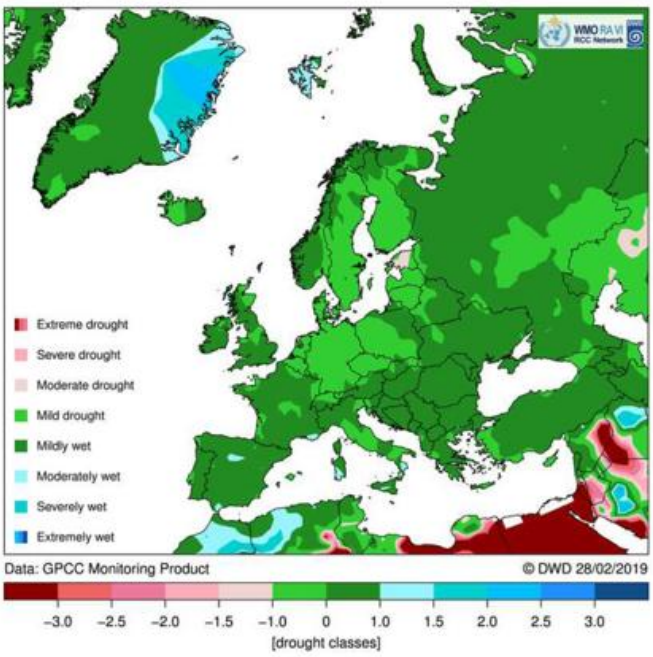

Figure 2-8: Annual GPCC –DI (GPCC-Drought Index) for the year 2018 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.7. Snow cover

The snow-season 2017/2018 (September 2017 – August 2018) was mostly warmer than normal, only February and March 2018 were significantly cooler (relative to 1961 -1990) over almost the entire RA VI region. Last snow in low land areas over central and western Europe and the Balkans occurred therefore mostly in March and resulted in rather long duration of snow cover as larger parts of western and central Europe already saw some first snow occurring in December, including even the UK, Ireland, Spain and Italy.

The rather large extent of snow cover in December was caused by a snow event taking place over parts of western- and central Europe between 9 and 12 December. In an area from the UK via the Netherlands into central Europe, 5 to 15 cm of fresh snow was reported in most places even in the lowlands. More than 30 cm was measured in Wales and in the Benelux Countries, with a maximum value of 43 cm recorded in parts of the Veluwe (eastern part of the Netherlands).

Throughout the month of January, several episodes of heavy rain and snow occurred over Western and Central Europe. These brought snow even to the lowlands not only in the UK but also in Central Europe. In the Alps these events led to several meters of fresh snow in large areas. In Davos at 1600 m altitude the amount of fresh snow reached in January 250 cm, the 4th highest snow accumulation for January since measurements started in 1931. Arosa reported even 285 cm of snow, the 5th largest snow accumulation for January since 1890. This resulted in a high to very high risk of avalanches in large parts of the Alps.

In February, two cold spells hit Central, Northern and Eastern Europe, which experienced almost 28 days (the entire month) with frost. These cold spells caused exceptional snow fall in large parts of Europe. In Ireland a major snow event occurred on 27 February and on the following 4 days, associated with Storm Emma. Observed snow depth estimates were up to 69 cm at Glenmacnass,

County Wicklow on Saturday 3 March 2018. Also the UK was hit by a spell of severe winter weather having occurred in late February and early March. Extreme precipitation fell also over central European Russia. The most severe situation was observed in the Moscow region, where snowfall persisted from February 3 to the night of February 5 and practically paralyzed city traffic and airports. More than monthly norm of precipitation (36 mm for February) was observed during that period at the meteorological station MOSKVA VDNH (55°50'N 37°37'E). In France, from February 5th to 7th, a remarkable snow episode in the region around Paris happened with a snow depth of 15 cm at Chartres and 12 cm at Paris on February 7th. During 26th and 27th of February, snowfall of 8-15 cm occurred in the Provence, on the Côte d'Azur and in Corsica. In Montenegro, due to the cold air from Siberia, snow cover was formed on February 26th in all regions of the country. Its maximum depth was in the range from 4 cm in Podgorica (southern central region) to 115 cm in Zabljak (mountainous region). In Iceland, snow covered the ground for 38 days in Reykjavík, 26 less than on the average 1971 to 2000. The snow cover in Reykjavík was quite heavy in January and February but March was completely without snow cover (for the first time since March 2005).

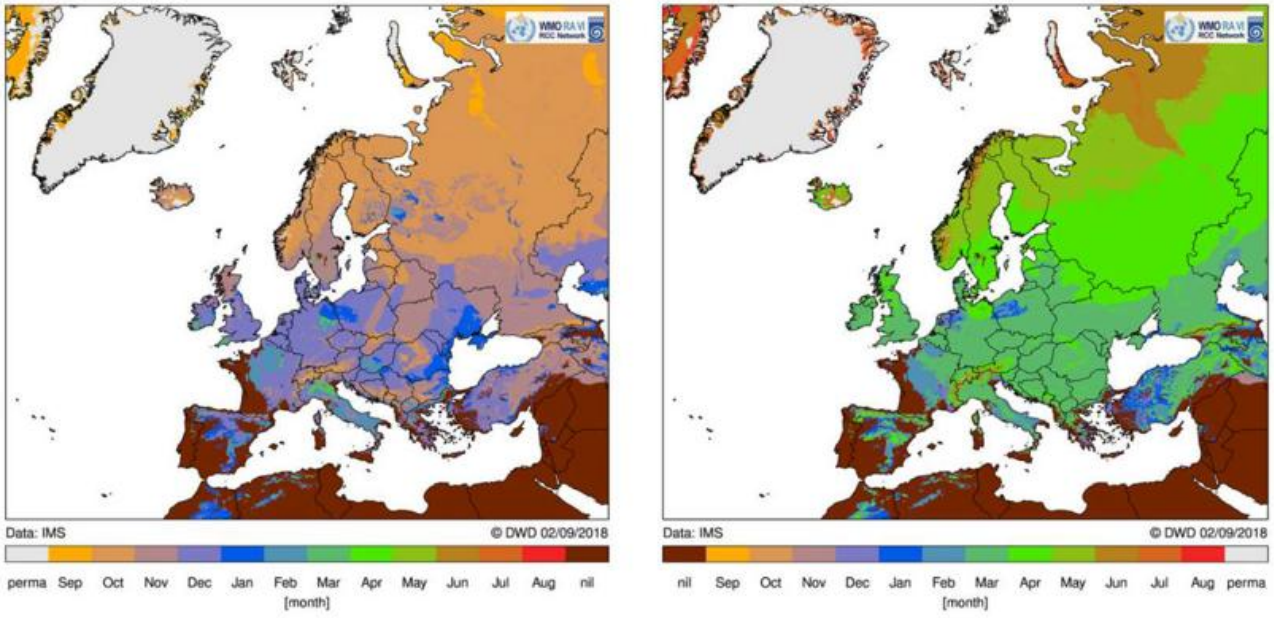

Figure 2-9: First occurrence of snow (left) and last occurrence of snow (right) during the snow season 2017/2018 from 09/2017 to 08/2018. (Source: http://www.dwd.de/rcc-cm).

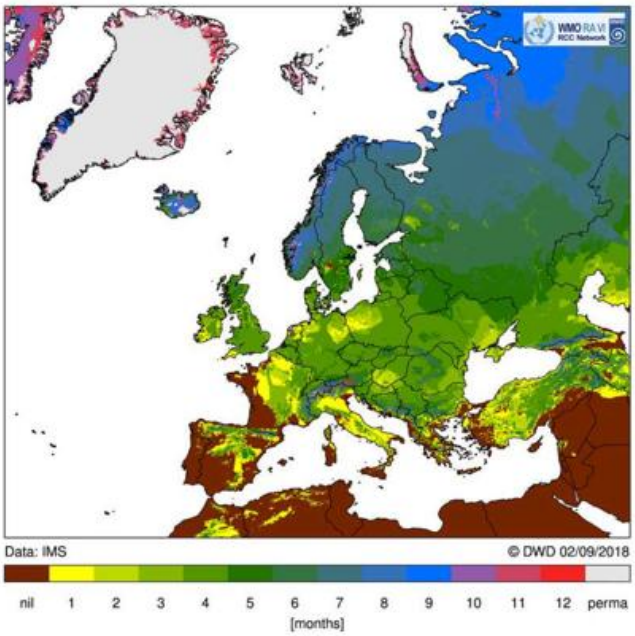

Figure 2-10: Duration of snow cover in the snow season 2017/2018 (from 09/2017 to 08/2018). (Source: http://www.dwd.de/rcc-cm).

2.2. *Selected climate indices for 2018*

This section presents selected temperature and precipitation indices calculated based on the station-based ECA&D (European Climate Assessment & Dataset; http://www.ecad.eu) dataset. Annual climate index maps are shown as well as anomaly and trend maps. The following climate indices are considered:

1. **RR1, Number of wet days**: count of days where RR (precipitation) ≥ 1 mm

Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally affected.

2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) ≥ 25°C

3. **WW, Number of warm and wet days**: days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile

4. **TR, Number of tropical nights**: count of days where TN ≥ 20°C

The maps showing the number of wet days (RR1, uppermost left panel in Figure 2-11) clearly depict the dry conditions prevailing in 2018. Over large parts of Central Europe and Scandinavia there were less than 100 wet days which correspond to -20 to -40 and even less rainy days with respect to the 1961 to 1990 mean in these areas. The southern parts of Europe on the contrary experienced more than normal wet days, mostly up to 20 days.

Looking at the number of warm and wet days (WW) it appears that above-normal numbers of WW were registered in most parts of Europe in 2018, also in the drier parts. Only very locally, the number of wet and warm days was fewer than normal.

The anomaly map for the number of summer days (SU, second row from the bottom on the right in Figure 2-11) also illustrates well the longer-than-normal summer conditions in 2018 over large parts of Europe. Over Central Europe there were up to 60 more summer days recorded than normal. In many countries new records were set. In Luxembourg (at Findel) for example, with a total of 76 summer days over the year, 2018 exceeds the former record from 2003 with 63 summer days. In the Netherlands, De Bilt also reported a new record number of summer days (56) since 1901. In the southern and northern parts of Europe less summer days than normal occurred.

Most meteorological stations in lowlands of west Slovakia recorded new record numbers of summer days e.g. Žihárec recorded 140 summer days, which is 71 more than the normal average of the period 1961-1990, respectively 57 days more than in 1981-2010. The second highest number of summer days was measured in Podhájska (139 days), which is 70 more than normal of the period 1961-1990, respectively 58 days more than in 1981-2010.

There were also more than normal tropical nights (TR) in 2018, but the anomaly values are smaller than for SU with mostly up to 30 nights. Locally, there were also less than normal tropical nights throughout the RA VI region.

Figure 2-12 shows the trend maps for the selected climate indices based on the years 1951 to 2018. In northern, northwestern, central and eastern Europe most stations showed an increase in the annual number of wet days (RR1) for the last 68 years (mostly greater than 3 days per year per decade) while in southern Europe a decreasing trend prevails. The decreasing and increasing trends

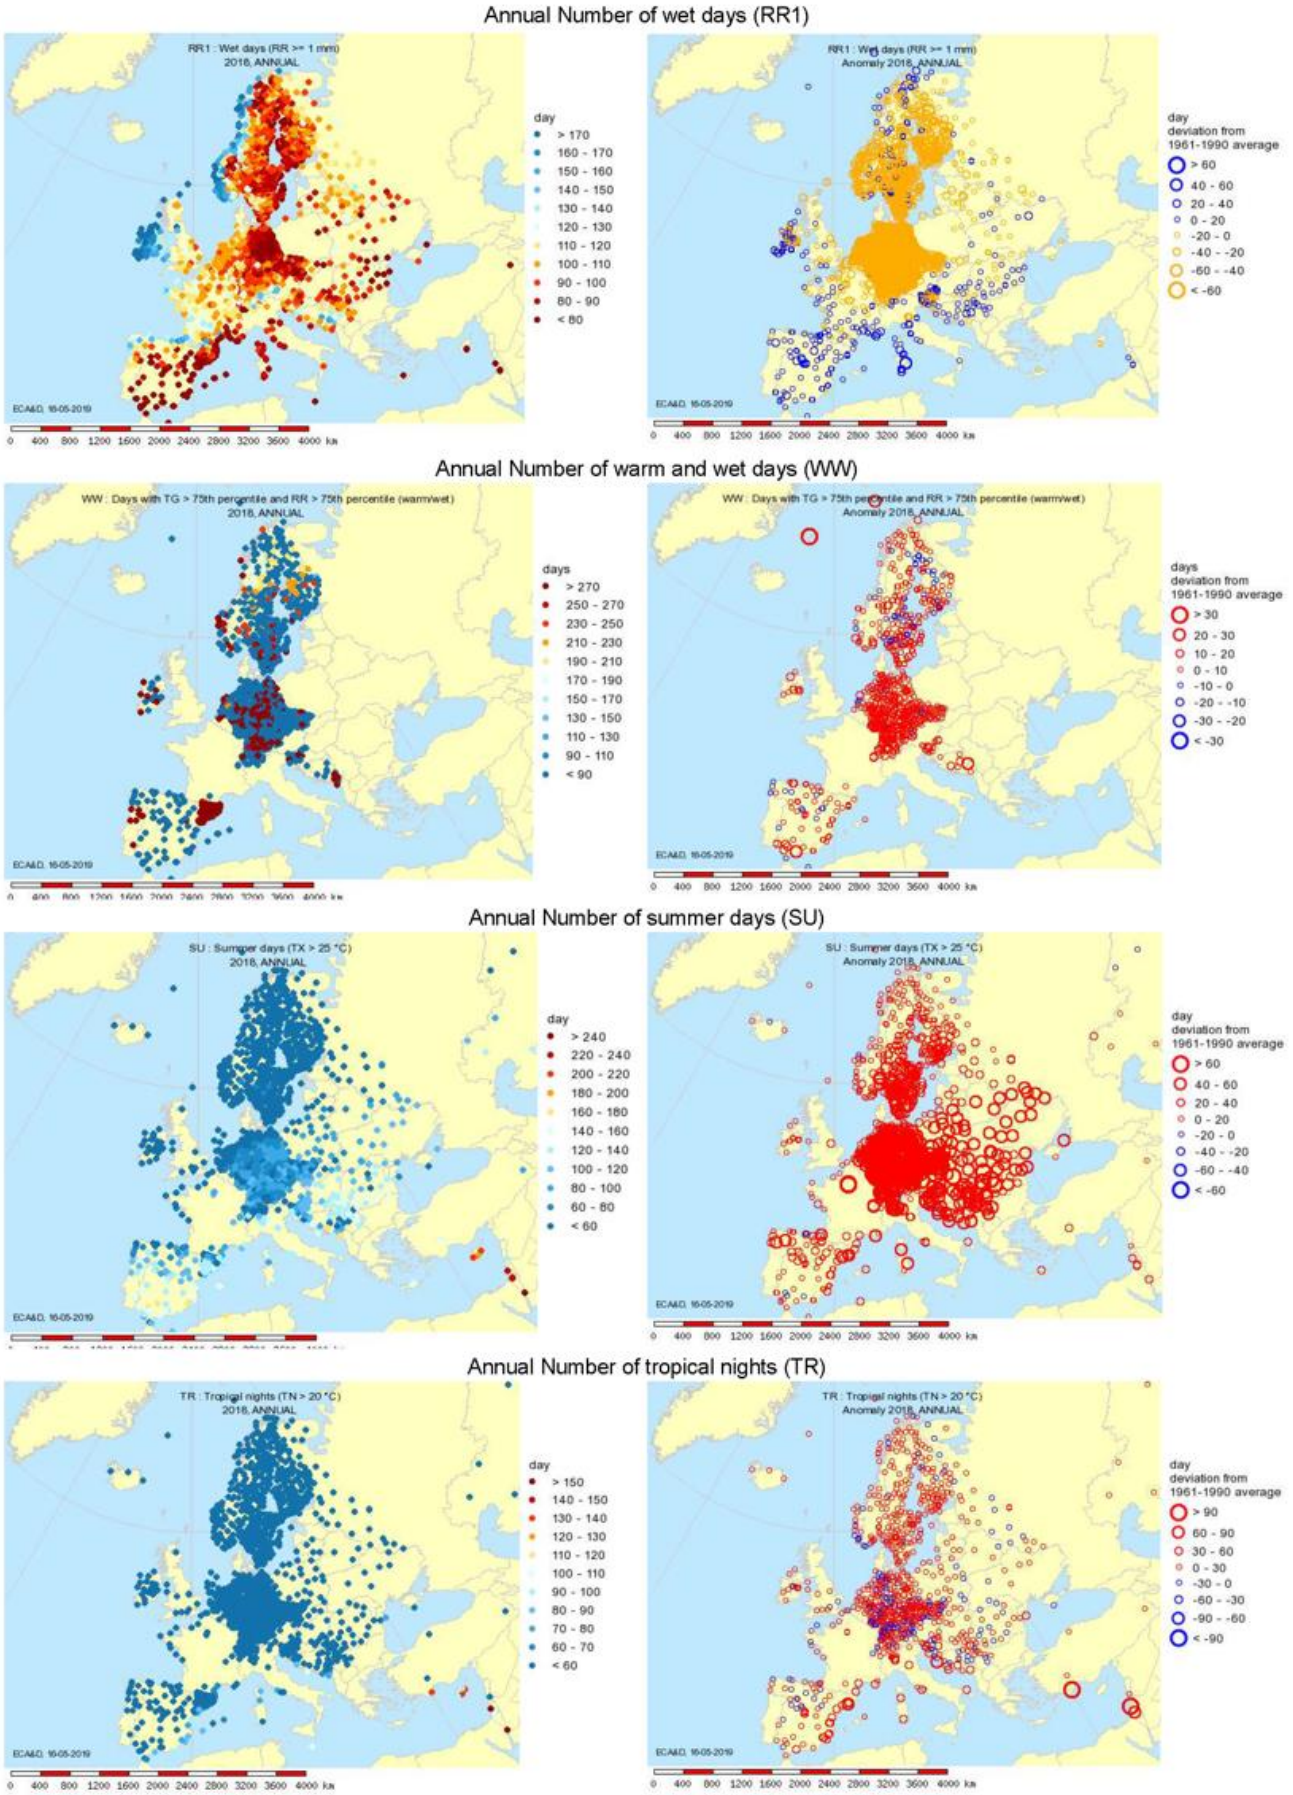

Figure 2-11: Selected Climate Indices for 2018 (left) and their anomalies (right) with respect to the 1961 to 1990 reference period (Source: ECA&D, http://www.ecad.eu).

at neighbouring stations, however, indicate inhomogeneities in the time series. The number of warm and wet days (WW) has increased over almost whole Europe by more than 1.5 days per year per decade. Only the Greek stations show negative WW trends of up to -1.5 days per year per decade. The annual numbers of summer days (SU) have increased in central and southern Europe and partly in Eastern Europe, while stations in northwestern and northern Europe do not indicate any significant trend. Annual numbers of tropical nights (TR) show an increasing trend in the southeastern part of Region VI but values are mostly small with 0 to 2 days per year per decade. In the northwestern part no significant trends are found.

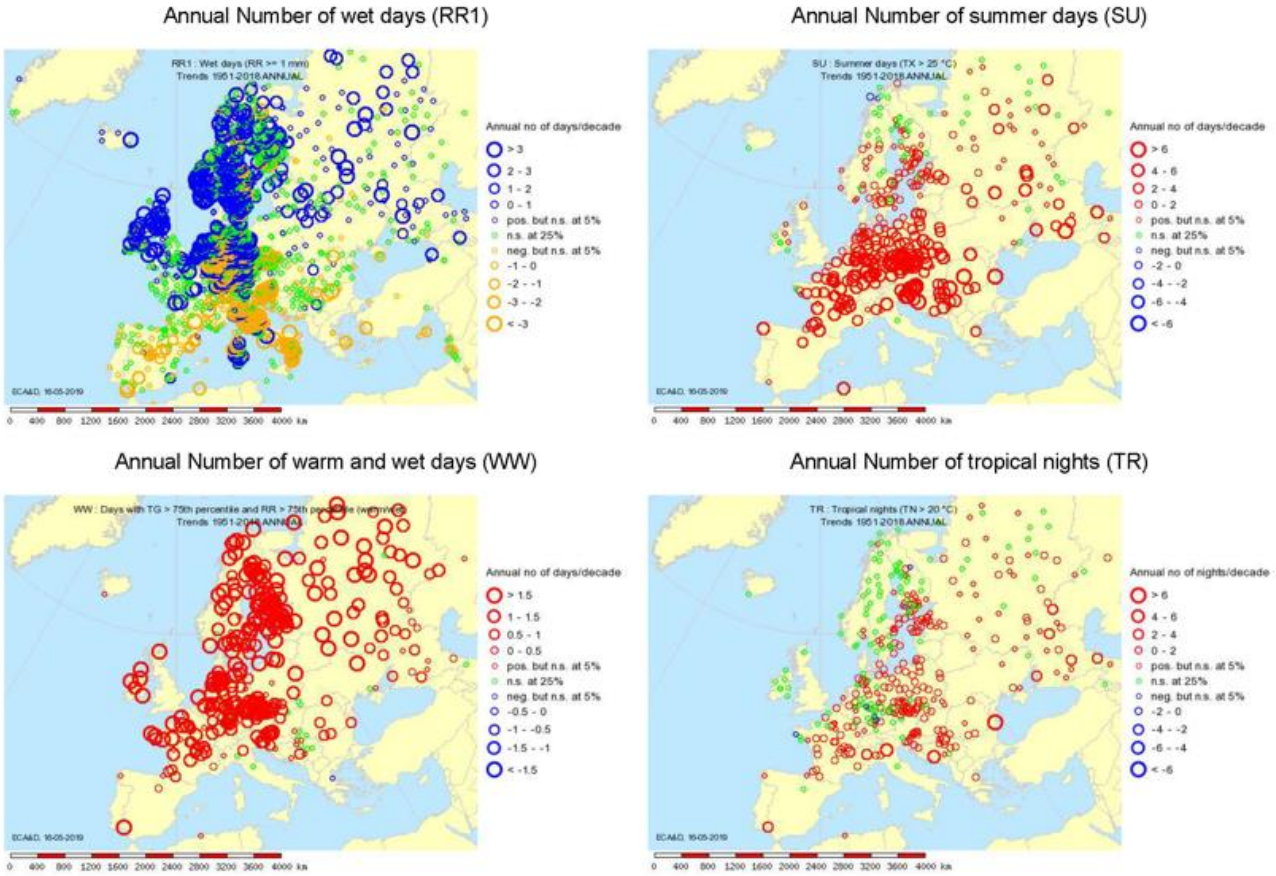

Figure 2-12: Trends of Selected Climate Indices 1951 to 2018 (Source: ECA&D, http://www.ecad.eu).

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2018 and anomalies related mainly to the normal period 1961-1990 of the following selected climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. *Seasonal averages and anomalies of selected climate variables*

3.1.1. Sea level pressure and circulation indices

Pressure distribution in **winter 2017/2018** shows that both circulation centres, the Icelandic Low and Azores High, were stronger than normal with anomalies of -4 to -6 hPa and up to +6 to +8 hPa respectively. That winter the North Atlantic Oscillation (NAO) was positive, but with 1.08 not very pronounced, the AO was in a neutral phase (-0.08). The dominant circulation patterns were the East Atlantic/West Russia Pattern (EA/WR) and the Polar/Eurasia Pattern (POL), with values of -1.55 and -1.89 respectively.

Table 3-1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference. Blue and yellow colors indicate index values lower than -1 and greater than 1 respectively

	NAO	EA	EA/WR	SCA	POL	AO
Winter 2017/2018	1,08	-0,44	-1,55	0,13	-1,89	-0,08
Spring 2018	0,61	0,15	1,02	0,40	-0,50	0,26
Summer 2018	1,74	1,21	-0,96	0,15	-0,36	0,61
Autumn 2018	1,02	0,03	0,04	0,01	-0,02	-0,04

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In **spring** pressure was lower than normal over the entire RA VI region except for Scandinavia. The Icelandic low was shifted south. Largest negative anomalies occurred southwest of Ireland and over Russia.

In **summer** the pressure anomalies were mostly only slightly positive or negative (within -2 to +2hPa). Larger negative anomalies occurred tough over the Arctic including Iceland.

The circulation centres in **autumn** were well pronounced with a core pressure between 1000 and 1005hPa around Iceland and between 1020 to 1025 hPa around the Azores. The latter formed part of high pressure belt extending further across southern and central Europe till western Kazakhstan with one maximum around the Azores and the second one over Eastern Europe. Above-normal pressure anomalies occurred over northeastern Europe, with largest anomaly values in the range of +4 to +6hPa over the Baltic countries. All circulation patterns were in a neutral phase except for the NAO which was positive with a value around 1.

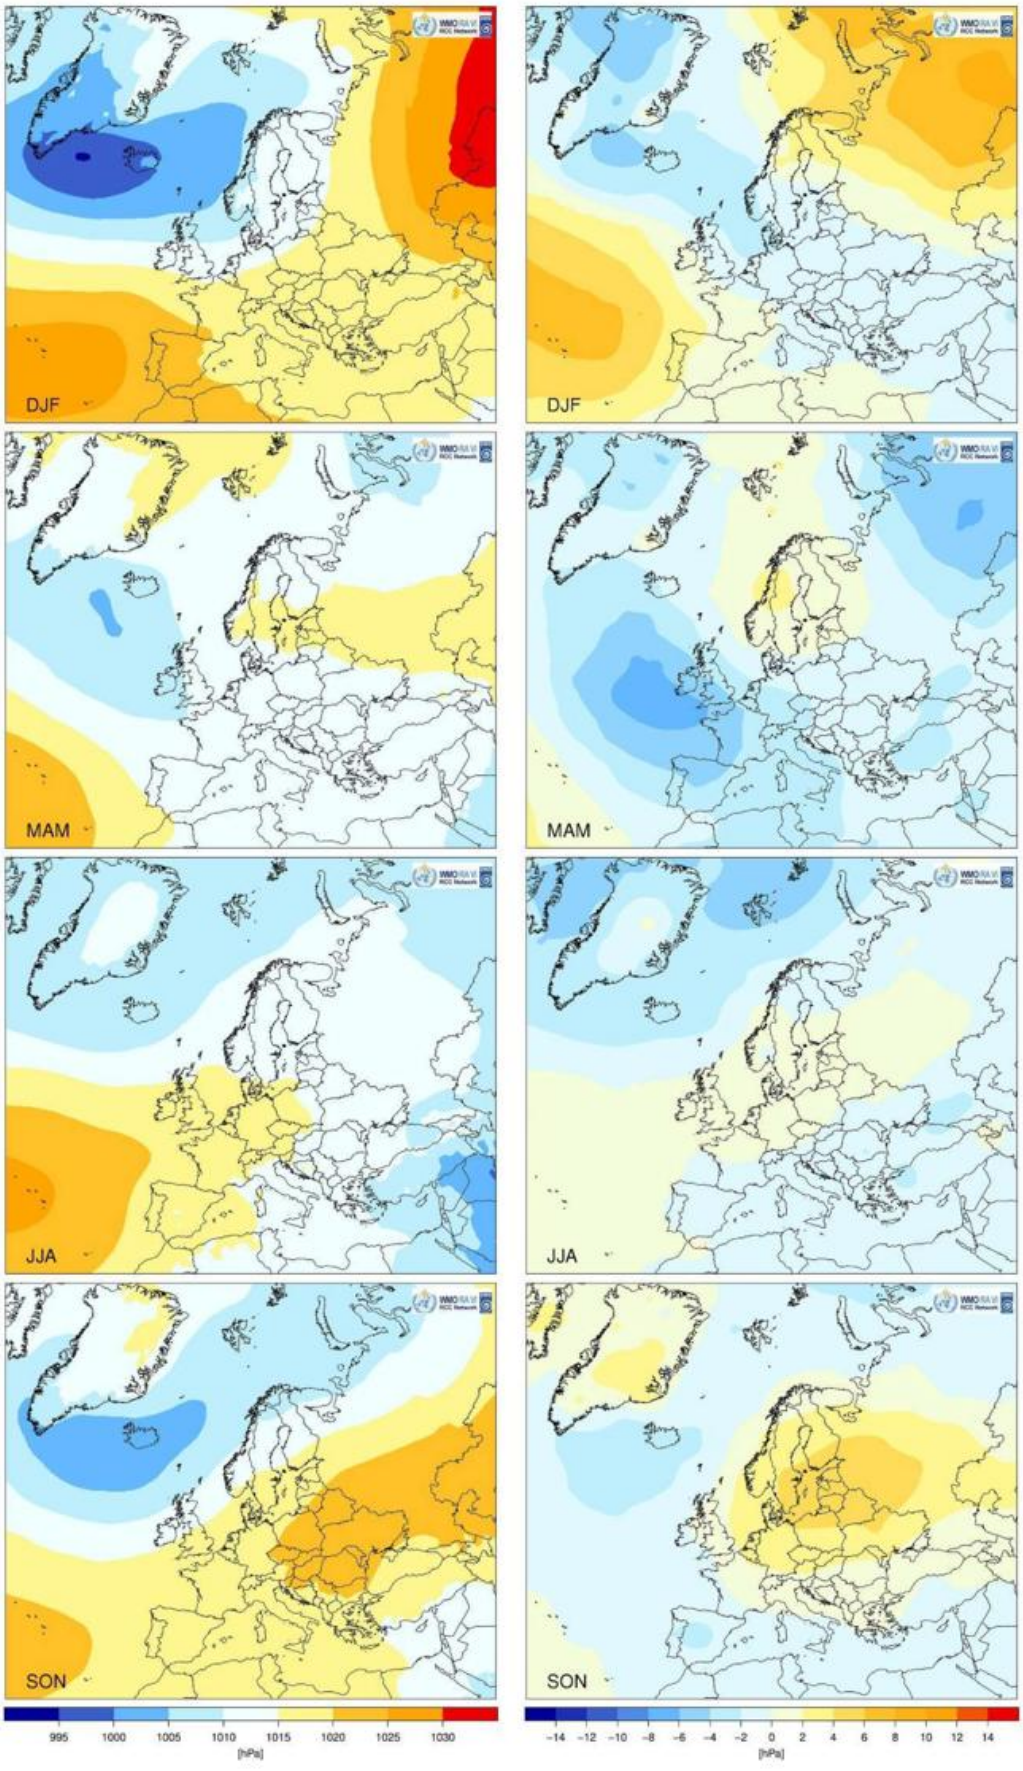

Figure 3-1: Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2017/2018, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.2. Temperature

In 2018, mean annual temperatures were higher than normal (w.r.t. 1961-1990) over the whole RA VI region which is reflected by positive anomalies in all sub-regions ranging from +0.9°C over Iberia to +1,95°C over central and western Europe(see Table 3-2). Temperatures were not only higher than normal on an annual basis but also in all seasons except for the winter season over Iberia which was normal with an anomaly value close to zero.

Table 3-2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2018 (reference period: 1961-1990; definitions of the sub-regions see Figure 1-1)

region	year	winter	spring	summer	autumn
Central and Western Europe	1.95	1.08	2.11	2.79	1.51
Nordic und Baltic Countries	1.62	2.8	1.25	0.84	1.73
Iberia	0.9	-0.04	0.53	1.42	1.2
Med. Italian and Balkan Peninsula	1.84	1.35	2.45	1.87	1.9
Eastern Europe	1.68	3.13	0.69	2.01	2.09
Middle East	1.83	2.33	2.07	1.59	1.64

Temperature anomalies for **winter 2017/18** show higher-than-normal temperatures over large parts of the RA VI region generally ranging from +1°C to +3°C over central and eastern Europe, and the Balkan countries. Over the southwestern part of Europe (Spain, southern France) and over parts of the United Kingdom and Ireland, and northern Scandinavia), however, temperature anomalies were colder than normal. These mostly too warm temperatures are also reflected in the subregional statistics with anomaly values ranging from 1.08°C in Central and Western Europe to 3.13°C Eastern Europe. Within the Nordic and Baltic region, largest anomalies occurred over the arctic part with values up to +6°C and more. In the northeastern part of Greenland for example, winter season (DJF) 2017-2018 was record setting at Kap Morris Jesup, Station Nord and Danmarkshavn in northern and northeastern Greenland. All countries in the Middle East region experienced also well-above-normal temperatures with anomalies >= +1.6°C (w.r.t. 1981-2010); Jordan observed a winter temperature anomaly of +2.6°C (w.r.t. 1981-2010) and Armenia even above +4°C.

Table 3-3: Seasonal rank statistics for temperature (2017/2018) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the to time series.

Country	Anomaly	Reference period	Rank /Start of time series
		winter	
Georgia	+2.52°C	1981-2010	4th warmest since 1956
		spring	
Bulgaria	+2.4°C	1961-1990	3rd warmest since 1930
Switzerland	+1.6°C	1981-2010	4th warmest since 1864
Georgia	+2.36°C	1981-2010	warmest since 1956
Romania	+2.1°C	1981-2010	warmest since 1961
Belgium (Brussels-Ukkel)	+1.4°C	1981-2010	4th warmest since 1833
		summer	
Germany	+2.4°C	1961-1990	warmest since 1881
Switzerland	+2.0°C	1981-2010	3rd warmest since 1864
Belgium	+2.3°C	1981-2010	warmest since 1833
Estonia	+1.8°C	1981-2010	4th warmest since 1961
France	+2.0°C	1981-2010	warmest since 1900
Denmark	+2.0°C (+2.5°C)	1981-2010 (1961-1990)	warmest since 1874
Finland	+1.9°C	1981-2010	3rd warmest since 1900
Latvia	+1.9°C	1981-2010	2nd warmest since 1924
United Kingdom	+1.39°C (+2.0°C)	1981-2010 (1961-1990)	warmest since 1884
Georgia	1.62°C	1981-2010	5th warmest since 1956
		autumn	
Switzerland	+1.8°C	1981-2010	3rd warmest since 1864
Latvia	+1.9°C	1981-2010	5th warmest since 1924
Estonia	+2,0°C	1981-2010	4th warmest since 1961

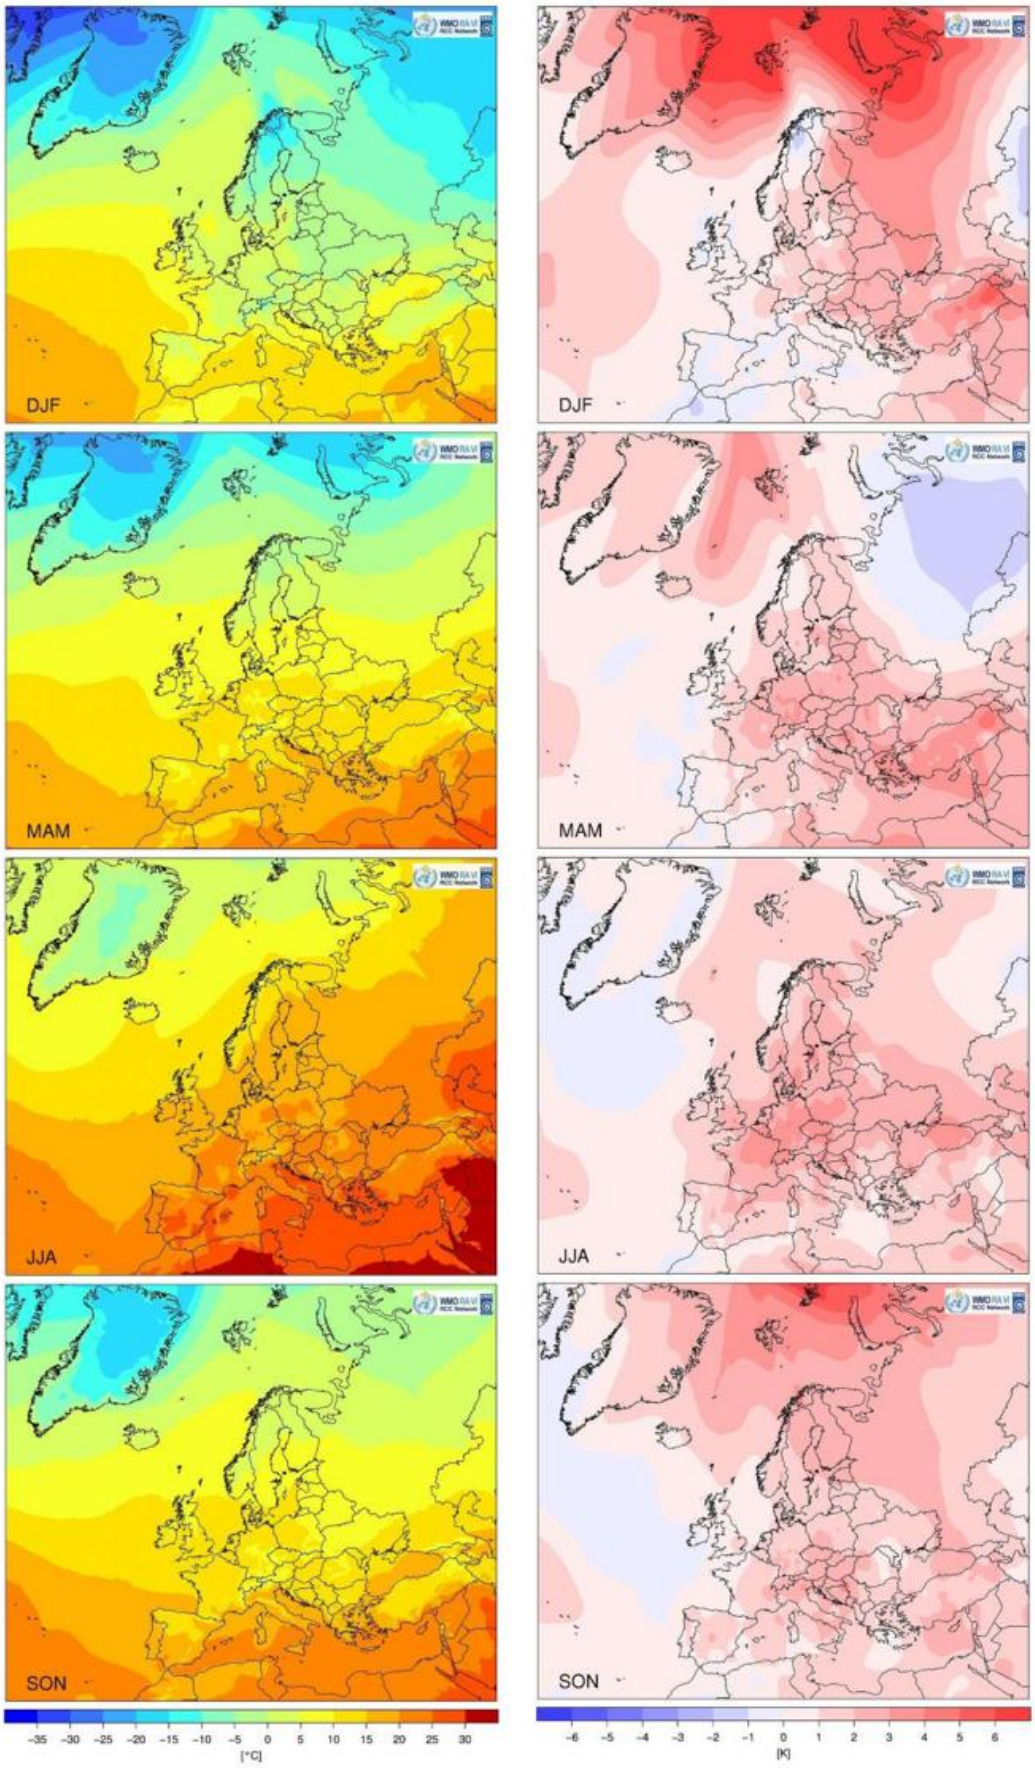

Figure 3-2: Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2017/2018, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

Spring was warmer than normal over most parts of the RA VI except for northern Russia and Portugal. Largest anomalies occurred over eastern part of the Mediterranean (Greece, Turkey, Syria) which also explains that largest regional anomalies are reached in the region covering the Mediterranean, Italian and Balkan Peninsula with an anomaly value of 2.45°C above normal. But also Central and Western Europe as well as the Middle East were more than 2°C warmer than normal. Except for the Mediterranean coast of Spain, spring was colder than average for the Iberian Peninsula (1981-2010 reference); it was the third coldest spring for Portugal and fourth coldest for Spain since 2000. In Hungary, on the contrary, 2018 was the second hottest spring. In Lithuania, spring was very warm, dry and sunny, so that the active start of plant vegetation (defined by an average daily air temperature reaching ≥10 °C) began very early this year – in the southern part of Lithuania on April 8 (on average 3 weeks earlier). In the northern part – in the middle of April (18 days earlier), on the seaside – 1 week earlier as usually. In Montenegro, the average seasonal temperature in spring was the warmest in the whole country. Serbia had its warmest spring since record-keeping began in 1951 with mean air temperature on average 1ºC above the previous record warm spring of 2007. Slovakia also reported an exceptionally warm spring 2018 with anomalies larger more than 1.5°C compared to air temperatures of the normal period 1981-2010 over the entire territory of Slovakia. In Slovenia, an exceptionally warm April together with well above mean temperatures in May resulted in above-normal spring 2018 mean temperature. On country average the anomaly was 1.7 °C. It was the warmest spring on record for Bosnia and Herzegovina, Bulgaria, Greece, Serbia and Turkey.

Summer was warmer than normal over the entire RA VI region with anomalies ranging from +0.84°C for the Nordic and Baltic countries to +2.79°C for the Central and Western Europe. Within Central and Western Europe, temperatures were locally even up to 4°C above normal (see Figure 2-2). Summer was one of the five warmest on record for many countries in Central Europe: Germany and Poland, warmest (+2.3°C and +2.2°C, respectively); France second (3.2°C) and Switzerland, third (+2.0°C). In Luxembourg, the summer of 2018 was characterized by an average temperature of 20.1°C, placing it in the second rank of the hottest summer seasons ever observed since 1947, the hot summer of 2003 keeping the first rank with an average summer temperature of 20.5 ° C. Findel-Aéroport meteorological station reported a new record of summer days (maximum temperature ≥ 25 ° C): 76 summer days were counted (last summer day on 19/09/2018), surpassing by far the emblematic years of 2003 (63 days), 1976 (54 days) and 1947 (51 days) characterized by strong heat waves or episodes of heat wave (1981-2010 gives an average of 32.5 summer days per year). In the Netherlands, the summer at De Bilt was with a mean temperature of 18.9°C the warmest since 1901. The summer of 2018 was exceptionally warm as well in many parts of northern Europe resulting in new records for Nordic and Baltic countries: warmest for Denmark, Finland, and Norway with anomalies (with respect to 1981-2010) of +2.0°C, +1.9°C and. +1.8°C respectively. Latvia reported its second warmest summer since 1924, when recordkeeping began. In Denmark, the summer season was record breaking warm with heat waves as well as a severe drought lasting from May to the beginning of August. Record breaking number of summer days (Tmax >25 ºC) were recorded. Summer in Estonia was very warm, sunny and drier than normal. The mean temperature of the three summer months was 17.8 °C (anomaly +1.8 °C) – 4th-5th place since 1961. In Lithuania, it was also a very warm season, by 1.9°C warmer than usual. All months were much warmer than normal: July had even +2.1°C anomaly, August +2°C anomaly, it was also warmer in June. The beginning of the meteorological summer in Lithuania (here defined by an average daily air

temperature reaching ≥15 °C), in comparison with the multi-annual data, arrived about 1–1.5 months earlier. This year, the meteorological summer throughout the country lasted on average 137 days (even 2 months longer than usually). Summer temperatures were also much warmer than average across several locations in the Arctic Circle recording maximum temperatures 30.0°C or higher. According to the World Meteorological Organization, Norway set a new national maximum temperature record when temperatures soared to 33.5°C (92.3°F) on 17 July in Badufoss. Similarly, the highest temperature of the year in Finland, 33.7°C, was recorded in Klemettilä, Vaasa, on 18 July. In Slovakia, summer 2018 (mean season temperature) 2018 was thermally exceptionally above normal (deviations more than 1.5°C compared to the normal period 1981-2010 in all the territory of Slovakia). Most meteorological stations (lowlands of west Slovakia) recorded a maximum number of summer days (e.g. in Žihárec up to 140 summer days, which is 71 more than the normal average of the period 1961-1990, respectively 57 days more than in 1981-2010, the second highest was measured in Podhájska with 139 days, which is 70 more than normal from the period 1961-1990, respectively 58 days more than in 1981-2010. In Slovenia, summer 2018 was 1.6 °C warmer than normal on national average and mostly ranking among 4 to 7 warmest on record. In the Middle East, summer temperatures were closer to normal; only Israel and southern Jordan had anomalies above +1°C (w.r.t 1981-2010).

Box 3 | Contributions by NMHS – Seasonal temperature: summer

Exceptional summer in France (Contribution from MeteoFrance)

The average summer temperature in France of 21.2 °C exceeded the normal (1981-2010) by +2°C. The summer of 2018 was ranked second warmest, far behind 2003 (+3.2 °C) but ahead of 2017 (+1.5 °C). After a first heat wave from 24 to 27 July, that mainly affected northern France, a second peak affected the entire country from July 30 to August 8, including the south-east quarter where the maximum exceeded 40 °C on 4th of August with 41.3 °C in Beziers (Herault), a new monthly record. These heat waves caused about 150 0 deaths according to the French Ministry of Health.

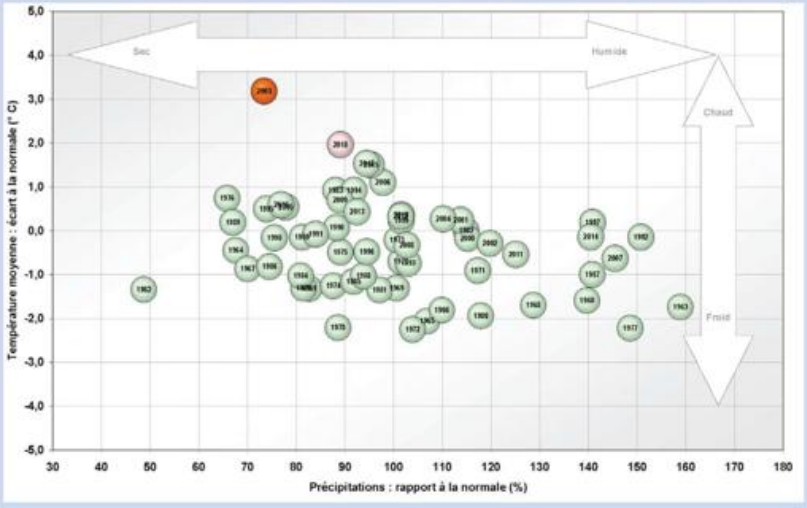

Figure 3 3: Temperature and precipitation in France for summer of 1959 - 2018 (provided by METEO-FRANCE)

Autumn temperatures in 2018 continued above normal for almost the entire RA VI region. Largest anomalies occurred again over the arctic region with anomalies up to 5°C and more. The anomaly values for the subregions were all above 1.5°C ranging from 1.51°C for central and western Europe to 2.09°C for Eastern Europe. Overall, autumn was one of the warmest on record in many countries in Central Europe: Hungary, second (+2.1°C); Switzerland, third (+1.8°C); Austria, third (+1.9°C); Belgium, third (+1.7°C); Poland, third (+1.6°C) and France, fourth (+1.2°C). Autumn was also much warmer than normal for Nordic and Baltic countries, especially in northern Norway, Finland, and Sweden, with November anomalies of +3°C to +5°C. At Summit Station on the Greenland ice cap, a new record low minimum temperature of −55.4°C for October was set on 26 October, surpassing the previous record by 0.2°C. Anomalies of 1.5°C and larger also occurred over large parts of the Balkan Peninsula: in Slovenia, autumn 2018 was on national average 2.0 °C warmer than on average in the reference period 1981–2010; in Slovakia, autumn 2018 was thermally exceptionally above normal compared to the normal period 1981-2010 with anomalies larger than 1.5°C.

3.1.3. Precipitation

Precipitation anomalies in **winter 2017/18** show normal to above-than-normal values in most parts of the RA VI region except for the southwestern parts of the Iberian Peninsula and the Middle East region as well as west Kazakhstan where partly even less than 40% of normal precipitation amounts were recorded. In Portugal, winter average precipitation was only 240.0 mm, 68 % of normal, and February was the 11th consecutive month with monthly precipitation values below the 1971-2000 normal and at the end of the month 83 % of the territory was in severe drought and 1 % in extreme drought, according to PDSI index. In Spain, winter was also dry in the south (below 60% of normal) but wet in the north (above 150%) where exposure to low-pressure systems was greater. Large surpluses of precipitation occurred as well over the Alps, along the Western coast of the Balkan Peninsula and also over France, which experienced a very wet and stormy winter, wettest winter on record even in several parts of France, along with floods especially in January. Overall, 40% surplus classifies it 3rd wettest winter since 1959. Burgundy even reported its wettest winter of the 1959–2018 period, with seasonal total anomalies ≥300 mm. Two exceptional snow fall events, 5-7 February in the North, and 26-27 February in Provence - Alpes -Cote d'Azur and Corsica. Winter was wet especially in the Balkans. Serbia and Slovenia each reported their fourth wettest winter with precipitation 160%–170% of normal. Winter was also wet in Azerbaijan which received a precipitation surplus up to 250% of normal. In Serbia, the registered number of days with snow cover was 8 to 23 days below the winter average in most of the country, apart from Kopaonik with 4 days above the winter average.

Spring 2018 was for most parts of the RA VI region the start of a very dry period. Especially in central, northern and eastern parts of Europe, precipitation amounts were below normal. The station in Visby (Sweden) reported only 38% of normal precipitation for the season, with a new low monthly record for May of only 1.7 mm of precipitation, breaking the previous record of 2.8 mm set in 1866. In Latvia, all stations measured below-average precipitation, making it the second driest spring since the beginning of the century and 12th driest since 1924. Total precipitation was less than 60% of normal, which was similar to Estonia. Above-normal precipitation amounts occurred over the Iberian Peninsula, along the Mediterranean coast in France (167 to 200 % of normal) and over Russia. In France abundant rains fell in the Mediterranean with rain amount almost double the normal. Spring

was very wet on the Iberian Peninsula. Under the dominant influence of low pressure reaching far to the south, four consecutive storms passed over the Peninsula. Consequently, in Portugal, spring of 2018 was extremely rainy with an average precipitation of 429.0 mm, which is about 200 % of normal and was the 3rd rainiest since 1931 (after 1936 and 1956). In central and northern Italy, precipitation ranged between 200% and 300% of normal, and in the cities of Lucca, Florence, Arezzo, and Livorno (all in Italy) seasonal totals were the highest since records began in 1955, locally exceeding 500 mm.

In **summer 2018** the dry conditions that started in spring continued over large parts of the RA VI region. Largest precipitation deficits occurred over Central and Western Europe (especially in Germany, Switzerland, the Czech Republic, and western Poland), over the Baltic countries, Russia and Kazakhstan with only 40-60% of normal rain (locally even larger with 20-40% of normal). Seasonal deficits were locally also large in Germany, e.g., with totals of 24% of normal or below, despite multiple low-pressure systems bringing heavy convective precipitation. The Netherlands reported one of its driest summers since records began in 1906: 105-mm precipitation received compared to its normal of 225 mm, with July the driest month observed since records began. Ireland reported its driest summer since 1962, with June and July each record dry (driest summer at Phoenix Park in Dublin since records began in 1850). In the UK; some rain gauges in southern England recorded more than 50 consecutive dry days. In Finland, dry summer kept the annual rainfall historically low at several observation stations. Particularly in the area from the western part of Finland to Sea Lapland, the annual rainfall was exceptionally low, occurring less frequently than once in 30 years. Various observation stations (in Finland) measured record low rainfall as a result of the dry summer. For example, in Merikarvia's Tuorila it only rained 425.5 mm (62%), while the typical precipitation is 683 mm. In Merikarvia, 2018 was the driest summer in the 50 years of measurement history. Many parts of Sweden also received only 40%–80% of normal precipitation for the season. At the beginning of summer, Latvia had a severe drought. For 75% of the reporting stations, the period of 4 May–20 June was the driest since 1961. Eastern Azerbaijan was also drier than normal during summer with precipitation totals as low as 20% of normal locally with only a few millimeters received in all summer months in contrast with the rest of the South Caucasus region (Georgia and Armenia), which mostly received near-normal precipitation. Much above-normal precipitation amounts were however recorded over the Italian and Balkan Peninsula and over Turkey where some parts received 200% and more of normal precipitation amounts. Summer in France was wet in the south, with Cevennes in Var and South Corsica receiving up to three times their normal, while northern and northeastern France had just 30%–60%.

Dry conditions also continued in **autumn 2018** over most parts already affected by drought, namely, central and western Europe as well as the Nordic and Baltic countries. Additionally Balkan Peninsula also only received less-than-normal precipitation. In France, persistent dryness persisted in the uppermost soil layers in the NE part from August to November (Alsace, la Lorraine and Franche-Compte). In Germany, in summer and autumn only 50 % of the usual rain amount was recorded. MeteoLux recorded for Findel, Luxembourg, only 86 mm in autumn, thus significantly lower than the normal (239 mm) at Findel-Airport, and number of precipitation days (RR≥ 0.1 mm) in autumn 2018 reached 28, thus significantly lower than the normal (48 days). Autumn was also very dry in the South Caucasus region, largely receiving only 60% to 80% of normal except for eastern Armenia. As with summer, an overall precipitation deficit was contrasted by some local records of heavy rain. Along the northern Mediterranean (e.g. Mediterranean region of France) and the western coasts of

Norway several intense rainstorms in October and November resulted in precipitation totals 1.5 to 2.5 times the normal. Several stations in Western Norway and in Nordland received from 150 to up to 200 % of the normal. A few stations in Eastern Norway and in Trøndelag received from 50 to 75 % of the normal precipitation. In Slovenia only 79 % of the precipitation fell in comparison with the average precipitation in the period 1981–2010. Also southern and eastern Spain reported above-normal precipitation while the rest of the Peninsula was near normal

Table 3-4: Seasonal rank statistics for precipitation (2017/2018) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the to time series.

Country	Anomaly	Reference period	Rank /Start of time series
		winter	
France	+40%		3rd wettest since 1959
Switzerland	158%	1981-2010	4th wettest since 1864
		spring	
Spain	190%	1981-2010	wettest since 1965
Estonia	-32.3mm	1981-2010	5th-6th driest since 1961
		summer	
Bulgaria	+96.4mm/155%	1961-1990	4th wettest 1930

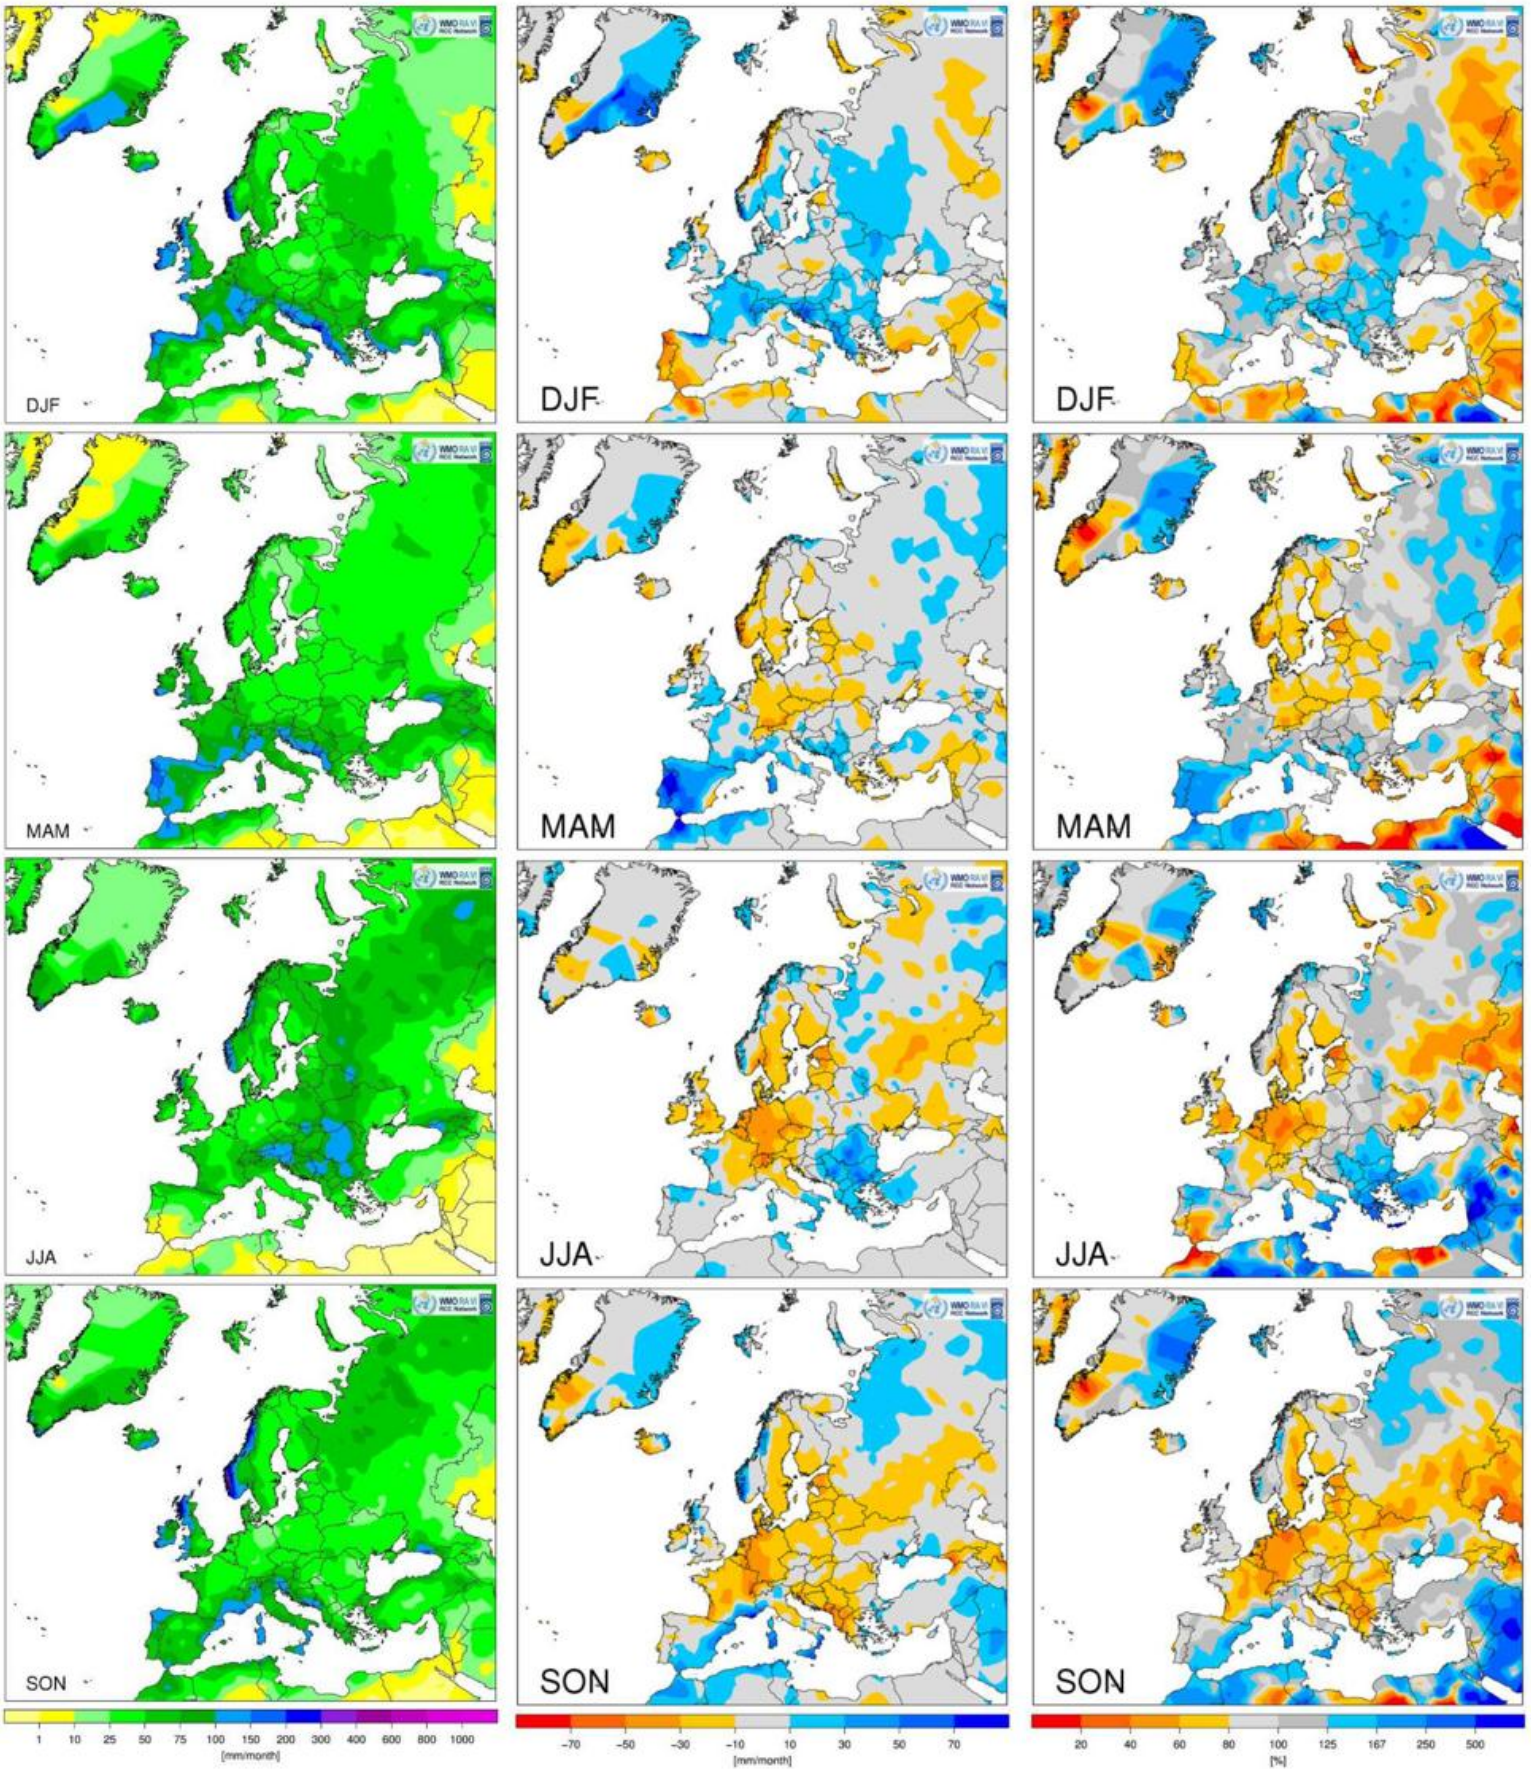

Figure 3-3: Seasonal total precipitation (left, in mm/month), absolute anomalies (middle, in mm/month) and relative anomalies (right, in % of normal) in 2017/2018, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.4. Sunshine duration

The year 2018 as a whole was exceptionally sunny with annually accumulated sunshine hours above the 90th percentile in many places of the RA VI region, especially in central, western, northern and eastern Europe (see section 2.1.5). This surplus of sunshine hours stems from seasonal surpluses in spring, summer and autumn which saw over large parts of the area 125% (summer) or even up to 150% (spring and autumn) of normal sunshine hours.

Winter 2017/18 is the only season where most parts of the RA VI region only recorded below-normal durations of sunshine (generally between 75 to 95 %). But there were also still some places which received more sunshine than normal: for example the UK, the Benelux countries as well as the Iberian peninsula, where mostly up to 125% of normal sunshine hours were recorded.

From **spring** onwards a long sunny, warm and dry period started for many places in the RA VI. Spring brought the largest surplus in terms of absolute sunshine hours to Scandinavia with a surplus of more than 200 hours and new records being set in many countries. In Lithuania, sunshine duration in most parts of the country was extremely long (358–399 hours), by 102 hours longer than the normal. The mean seasonal sunshine duration in Estonia was 774.1 hours (normal 596.5 hours) making it the second sunniest spring since 1961.

In **summer,** largest surpluses of sunshine hours were recorded in Norway with more than 200 hours. In Denmark it was the sunniest summer on record for the country as whole with more than 180 hours extra. In Estonia, the mean seasonal sunshine duration was 874.6 hours (normal 790.4 hours) - 10th sunniest since 1961.

In **autumn**, largest anomalies in sunshine hours occurred over central Europe, Russia and the Balkan Peninsula (between 100 and 200 hours more). In these regions, the surpluses correspond to percentages ranging between 125% and 150% of normal. Also in autumn, many new records were set. In the Netherlands for example, autumn 2018 was the sunniest autumn since 1901.

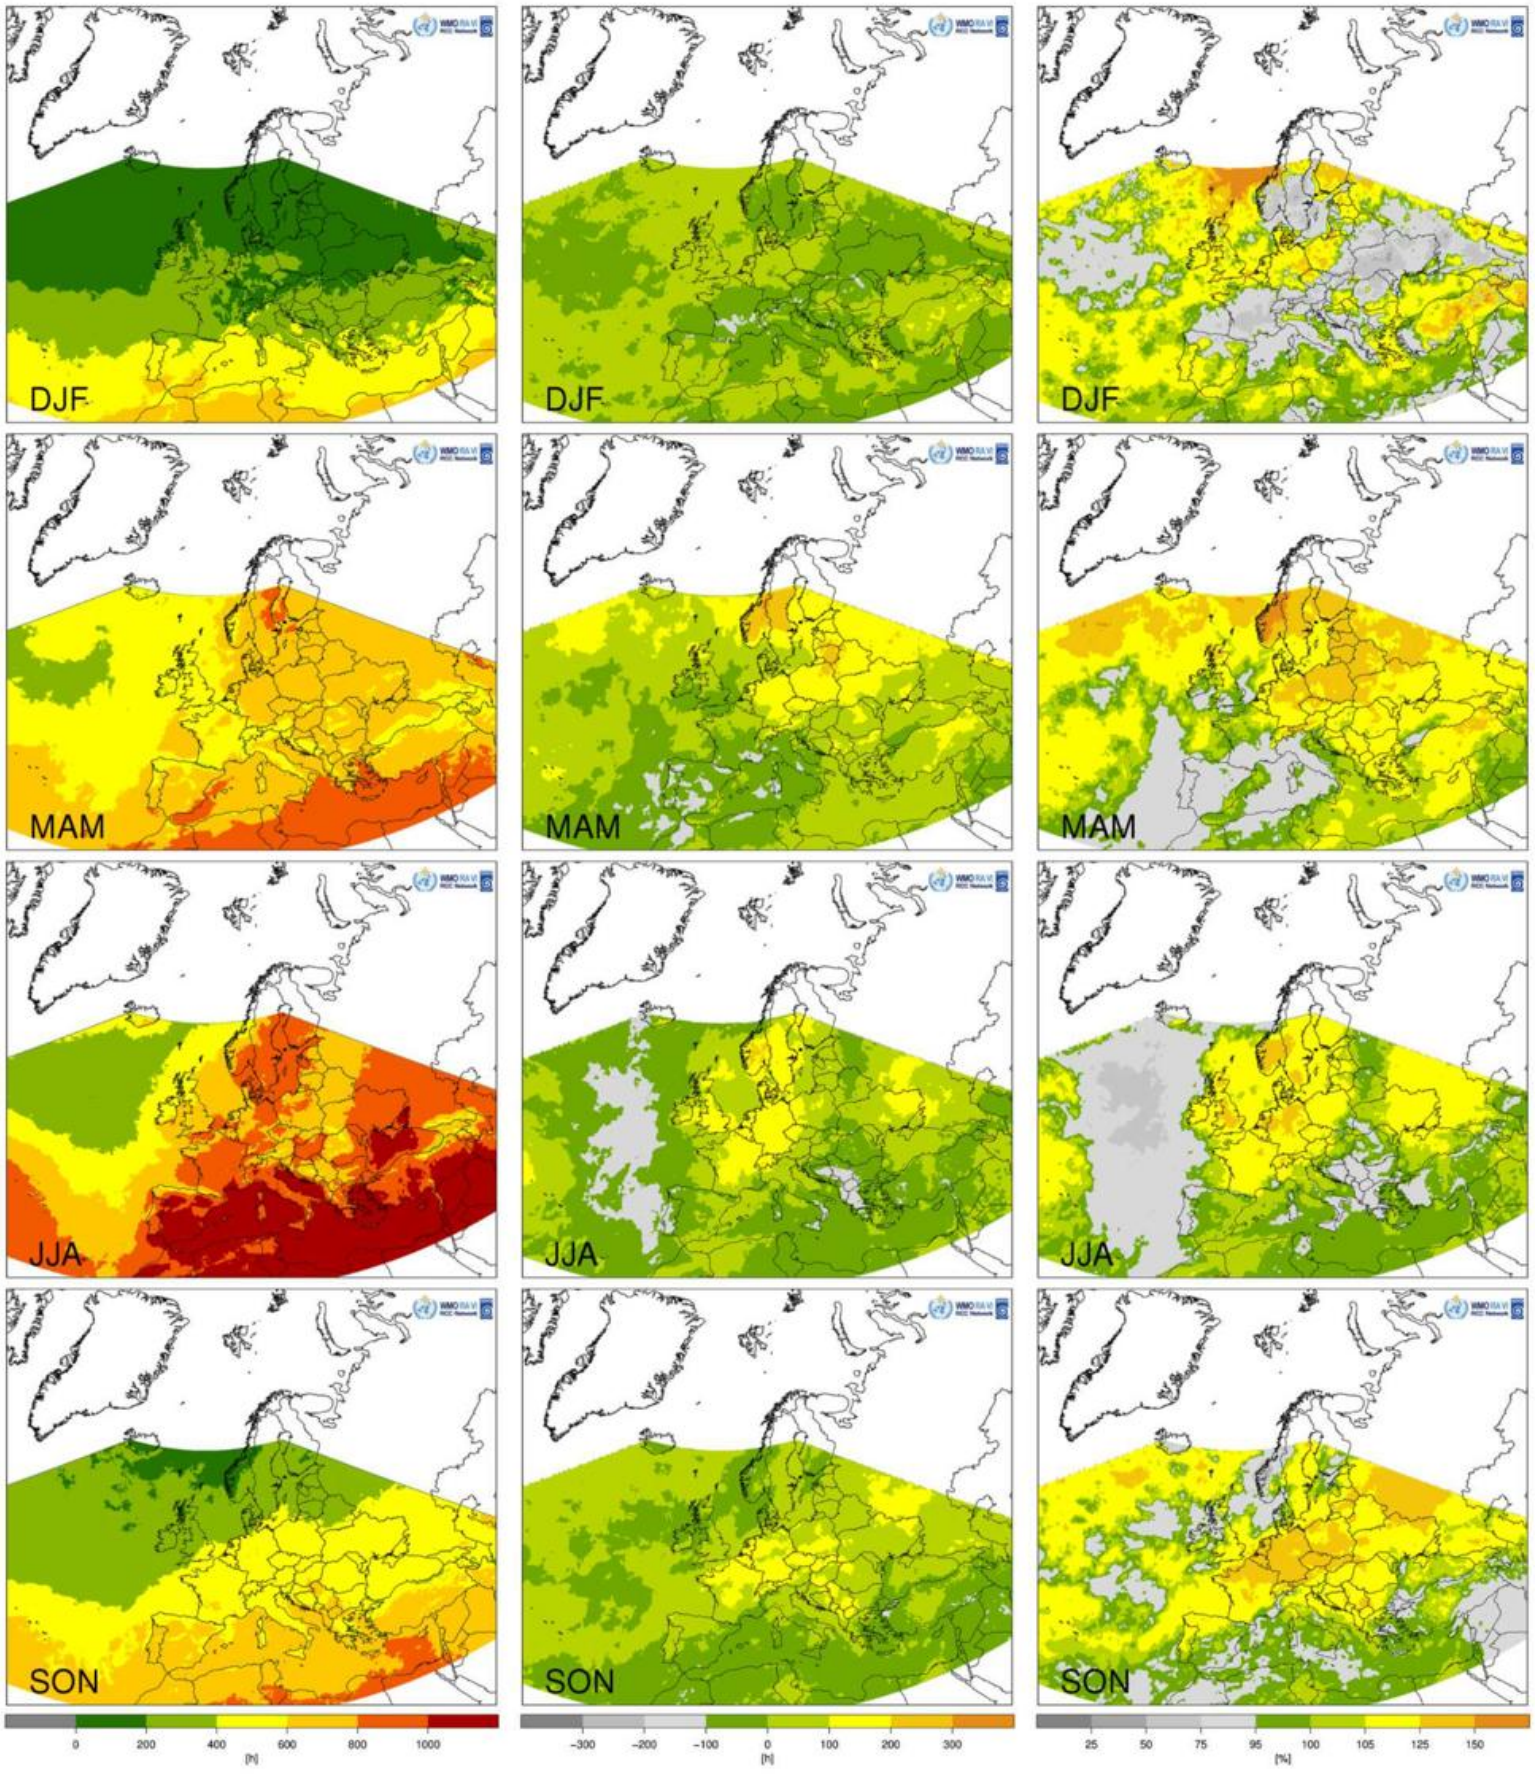

Figure 3-4: Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and percentage of mean (right, in %) in 2017/18, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

3.1.5. Drought

In 2018, many countries were affected by a prolonged drought period (as mentioned in 2.1.6). The seasonal maps of the GPCC-DI (GPCC-Drought Index, Ziese et al. 2014) give a more detailed look at the situation to identify the seasons most affected by the drought conditions.

In **Winter 2017/18,** precipitation deficits were most severe in the Middle East where partly even less than 40% of normal precipitation amounts were recorded (see section 2.1.3). These are the regions for which the GPCC-DI indicates moderate drought conditions with values between -1 and -1.5. And small area affected by moderate drought is also visible in the southern part of Poland. Mild drought conditions (GPCC-DI values between 0 and -1) occurred over Western and Northern Europe, which also received less-than-normal precipitation. The rest of the RA VI region experienced mildly wet conditions

Spring was the start of an unusually long and severe drought period for many places. According to the GPCC-DI, mild drought extended in spring from Central to Northern and eastern Europe. Lowest GPCC-DI values occurred in Estonia (-1 to -1.5) indicating a moderate drought level.

In **summer,** mild drought conditions continued over Central Europe and further extended towards the West (UK, France) and South (Iberian Peninsula, Italy). Also Eastern Europe was affected again. In both regions moderate drought occurred locally (e.g. Germany, Kazakhstan). In France, rain deficits reached up to 30 - 60% in the North and North East. In Germany, in summer and autumn only 50 % of the usual rain amount was recorded. In Ireland, the summer of 2018 was one of the hottest and driest on record, with heat wave and drought conditions affecting many parts of the country. Many places had half its normal rainfall. The prolonged dry spell led to water restrictions and a fodder crisis. Drought conditions prevailed from early June until late July. The combined June and July rainfall total at Dublin (Phoenix Park) was 19,5 mm and was the lowest on record (since 1850). Summer soil moisture deficits up to 93 mm have been recorded in South and East. Apart from Latvia, where moderate drought was indicated by GPCC-DI during the summer season, heat and drought anomalies were also observed in other Baltic and Nordic countries. Thus, in August 2018 the Nordic-Baltic meteorological cooperation association (NORDMET) issued a joint statement on the weather anomalies observed in the summer of 2018, highlighting the severity of climate change in the region and the need for adaptation.

In **autumn,** mild drought conditions extended from France over Germany until Eastern Europe, in Germany still moderate conditions in some areas.

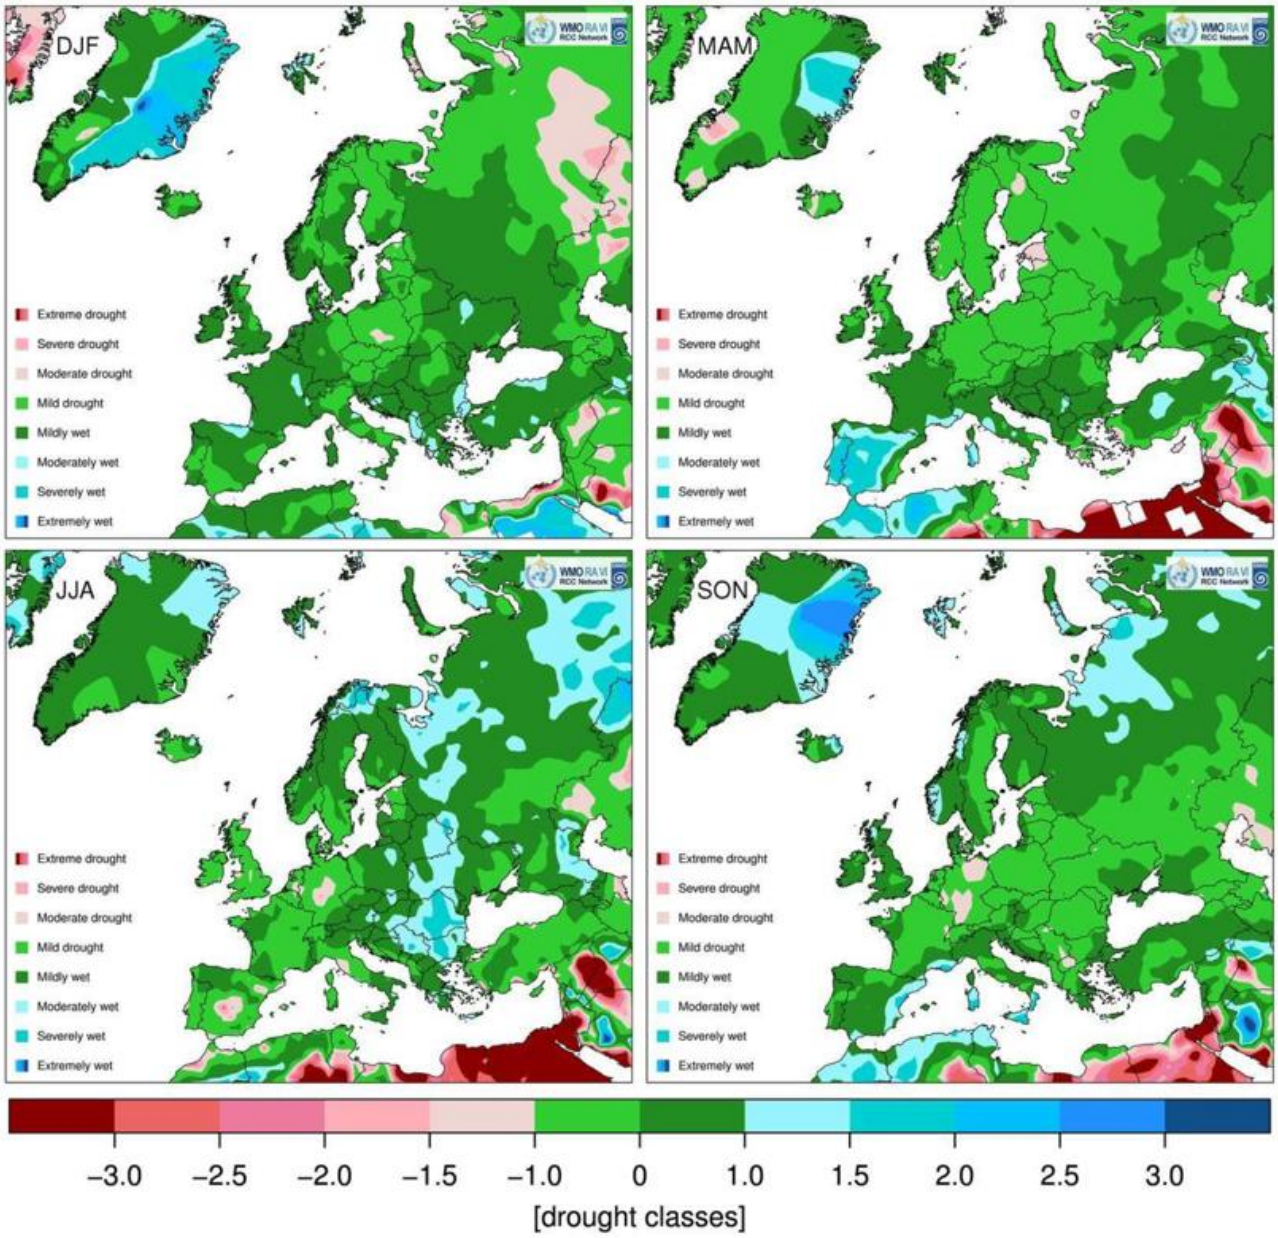

Figure 3-5: Seasonal GPCC-DI (GPCC-Drought Index, in drought classes) in 2017/2018, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2018 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm).

It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each month as well as monthly overviews of extremes and notable events.

4.1. *Sea surface pressure and circulation indices*

This chapter about atmospheric circulation provides information on selected northern hemisphere teleconnection indices relevant for WMO RA VI and discusses influences of circulation patterns upon anomalies and outstanding events. The information is based on the "Monthly Bulletins on the Climate in WMO RA VI" and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/ upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4-1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference including the Arctic Oscillation, for January to December 2018.

Year	Month	NAO	EA	EA/WR	SCA	POL	AO
2018	1	1,17	0,55	-1,62	0,44	-1,48	-0,28
2018	2	1,34	-1,38	-1,4	0,43	-2,24	0,11

North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In **January**, the North Atlantic Oscillation (NAO) was only moderate with a value of 1.17 although several storms passed Europe and the Icelandic low as well as the Azores high were more intense than normal with anomalies of -6hPa for the Icelandic low and up to +8hPa and even more for the Azores high. The other circulation indices of the European sector were not well pronounced except for the East Atlantic/West Russia Pattern (EA/WR) with a value of -1.62. The negative EA/WR phase is marked by low pressure over the North Sea and high pressure over Eastern Europe.

During most of **February**, the NAO was positive but at the end of the month it became negative as a cold wave reached Europe. The monthly average of the NAO was 1.34. The Icelandic low as well

as the Azores high were again more intense than normal in the monthly pressure field. The cold spell end of February was caused by a shift in the polar vortex and the development of a strong high-pressure system over Scandinavia, extended from the Russian High, clearly visible in the anomaly map with values of +12hPa and more. This positive pressure anomaly in northern Scandinavia explains the positive phase of the Scandinavia Pattern (SCA) and the strong negative phase of the Polar/Eurasia Pattern (POL).

In **March,** the Icelandic low as well as the Azores high were both shifted to the south with the core of the Icelandic low being located south of Ireland. Both circulation indices, the NAO and the Arctic Oscillation (AO) were negative at the beginning of the month and increased to around zero at the end of March. The index with most significant impact was the EA/WR with a value of 4.03. This high value occurred for the first time since the beginning of the calculation of these indices in 1950. It resulted from significant high-pressure anomalies over Greenland/Iceland and low-pressure anomalies over western Russia, and caused inflow of cold arctic air into Europe.

In **April,** the NAO was only moderate with a value of 1.20. The Icelandic low as well as the Azores high were shifted again to the south while above normal pressure anomalies were situated above the Balkans. The East Atlantic Pattern (EA) with 1.13 was in the same order as the NAO. The EA is marked by higher pressure over the Balkans and lower pressure over the Atlantic between Iceland and Ireland.

May 2018 was dominated by high pressure over Scandinavia blocking the propagation of the intensive action centres over the North Atlantic into Europe. The anomalies in the area of the Azores high were more than +4 hPa above normal. The anomalies between Greenland and Iceland were below -12 hPa making the NAO the dominating index for the North Atlantic with a monthly value of 2.02. The other circulation indices sticking out in May, were the EA/WR with a value -1.45, which is characterized by higher pressure over western Russia and lower pressure west off the British Isles, and the positive SCA pattern (+1.69) due to the blocking high over Scandinavia.

In **June** 2018, both North Atlantic circulation centres were shifted to the north. Therefore positive pressure anomalies of more than +4 hPa occurred between Iceland and the United Kingdom and negative anomalies in the north with values below -6 hPa. In the eastern Mediterranean, below-normal pressure anomalies were observed as well. The NAO was still the dominating index for June with a monthly value of 1.41 while the other circulation indices were all below 1.

In **July** 2018, the Azores high was shifted to the north-west and the Icelandic low was more intense than usual. In northern Europe higher-than-normal pressure occurred while below-normal pressure anomalies were observed in the eastern Mediterranean. The dominant indices in July were the EA, the EA/WR and the SCA with monthly values of +2.4, -2.2 and +2.3 respectively.

In **August** 2018 the Azores high was shifted to the north again and influenced most parts of Europe. The Icelandic low was more intense than usual with a second low pressure centre located in the Barents Sea. Therefore, the NAO was the dominant index with a monthly value of +2.4 related to warm and dry conditions in Western and Central Europe due to extension of the Azores high to the continent. The second highest index was the EA with a monthly value of 1.82 related to above normal temperature in southern Europe, especially in the Balkans.

In **September** 2018 the Icelandic Low was slightly more intense than normal; its main core was shifted to the European Arctic Sea. The Azores High extended far north and was more intense than normal over Europe. As a result, a strong pressure gradient built up over the North Atlantic and southern parts of Northern Europe with cyclonic conditions over Scandinavia and prevailing high-pressure influence over the European middle latitudes. NAO and AO continued their positive phase since April (though with fluctuations on daily scale) with monthly values of 1.78 and 0.59 respectively. The Mediterranean was rather cyclonic.

In **October**, the Icelandic Low with its low pressure zone extending to the Arctic Sea was more intense than normal, while the Azores High was shifted to the north. This resulted in a strong pressure gradient between Iceland and Scotland, with Scotland and western Norway being particularly affected by a moist westerly flow. NAO and to a lesser extent also AO have been in a positive phase since April 2018 (7 successive months!), but turned to a negative phase in the last week of October 2018, leading to cold spells in parts of Europe. The middle latitudes remained most of the time in a large high-pressure zone extending from the North Atlantic to Russia, causing a continuation of mostly warm and dry weather by subsidence, even in southeastern Europe. Particularly the western Mediterranean sub-region had rather cyclonic conditions in October causing frequently heavy precipitation events.

In **November,** the Icelandic Low was very strong with pressure values more than 14 hPa below normal and relocated towards the south. The Azores High also was more intense than normal, but only slightly. As a result, a strong airflow from the North Atlantic was directed to Iberia and the Mediterranean, where much cyclonic activity took place. Another strong sea level pressure pattern was the Russian High, which extended very far into Europe with high intensity. Therefore, much of Northern, Central and Eastern Europe were under high-pressure influence most of the month with only short interruptions. NAO and AO indices were both in a neutral phase during the first two thirds, oscillating around zero. In the last third, however, both patterns turned to a negative, meridional phase, mostly with high pressure over Northern or Eastern Europe. This produced a blocking, and warm air could flow very far to the north.

In **December**, the Azores High was more intense than normal as well as the Icelandic Low, which additionally had a large extension to the south. This resulted in a stronger-than-normal westerly flow over the eastern North Atlantic bringing mild air to Europe. It was most effective on early days of the month, as reflected by a highly positive NAO phase, which turned to neutral conditions after the first ten days. Especially southwestern Europe was under high pressure influence most of the month. The Russian High advanced far to the west, up to Scandinavia, blocking the westerly flow and redirecting the warm air to northern Europe. Low-pressure anomalies occurred over south-eastern parts of RA VI due to frequent low-pressure systems passing over the Eastern Mediterranean.

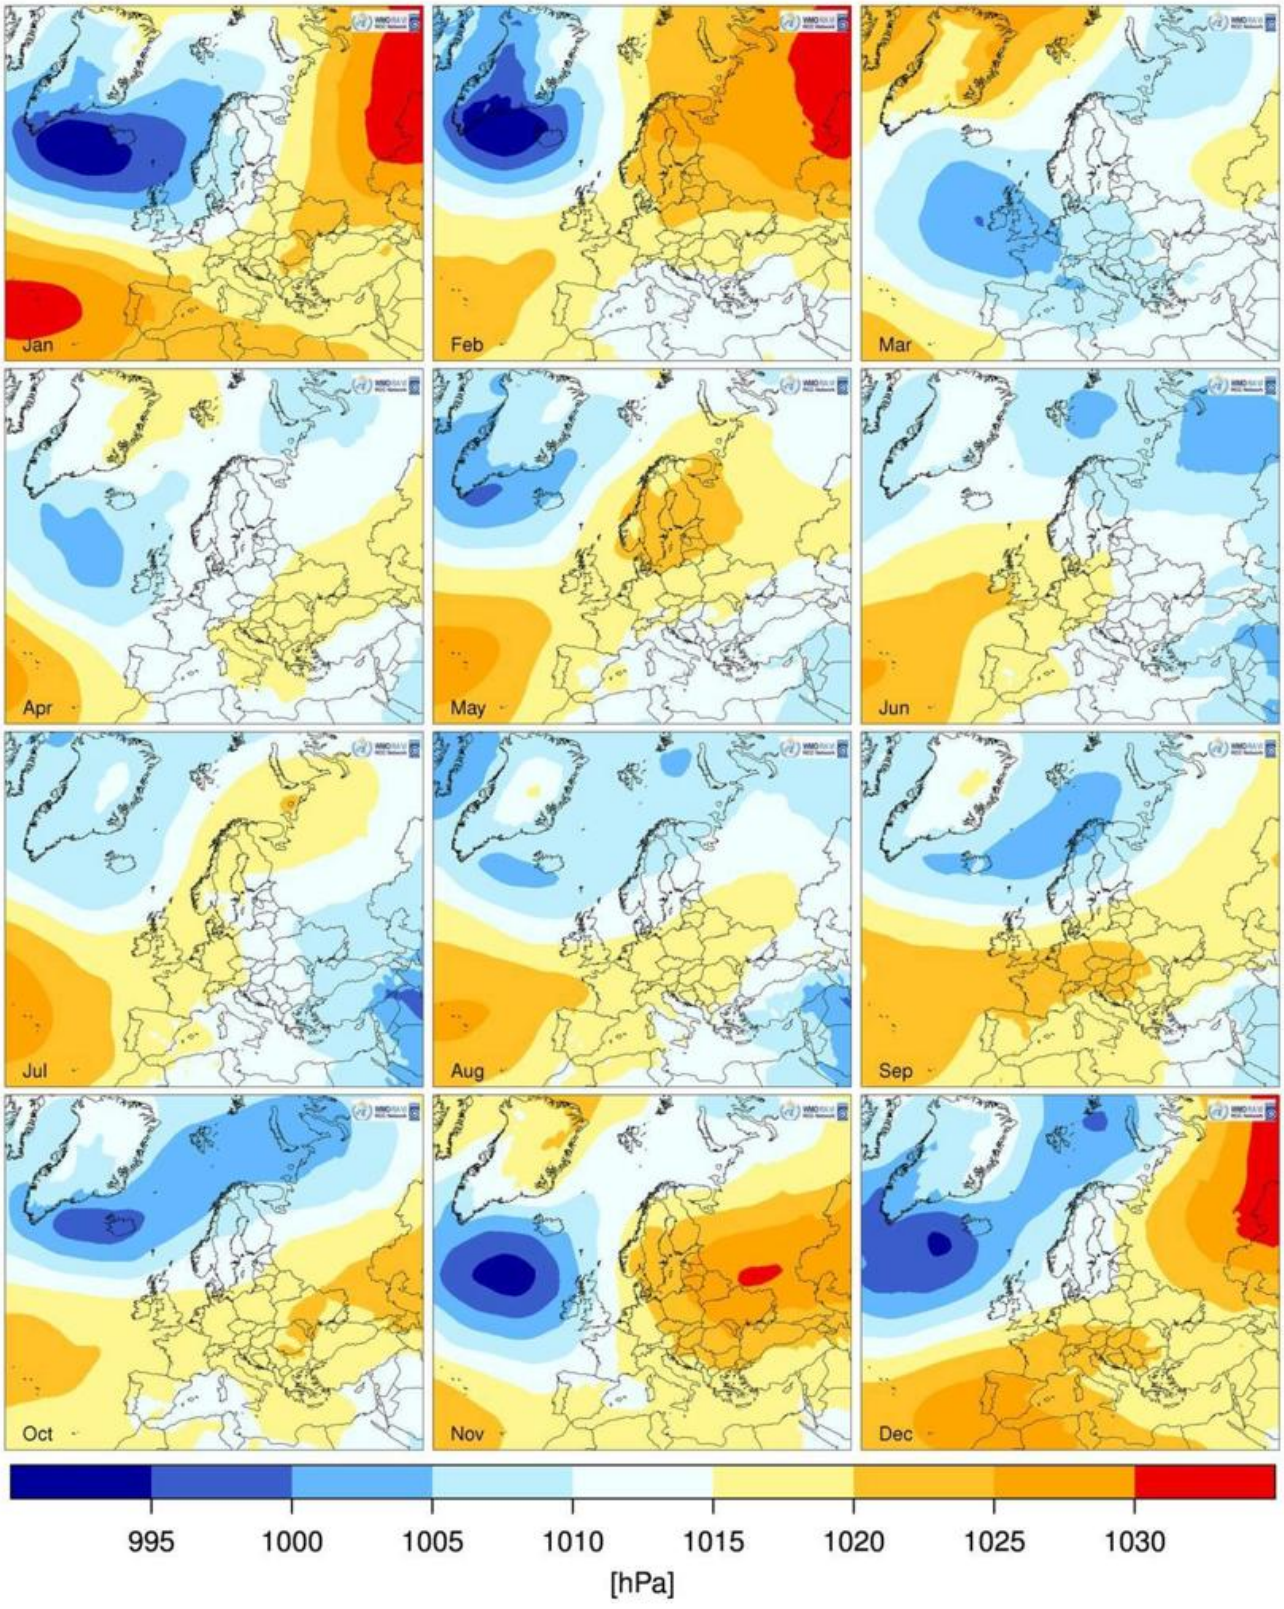

Figure 4-1: Monthly mean sea level pressure in hPa for the year 2018 (reference period 1961-1990).

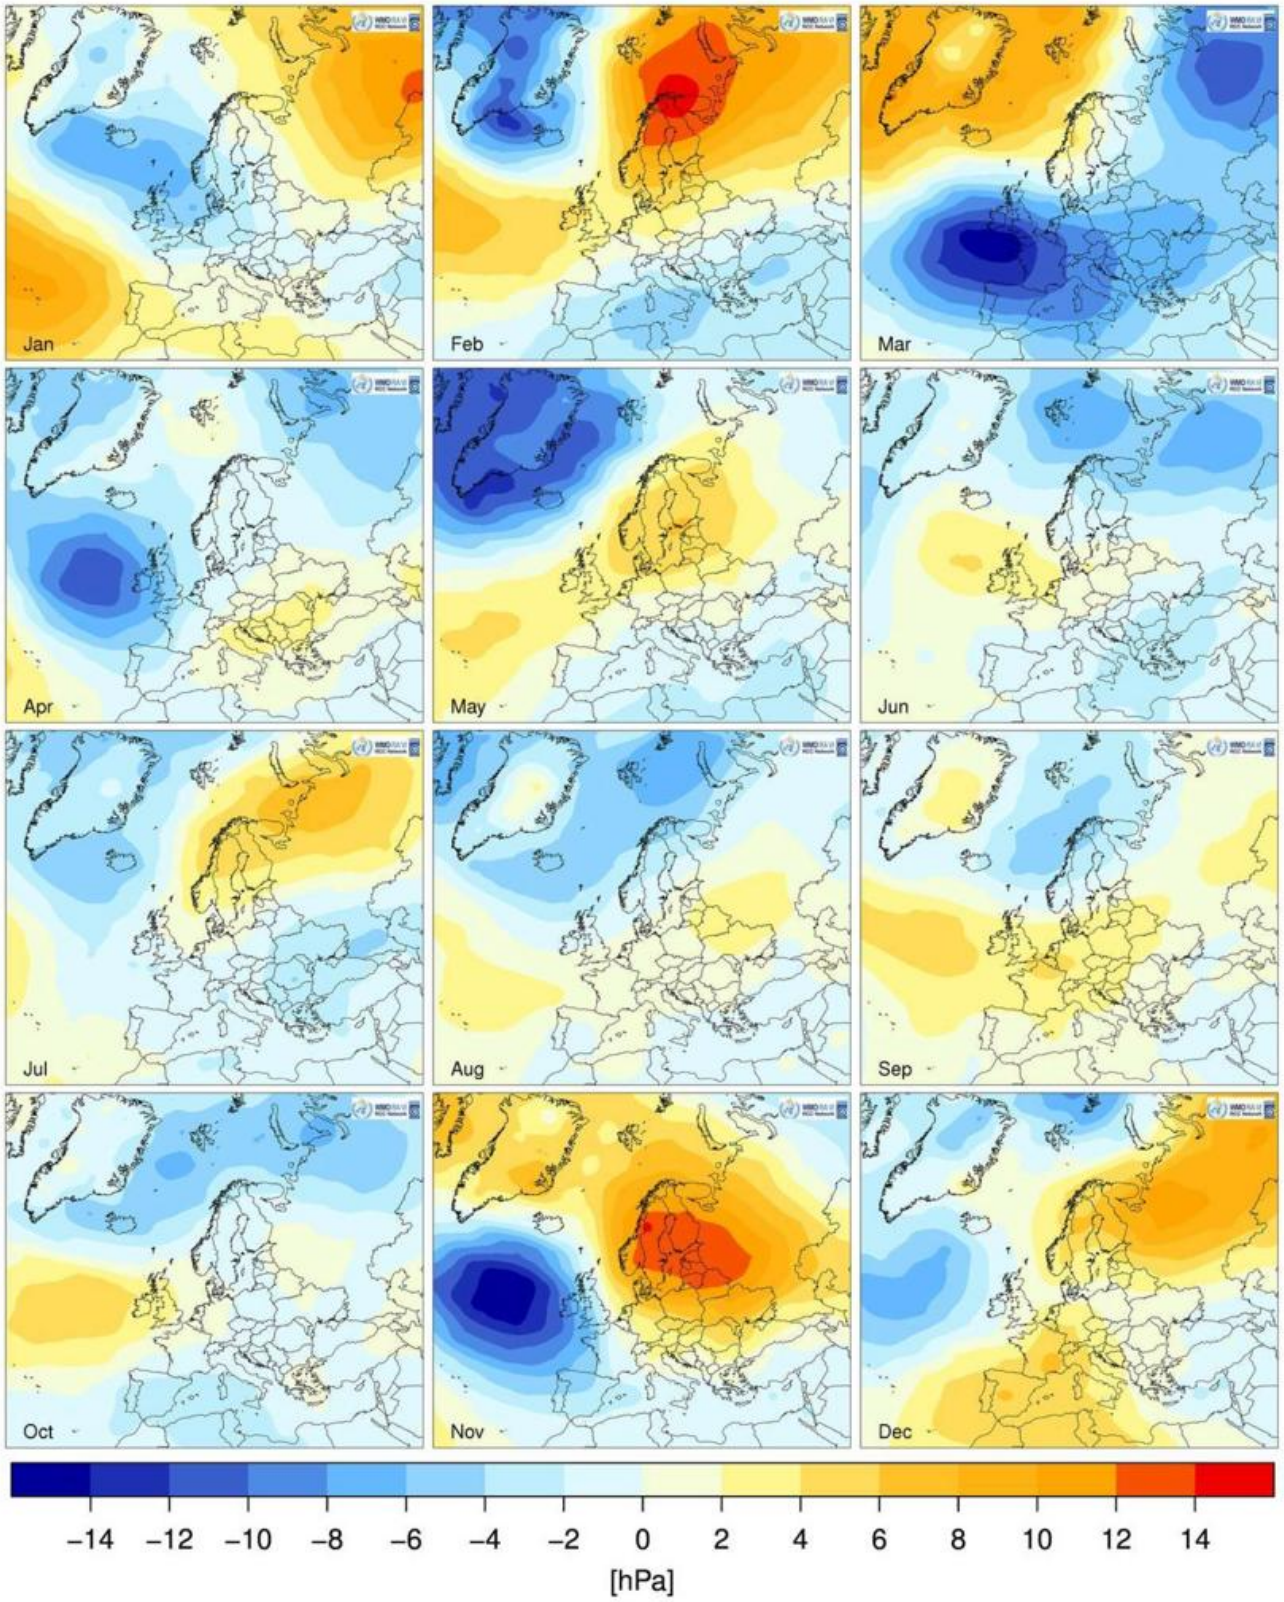

Figure 4-2: Monthly anomalies of sea level pressure in hPa for the year 2018 (reference period 1961-1990).

4.2. *Temperature*

In most of the months and sub-regions it was warmer than normal as can be seen from Table 4-2, with February and March being the only two months with temperatures below normal in some regions, namely Central and Western Europe, Iberia and Eastern Europe. Largest anomalies with anomaly values exceeding +4°C occurred in Eastern Europe in January and over Central and Western Europe as well as over the Mediterranean, Italian and Balkan Peninsula in April.

Table 4-2: Monthly and annual area average temperature anomalies in °C for each sub-region in the year 2018 (reference period: 1961-1990; definitions of the sub-regions see Figure 1-1).

Region	Year	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec

October				
Romania	11.6	+2.1	1981-2010	2nd warmest since 1961
November				
Norway		+3.7	1961-1990	4th warmest since 1900

January temperatures were warmer than normal over the entire RA VI region except for west Kazakhstan. In several countries new records were set or the month ended up among the five warmest on records: e.g. France, warmest at +3.4°C above normal w.r.t. 1981-2010, Switzerland (warmest since 1858; +3.1°C) and Austria (third; +3.8°C). In all subregions the monthly temperatures were much warmer than normal with anomalies ranging from +1.2°C for Iberia to +4.43°C for Eastern Europe. The latter is also the region were the overall largest anomalies were reached: over northern European Russia January temperatures were more than +6 °C above normal, mainly due to the first ten-day period, which was abnormally warm with anomalies of mean ten-day temperatures being 6-13°C. Also in several Mediterranean and Balkan countries, anomalies ranged between +3°C and +4°C (w.r.t 1981-2010). In Slovakia, for example, monthly mean temperatures for January were thermally +3.6 °C to +5 °C above normal (w.r.t 1981-2010), especially in west and east of Slovakia and in the utmost north.

After a such mild January, a significant change took place in February. Due to a high-pressure system over Scandinavia easterliy winds brought cold air from Siberia and thereby several periods of cold weather to most areas. As a consequence, **February** temperatures were well below normal across all central and western Europe (regional anomaly of -1.78°C) as well as over the Iberian Peninsula (regional anomaly of -1.38°C), Scandinavia and Baltic countries. The cold weather period lasted mostly until the first decade of March. Many countries reported anomalies between -1°C and -3°C (w.r.t 1960-1990), for example Slovakia up to −2.4°C, Switzerland –3.0°C, and Germany −2.8°C. In Luxembourg, at Findel station, monthly mean air temperatures in February decreased to -1.3°C, thus 2.9 °C below normal of the reference period 1981 to 2010. February was the coldest month of the season in the Nordic and Baltic countries with widespread anomalies of around −2.0°C, resulting in the third and fourth coldest February of the twenty-first century in Latvia and Sweden respectively. In Latvia, the cold wave lasted from end of February to early March, 13 days in total (21 February to 5 March). It was the strongest cold wave in the last 5 years. During this time, the thickest snow cover of this year was registered - 31 cm at Stende on February 26. In the last decade of February (from February 21 to February 28) the average air temperature was on average -11 °C below the norm. In Estonia, the monthly mean temperature was −6.9 °C (anomaly −2.4 °C). Especially cold was the last decade of February with new cold records were being set at some stations. The mean temperature for the country in the third decade was −13.2 °C (anomaly −9.1 °C) – the second place since 1961. The mean temperature at Tartu station in the third decade was −15.3 °C (anomaly −10.7 °C) – the 1st place since 1866. In Lithuania, the third decade of February was extremely cold as well: mean temperature fell to values between -10,5°C and -15,6 °C (even 10,7° lower than norm). During the 24 – 28 February spell, also Romania was affected by a cold wave, so

that the weather was frosty in all regions. February was also cold over the Iberian Peninsula resulting in below-average temperatures for most of Spain and slightly-below-normal for Portugal. February was the third coldest since 2000 and the ninth coldest since 1931 for Portugal. Spain reported its sixth coldest February since 1965. The southeastern part of the RA VI region on the contrary experience above normal temperatures, for example Albania, North Macedonia, Bulgaria and Turkey. In the South Caucasus and Middle East region all regions expecienced well-above normal temperatures as well. At many stations exceptionally high monthly average temperatures were reported: e.g. Lattakia (Syria) and Ma'an Airport (Jordan) stations reported February as their warmest on record. In the arctic region, February also continued warmer than normal, for example in north and northeastern Greenland (Denmark) with even new station records being set (see also box below with contribution by Contribution from Danish Meteorological Service). These warm temperatures are the reason why the regional anomaly for the Nordic and Baltic Countries regions stays positive, despite the cold temperatures over Scandinavia and the Baltic.

March was also unusually cold over western Europe, the Iberian Peninsula and eastern Europe with regional anomalies of -1.78°C (central and western Europe), -0.41°C and even -2.88°C respectively, featuring two cold waves in many countries. In other parts, however, above-normal temperature continued such as in the Middle East region with regional anomalies of +2.95°C. Israel reported its warmest March on record for the central and southern parts of the country with daily maximum temperatures +4 to +5°C above normal and daily minimum temperatures +2 to +2.5°C above normal. It was the warmest March since records began for day-time temperatures in central and southern Israel. In Azerbaijan and Georgia widespread anomalies of +4°C to +5°C (w.r.t. 1981-2010) occurred, even larger in Armenia.

April and **May** were then both very warm across the entire RA VI region with largest anomalies occurring over central and western Europe (+4.08°C) and the Balkan Peninsula (+4.06°C) in April and over southern Scandinavia in May with anomalies of more than +4°C above normal. Many new station and national records were set. Slovakia had its warmest April since records began in 1901, with temperature anomalies between +4.5°C and +6.1°C (w.r.t.1981-2010). The first summer day (Tmax ≥ 25 °C) was recorded on 9 April. Austria reported its second warmest April since records began in 1767, with +4.7°C above normal, only cooler than that recorded in April 1800 (+5.7°C above normal) and an unusually high number of summer days (temperature ≥25°C), with many regions breaking their record. Hungary had the warmest April and May (since 1901) as well, making spring 2018 as a whole the second warmest on record. Within the Mediterranean and Balkan peninsula region Malta reported a record warm April and also in Greece monthly temperature anomalies of up to +5°C and, in the northern parts, up to +7°C were recorded (w.r.t. 1981-2010). Many Greek weather stations registered the warmest April since 1960. Monthly maximum temperature anomalies were +4 to +5 °C above-normal values (1971-2000) in mainland while locally in northern parts anomalies exceeded 6-7°C. In Montenegro, the average temperature in April was the highest since the beginning of measurements anomalies (w.r.t. 1961-1990) in the range of 4.1 °C in Ulcinj (southern part of coastal region) to 6.1°C in Rozaje (eastern part of mountainous region). In the Republic of Moldova, the average monthly air temperature ranged from +14.0°C to +15.5ºC, which is +4°C to +5°C above normal and was observed for the first time over the entire observation period. The beginning of the meteorological summer (defined by average daily air temperatures above 15ºC) occurred in most of the republic's territory on 9 to 11 April, which is a month ahead of normal periods

Box 4 | Contributions by NMHSs – Temperature February

In Greenland (Denmark), winter season 2017-2018 was record setting at Kap Morris Jesup, Station Nord and Danmarkshavn in north and northeastern Greenland. February was particularly warm (up to +14.4ºC above the mean at Kap Morris Jesup. New record set at Kap Morris Jesup, Station Nord, Danmarkshavn, Daneborg and Ittoqqortoormiit. At Aputiteeq February was second warmest, only second to February 2018. Remarkable four times during February the temperatures at Kap Morris Jesup, the world's northernmost station, was above zero for shorter and longer periods due to foehn conditions, up to +6.2 ºC on February 25, which on the other hand not broke the record (+7.8 ºC) set February 11, 2011.

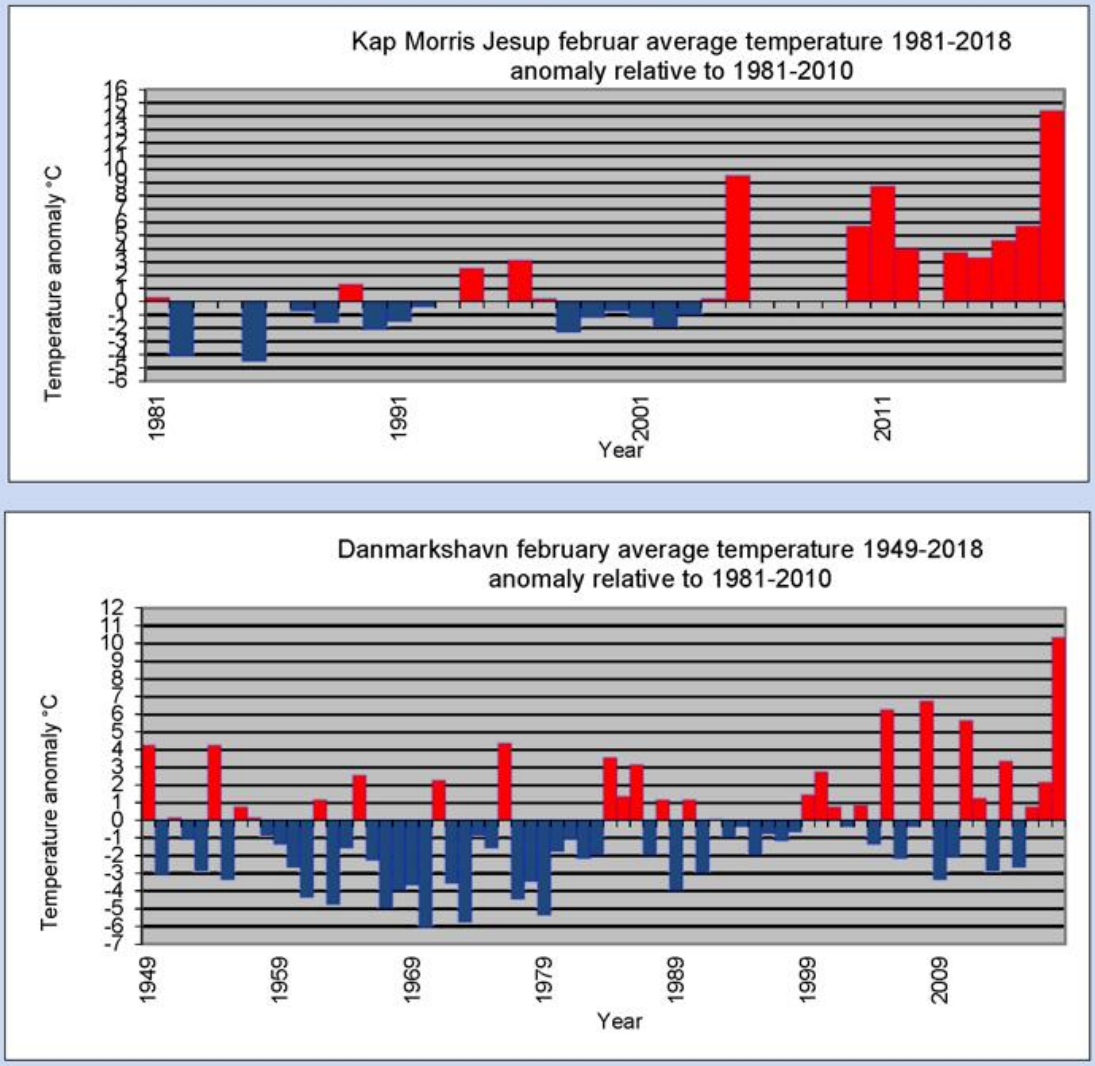

Figure 4 3: Monthly average temperature anomaly for February during 1949-2018 relative to 1981-2010 at Kap Morris (top) and Danmarkshavn (bottom).

and is observed on average once every 30 years. In Romania, the mean air temperature in April over the country as a whole was 14.1°CºC, thus +4.9ºC higher than the climatological normal (1981-2010), making the month the warmest April in the last 60 years.The largest positive deviations, above 5.5ºC, were recorded in the mountain area, the highest value, 6.0ºC being recorded at Sinaia 1500 m weather station. Serbia also had its warmest April since the measurements started, passing the

previous record from 2000 by 2 degrees basis. Record-breaking numbers of summer days were registered at 9 main meteorological stations, and the maximum daily air temperature in April was measured in Sombor.

May 2018 was the warmest on record for several countries in central and western Europe: for example in the Netherlands, Luxembourg, Austria (+5.7°C) and Germany (+3.0°C). The United Kingdom reported its second warmest May. For the region as a whole (central and western Europe) the May temperature was +3.11°C above normal. Under dominating high pressure, exceptionally high anomalies between +3°C and +4°C were also observed in the northern and Baltic states in May, with some parts of Norway and Sweden even exceeding anomalies of +5°C. It was the warmest May on record for Latvia, Lithuania, Denmark, Estonia, Finland, Norway (+4.2°C), and Sweden. Norway broke its previous record of 2013 by 1.7°C. Highest temperatures were reached in Etne outside Bergen with 32,7°C on 30 May. Record high temperatures were also recorded in May at all regular Svalbard meteorological stations in the Norwegian archipelago, including the composite series from Longyearbyen that began in 1898 where a mean temperature of 1.8°C was recorded, which is +6°C above normal. Also the other Norwegian Arctic islands experienced a warm May, the institute reports. Bjørnøya in the Barents Sea was the warmest with a mean temperature of 3.7°C. That is 5.1°C above normal. Hopen was +5°C above normal, while Jan Mayen had +5,1°C warmer than normal for May. Ny-Ålesund, further north on Spitsbergen, had a mean temperature of 1,6°C, which is +5,6°C above normal for the month. During May, lowest (coldest) minimum temperature records were broken two times at the summit on the Greenland ice cap with the final record being −46.5°C.

June was warmer than normal in most parts of the RA VI region, like the two previous months. Anomalies were a bit smaller though with regional values ranging between +0.8°C for Eastern Europe and +2.48°C for Central and Western Europe. Only northern Scandinavia and Greenland as well as parts of European Russia experienced temperatures up to -2°C colder than normal. These cooler-than-normal temperature make the Nordic and Baltic countries region the only one with a negative anomaly value in June: -0.2°C.

Due to a blocked weather pattern over Europe with a vast anticyclone over Scandinavia, many countries experienced an intense heatwave in **July** with many new records being set. Temperatures were warmer than normal over the whole RA VI region with regional anomalies ranging from +0,67°C for Iberia to +3,02°C for central and western Europe. Temperature anomalies were largest (greater than +3°C) over Scandinavia, western Europe (especially Benelux countries and northern France) as well as over the southern Caucasus region (see Figure 4-4). In Armenia, anomalies were as high as +4°C and made July 2018 become the hottest July in the entire history of observation. The heat wave was recorded from June 29 to July 12 2018, when the average daily air temperature was by + 4-7°C above normal, locally even up to +9°C. At Yerevan (Armenia), a new local maximum temperature record of 43.7°C was set on 12 July, tying with the countrywide maximum temperature set on 31 July 2011 in Meghri. Also in Kazakhstan, new temperature records (since 1936) were set at several stations: Sam (32.1°C), Fort Shevchenko (29.7°C), Beyneu (33.2°C). Temperatures were +3°C above normal in Georgia and Azerbaijan. In Norway, the monthly mean temperature was +4.3°C above normal. This is, together with 2014, the warmest July recorded in Norway, in the series that starts in 1900. Latvia saw its second heat wave during the second half of July and early August, during which around 60 new highest maximum temperature records were set: Ainažu (+ 33.7 °C) and Cape (+ 32.1°C). The heat also caused several forest and bog fires. As a result of the heat

wave, July became the 3rd warmest on record. In the Netherlands, July was the second warmest since 1901 with mean temperarature of 20,7°C and also over European Russia the monthly mean air temperature in July was +2 to +3°C above normal. The focus of heat was in the northwestern areas, and even inside the Arctic circle, in the Murmansk Region, daily air temperature rose above 30°C.

During **August,** daily minimum, average, and maximum temperatures were also exceptionally above normal throughout Europe, especially over central and eastern Europe where largest anomalies occurred ranging mostly between +3°C and +4°C, locally even above. On the regional scale, temperature anomalies were larger than 1°C for all regions ranging from +1,14°C for the Middle East to +2,86°C for central and western Europe. In Hungary, there were three severe heatwave periods in the summer that Hungary suffered between 30 July – 5 August, 7-10 August and 21-23 August, thus August was the fourth warmest month and summer the sixth warmest since 1901. In Moldova, average monthly air temperature was 21.8 to 24.7 ºC, which is + 2.5-3.5 ºC above the norm with the number of days with the maximum air temperature ≥30ºC in August was on the territory mainly 15-25 days (norm of 3-10), which in most of the territory is observed on average once every 10-30 years. This number reached even 27-30 days in places, which in August was registered for the first time in the entire period of instrumental observations. August was also very warm, with an anomaly of +1.7°C, for Spain, and Portugal reporting its second warmest August in its 88-year record (after 2003). Record-breaking temperatures were observed in both Spain and Portugal, particularly during 1–7 August when new summer records of daily minimum temperature were set at eight stations in Spain, and three of the main stations of AEMET (Spanish Meteorological Service) reported record high absolute maximum temperatures. The highest value among the Spanish main stations in 2018 was 45.1°C in Cordoba on 4 August. In mainland Portugal, 4 August was the hottest day of the twenty-first century, with a daily maximum of 46.8°C in Alvega. In Portugal, it was the secondwarmest

August since 1931 (highest in 2003), with an anomaly of +2.35 °C above normal (w.r.t. 1971-2000). During the period from 1 to 6 of August, a heat wave occurred that covered almost the whole territory, except coastal areas and some areas of northern inner region. Maximum air temperature values (mainland mean) were above 40 °C on three consecutive days (40.1 °C, 40.9 °C and 41.6 °C, respectively on August 2, 3 and 4) exceeding the absolute extremes of maximum air temperature in at more than 40 % of stations, and at 25 % of stations the highest values of minimum air temperature were exceeded.

September was again a very warm month, the warmest September on record for Europe according to data published by the NOAA National Centers for Environmental Information (https://www.ncdc.noaa.gov/cag/). with an anomalies of 2.11°C relative to 1910-2000. In September largest anomalies occurred over Western Russia and adjacent countries to the west (e.g. Baltic countries) as well as over the Iberian Peninsula with anomalies up to +4°C and locally even higher. This is also reflected in the regional anomalies with the highest anomaly found over Eastern Europe with +2.96°C and Iberia (+2.47°C). Latvia reported its second warmest September since 1934, with a mean of 14.6°C. For the first time, a temperature of 30°C was observed during the second half of the month in the country. Finland observed temperatures exceeding 20°C after the middle of the month. Spain and Portugal reported their warmest September with an anomaly of +2.4°C and +2.78°C above normal respectivly. Additional new records were set at Santiago de Compostela (Lavacolla) and Reus Airport on 2 and 3 September, respectively, with the highest daily minimum

temperatures of autumn since records began. At Coruña Station, a new record maximum temperature of 31.9°C was recorded on 2 September. At some Portuguese stations (inner Centre and South region) the number of hot days was about 2 to 3 times the average value.

The main part of Europe was dominated by high pressure weather in **October** and average temperatures were therefore above normal in largest parts of the RA VI region, this time especially over the Balkan Peninsula and the southern part of Euopean Russia with anomalies up to +3°C above normal. Largest regional anomalies are found therefore over the Mediterranean, Italtian and Balkan Peninsula (+2.2°C), Eastern Europe (2.38°C) as also over the Middle East (2.5°C). Bosnia and Herzegovina and Serbia observed their warmest and third warmest October on record respectivly. In Romania, the mean all-country air temperature (11.6ºC) exceeded by +2.1ºC the climatological normal (1981–2010) making it the second warmest on record. Over Central Europe, anomalies were between +1.0°C and +2.0°C. A new record was set in Locarno-Monti, Switzerland, which reported a high temperature of 30.5°C on 24 October.

November brought exceptionally warm and dry weather to northern Scandinavia. This time temperatures were also above normal over Greenland, which made the Nordic and Baltic countries region the one with the highest anomaly (+2.69°C). In Norway, Finnmarksvidda and the mountains in southern Norway had deviations of +6°C to +8°C above the normal. Several stations with long series in Troms and Finnmark set a record for the highest monthly temperature. Vardø, with measurements back to 1829, beat the old record from 1967. Below-normal temperatures were observed over Eastern Europe and western Kazakhstan.

The winter continued warmer than normal with daily minimum, average, and maximum temperatures in **December** exceptionally above average, particularly in Western and Central Europe and the Nordic countries. On the regional scale these two regions had the highest anomalies with values of +2.38°C (central and western Europe) and +2.8°C (Nordic and Baltic countries).

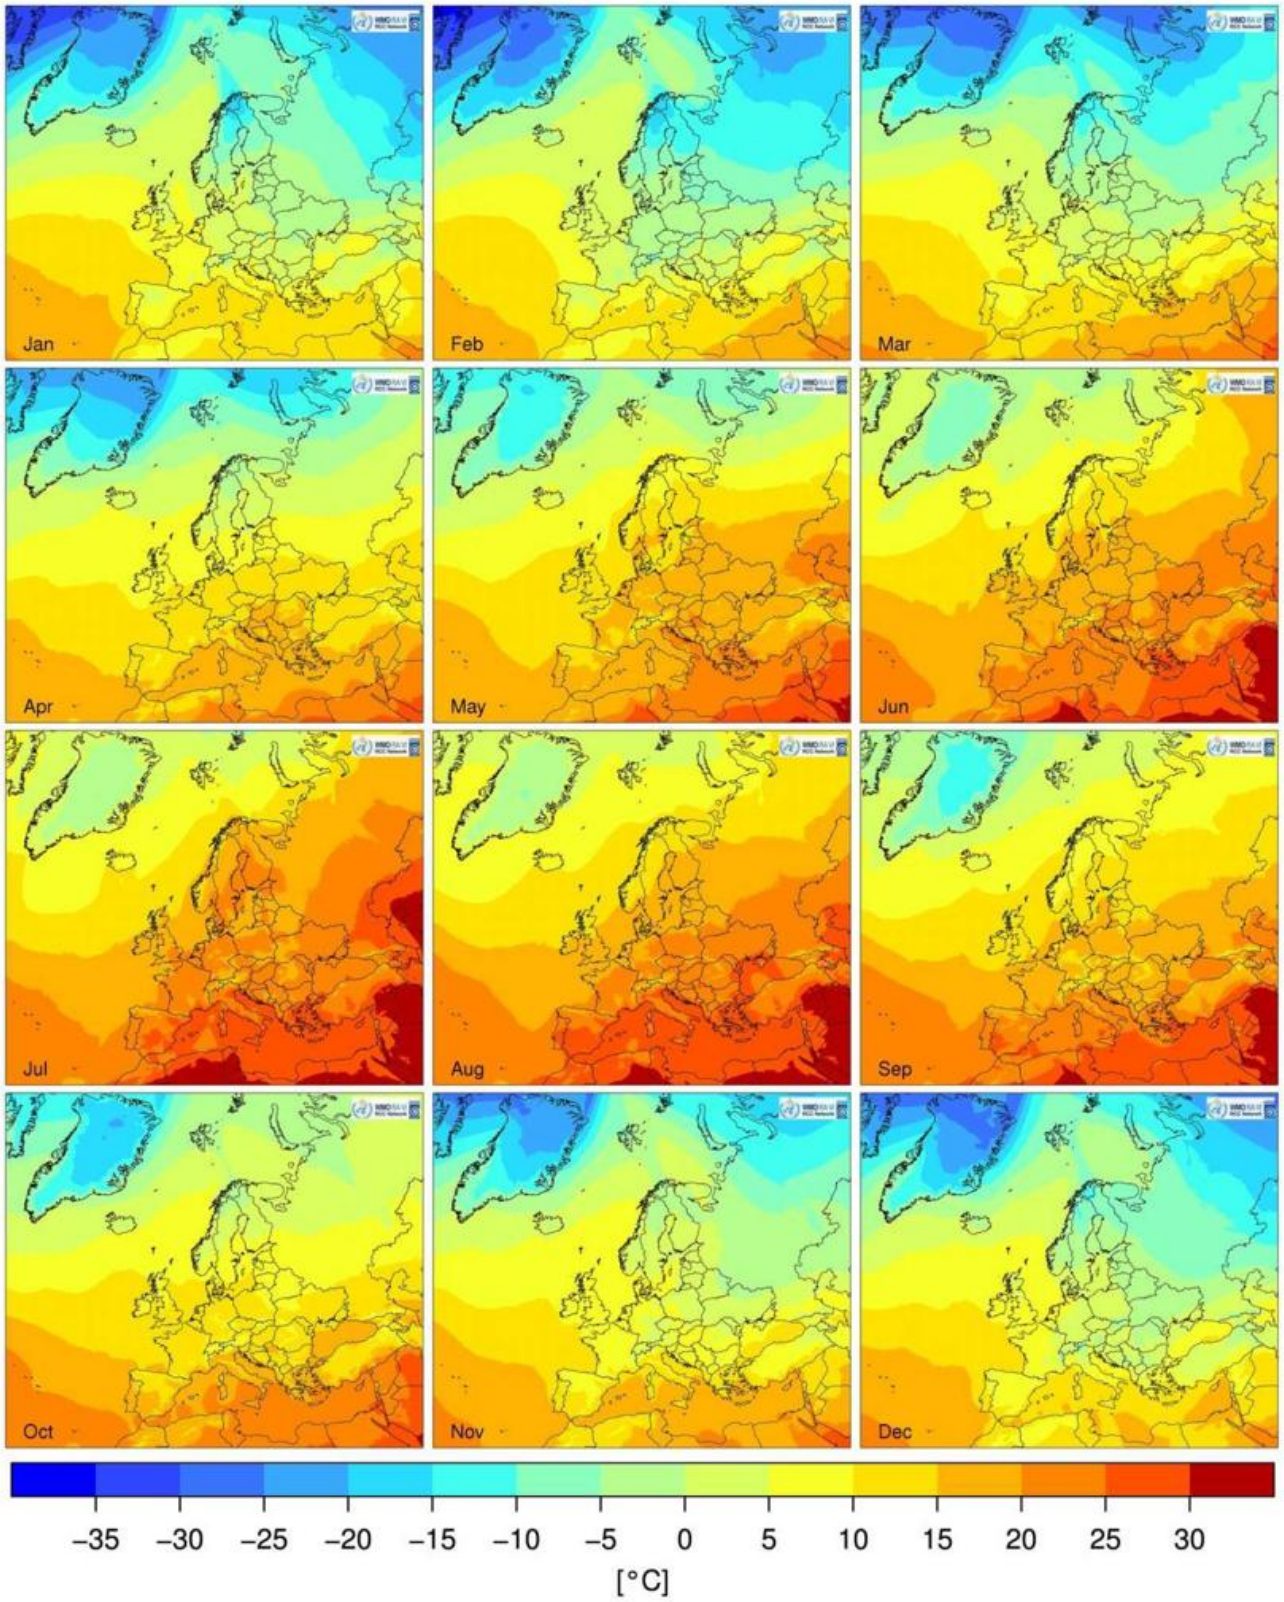

Figure 4-3: Monthly mean temperature (in °C) for the year 2018.

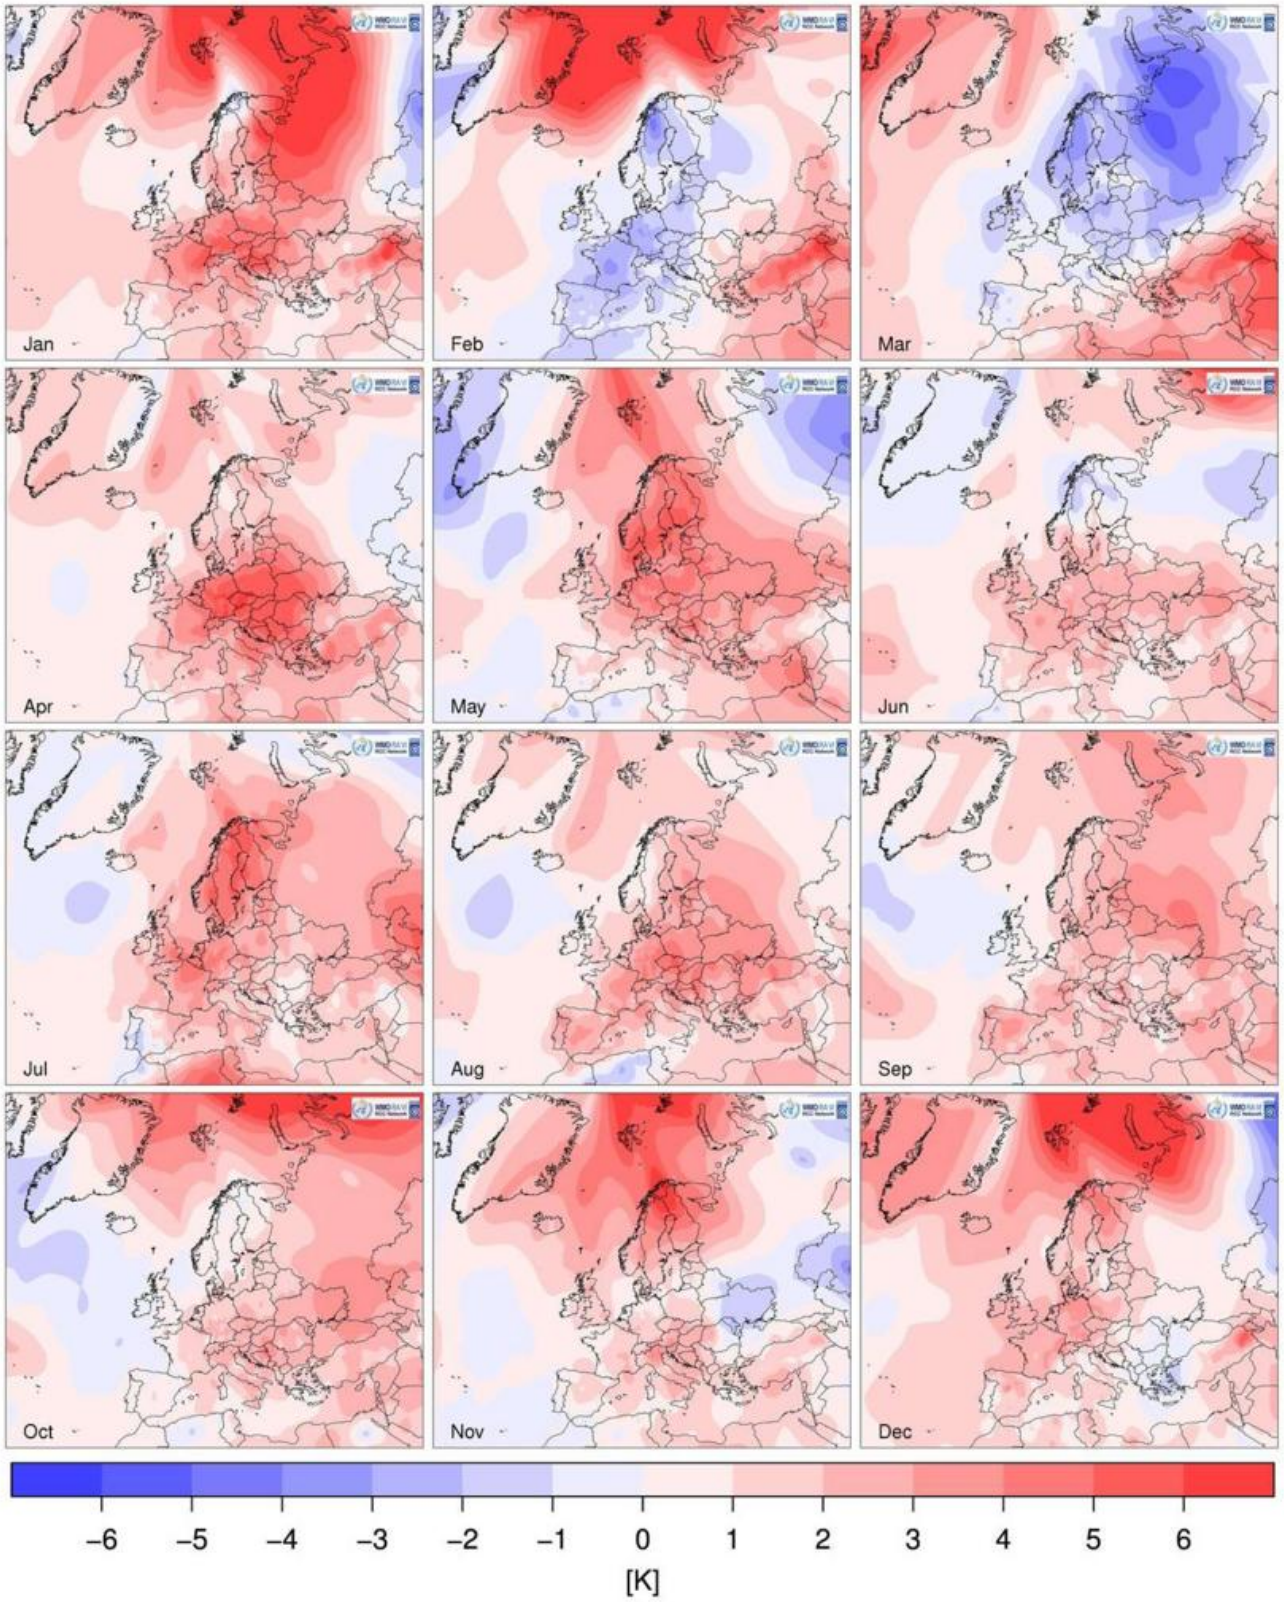

Figure 4-4: Monthly anomalies of temperature (in °C) for the year 2018 (reference period: 1961-1990).

4.3. *Precipitation*

January was wetter than normal over most of central and western as well as over the Nordic and Baltic countries, except for Estonia, which only received 70% of normal. With multiple storms passing over Europe, northern Germany received 125% to 167% of normal precipitation while southwestern Germany, Switzerland and northern France received even up to 250%. Over the Middle East it was also wetter than normal: In Israel, it was especially rainy in northern Israel where monthly totals were 250-350 mm, which is twice the monthly normal. A prolonged precipitation event occurred on January 22nd-27th with totals of 100-160 mm in northern Israel and the Coastal Plain and 30-50 mm in the Judean Mountains. Due to significant rainfall intensities on January 25th and 26th, flooding occurred in several places, e.g. in the coastal cities of Hadera and Netanya. January was on the other hand drier than normal over the Italian and Balkan Peninsula with Italy, Greece, North Macedonia, and Bulgaria reporting precipitation totals as low as 60% of normal. Portugal recorded a precipitation deficit of -76.5 mm (which corresponds 65 % of normal). At the end of the month 56 % of the territory was in severe drought, 40% in moderate drought and 4% in slightly drought, according to PDSI index.

In **February,** a high-pressure system over Scandinavia brought cold, dry air from the east, making the month drier than normal for Western Europe (France, BeNeLux, and the United Kingdom) and over Central Europe. Germany, Poland (totals below 20% of normal for eastern Germany and western Poland), the Czech Republic, and Switzerland were exceptionally dry. Saxony (Germany) reported its driest February since 1881, when records began. February was also very dry in the Nordic and Baltic countries: precipitation totals were <20% of normal in northern Norway and Sweden as well as in many parts of Finland. Latvia reported its third driest February in the twenty-first century. Portugal only received 65% of normal precipitation. By the end of the month, 84 % of the territory was in severe and extreme drought, according to PDSI index. Conversely, Pituffik (Greenland) experienced a record wet winter. The station Ittoqqortoormiit (Greenland) reported winter as their its third wettest in history. February was the wettest winter month in the Balkans, Italy, and Greece with precipitation totals ranging between 167% and 250% over large parts. February was also unusually wet over parts of Eastern Europe: At the Bucharest–Băneasa, Bucharest–Afumaţi, Brăila, and Stolnici stations in Romania, February precipitation records were broken, and at the station in Urziceni, Romania, a new 24-h precipitation record was set.

In **March** precipitation was much above (75-90 percentile range) or exceptionally above (>90 percentile range) the 1981-2010 average in Southern and Eastern Europe. In Bulgaria, March was very wet with average precipitation about 2.4 times more than normal (343% in Karnobat, Burgas district; 340% in Novachene, Pleven district). In Montenegro, precipitation in March 2018 was highest on record (?) in Herceg Novi (northern part of coastal region), and the second in rank for many parts of the country. In the Republic of Moldova, the amount of precipitation of the month at 65% of the territory was 75-120 mm (270-400% of the norm), which is observed on average once in 20-30 years in March, and isolated - for the first time over the entire observation period. The rest of the territory received 45-70 mm (150-260% of the norm). Over European Russia, in March, a vast over-wetting zone covered southern and eastern regions, where monthly precipitation norm was exceeded two- to threefold, and in individual regions of North Caucasus, by the factor of 3.5-4. In Serbia, it was the second wettest March since … with a record-breaking number of days with precipitation at 8 main meteorological stations. In Portugal, March was extremely wet with monthly precipitation amount of

272.1 mm, which was about 4 times the monthly average, being the second rainiest March since 1931 (rainiest in 2001). In some meteorological stations it was the rainiest March since the beginning of the respective time series. By the end of March, meteorological drought that occurred in mainland Portugal ended. March was also wetter than normal over almost the whole Iberian Peninsula, showing widespread precipitation values well above 250% of normal. Penhas Douradas in Portugal reported a record 585 mm of precipitation, the most rain received since 1968 (516 mm). It was the second wettest March in Portugal. Spring started also wet for Romania, Moldova, Ukraine, the southern parts of European Russia, and west Kazakhstan, with March precipitation totals 170% of normal. In eastern, central, and southern Ukraine, new monthly precipitation records were set (observations starting in 1961), at 250% to 450% of normal. In Romania, six weather stations reported new monthly total precipitation records, and four stations set new records for maximum 24-h precipitation totals in March. During March, also southern England and France received up to 170% of normal precipitation. France reported one of its wettest Marches of the 1959–2018 record, especially in Provence-Alpes-Côte d'Azur and Corsica, where it was the second wettest March following 2013.Slovakia and southern Austria, too, received up to 170% of normal precipitation while below-average precipitation continued across many parts of Germany, Poland as well as over the Nordic and Baltic countries. In the Middle East region, March was very dry as well, with either no rain or only a few millimetres across large parts of Syria, Israel, and Jordan, which was unusual for that time of year. In Israel, in the northern mountains, rainfall amounts in March were only 15-35 mm compared to an average of 70-110 mm and in central Israel only 5-15 mm (the average being 50-100 mm).

In **April,** southern central Europe, the Mediterranean, Italian and Balkan Peninsula as well as parts of Eastern Europe observed below-average precipitation (20%–60%, locally even less) while Northern, Central and Western Europe, the Iberian Peninsula and western Russia were wetter than normal (locally up to 250%). The deficit in Greece during April was exceptional—with little to no rain reported at many stations. In Bulgaria, April was the driest month of the year / on record (?) (on average 27% of the normal). In Montenegro, monthly precipitation sum was below the climatological mean for the period 1961-1990, and mostly in the classes dry, very dry and normal, expressed in % from climatological mean 1961-1990, the amount of precipitation ranged from 11% in Ulcinj (southern part) to 73% in Rozaje (eastern part of mountainous region). In the Republic of Moldova, the amount of precipitation of the month for 80% of the territory did not exceed 1-7 mm (5-15% of the norm). In Romania, the mean monthly precipitation amount countrywide was 19.7mm, 61% less than the climatological normal (1981–2010). The South Caucasus region was also affected by dryness around the Black Sea with precipitation totals as low as 60%-80% of normal. In the northern part of Norway, a few stations in Troms and Finnmark received from 30 to 50 % of the normal while in the rest of the country normal or above-normal amount of precipitation was recorded.

A dominant high-pressure system developed over Scandinavia in **May** and caused below or exceptionally below-average precipitation sums in many parts of Eastern, Western and Central Europe as over the Nordic and Baltic states where only 40%–60% of normal precipitation was observed, in Southwest Russia and Kazakhstan even less. The Novy Ushtogan Station in Kazakhstan set a local record for low precipitation with no measured precipitation at all. In European Russia, the Low Volga region also recorded a significant precipitation deficit (less than 40% of monthly norm) with some of the meteorological stations (e.g. Elton) not registering any precipitation

Box 5 | Contributions by NMHSs – Precipitation April

Intense rainfall event over Israel (Contribution from the Meteorological Service of Israel)

A major weather event occurred on April 25-27th featuring intense rainfall, severe hail, thunderstorms and heavy wind gusts. Flash floods resulted in casualties.

The synoptic situation: An upper-level low which was located over the Sinai Peninsula on April 25th and moved slowly to the east, accompanied by a low-level trough with warm and humid air. This resulted in severe atmospheric instability and the creation of well-developed Cumulonimbus clouds (see figure below). These clouds affected various regions in Israel on April 25th-26th and to a lesser extent on April 27th. They caused very intensive rainfall, mainly for short periods of 10-15 minutes over widespread areas in the country. Many stations received more than 15 mm within 10 minutes and some more than 20 mm (in Hafez Haim, southern Coastal Plain, 24 mm within 10 minutes were measured on April 25th, in Tel Aviv 22 mm (in 10 minutes) fell on the same day and in Eden Farm, north east Israel, 20 mm were measured within 10 minutes on April 26th). The rainfall intensities are considered rare to exceptional in many areas and in a few places they were unprecedented (return periods of more than 100 years).

Flash floods hit Israel due to the intensive rains, on 25 and 26 April, especially in the arid zones of the Judean Desert, the Arava and the Negev. The flash floods caused at least 13 deaths. Additionally, the rainfall, the hail and the strong winds that accompanied the well-developed Cumulonimbus clouds also resulted in property damage. Agricultural infrastructure was damaged in northern Israel and several cities (Jerusalem, Tel Aviv, Rishon LeZion) experienced flooding with road closures and traffic jams.

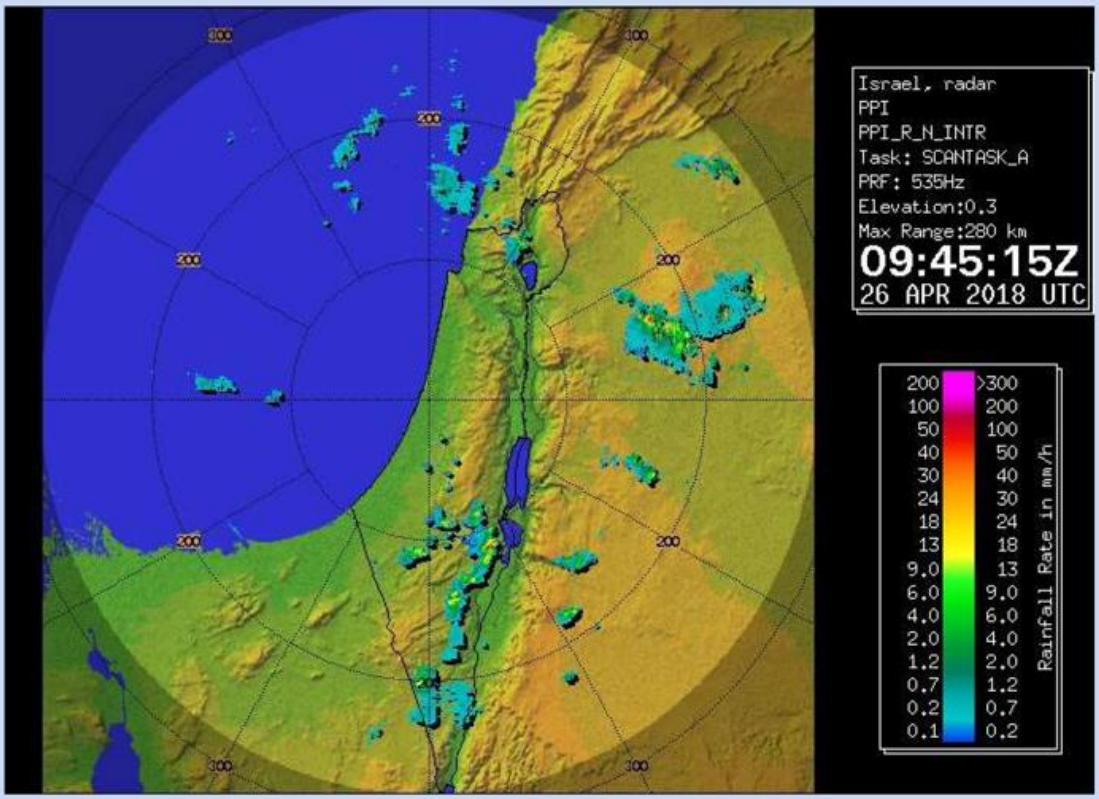

Figure 4-5: Radar images of Israel (PPI basic scan) on 26/04/2018, 09:45 UTC (12:45 LT). The arrow indicates the area near Zafit Stream where the the flash floods with casualties occurred as a result of rapid development of Cumulonimbus clouds (Source: Israel Meteorological Service)

at all. A rainless May was also recorded in the Crimea. In the Republic of Moldova, the amount of precipitation of the month for 75% of the territory of the republic did not exceed 10-35 mm (20-75% of the norm). In Norway, the monthly precipitation was 70 % of the normal. Several stations in Southern Norway received below 50 % of the normal precipitation. In Portugal, May was very dry ith only 54% of normal. However, severe thunderstorms caused large spatial differences in precipitation amounts and locally even exceptionally above average rainfall. Portions of France, Italy and Turkey as well as the Middle East region received above-normal precipitation.

Many parts of Europe were drier than normal in **June,** especially in Western and Central Europe, the Baltic countries as well as European Russia and Western Kazakhstan. In Lithuania, June was very dry receiving only 42 % of normal precipitation. In European Russia, the Volga region received precipitation that is 40% below monthly norm (thus significant precipitation deficit). A particularly serious problem of moisture deficit was experienced in the Low Volga region (which also experienced sign. precipitation deficit in May), Kalmykia and the Rostov Region, where monthly precipitation total was as low as 3-7% of normal. In the third decade, southern regions faced soil drought accompanied by strong dry winds. In contrast to these dry regions, it was very wet over the southeastern part of the RA VI region: multiple cyclones crossed southern Italy and the southeastern Balkans, bringing heavy precipitation accompanied by thunderstorms and hail. For example in Greece, almost all stations registered monthly total precipitation of more than 200 % of the normal values (1971-2000), some stations reaching multiples of their monthly normals in only a few days. For example, on 26 and 27 June, Argostoli received 83.5 mm of precipitation, which is 12 times its monthly normal. In Portugal, June was also very rainy: average precipitation in June was above normal (150 %), being the second rainiest since 2000 (after 2007). In Romania, the mean precipitation amount across the country in June was 155.9 mm, 84% more than the climatological normal (1981 – 2010). The monthly precipitation amounts in June were higher than 100 mm in most of the country's areas. The largest amounts, larger than 150 mm, were mainly recorded in the hill and mountain areas. At seven weather stations (four in Wallachia, two in Transylvania and one in northern Moldavia) departures of the precipitation amounts were recorded higher than 200%, with a peak of 257% at Turnu Măgurele weather station. At 11 weather stations from the centre and west of the country the corresponding absolute monthly maximum precipitation amounts were exceeded.

The exceptionally high-pressure anomalies in **July** also resulted in an intensification of the drought conditions in large parts of central and northern Europe. Norway had its second driest July since national records began in 1900, receiving only 55% of its normal July precipitation total. July 1901 is the driest July on record with 50% of normal precipitation. Wetter-than- normal conditions occurred, however, over the Balkans and adjacent eastern European countries such as Romania, Ukraine and Moldova. Exceptional precipitation totals were recorded at stations in the Ukraine districts of Ternopil, Chernivtsi, Ivano-Frankivsk, and Zaporizhzhya: 200%–360% above normal. In the districts of Zaporizhzhya and Kherson, new daily maximum rainfall records were set. Also in July, five stations in Romania exceeded previous monthly precipitation totals, and two stations set new records for 24-h precipitation.

August was drier than normal over large parts of the RA VI region with largest deficits over the Iberian Peninsula, central Europe (Germany and Poland) and eastern Europe ranging between 20% and 40% of normal. Eastern Ukraine and Moldova even received less than 20% of normal. In Romania, the mean monthly precipitation amount for August at country level was 34.2 mm, 47% less

than the climatological normal (1981 – 2010). Above-average precipitation amounts occurred only over Norway and in the Mediterranean region.

September was over large parts of the RA VI area drier than normal. Especially the parts of Europe within persisting high pressure influence were very dry, such as western Iberia, much of France, parts of Central Europe and the Balkans. Less than 20% of normal precipitation was registered locally. In Portugal, it was not only the warmest but also the driest September of the last 87 years in mainland Portugal, with a total precipitation of only 2.0 mm, about 5% of average value. Many parts of northern Spain received less than 50% of normal. September was also very dry in the Balkans. Ulcinj (Montenegro) and Vranje (Serbia) stations, each observed a monthly precipitation total of only 1 mm, making it the driest September on record at both stations. Serbia reported its third driest October and Bulgaria its second driest, with precipitation <20% of normal. In Moldova, the amount of precipitation of the month on 55% of the territory was 20-35 mm (35-70% of the norm). In Romania, the mean monthly precipitation amount (26.1 mm) was 52% less than the climatological normal (1981 – 2010). September 2018 was France's third driest September since the start of the record in 1959, following 1977 and 1985. In Norway, on the other hand, September was among the wettest such months since 1900 (tying with the Septembers of 1931, 1975, and 1982) with a monthly precipitation total of 150 % of the normal. A few stations in Western Norway recorded 300 to 400 % of the normal.

October was wetter than normal over northern Italy, eastern parts of Spain and southern France with most of the precipitation falling during intense and often stormy events. For example, during 18–19 October, a 1-h total of more than 150 mm was registered in Vinarós (Castellón) and on 20–21 October, a 24-h total of 335 mm (including 118 mm in 1 hour) was recorded in Alpandeire (Málaga). Over large parts of the Balkans very dry conditions dominated in October with deficits up to 20% to 40% of normal. October was also very dry in parts of Eastern Europe, e.g. in Romania, eastern Ukraine, and Moldova, with the latter mostly receiving only 5%–30% of normal. At Fort-Shevchenko Station, it was the driest autumn since 1937.

November was drier than normal over large parts of Central, Northern and Eastern Europe with locally only 20% of normal precipitation. In Lithuania, November was exceptionally dry with only 33 % of the norm. In Norway, the monthly precipitation was 85 % of the normal, but many stations in Western Norway and Trøndelag recorded less than 25% of the normal. In Poland only 32 % of normal precipitation w.r.t. 1981-2010 was recorded. Latvia observed its fourth driest November since 1924, with only 19.2 mm of precipitation (31% of normal).

The year ended with above-average precipitation in **December** for most of central Europe, parts of Eastern Europe (Belarus, Ukraine and Romania) and Turkey, terminating the drought of the previous two seasons in many areas. In Norway, the monthly precipitation was close to normal, however, a few stations in Eastern Norway and Southern Norway received 200-300% of the normal. Several stations in Western Norway recorded less than 50 % of the normal precipitation. In Poland, a precipitation anomaly of 147% was recorded for December w.r.t. 1981-2010. December was also very wet in the Middle East region, especially in Cyprus, along the Mediterranean coast, and northern Syria, due to frequent cyclonic activity over the eastern Mediterranean. Monthly precipitation totals were more than 200mm along the coast of northern Syria, and anomalies were +70mm or more over these areas, with some localized monthly totals up to above 500% of normal. In Israel, December was very rainy in northern and central Israel with monthly totals of 250-350 mm which is 1.5-3 times

the monthly average. In Southern Europe, Croatia and Slovenia, and parts of Northern Europe, on the contrary, precipitation was (much or exceptionally) below average.

Box 6 | Contributions by NMHSs – Precipitation October

Intense and persistent precipitation over Italy (Contribution from the Italian Meteorological Service)

From 27th-30th October intense and persistent precipitation occurred over the whole region (as part of a system extended to a great fraction of the national territory). Maximum cumulated precipitation over the event: 340,4 mm recorded at Casoni di S.Maria di Taro (PR, 853 m asl). At the highest areas of the basin of the Trebbia river, mostly included in Emilia-Romagna, maximum precipitation totals of 620.4 mm and 567.4 mm were recorded at Torriglia (GE, 769 m asl) and Cabanne (GE, 848 m asl). Over the Taro basin return periods for precipitation intensities cumulated over 3h were locally greater than 100 years values at Bardi (66.2 mm) and Noveglia (75.6 mm), precipitation intensities over 6h were locally greater than 200-year data at Bardi (93.6 mm) and Noveglia (108.8 mm), and greater than 100-year values at Valdena (134.8 mm), precipitation intensities cumulated over 12h and 24h were greater than 50-year values at Bardi (105.4 and 132.0 mm) and Noveglia (75.6122.8 and 148.0 mm). In these days, the winds were very intense with gusts reaching 38.3 m/s at Loiano (BO, 741 m asl), 37.7 m/s at Varsi (PR, 451 m asl) and 33.1 m/s at Teruzzi (PC, 1077 m asl) associated with an intense coastal storm with 4m waves producing significant coastal erosion along the sea shore. In Figure 4-7 shows the precipitation rate at two instants on the 29th of October when the cold front was sweeping the western part of Italy.

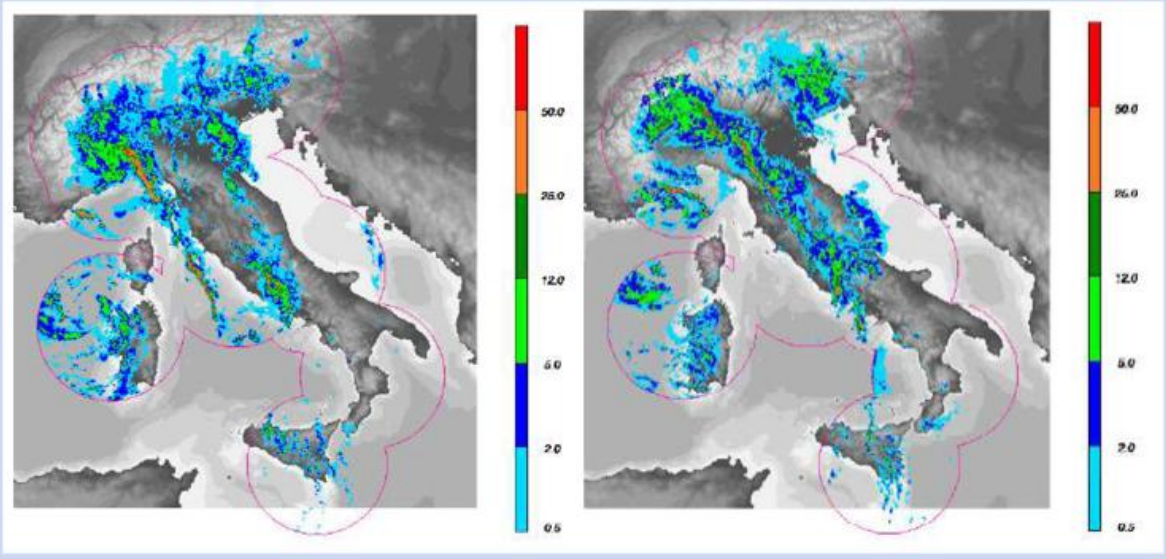

Figure 4-6: National radar composite of precipitation rate (mm/h) on the 29th October 2019 at 13:30 UTC (left) and at 15 UTC (right) (Courtesy of the National Civil Protection Agency).

Table 4-4: Rank statistics, monthly average precipitation (mm) and anomalies (mm or %) from several countries of the RA VI for the individual months in 2018 including countries with rankings among the top 5 (*ranks 1–5*) since start of the to time series.

Country (station)	Monthly average precipitation (mm)	Anomaly (mm or %)	reference period	rank
		January		
Switzerland	196	236%	1981-2010	wettest since 1901
		February		
Bulgaria	99.1	+53.3mm/ 216%	1961-1990	3rd wettest since 1930
		March		
Bulgaria	103.8	+57.1mm/ 222%		2nd wettest since 1930
Moldova (Chisinau)	103	294mm		2nd wettest since 1891
Spain	171	363%	1981-2010	wettest since 1965
Romania	70.3	+32.6 mm// +87%	1981-2010	4th wettest since 1961
		April		
Georgia	42	-35mm/55%	1981-2010	3rd driest since 1956
Moldova (Chisinau)	4	10mm	1982-2010	3rd driest since 1891
		June		
Switzerland	71	53% of normal	1981-2010	5th driest since 1901
Bulgaria	128	+55.1mm/ 176%	1961-1990	3rd wettest since 1939
Romania	155.9	71.4mm/ +84%	1981-2010	2nd wettest since 1961
Belgium (Brussels-Ukkel)	15.8	-56.0mm	1981-2010	3rd driest since 1833
		July		
Norway		53% of normal		2nd driest since 1900
Bulgaria	120	+64.5mm/ 216%	1961-1990	2nd wettest since 1930
		August		
Norway		161%		2nd wettest since 1900
Moldova (Chisinau)	1	2mm	1891	driest since 1891
Estonia	25.4	-46.6mm	1981-2010	4th driest since 1961
		September		
Norway		152%	1961-1990	wettest since 1900
		October		
Moldova (Chisinau)	2	5mm	1981-2010	3rd driest since 1891
		November		
Estonia	23,6	-39,4	1981-2010	2nd driest since 1961

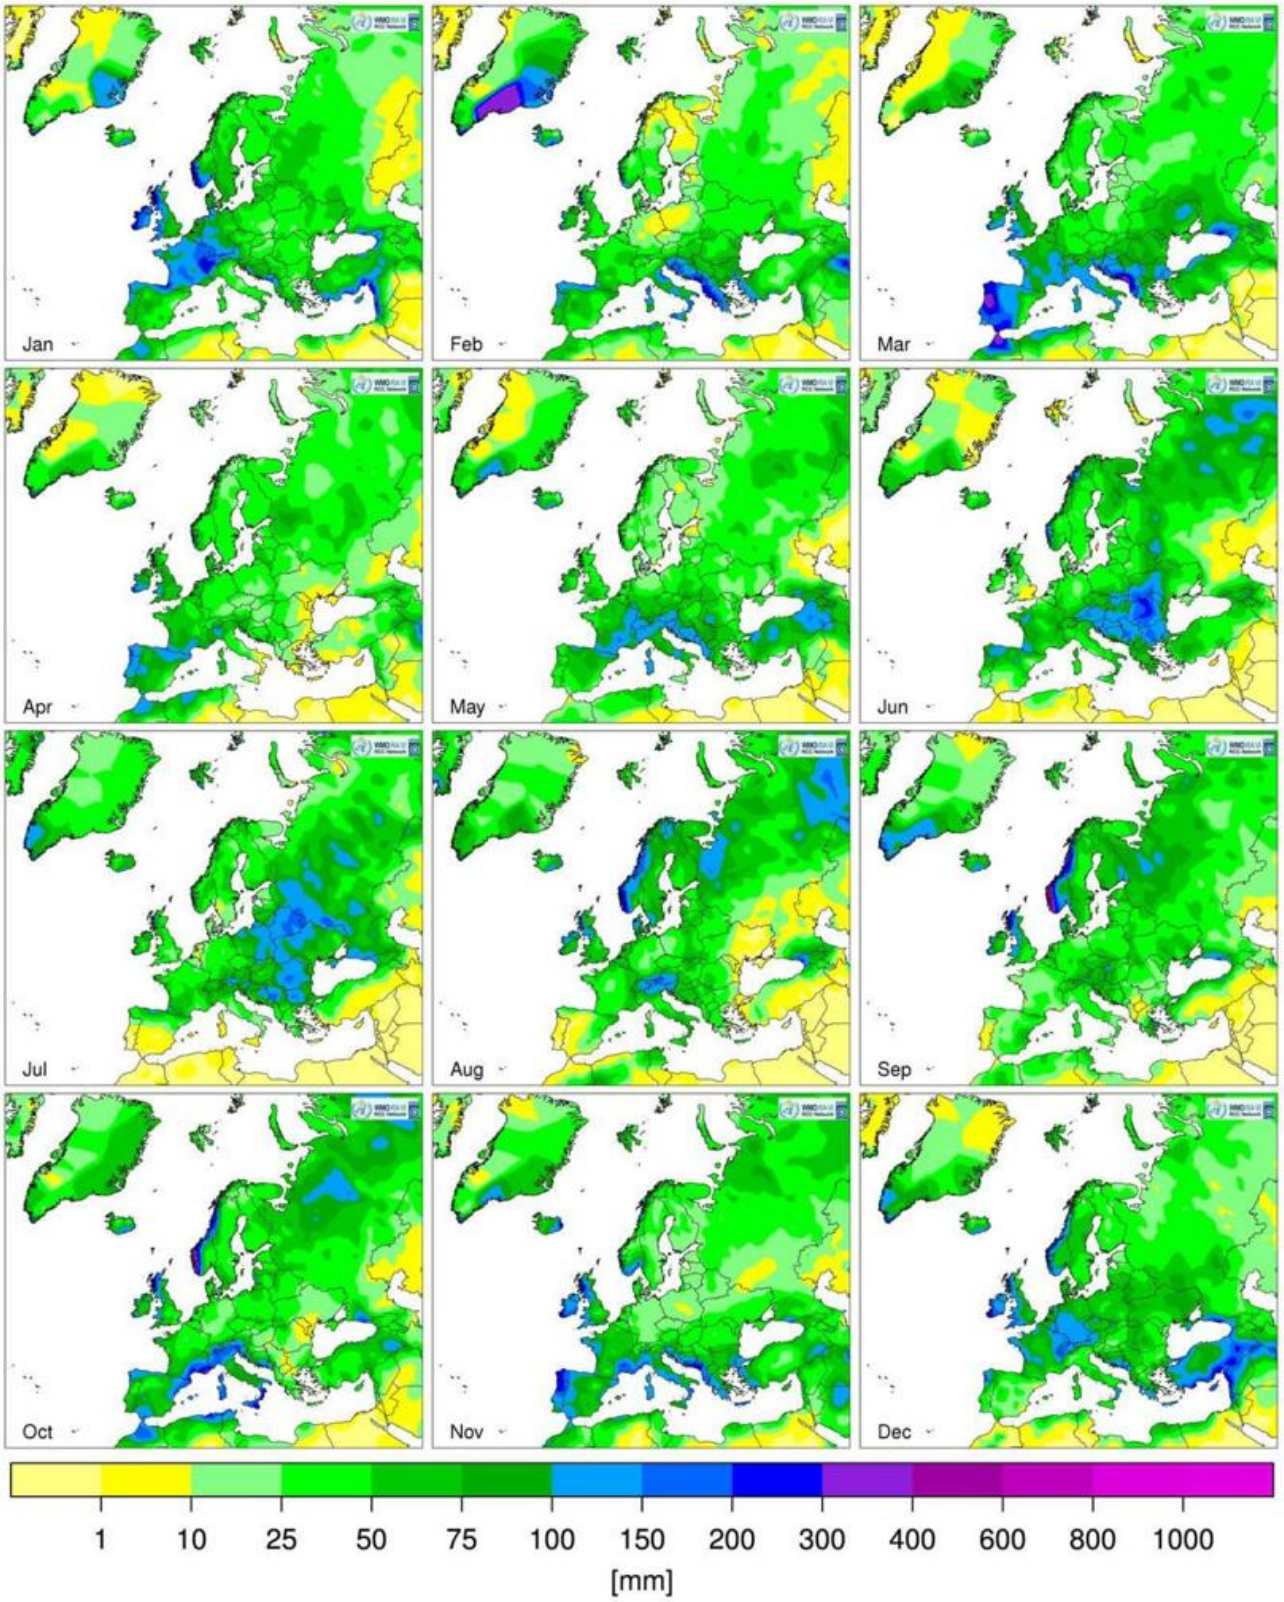

Figure 4-7: Monthly mean precipitation (in mm/month) for the year 2018.

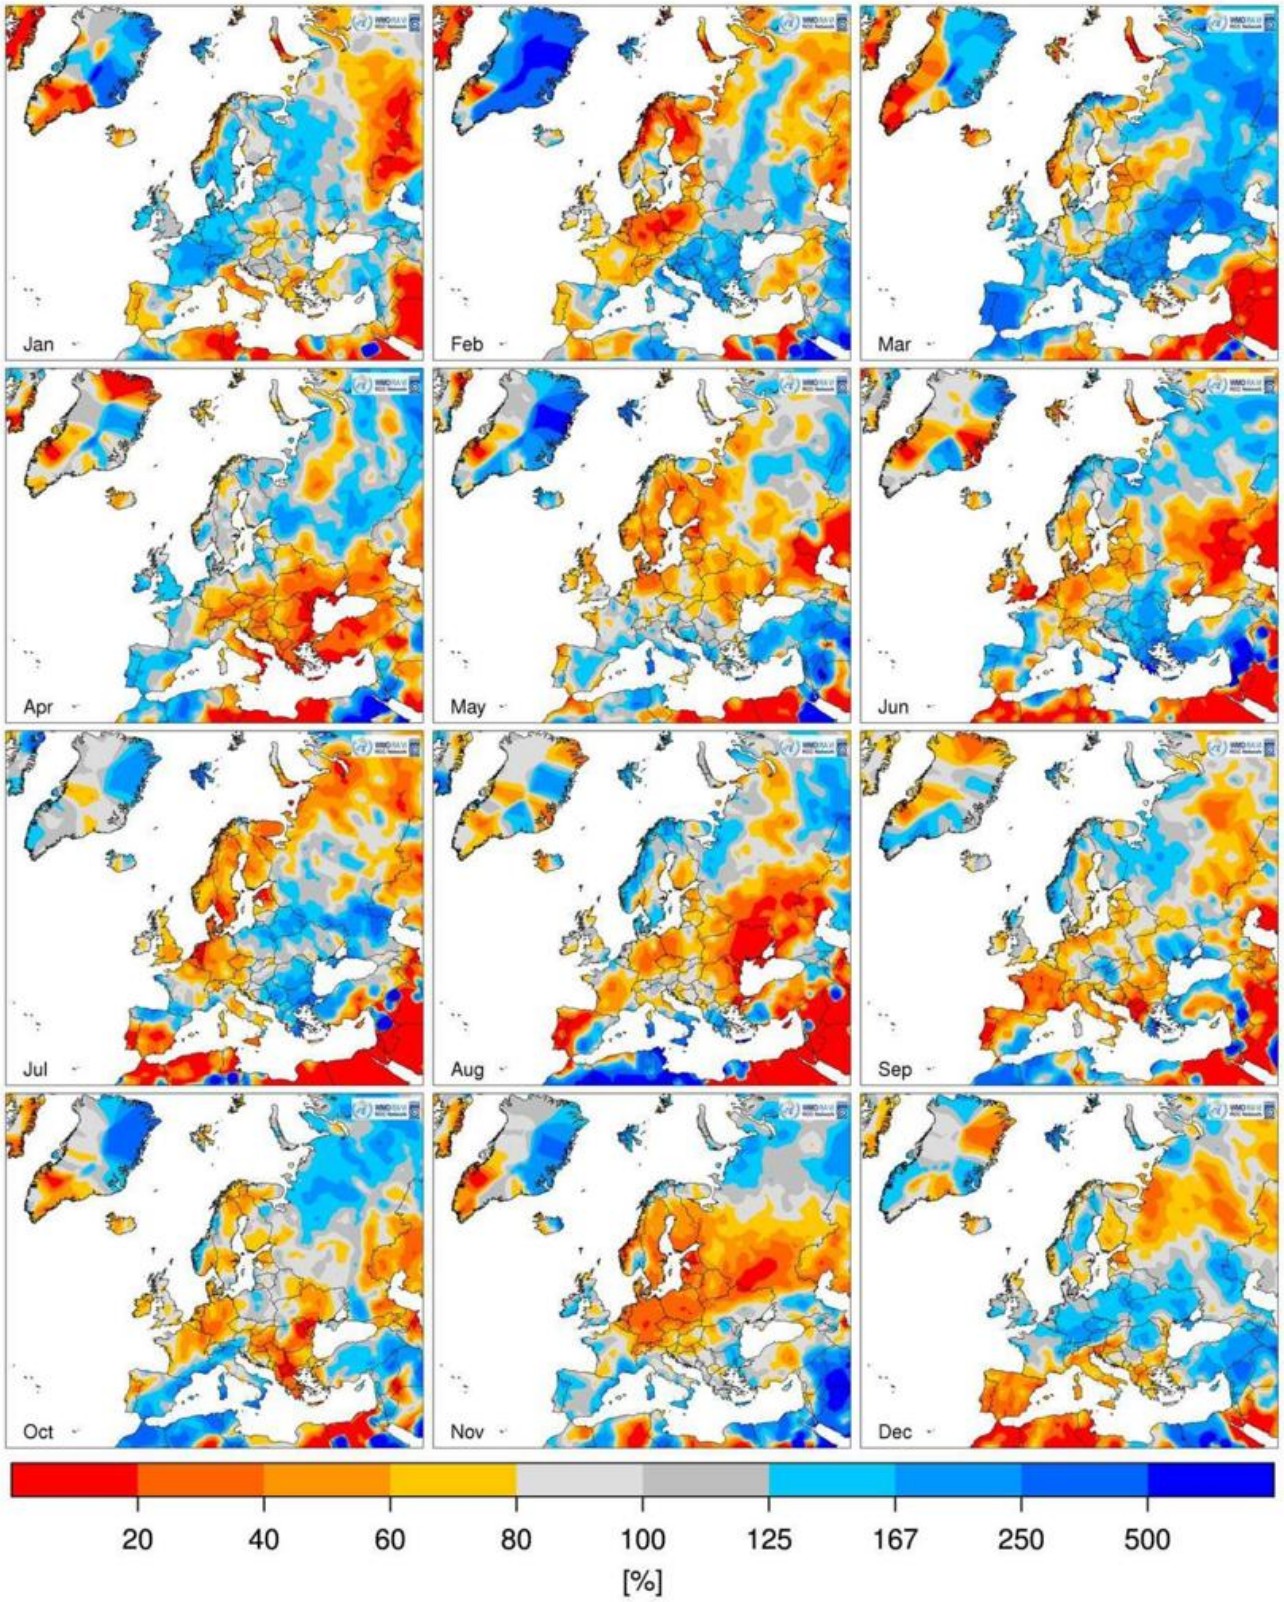

Figure 4-8: Monthly anomalies of precipitation (in mm/month) for the year 2018 (reference period 1961-1990).

4.4. *Sunshine duration*

Monthly sunshine duration in **January** was below normal over large parts of central and western Europe, the Nordic and Baltic countries as well as over eastern Europe with mostly 20 hours less of sunshine. Both southeastern and southwestern parts of Europe, on the contrary received a surplus of largely 20 to 50 sunshine hours.

In **February** the anomaly pattern was reversed compared to January situation with sunshine deficits in the southern parts of Europe and surpluses over the northern parts with anomalies of up 50 to 100 hours more sunshine, especially over Germany and the BeNeLux countries.

For the southern parts of Europe **March** continued with less sunshine than normal and anomalies of up to 50 to 100 sunshine hours less than normal. Largest surpluses occurred over Russia, Scandinavia and the Baltic countries with 50 to 100 hours more sunshine than normal.

April was not only much warmer than normal but much more sunny over large parts of the RA VI region. In an area extending from Germany to western Russia and towards the south to Greece and Turkey 50 to 100 hours more sunshine than normal was recorded, locally even more. Only in the most western parts of Europe, April closed with a deficit in sunshine hours with anomalies up to 50 hours less than normal.

May continued very sunny over most parts of Europe except for southern parts. Largest surpluses occurred over Scandinavia and the Baltic countries with more than 100 hours of sunshine more than normal: In Denmark, May 2018 was the month with the most sunshine ever since 1920, when the Danish Meteorological Institute (DMI) began recording sunshine hours. There were on average 11.5 hours of sunshine daily. May was also the sunniest on record for the UK. Estonia recorded a monthly total of sunshine of 408.4 hours which is 148% of normal – the 1st place since 1961.

June closed with more than normal sunshine hours over most parts of the RA VI region with largest surpluses again over Scandinavia but also over UK and Ireland as well as over southern parts of European Russia. However, the anomalies were smaller compared to May reaching maximum values in the range of 50 to 100 hours more sunshine than normal. The number of sunshine hours in Reykjavik (Iceland), on the contrary, was only 70 which is the fewest since 1914.

The summer continued very sunny for Western Europe and Scandinavia which over large parts received more than 100 hours more sunshine than normal in **July**. In Denmark, it was the sunniest July in Danish weather history with 339 hours of sunshine on a national level beating the old record from 2006 of 321 hours. With 348 hours of sunshine recorded, Luxembourg broke all records for the month of July as well, beating the previous record set in July 2006 of 345.5 hours.

August, September and **October** brought more sunshine hours than normal for almost the entire RA VI region with mostly 20 to 50 more sunshine hours than normal and largest surpluses in the range of 50 to 100 hours more than normal. Only in the Mediterranean region smaller surpluses and even deficits up to 20 hours less than normal were recorded.

November was still more sunny than normal in a band from France over Germany towards Russia (mostly 20 to 50 hours more) but brought less than normal sunshine hours to the regions north and south of it.

In **December** most parts of the RA VI region recorded less than normal sunshine hours with deficits up to 50 hours. In Estonia there were very few sunny hours in December. The monthly total of sunshine in Estonia was only 7 hours (34% of normal) – the second place since 1961. The monthly

total of sunshine in Tartu was even only 2 hours (only 8% of normal) – the second place since 1950. Only in the south from Iberia over Italy to the western coast of the Balkan Peninsula, sunshine hours were above the climatological average, generally 20 to 50 hours more than normal, locally even more.

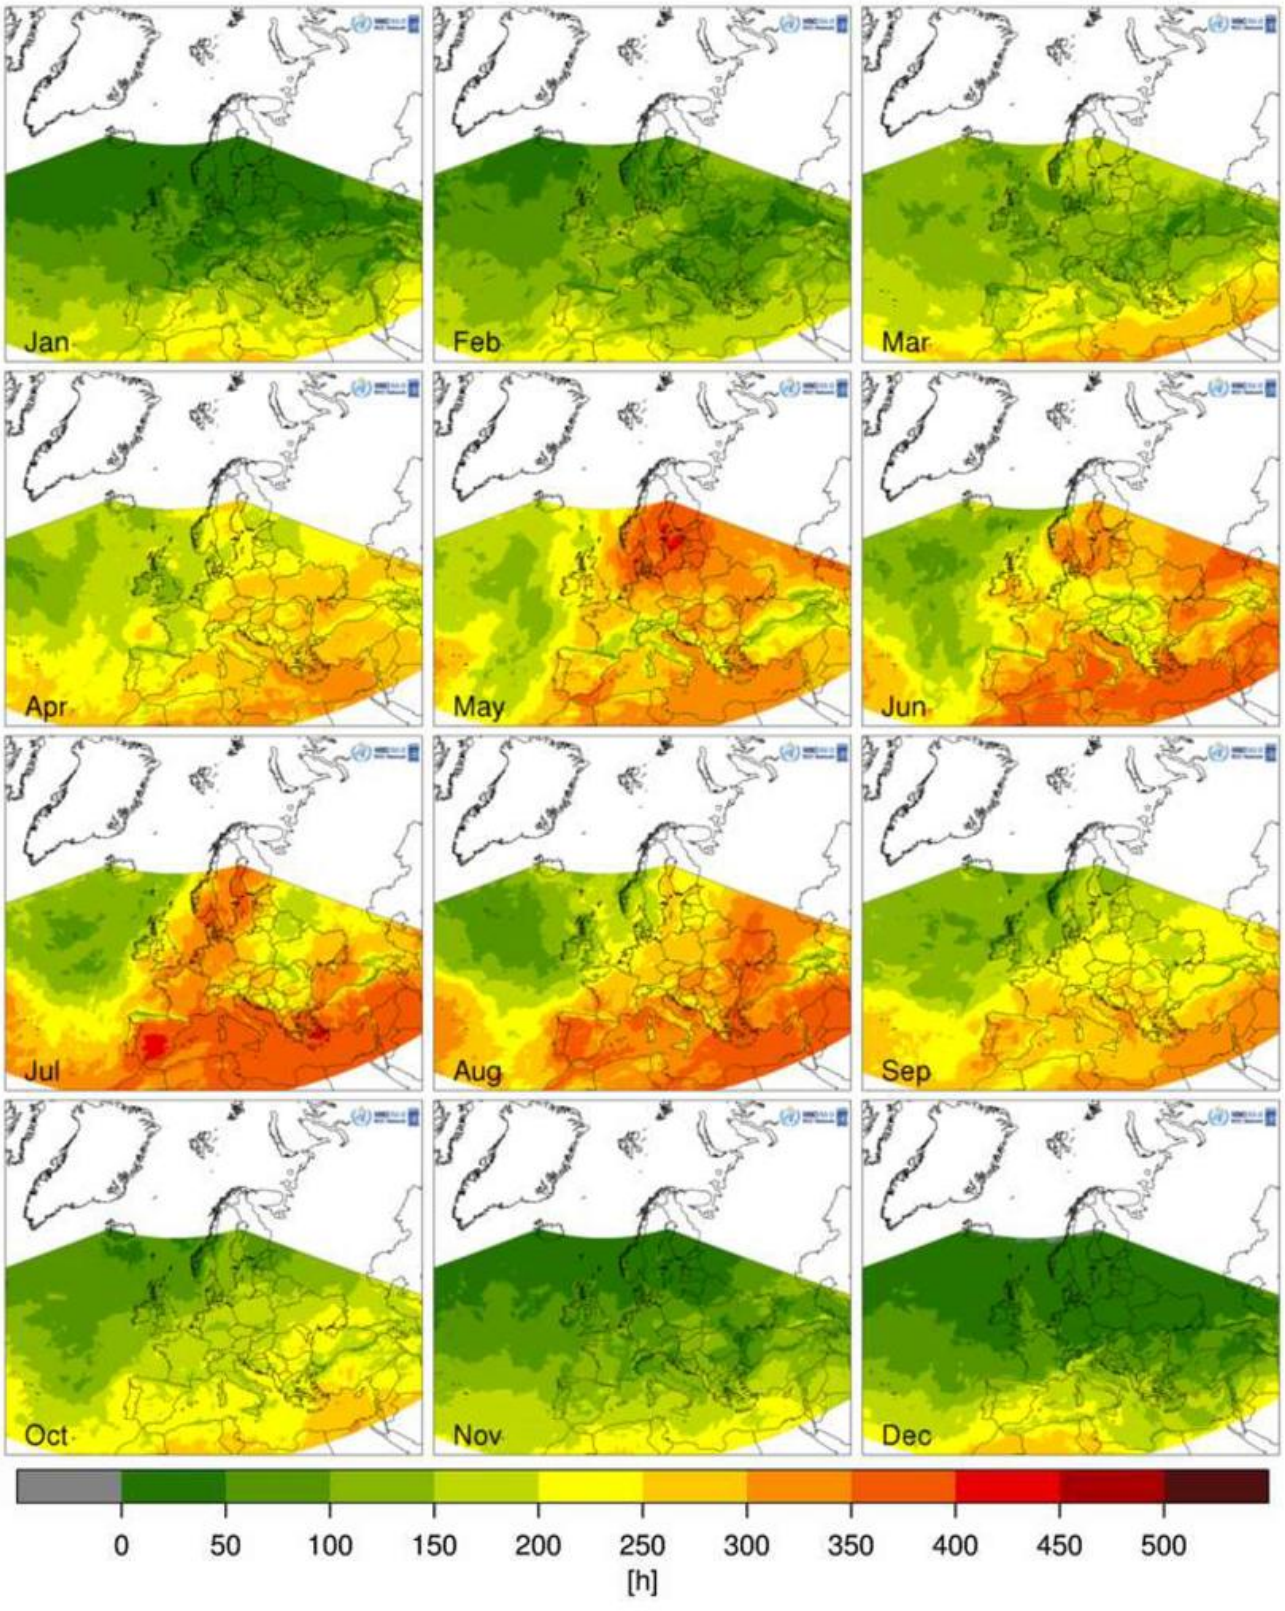

Figure 4-9: Mean of sunshine duration (in hours) for each month of the year 2018.

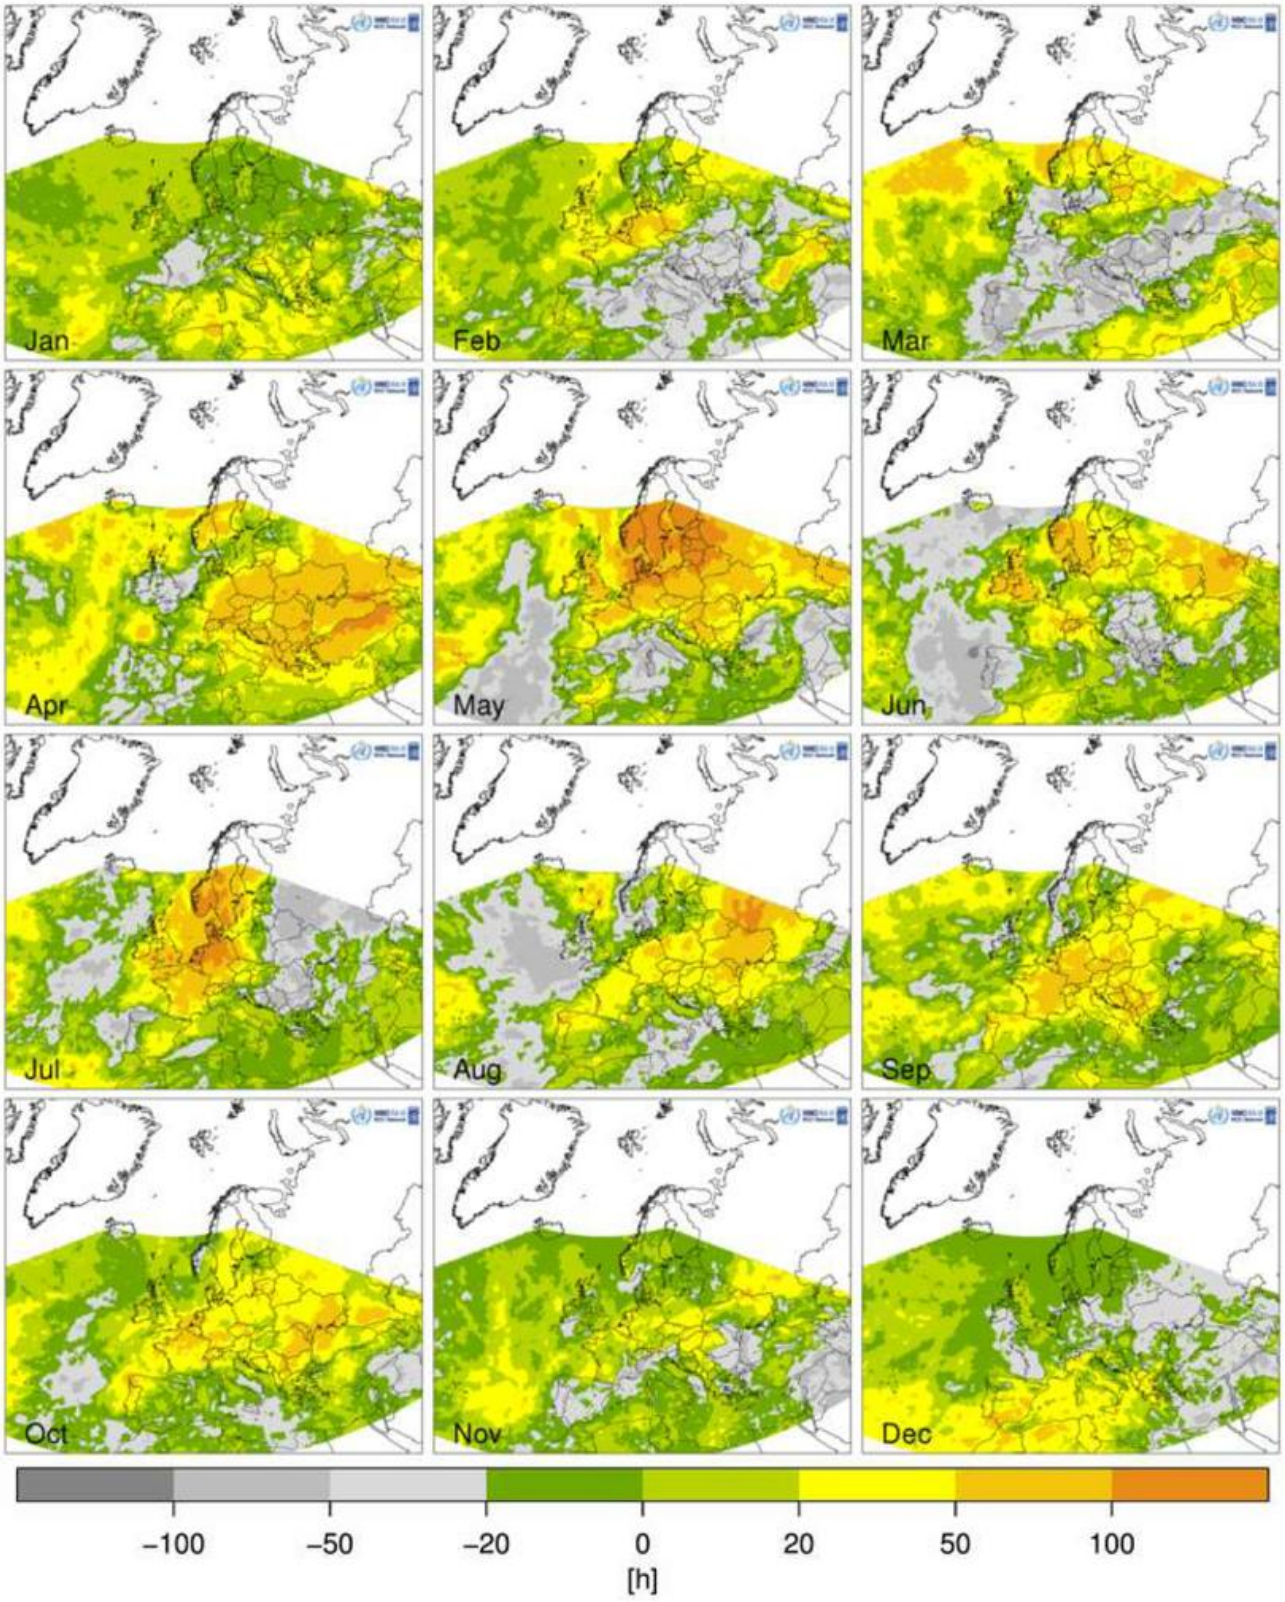

Figure 4-10: Monthly Anomalies of sunshine duration (in hours) for the year 2018 (reference period 1986-2015).

4.5. *Maps of monthly climate extremes and events*

The following maps are based on different data (as noted in the legends in parentheses), and are meant to summarize weather conditions in each month of the year 2018. The Monthly Event Maps contain information about the extreme anomalies of temperature, precipitation and wind gusts. Points are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (>=32 m/s) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

In **January** the coast of Greenland, Norway, France and the UK were affected by strong wind gusts in the context of severe winter storms passing over Western and Central Europe at the beginning and in the middle of the month. First, storm Eleanor passed over Ireland on the 2 January bringing rain and some of the strongest winds of the month. The highest gust was 43 m/s (155.6 km/h) at Knock Airport. When crossing the United Kingdom during the 2 and 3 January, storm Eleanor caused gusts exceeding 33 m/s in England and Wales and even 40 m/s Northern Ireland. The storm moved then over Central Europe and dissipated. The Netherlands registered a wind gust of 34 m/s (122 km/h) at Vlieland. France was affected by Storm Eleanor on the 3rd. Gusts reached 54 m/s (196 km/h) at Cap Corse (new monthly record), up to 50 m/s (180 km/h) on the alpine ridges, 47 m/s (170 km/h) on the Vosges and 31 m/s (111 km/h) at Paris. Storm Friederike (in German, David in French) then moved on 17-20 January over central Europe from the United Kingdom to the Baltic Sea with its cold front reaching the Alps. In the UK wind gusts of 42 m/s were observed at Capel Curig on 18th with wintry showers of rain and snow. At the Netherlands coast, the storm reached a wind speed of Beaufort 11 (more than 32 m/s) but decreased rapidly with the distance from the coast to Beaufort 8 and 9. The storm was among the ten heaviest since 1970 in the Netherlands. Throughout the month of January, several episodes of heavy rain and snow occurred over Western and Central Europe. Especially in France, Germany, the Alps and parts of the UK, extreme amounts of rain fell with sums up to 250 mm as seen from the positive anomaly of very wet days. These occurred also over large parts of Scandinavia. Over most of the area, it was warmer than normal which goes along with the higher-than-normal number of warm days.

February and **March** were for most of the RA VI region the only months with below-normal temperatures due to several cold spells, which resulted in more than normal cold days over Central, Northern and Eastern Europe in both months. Southern Europe was only affected in February. In both months positive temperature anomalies occurred over the southeastern part of the RA VI region, Turkey and the Middle East. During February several storms moved over the Mediterranean with high precipitation amounts e.g. in the Pyrenees of more than 200 mm, at the Balkans 300 to 600 mm and in Greece locally more than 300 mm. For Malta the 9th of February was the second wettest day in February since 1923 with 117 mm of rain measured, causing flooding. In southern France, there were 14 days of significant precipitation in Nice, 18 days in Cape Pertusato (Corse-du-Sud) and up to 20 days in Socoa (Pyrénées-Atlantiques), which is 8 to 11 days more than normal. In France, from February 5th to 7th, a remarkable snow episode in the region around Paris happened with a snow depth of 15 cm at Chartres and 12 cm at Paris on February 7th. During 26th and 27th of February, snowfall of 8-15 cm occurred in the Provence, on the Côte d'Azur and in Corsica.

In **April,** it was extremely warm from Central Europe up to Moldova with temperatures more than +4 K above normal. Many countries (such as Germany, Czech Republic, Luxembourg, Moldova, and Montenegro) registered the warmest April since their weather analysis begun. Large parts of eastern and southeastern Europe experienced much below-average precipitation as indicated by standardized precipitation index values below -1.5.

May was exceptionally warm over Central Europe and the Nordic and Baltic countries, which experienced temperature anomalies above +4 K and more than normal warm days. Several countries reported not only their warmest May for centuries but also new station records. These regions were also affected by a significant deficit in precipitation with values of the GPCC-DI dropping below -1.5. May was characterized by high pressure over northern Europe and lower-than-normal pressure over the southeastern Mediterranean due to several cyclones crossing the Mediterranean Sea from west to east. They were accompanied by thunderstorms and hail with locally heavy precipitation. On the 22nd of May 2018 at the Swiss station Belp 46.6 mm was measured during one hour and 71 mm during 2 hours at station Ehrendingen with hail, local flooding and damages. In France the monthly totals of the number of lightning strikes reached 180,000, which is three times the average of measurements in May since 2000 (start of measurements). At the beginning of May several thunderstorms moved from the Alps to the Pyrenees with hail and heavy precipitation, e.g. on the 7th a daily total of 63.2 mm at station Apt (Vaucluse) of which 60.4 mm fell during one hour.

June was also warmer than normal over most of the RA VI region, similar to the two previous months with above-normal numbers of warm days except for some parts of northern Scandinavia as well as European Russia were more than normal cold days occurred. Mean temperature anomalies, in contrast, were not extreme (below +4 K).

In **July** a blocked weather pattern over Europe with large positive pressure anomalies over Scandinavia and northern Russia caused heat waves in many countries of the RA VI, also visible from the increased number of warm days and exceptionally above-normal temperatures over central and northern Europe. The heat was accompanied by drier than-normal conditions as seen from GPCC-DI values below -1.5. Next to the high pressure over the northern Europe, July was characterized by lower-than-normal pressure anomalies over the Mediterranean leading to several cyclones crossing the Mediterranean Sea from west to east. They were accompanied by thunderstorms and hail with locally heavy precipitation.

In **August** the long drought conditions in Western and Central Europe continued, but in Southern Europe, the Balkans and over Norway more precipitation than usual was reported. Extremely warm temperatures occurred over the southeastern part of Europe (Balkan Peninsula) with temperature anomalies of more than +4°C.

September was again a very warm month, the warmest September on record for Europe according to NOAA and Copernicus data. This resulted in more than normal warm days over most of the RA VI region. Temperature anomalies stayed below +4°C though except for a small region in Western Russia. In the UK and Ireland, Storm Ali and storm Bronagh brought in mid-September very strong winds with wind speeds exceeding 32m/s. The highest gust at Mace Head station on that day was 146 km/h, its highest September gust since the station opened in 2004. Parts of Wales, the Midlands and the east and northeast of England were especially affected by flooding and fallen trees on roads, and a landslip onto a railway line in the Rhondda valley closed the line to Cardiff. In several parts of RA VI region accumulation sums exceeded 150% of climatological mean. In Slovakia for example,

intensive rainfall also occurred in early September in the southwest of Slovakia. For the first three days in September 2018, a precipitation total of more than 100 mm in western Slovakia at some meteorological stations was recorded, which is twice the monthly normal total in this area. The highest precipitation totals were recorded at the meteorological stations: Smolenice 124 mm, Siladice 129 mm, Jaslovské Bohunice 138 mm (here for the first four days of September together up to 176.3 mm precipitation).

In **October** the main part of Europe was dominated by high pressure weather. Average temperatures were therefore above the 1961-1990 average in large parts of the continent, which resulted in a larger-than-normal number of warm days. Ireland was hit by Storm Callum having a minimum pressure of 938 hPa and thus the lowest early season pressure for an extratropical Atlantic storm since at least 1979. Storm Callum moved northwards close to the west of Ireland on the 12th giving the windiest spell of the month and widespread heavy rain on the 12th and 13th. On October 13th and 14th, mainland Portugal, especially Centre region, was strongly affected by the passing of the tropical storm (ex-hurricane) Leslie, which caused very strong winds. Highest value of gust was 176 km/h at the meteorological station of Figueira da Foz (coastal centre region) on 13th; this was the highest gust ever recorded in Portugal (see below). The exceptional drought (GPCC-DI < -1.5) continued over much of Central Europe, particularly over southern Germany, but also in parts of southeastern Europe. Soil moisture and groundwater levels were very low, restrictions of water use came into force, record low water levels in rivers caused restrictions in ship traffic with economic losses. Wetter conditions than normal with monthly precipitation sums greater than 150% of the climatological norm occurred along the Mediterranean coasts of Spain, France and Italy for example. In Italy, on 27th-30th October intense and persistent precipitation occurred over the whole region (as part of a system extended to a great fraction of the national territory). Maximum cumulated precipitation over the event were 340,4 mm recorded at Casoni di S.Maria di Taro (PR, 853 m asl). Over the Taro basin, return periods for precipitation intensities cumulated over 3h were locally greater than 100 years at Bardi (66.2 mm) and Noveglia (75.6 mm), for precipitation intensities over 6h were locally greater than 200 years at Bardi (93.6 mm) and Noveglia (108.8 mm), and greater than 100 years at Valdena (134.8 mm), for precipitation intensities cumulated over 12h and 24h were greater than 50 years at Bardi (105.4 and 132.0 mm) and Noveglia (75.6122.8 and 148.0 mm). Moreover, at the end of October, the low pressure area called Vaia crossed the Alps causing heavy damage especially in southern Switzerland and northern Italy, at some places even whole forests were devastated by hurricane gusts. Vaia took a very unusual trajectory, as Italian lows usually move east or southeast. In the northern Alps there was a foehn storm with hurricane gusts of 200 km/h measured at some mountain peaks. But also in the valleys there were gusts of up to 130 km/h like in Elm in Switzerland.

November had exceptionally warm and dry weather in northern Scandinavia with temperature anomalies exceeding +4°C and GPCC-DI values lower than -1.5. Drought conditions also affected Central and Eastern Europe. Over large parts of Europe, the number of warm days was larger than normal. Storms across Southern Europe brought strong winds and heavy rain to the Mediterranean region, affecting the Iberian Peninsula, southern France, Italy, the Middle East and South Caucasus where precipitation sums exceeding 150% of the climatological mean occurred. In Portugal, for example, on 11th November, there were record high values of precipitation, particularly in the region of Lisbon, causing floods. Heavy rain events also led to flash floods and landslides in southern parts

of France and in Spain where 24h totals of 160mm were recorded in Vauvert (France), 206mm at Barx (Spain). Much of this heavy rain fell just in few hours.

In **December,** heavy precipitation events in the Eastern Mediterranean as well as over Central and Eastern Europe resulted in monthly precipitation sums exceeding 150% of the climatological norm. These were caused by several low-pressure systems developing over the North Atlantic. One of

Box 7 | Contributions by NMHSs – Extreme events October

Tropical storm Leslie (Contribution from the Portuguese Meteorological Service)

On October 13th and 14th the tropical storm Leslie passed in continental Portugal. It was first designated a subtropical storm by the National Hurricane Center of Miami (NHC) on 23 September 2018, when it was located about 2000 km southwest of the Azores. This storm passed on the 12 October north of the archipelago of Madeira, still as a hurricane, and later headed towards the mainland, having already entered the territory (north of Figueira da Foz) as a post-tropical storm on the 13th at 21:40 UTC (22:40 local time), however still maintained winds with a force corresponding to tropical storm.

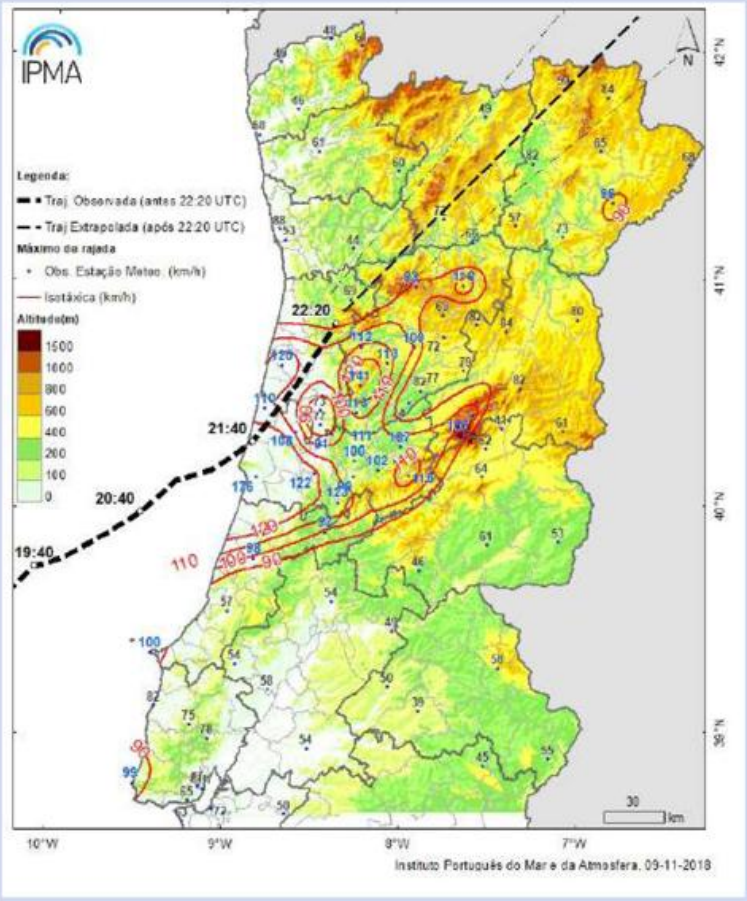

Figure 4 10- Maximum instantaneous wind values (gust), recorded at the passage of the post-tropical storm Leslie, on 13 and 14 October 2018 and the trajectory of the same (dotted line segments delimit territorial range on which the nucleus, or nuclei, of the storm passed after 22:20 UTC)

Storm Leslie caused very strong winds in the districts of Lisbon, Leiria, Coimbra, Aveiro and Viseu. The gusts of 176.4km/h, recorded at the weather station of Figueira da Foz/Vila Verde at 21:40 UTC on the 13th, correspond to the highest value recorded at stations of the national weather network (previous maximum of 169 km / h on October 17, 2015). The second and third highest values were, 141.1 km/h (day 13, 23:10 UTC) in Tondela/Caramulinho and 122.8 km/h (day 13, 21:40 UTC) in Penela/Serra do Espinhal, respectively. Figure 14 shows the highest values of maximum instantaneous wind (gust), recorded at the passage of the Posttropical Storm Leslie, on October 13 and 14, 2018 and its trajectory.

them was a storm named Marielou II with a core pressure of 965 hPa over northwestern Europe. Due to large pressure difference between this low and the Azores High, a storm field was generated which passed Western and Central Europe on 07-09 December and brought gusts up to hurricane-force, e.g.in northwestern France (Caen) at 144km/h, in Germany on the Brocken peak (1100m altitude) at 157 km/h and on peak Zugspitze at 144 km/h. Within the precipitation of the cold front of this low there were some showers and thunderstorms over Western and Central Europe, which is not very typical for the winter season. On 9 December, the storm also affected south-eastern France including Corsica with gusts up to 186km/h at Cap Corse station. Storm Deirdre ("Oswalde" in Central Europe) then formed in the Atlantic by mid of the month, bringing severe weather to the UK on 15 and 16 December 2018, reaching a minimum pressure depth of 980hPa. Strong winds and heavy rain spread to many areas, with severe gales in the southwest, resulting in a wind gust of 79 mph (127km/h) at Aberdaron. Although it was a windy day, the most dangerous impacts were from snow and freezing rain. Heavy snow affected central parts of Scotland and northeast England. Widespread freezing rain also caused impacts in northern England and southern Scotland, giving icy conditions on roads. While the western and central Mediterranean mostly received very little precipitation for this time of year, the eastern basin and adjacent land areas of Turkey and the Middle East suffered from abundant rain, violent thunderstorms and snowfall, more or less throughout the month. Flooding occurred in many places, particularly in the coastal areas of the eastern Mediterranean including Cyprus, together with several fatalities and injured, losses of animals, blocked roads and rails due to landslides near slopes or deep snow particularly in higher elevations, local hail layers of several cm, power outage, cancellation of flight and ship connections, several tornados, buildings and greenhouses damaged. Refugee sites were especially vulnerable to that heavy weather. Monthly totals near the eastern Mediterranean coasts were above 200mm in many places. December rainfall was a record high in the south-eastern Anatolia Region in Turkey; the region received the highest rainfall in the last 37 years since 1981. In Israel, the precipitation event of December 5-8th was the most significant one, obtaining half of the monthly totals. The amounts in the Coastal Plain were more than 200 mm, locally close to 250-280 mm. The intensive rainfall caused widespread flooding in the Coastal Plain.

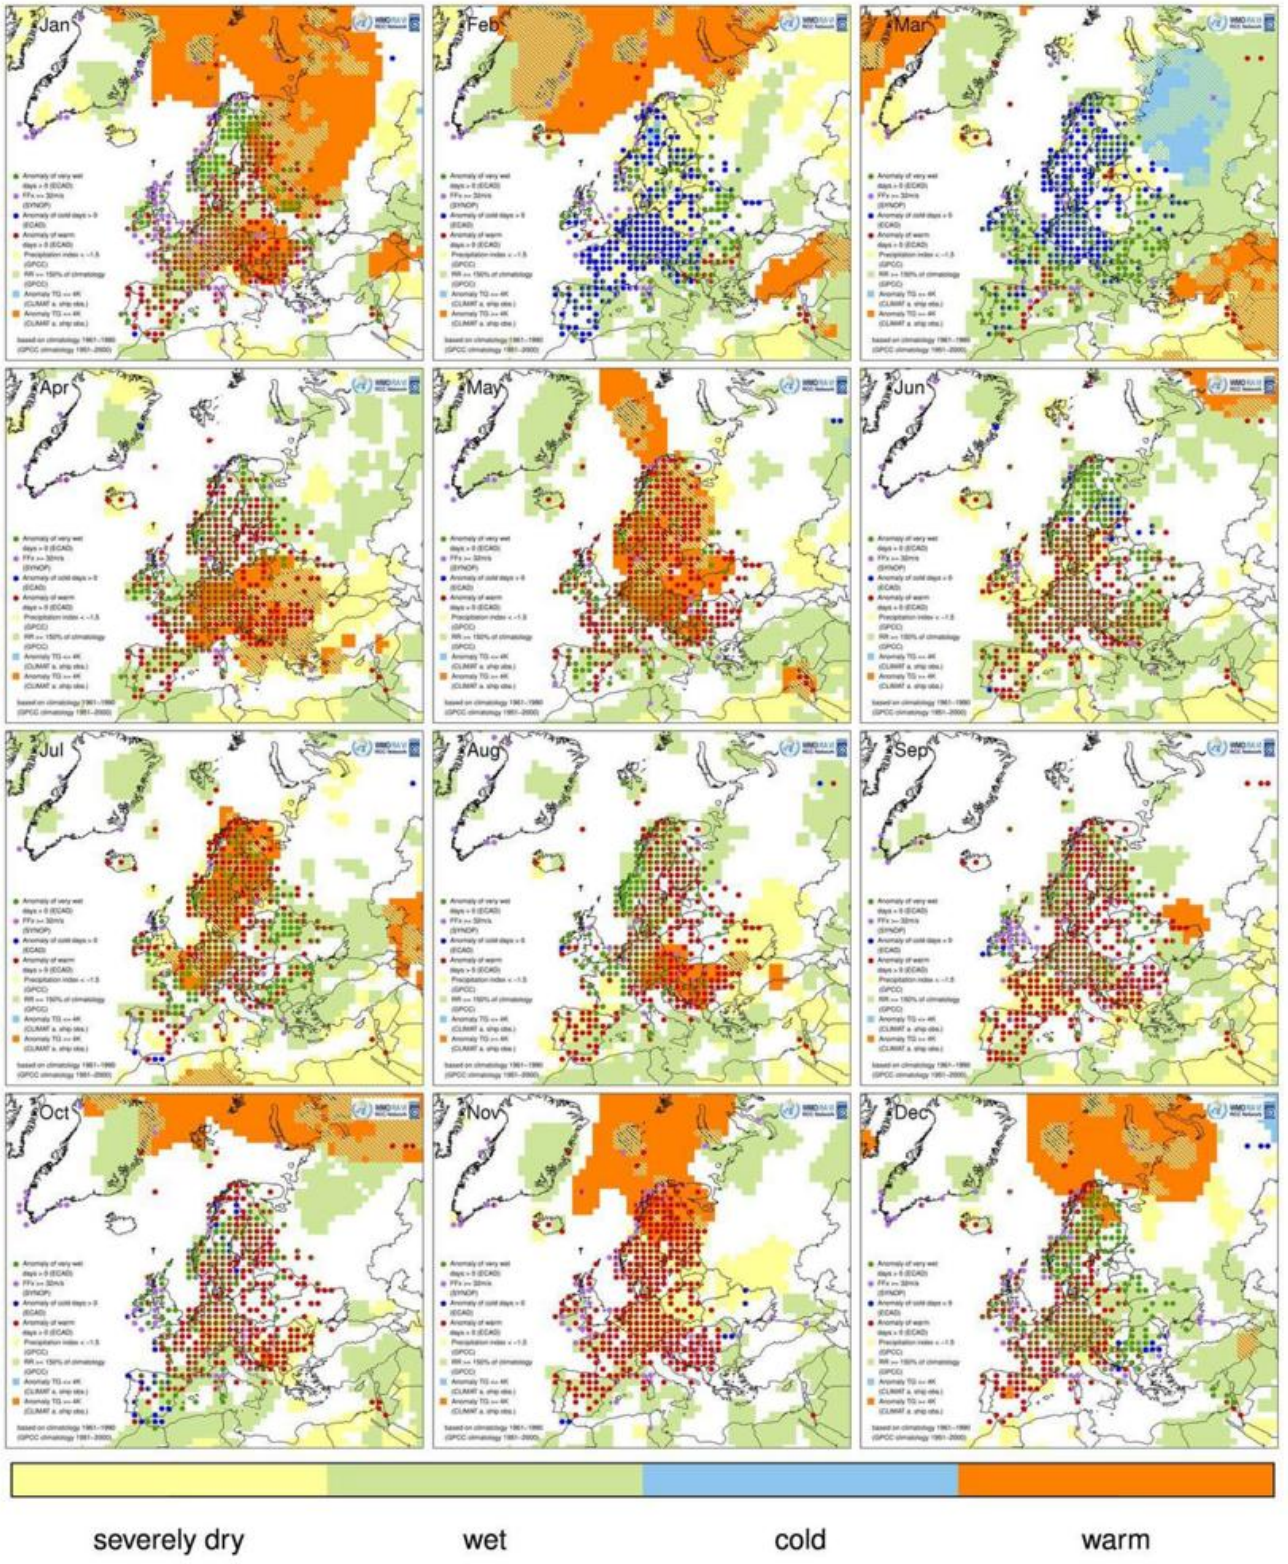

Figure 4-11: Monthly maps of Climate Extremes for the year 2018.

5. Long-term variability of the selected climate parameters - Regional examples

On the following pages graphs of long time series of temperature, precipitation and sunshine duration as provided by the National Meteorological and Hydrological Services (NMHSs) are presented to give an overview of the temporal development of the basic climate elements. The graphs are grouped with respect to the 6 sub-regions defined above (Figure 1-1). An overview of contributing countries, time series' lengths and area representativeness can be found in Table 5-1. Most time series are available for temperature. Each sub-region is at least represented by one country. Time series of precipitation totals are fewer but each sub-region is represented by at least one time series for precipitation. Diagrams of long-term annual sums of sunshine duration are provided by few countries, belonging to different sub-regions.

Table 5-1: Availability of the long-term records (start year) of temperature, precipitation and sunshine duration from some participant countries.

Sub-region	Country	Temperature		Precipitation		Sunshine Duration	
		Spatial Mean	Single Station	Spatial Mean	Single Station	Spatial Mean	Single Station
Central and Western Europe	Austria	1768					
	Belgium		1833		1833		1887
	France	1900		1959

Israel

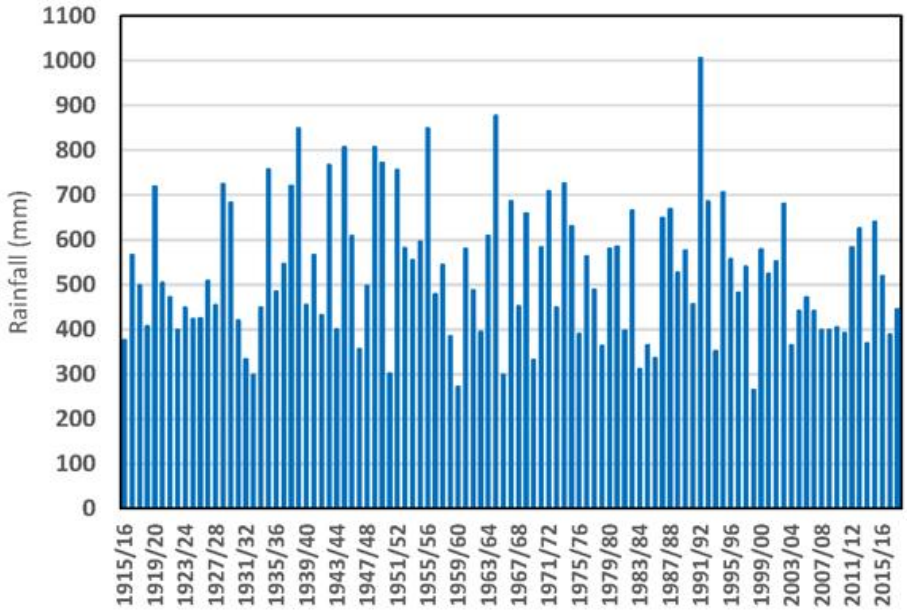

Figure 5-47: Yearly rainfall amounts (mm) in Miqwe Yisrael (Central Coastal Plain) **prepared according to the rainfall seasons** starting **in rainfall season 1915/16 and ending in rainfall season 2017/18**, (diagram as provided by the NHMS)

Kazakhstan

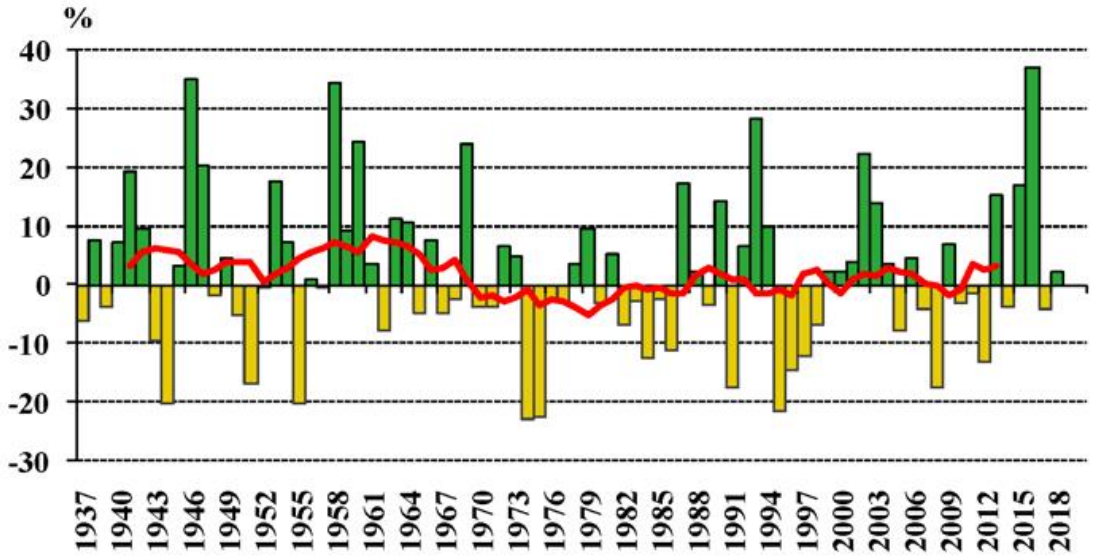

Figure 5-48: Anomalies of annual precipitation totals (in %) averaged over Kazakhstan in the period 1936-2018 (reference period 1961-1990, diagram as provided by the NHMS).

5.3. *Sunshine duration*

Central and Western Europe - sunshine duration anomalies

Germany

Germany

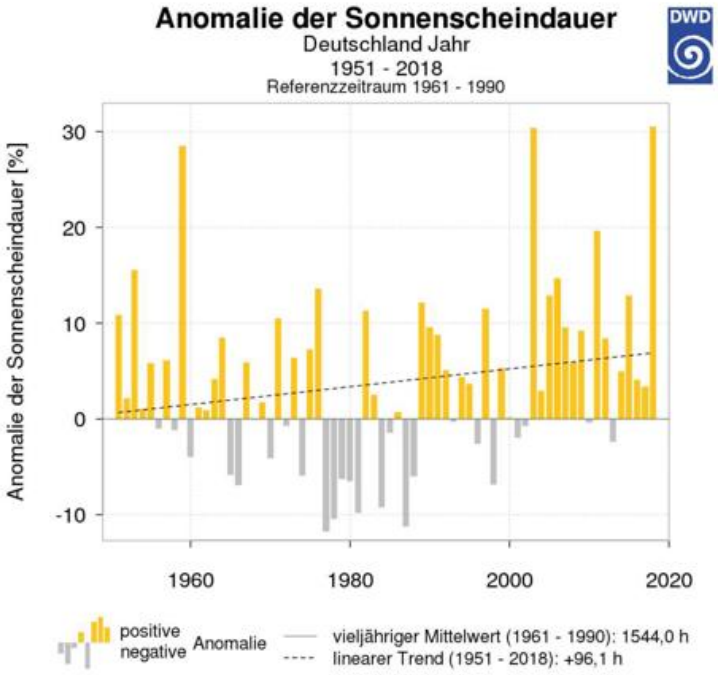

Figure 5-49: Time series of annual anomaly of the sunshine duration [%] for Germany with respect to the long-term mean 1961-1990 (dotted line: linear trend; diagram as provided by the NHMS)

Nordic and Baltic Countries - sunshine duration

Denmark, Estonia

Denmark

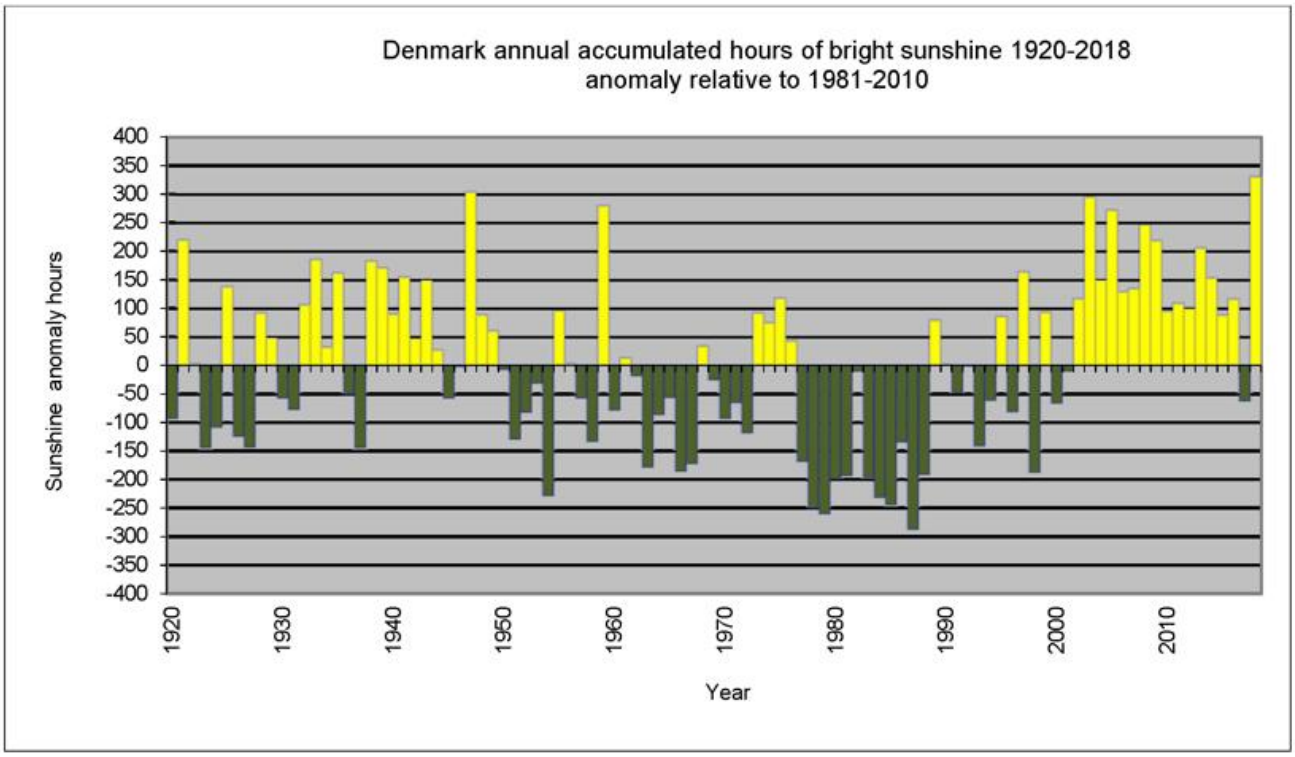

Figure 5-50: Time series of annual sunshine duration in hours for Denmark: anomaly relative to 1981-2010. The values are calculated as national average based on a number of selected stations. (Diagram as provided by the NHMS)

Note: *OBS! DMI has since 2002 observed the hours of bright sunshine using measurements of global radiation instead of measurements from a traditional Campbell-Stokes sunshine recorder. For that reason "new" and "old" hours of bright sunshine cannot directly be compared. It should also be noted that all values before 2002 are adjusted ensuring comparability to the new level. For details on that, see DMI Technical 02-25: Ellen Vaarby Laursen, Stig Rosenørn: New hours of bright sunshine normals for Denmark, 1961-1990.*

http://www.dmi.dk/fileadmin/user_upload/Rapporter/TR/2002/tr02-25.pdf

Data up to 2016 are published in DMI report series, No. 17-02 John Cappelen (ed)(2017): Denmark - DMI Historical Climate Data Collection 1768-2016.

1. Introduction

The Annual Bulletin on the Climate in WMO Regional Association VI (RA VI, covering Europe and Middle East with 51 Members) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official websites. Supported by the European Climate Support Network (ECSN) and WMO´s World Climate Data and Monitoring Programme (WCDMP) the Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's Annual Statement on the Status of the Global Climate and the State of the Climate published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ among the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process. Websites of NMHSs as well as the webpages of the RA VI RCC Network (http://www.rccra6.org) offer useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes four parts: the annual, seasonal and monthly survey of the climate state in 2019. The long time series of temperature, precipitation and sunshine duration provided by NMHSs in order to illustrate long-term variability up to 2019 (previously presented in section 5) will be made available on the RA VI webpages.

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collecting Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC), operated by the Deutscher Wetterdienst
- Sunshine: Meteosat Satellite data (introduced in 2018).
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by Royal Netherlands Meteorological Institute (KNMI)

1.1 The following sub-regions are used in this bulletin:

Central and western Europe (14 countries):

Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxemburg, Monaco, the Netherlands, Poland, Slovakia, Switzerland, and United Kingdom

Nordic and Baltic Region (9 countries/territories):

Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, and Sweden

Iberia (2 countries):

Portugal, and Spain, Andorra

Mediterranean, Italian and Balkan Peninsula (12 countries):

Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Montenegro, North Macedonia, Serbia, Slovenia, and Turkey

Eastern Europe (5 countries/territories):

Belarus, European Russia, Moldova, Romania, and Ukraine

Middle East (9 countries):

Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, and Western Kazakhstan

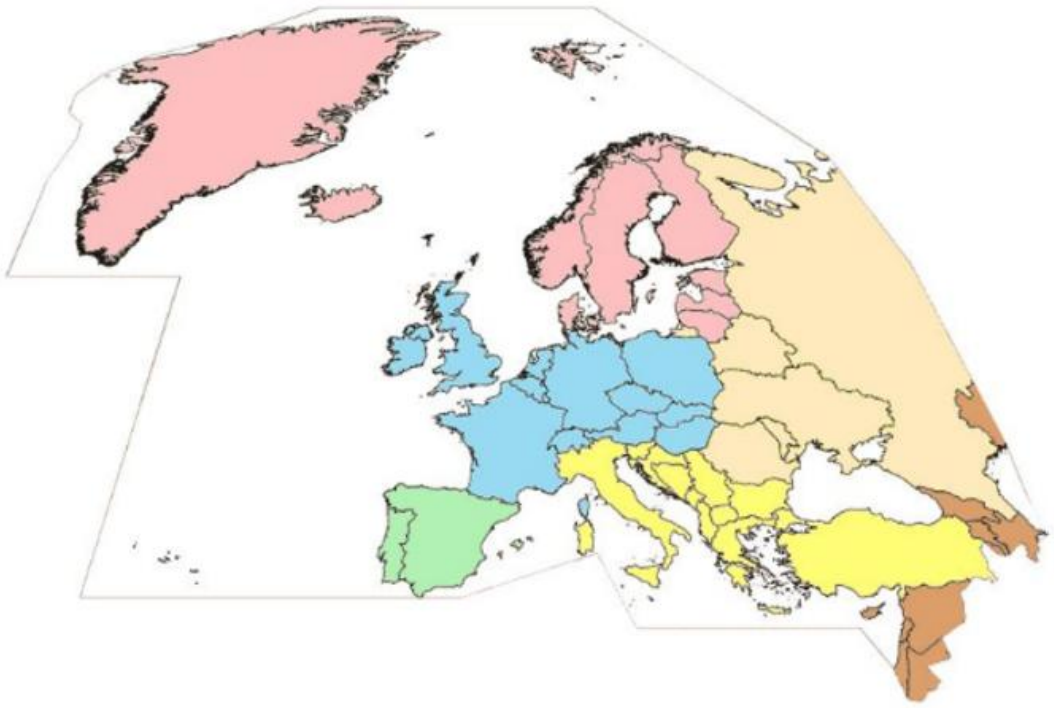

Figure 1-1: Definitions of the six sub-regions used in this bulletin.

1.2 The climate in 2019 - Overview

1.2.1 Anomalies

Temperature

Based on the Global Historical Climate Network (GHCN) v4.0.1 dataset (Menne et al. 2012), Europe (35°–75°N, 10°W–30°E) experienced its second warmest year since at least 1950 with an anomaly of +1.1 °C, very close to 2018. All over the RA VI Region annual temperatures were warmer than normal (1981-2010). Largest anomalies occurred over Greenland and over the eastern part of the RA VI Region, for example over Poland, Ukraine and Belarus where annual temperatures were more than 2 °C above normal.

Precipitation

Annual precipitation totals in 2019 were slightly above average over the RA VI Region. Generally, northern Europe and some parts of western and southern Europe experienced a wetter-than-average year. Precipitation was especially above average in parts of northern Spain and the Alps. In contrast, drier-than-normal conditions occurred across large parts of the Iberian Peninsula, especially in the south, in a band reaching from France through central Europe into Eastern Europe as well as over Iceland.

Sunshine Duration

Most parts of the RA VI Region experienced a sunnier-than-normal year. The widespread positive anomalies of +150 hours to +250 hours caused the average annual sunshine duration over Europe to reach a new record with 2348 hours in 2019 (Bissolli et al. 2020). Largest surpluses in sunshine were recorded in Central and Eastern Europe as well as in Iberia which. These regions saw exceptionally sunny conditions (sunshine duration totals > 90th percentile) with 200 to 500 hours (in relative terms up to 125 %) more sunshine hours than normal.

1.2.2 Events:

- Exceptionally high temperatures occurred throughout Europe during a warm spell end of February, with many areas in central Europe exceeding 20 °C and many local records of maximum temperatures being broken.
- Record June and July heat waves occurred across western and central Europe due to the inflow of warm subtropical air. Numerous temperature records were broken in both months. June ended up the warmest on record for Europe as a whole.
- From October to December, a series of heavy storms brought exceptionally high amounts of precipitation to regions bordering the northern Mediterranean and Atlantic coasts. Some regions recorded precipitation of two to four times the normal amounts and for several countries it was one of the wettest November months on record.

2. Annual survey

The climate of 2019 was characterised by a broad range of spatial and temporal anomalies outlined in section 1.2. This section presents an overview of the spatial patterns of mean annual climate conditions in 2019 and anomalies related mainly to the normal period 1981-2010 considering the following climate variables: sea level pressure, surface air temperature, precipitation, sunshine duration and snow. Sub-section 0 reveals selected climate indices for individual countries. Long-term trends in temperature and precipitation indices are presented in section 2.2. Section 0 and 4. present the seasonal and monthly patterns and statistics for selected climate variables including also reports from individual countries. Annual averages and anomalies of selected essential climate variables

2.1 Annual averages and anomalies of selected essential climate variables

2.1.1 Sea level pressure

Generally, the mean annual sea level pressure distribution in 2019 over RA VI was dominated on one hand by a band of low pressure with the minimum pressure extending from southern Greenland over Iceland until northern Russia. On the other hand, there was a high pressure belt with maximum pressure in the area of the Azores (Azores High) extending further across southern and central Europe into Russia.

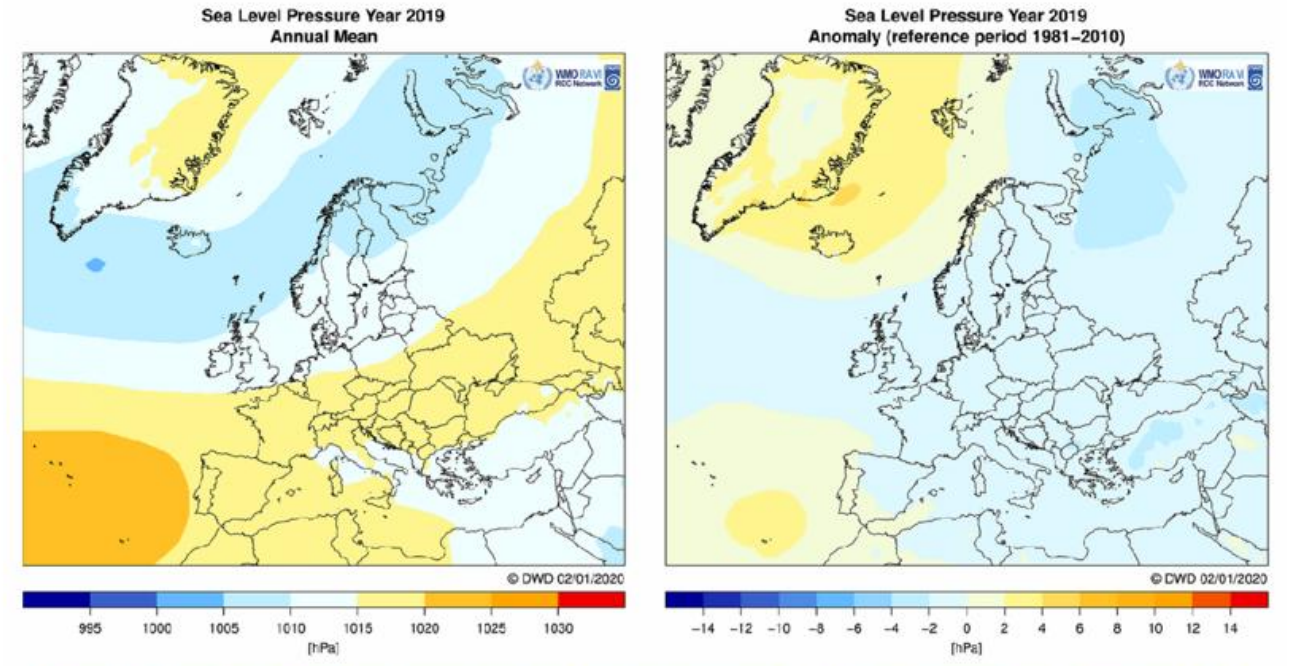

Figure 2-1: Annual mean (left) and anomalies (right) sea level pressure in hPa for the year 2019 with respect to the reference period 1981-2010. (Source: http://www.dwd.de/rcc-cm).

The mean sea surface pressure in 2019 differs to some extent from the long-term mean with reduced pressure over the most parts of the RA VI area with anomalies generally between 0 and -2 hPa as visible in Figure 2-1 (right; normal period 1981-2010). Higher-than-normal pressure occurred especially over Greenland and Iceland with largest anomalies ranging between +2 and +4 hPa and in the area of the Azores High.

2.1.2 Temperature

Overall, the year was exceptionally warm and over the entire RA VI Region temperatures were higher than normal (1981-2010) with anomalies mostly above +1.0 °C – parts of Greenland and of Central and Eastern Europe even experienced annual mean temperatures more than 2 °C warmer than normal. For the European region as a whole, 2019 was the second warmest since at least 1950 considering the Global Historical Climate Network (GHCN) v4.0.1 datasets (Menne et al. 2012; Bissolli et al. 2020) with an overall anomaly (with respect to the base period 1981-2010) of +1.1 °C (Figure 2-3). For many countries the year proved to be the warmest on record: Estonia +1.6 °C (tied with 2015), Serbia +1.7 °C, Belarus +2.0 °C, Latvia +1.8 °C, Lithuania +1.9 °C, Ukraine +2,7 °C (w.r.t. 1961-1990) and Romania +1.9 °C (see also Table 2-1).

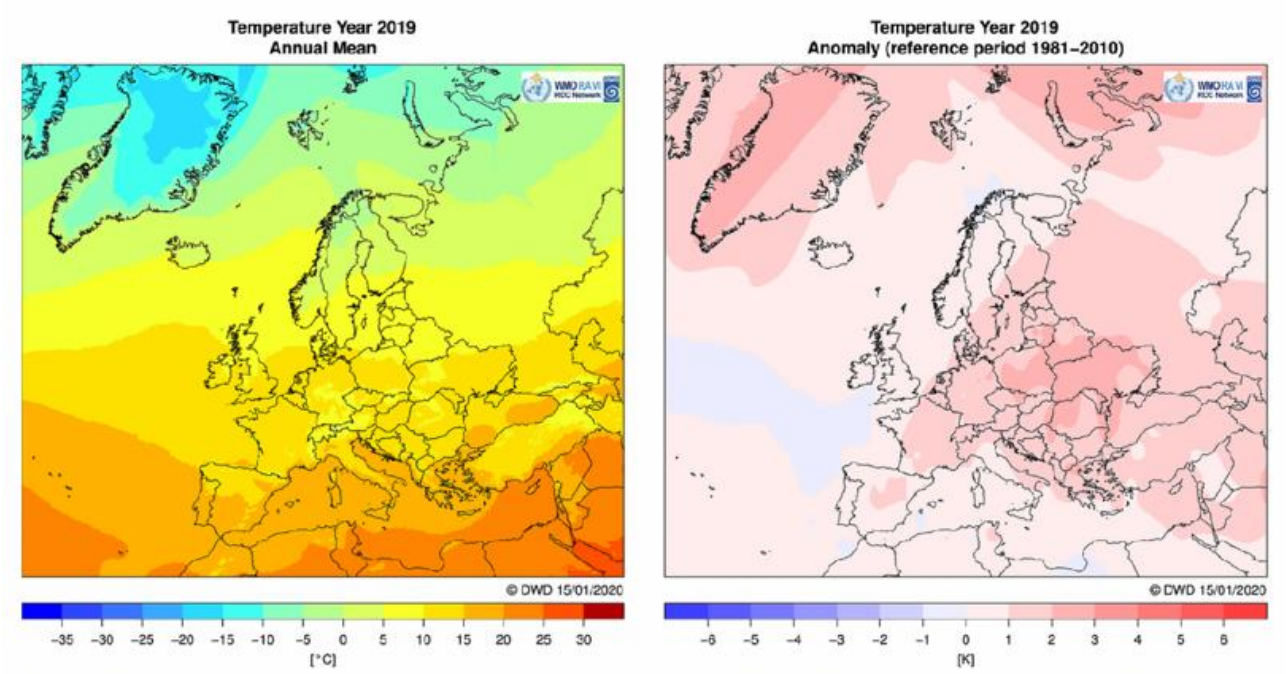

Figure 2-2: Annual mean (left) and anomalies (right) temperature in °C for 2019 (reference period 1981-2010, source: http://www.dwd.de/rcc-cm).

Looking at the specific sub-regions, the year 2019 was characterized by well-above-normal temperatures for **Western Europe** with an anomaly of +1.0 °C and above except for the United Kingdom and Ireland. For all continental countries the year ranked in the top five of the warmest years (third or fourth warmest).

Temperatures for the year were well above normal by +1.0 °C to +2.0 °C in **Central Europe** with 2019 among the five warmest years for all countries of the region. Hungary reported the warmest year on record with an anomaly of +1.9 °C, while for Germany (+1.4 °C), Slovakia (+1.8 °C) and the Czech Republic (+1.6 °C), 2019 was the second warmest.

Concerning the **Nordic and Baltic countries** the year was slightly warmer than normal with anomalies around +0.6 °C (w.r.t.1981-2010) in Norway and +1.2 °C (w.r.t. 1961-1990) in Finland. In the Baltic countries 2019 was even among the 5 warmest years with temperatures more than +1.0 °C above average. In northwestern, southwestern and southern parts of Greenland annual temperatures were much warmer than normal (partly more than 2 °C). At Pituffik/Thule Air Base, at Paamiut, as well as at Narsarsuaq and Qaqertoq, the year2019 finished up as second warmest on record, only second to 2010.

The annual mean temperature over the **Iberian Peninsula** was mostly between +0.0 °C and +1.0 °C above normal. Spain reported a countrywide anomaly of +0.8 °C and the sixth warmest year since 1965. However, anomalies in some parts of Spain exceeded +1.0 °C.

The year was warmer than normal for the **Mediterranean and the Balkan states**. Serbia reported its warmest year on record with +1.7 °C above normal, Slovenia its second highest since 1961 also with +1.7 °C above normal, Italy its third warmest (+1.6 °C, w.r.t. 1961-1990) and Turkey its fourth warmest (+1.2 °C).

Eastern Europe had an overall warm year. The Ukraine (+2.7 °C anomaly w.r.t. 1961-1990), Moldova (+2.1 °C anomaly) and Belarus (+2.0 °C anomaly) reported their warmest year on record.

In the **Middle East**, the year was more than +1.0 °C warmer than normal in most of the region. Temperature anomalies below +1.0 °C were only recorded in Syria and northern parts of Jordan. It was the 7th warmest year in 69 years in Israel, but also the coolest since 2013. It was the 4th warmest year in Georgia since 1960 with an anomaly of around +1.5 °C. In the capital, Tbilisi, it was the 2nd warmest (after 2018) since records began in 1881.

Globally, 2019 was among the three warmest years on record (WMO 2020; Blunden and Arndt 2020) with an average global temperature 0.44°–0.56 °C above the 1981–2010 average according to four independently constructed in-situ analyses (Sánchez-Lugo et al. 2020) and approximately 1.1 ±0.1 °C above pre-industrial levels (WMO 2020). The 2019 Arctic land surface temperature was +1.7 °C above the 1981–2010 average, tying for second highest in the 119-year record, following 2016.

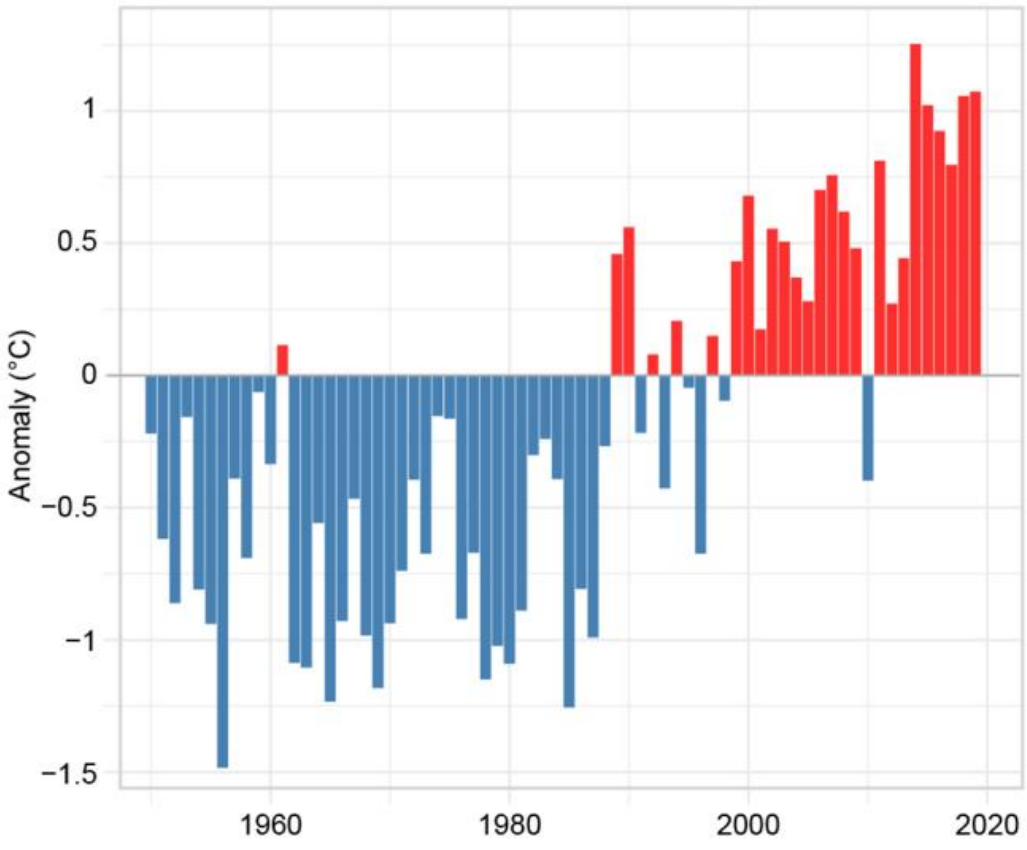

Figure 2-3: Annual average land surface air temperature anomalies for 1950–2019 for Europe (35°–75°N, 10°W–30°E) relative to the 1981–2010 base period. (Source: GHCN version 4.0.1 dataset, Menne et al. 2012.)

Table 2-1: Rank statistics and anomalies of annual temperature in 2019 as reported by the National Meteorological and Hydrological Services (NMHSs). Information about all-time temperature records as provided by the individual NMHSs can be found here: https://rcccm.dwd.de/DWD-RCCCM/EN/products/significant/records/download_tabelle.html?nn=500100?

[1] Annual mean temperature is given in brackets

2.1.3 Precipitation

Annual precipitation totals in 2019 were slightly higher than normal in Region VI, but considerably higher than 2018. Annual totals were above 125 % of normal (and thereby above the 90th percentile) in some places in the north (parts of United Kingdom, Norway, and an extended area in northern European Russia) and in the south around the Mediterranean due to locally heavy rain (Figure 2-4). Dry conditions with less than 80 % of normal precipitation or values below the 10th percentile occurred in other places in the north (southern Greenland, Iceland, Svalbard, Baltic States), but also in the Ukraine and in the southern parts of Iberia. The middle latitudes, too, were generally mostly drier than normal due to a longer drought period in the summer half year, but precipitation was only less than 80 % of normal in limited areas.

The year as a whole was wetter than normal in western parts of **Western Europe**. Precipitation of 100-125 % of normal was reported for Ireland, United Kingdom and western France, while much of the Benelux countries, central and eastern France had below-normal precipitation (80-100 %). Overall, the year had close-to-normal precipitation in most of the **Nordic countries**. Only places in southeastern Norway recorded above 125 % of normal precipitation. Iceland was remarkably dry with locally around 40 % of normal precipitation. The **Baltic states**, too, reported below-normal precipitation, particularly Estonia with 40 % to 60 % of normal. In **Iberia**, Spain reported a close-to-normal year with countrywide precipitation of 97 % of normal. Although precipitation was above 125 % of normal locally in southeastern parts of Spain, most of Iberia had below-normal precipitation, dropping below 60 % of normal in the southwest. Episodes of intense and persistent precipitation occurred often during the year, sometimes causing flooding. Multiple stations reported new local records of daily maximum precipitation. Over the **Mediterranean, Italian and Balkan Peninsula**, annual precipitation was mostly around normal, but locally it was well above average due to some heavy precipitation events, resulting in mostly above-normal country averages. Italy reported 122 mm more than normal precipitation (5th wettest) and Slovenia 109 % of normal. In Serbia, precipitation was around normal. Over **Eastern Europe**, annual precipitation was below normal for all countries of Eastern Europe except for the northern parts of European Russia. Belarus reported 91 % and Ukraine 84 % (fifth driest year) of normal precipitation, Moldova reported a deficit of 146 mm. West Kazakhstan received only 60 % to 80 % of normal precipitation. In the **Middle East**, overall, the year was normal with wetter than normal conditions especially in the northern parts (above 150 % locally) in Syria, Lebanon, Cyprus (wettest since 1902), northern Jordan (5th wettest since 1981 at Amman Airport) and in northern Israel and drier than normal conditions in the southern parts. In the **South Caucasus** region, the year was drier than normal in Georgia (particularly in the east where precipitation was only 50-60 % of normal) while it was close to normal in Armenia and Azerbaijan.

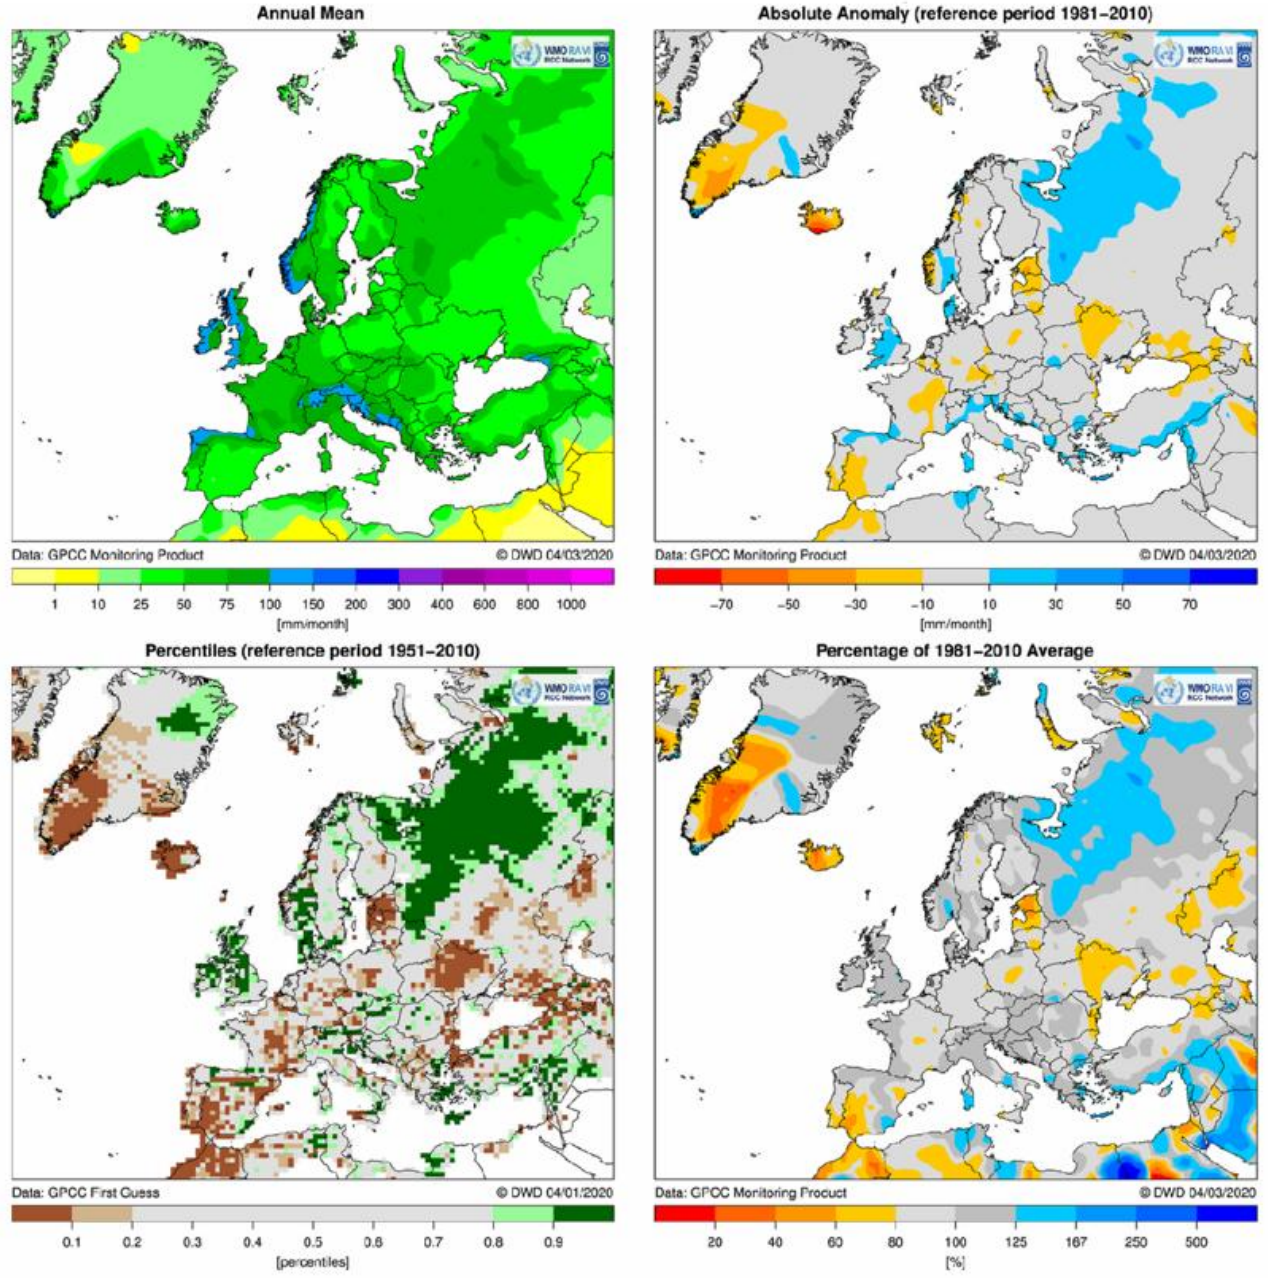

Figure 2-4: Total precipitation (left, top), anomalies (right, top) in mm/month, percentiles (left, bottom) and percentage of precipitation in % (right, bottom), for 2019. Reference period for the anomalies is 1981-2010, for the percentiles the reference period reference period is from 1951-2010); source: http://www.dwd.de/rcc-cm).

Table 2-2: Rank statistics and anomalies of annual precipiation in 2019 as reported by the National Meteorological and Hydrological Services (NMHSs). Information about all-time temperature records as provided by the individual NMHSs can be found here on the RCC RA VI website[2].

Country	Rank	Annual Anomaly (1961-1990)	Annual Anomaly (1981-2010)	start of time series
Armenia	4 (driest)	-143.3 mm	-	1935
Belarus	-	-	91 %	1945

2.1.4 Sunshine duration

Most parts of the RA VI Region experienced a surplus of sunshine hours in 2019 (see Figure 2-5). Especially in Central and Eastern Europe and over Iberia, it was exceptionally more sunny than normal (>90th percentile) with 200 to 500 hours (in relative terms up to 125 %) more sunshine hours. Over the Eastern Mediterranean, it was less sunny than normal with deficits in the range of up to 200 hours which corresponds to deficits of only 5 % in relative terms though.

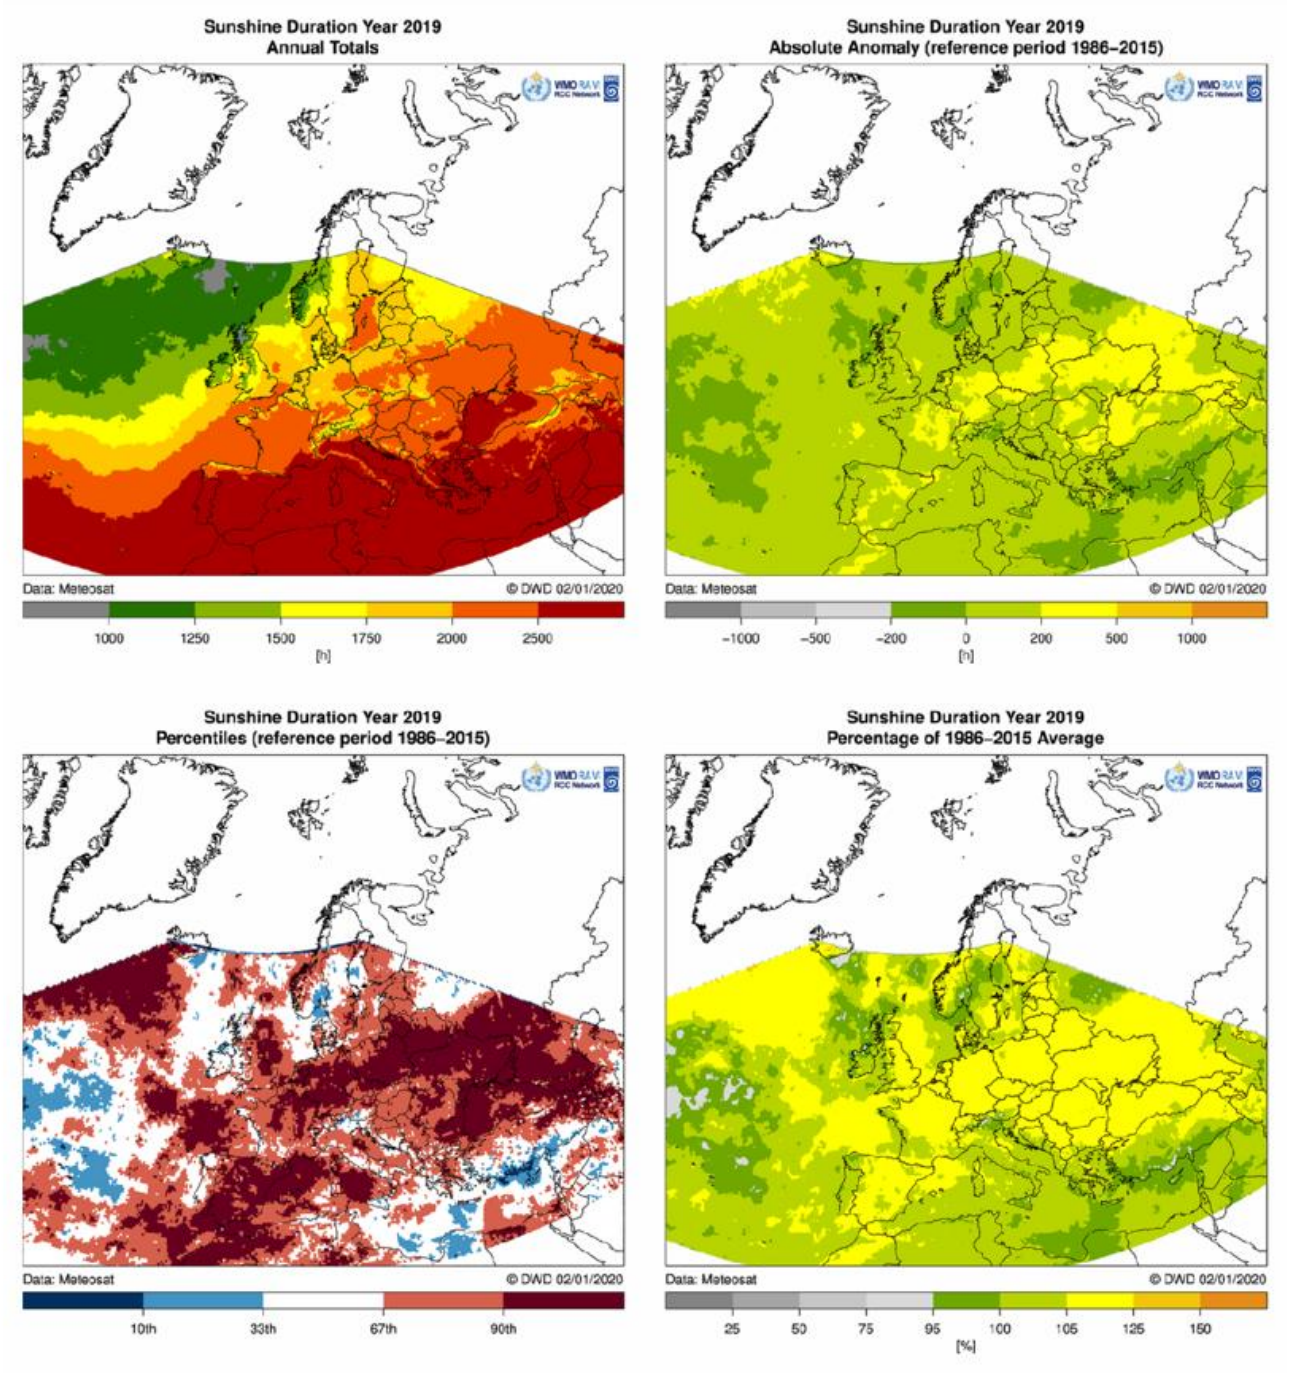

Figure 2-5: Annual sum of sunshine duration (upper left) as well as absolute anomalies (upper right), percentiles (lower left) and percentages of the long-term mean (lower right) with respect to the reference period 1986-2015 for the year 2019. (Source: http://www.dwd.de/rcc-cm).

In Germany overall, the year 2019 brought 1834.2 hours of sunshine on average (Fig. 4), which was above the multi-year mean annual totals. The surplus for the period 1981-2010 was 233.5 hours or 14.6 %. Compared to the climate reference period 1961-1990, there was a surplus of 290.2 hours

or 18.8 %. The year thus ranks as the 5th year with the most sunshine since 1951 in the present climate time series.2019 was also particularly sunny in the southwestern and western part of Iceland. 2019 finished up as third sunniest year on record in Reykjavík.

2.1.5 Drought situation

When looking at the Global Precipitation Climatology Centre Drought Index (GPCC-DI, Ziese et al. 2014) as a metric for characterizing meteorological drought, the values for the year as a whole range mostly between -1 and +1 (see Figure 2-6). Most regions with large precipitation deficits (for example areas neighbouring the Black Sea and the Baltic countries, see also 2.1.3) appear here with values between 0 and -1 indicating mild drought conditions on annual average. Over parts of Spain and the Middle East the drought situation is even classified as moderate drought with values up to -1.5 (Spain) or up to extreme drought (Syria). Several countries reported national or local low records of annual precipitation. For Armenia, for example, 2019 was the 4th driest year since 1935, after 1961, 2000 and 2008. In Spain it was very dry from January to October, especially in the central areas of the peninsula. It was very dry in some areas of Extremadura, Avila, Toledo, western half of Andalusia, Tarragona, Castellón, Ceuta y Melilla. Málaga and Cádiz only received less than 50 % of normal precipitation amounts.

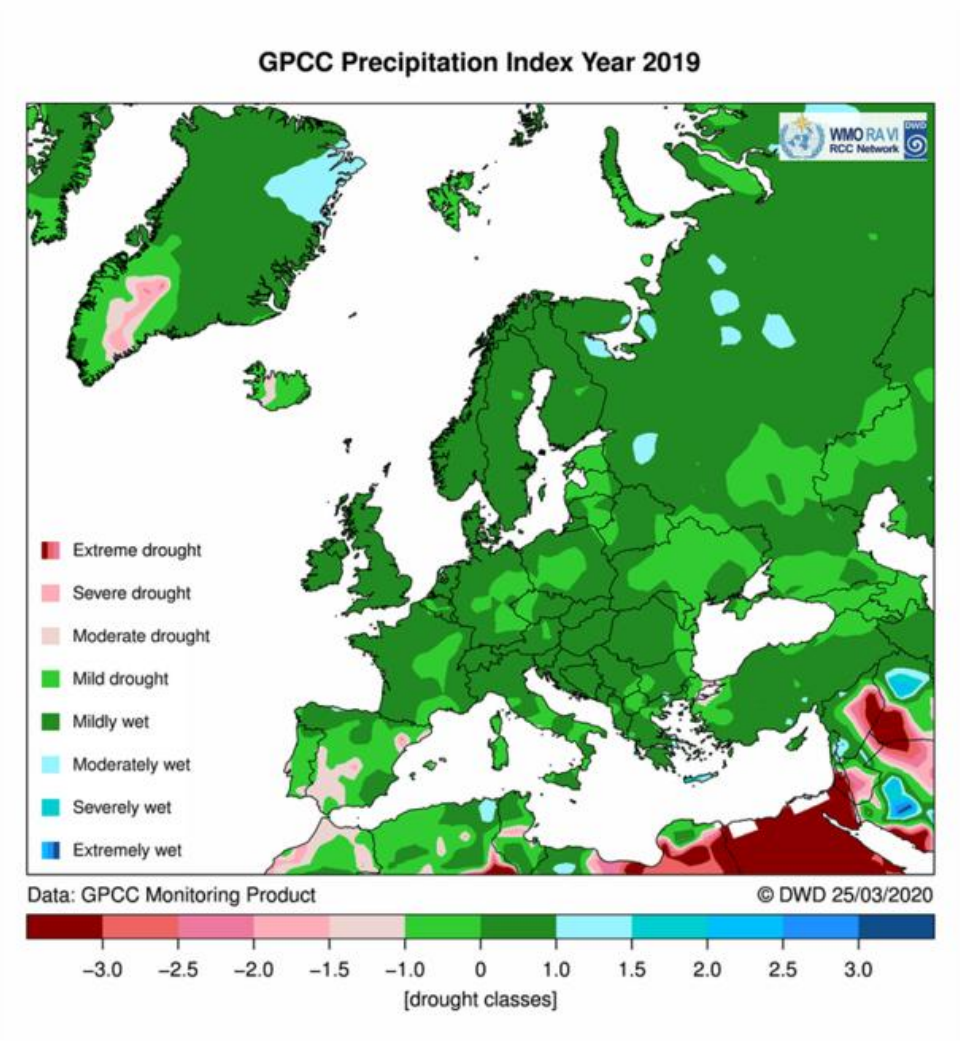

Figure 2-6: Annual GPCC –DI (GPCC-Drought Index) for the year 2019 with respect to the reference period 1961-1990. (Source: http://www.dwd.de/rcc-cm).

2.1.6 Snow cover

In January, there was considerable **snow** in many parts of Iceland. In Sweden, snow came only in parts of the country at the beginning of the month, but on 27-28 January, when an extensive snowy weather entered southern Sweden, almost all of Sweden apart from parts of Skåne became snow covered. The largest snow depth in Sweden was measured in Katterjåkk, where it was 120 cm in the morning on January 13. In Finland, too, the snow depth was exceptionally high in the south (roughly 50 cm, occurring about once in 10 years), whereas Lapland had less snow than normal. Similar depths were measured in European Russia; the resulting snowdrifts blocked railway and motor traffic in certain places. In Moscow, heavy snowfall, which started on January 26 and continued without interruption for 37 hours, had set a new record for total daily precipitation. The deepest snow cover in Latvia (35 cm) was observed on 29 and 30 January in Aluksne, in Belarus it was 39 cm. Also in Lithuania, the thickest layer of snow reaching 28–33 cm was recorded in the last days of the month near Vilnius and Šilalė. The thickness of the ice cover on water surfaces in Belarus was less than average for that month. The monthly number of days with snow cover in Belarus was 5.4 on national average, these were relatively few (1961-90 normal is 12 days). Lots of snow fell in Ukraine; the snow depth reached 39 cm in Kiev (highest maximum in January was 47 cm in 1987). In Moldova, a snow cover existed almost the whole month, only at the end of January the snow melted in isolated places in the south of the country. Maximum snow cover in Moldova was 40 cm in Ribnita.

In Central Europe, heavy snowfalls took place at the beginning of the month in southern Germany and Austria, producing up to 80 cm of snow cover per day. This resulted in some new records, e.g. at station Reutte (850m altitude) in Austria with a maximum depth of 116 cm, the highest since beginning of measurements in 1937. Switzerland received much snow in mid-January, leading to a high risk of avalanches. In the Czech Republic, 37 cm of fresh snow fell on 8 January at Kvilda station; the highest total snow depth was 235 cm at Labská Bouda station on 30 January. In the west of the continent, everybody was readily accustomed to the absence of snow, and the more surprising was the snowfall that hit the western coast of France, England and Scotland in the last days of the month and delivered up to 10 cm of snow per day. In the Netherlands and Belgium, too, snowfall came rather late in the month (22 to 23 January) with only a few cm in the Netherlands, but up to 14 cm in the western part of Belgium (Lissewege). In Luxemburg, snow depth was 16 cm on 31 January at Findel Airport, the same depth in the United Kingdom on 23 January at Malham Tarn in North Yorkshire. In the Pyrenees Mountains, abundant snow fell reaching depths up to above 260 cm in high altitudes.

In Slovenia on the other hand, Kredarica Mountain had a snow depth of only 85 cm on 28 January, the third lowest monthly January maximum since beginning of observations. The number of days with snow cover in Croatia ranged from 17 to 29 days and was 6-16 days above the January average in most of the country. A snow cover was observed even in Albania at 1400m altitude on 30 January. In the south, Athens was hit by a severe snowstorm that required closing the schools, as they were normally not heated and unfit for operation in such conditions. Snowstorms in Lebanon and Israel occurred several times that month. In Jerusalem, snow fell for the first time in the last five years.

Snow cover was persistent as usual in much of Northern and Eastern Europe in February, but for the rest of the Region, snow was mostly rare with only a few snow days (snow cover at least 1 cm) even in Central Europe. Denmark recorded only 2 snow days on spatial average (normal 1961-1990

is 9 days), Belgium 6 days, Luxembourg 3 days (normal 8 days). The United Kingdom, Ireland and the Netherlands saw some snow mainly at the beginning of the month. Even Slovenia and Serbia saw some snow on 1 February in the lowlands in some places, but the snow cover did not persist. In the course of the warming during the month, the snow melted even in southern Sweden. Snow depths of more than 50 cm were recorded in much of Northern and Eastern Europe, while other parts in the lowlands mostly saw only a few cm. The eastern Swiss Alps recorded 50-70 cm fresh snow at the beginning of the month on 1-2 February. During the month, snow depths were around or above average in large parts of the Swiss Alps. Combined with warmth and much sunshine, winter sport conditions in the Alps were excellent, due to previous snowfall in January. In Sweden and Finland, the snow depth was generally around or below normal except in the northern Lapland Mountains with the largest depth of 158 cm in Cattery (Sweden). Heavy snowfall occurred in central regions of Russia including Moscow around the middle of the month. The United Kingdom measured 33 cm in Morayshire Province on 2 February. In Israel, some snowfall occurred in the northern mountains in mid-February and end of February. In **March**, snow cover persisted in continental Scandinavia (except the south) and Russia/ West-Kazakhstan (except the south) during the entire month. In mid-March, snowfall even reached southern parts of European Russia. In central Sweden, some melting occurred only in the last week. In Iceland, snow had much regional variability: 6 snow days were registered in Reykjavik, 22 in Akureyri. In the United Kingdom, from the Midlands northwards, it was occasionally cold enough for sleet and snow to penetrate to low levels. Ireland, too, saw some snow in places. Belgium saw 10 snow days, Luxembourg Airport 1 day (normal 5), Innsbruck in Austria also 1 (normal 6). The Baltic countries, Belarus and northeastern Ukraine also had snow only temporarily, mostly in the first and second decade of the month, other parts of the Region mainly in higher elevations throughout the month, only temporarily partly a thin snow coverage in the lowlands.

In terms of anomalies, snow was more frequent than normal in southern Norway, central Sweden, southern Finland, central European Russia, and eastern Turkey, but less frequent in the other Eastern European countries, Central Europe, the Balkan Peninsula and western Turkey (data after Rutgers University[3]). In the Alps in Austria (above 800m a.s.l), the number of snow days was around the climate mean or above.

Snow depths reached above 100 cm in high mountains, above 50 cm in Lapland and northern European Russia. Katterjakk, often the snowiest station in Sweden, recorded 206 cm on 1 April (there was an interruption of measurements in the second half of March). Finland had between half a meter and one meter of snow in the north from Northern Karelia to Lapland, and mostly 10–50 cm the rest of the country. Areas near the southern and western coastline of Finland were free of snow in many places. At the end of the month, snow depth was lower than usual in large parts of the country. Russia recorded a depth up to 70 cm in the Volga region. Latvia reported up to 31 cm (Aluksne). In the United Kingdom, a snow depth of 6 cm was measured at Middleton (Derbyshire) on the 10th and at Mugdock Park (Stirlingshire) on the 11th.

Western parts of Eastern Europe, Turkey and South Caucasus still recorded some snow, even parts of Central Europe and locally southern Europe. Belgium had 3 cm snow on Mont-Rigi on 11th. Denmark saw only a small snow cover of 0.5 cm on some days in places. Extremely rare was snow

[3] See https://climate.rutgers.edu/snowcover/index.php

in the Southern Alps. The station Bosco-Gurin in southern Switzerland (1486m a.s.l.) measured 4 cm of snow on monthly average, the lowest depth since 1961. In the 1970s, up to above 200 cm were observed at this station. The French Alps and the Pyrenees, too, had a deficit in snow, which was near record. On the Kredarica Mountain in Slovenia, the greatest depth this month was 190 cm, in the lowlands of Slovenia up to 26 cm, in Bosnia-Herzegovina 220 cm in the mountains and up to 21 cm in the lowlands, in Serbia 99 cm in the mountains (Kopaonik), 6 cm in the lowlands, in Montenegro 84 cm (Zabljak), in North Macedonia 26 cm (Mavrovo).

In **April,** areas north of around 60°N had a snow cover during the whole month. Normally snow comes down further south at least on some days in April (to around 55°N) according to data of Rutgers University (https://climate.rutgers.edu/snowcover/index.php). Depths were especially large at the beginning of the month due to previous snowfalls (e.g. up to 206 cm in Sweden), but decreased rapidly due to the warmth during the following days. At the end of the month, there was still up to 50 cm of snow in northern Finland. In the United Kingdom, a snow depth of 13 cm was measured at Warcop Range (Cumbria) on the 3rd. Russia saw some snowfalls in areas, where the snow previously melted in March, e.g. in the Moscow Region and in St. Petersburg (2-4 cm depth). Other parts in the RA VI Region had snow mainly in higher elevations. The Alpine valleys saw record snowfalls at the beginning of the month, e.g. 99 cm in 24 hours in Guttannen (northern Switzerland, 1055m a.s.l.) on 4-5 April, the highest fall since start of measurements in 1877. However, even the lowlands received some snow in Switzerland, e.g. 6 cm in Geneva on 4 April, a new April record, also Tirana in Albania saw a thin snow cover on 11 April. At the end of the month, snow came again down to the Alpine valleys (e.g. 11 cm in Defereggental, east Tyrol, Austria, 1383m a.s.l. on 28 April). The mountain station Lomnicky Stit in Slovakia (2633m a.s.l.) had a depth of 252 cm at the beginning, which decreased to 170 cm at the end of the month, but even in the last days of the month it was snowing. Kredarica in Slovenia (2514m a.s.l.) had its largest depth late in the month (220 cm on 29 April).

In **May,** snow occurred mostly only in Northern Europe and at high elevations. In Norway, snow came down to the south, while even parts of northern Sweden, southern Finland and northern European Russia remained free of snow. On the other hand, Lapland and northern European Russia still recorded local maximum depths of more than 50 cm. The largest depth in Sweden was 144 cm in Katterjåkk on 6 May. However, snow fell also in the lowlands of Central Europe at the beginning of the month, leading to short-living snow depths of a few cm. The Netherlands reported around 2 cm at the beginning of the month, Belgium 8 cm (in Presgaux, Couvin and Stembert, Verviers), Bern in Switzerland 4 cm, the latest fresh snow since 1898. Several snowfall periods occurred in the Alps, especially on northern slopes, compensating the snow deficit of the previous months. Peak Zugspitze in the German Alps reached a depth of 645 cm on 30 May, the largest of the year so far, Kredarica Mountain in Slovenia 320 cm on 31 May (largest of the month). Snow depths in Austrian highlands were close to new records. Hungary, too, had a snow cover of 5-10 cm in the mountains, which did not occur in May in this country for 34 years. Unusual snowfalls for May also occurred in middle elevations (1000-1500m a.s.l.) in Italy, partly with new record depths.

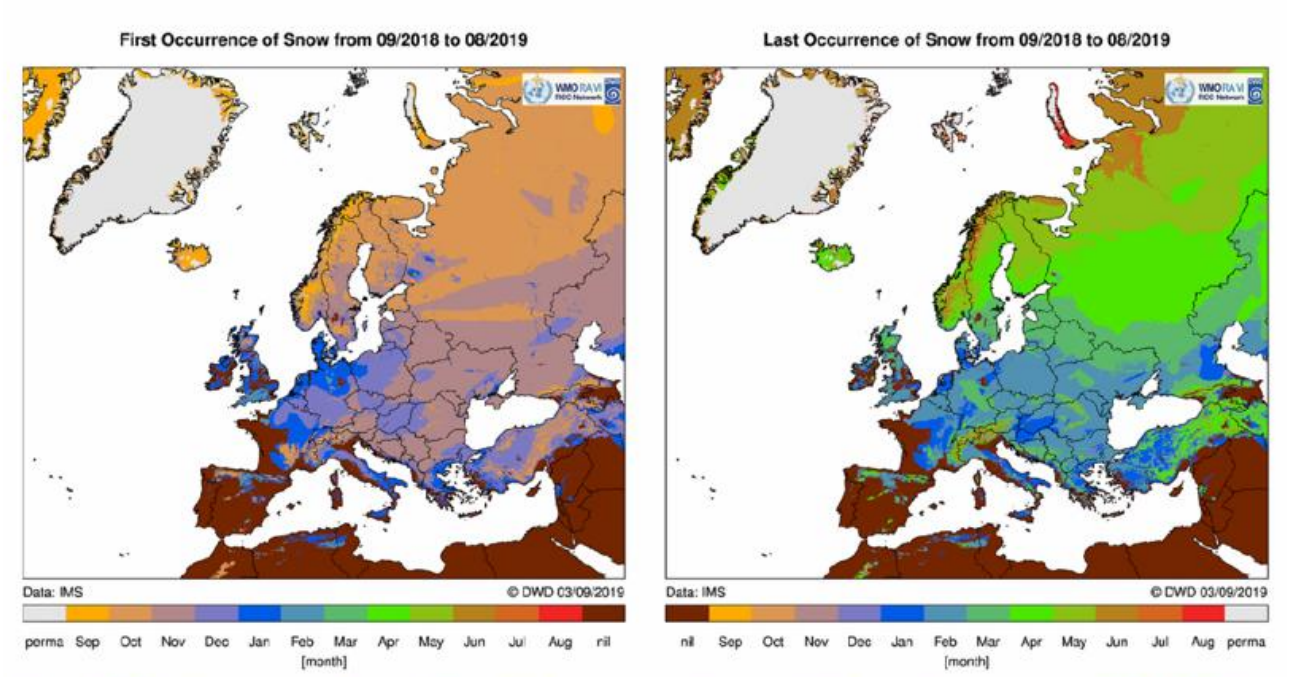

Figure 2-7: First occurrence of snow (left) and last occurrence of snow (right) during the snow season 2018/2019 from 09/2018 to 08/2019. (Source: http://www.dwd.de/rcc-cm).

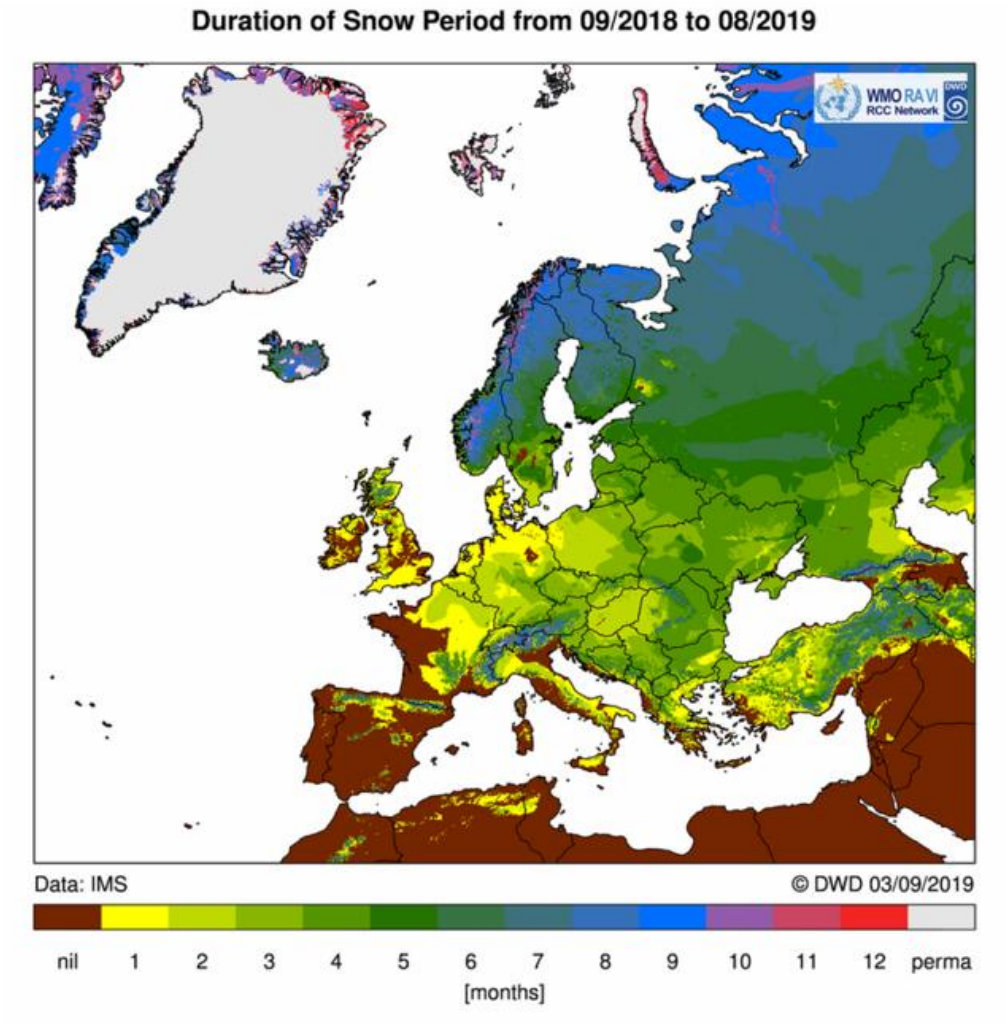

Figure 2-8: *Duration of snow cover in the snow season 2018/2019 (from 09/2018 to 08/2019). (Source: http://www.dwd.de/rcc-cm).*

2.2 Selected climate indices for 2019

This section presents selected temperature and precipitation indices calculated based on the station-based ECA&D (European Climate Assessment & Dataset; http://www.ecad.eu) dataset. Annual climate index maps are shown as well as anomaly maps. The following climate indices are considered:

1. **RR1, Number of wet days**: count of days where RR (precipitation) ≥ 1 mm

Precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally affected.

2. **SU, Number of summer days**: count of days where TX (daily maximum temperature) ≥ 25 °C

3. **WW, Number of warm and wet days**: days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile

4. **TR, Number of tropical nights**: count of days where TN ≥ 20 °C

The maps showing the number of wet days (RR1, uppermost left panel in Figure 2-9) clearly depict the dry conditions prevailing in 2019. Over parts of Central Europe, in southern and eastern Europe there were less than 110 wet days which correspond to up to 60 less rainy days with respect to the 1961 to 1990 mean in these areas. The northern and northwestern parts of Europe, on the contrary, experienced more than normal wet days, mostly up to 60 days.

Looking at the number of warm and wet days (WW) it appears that above-normal numbers of WW were registered across most parts of Europe in 2019, also in the drier parts. Only very locally, the number of wet and warm days was fewer than normal.

The anomaly map for the number of summer days (SU, second row from the bottom on the right in Figure 2-9) also illustrates well the longer-than-normal summer conditions in 2019 all over the entire RA VI domain. Over Scandinavia, the UK and Ireland up to 10 summer days more than normal were observed, locally even less summer days than normal occurred. The rest of the RA VI domain saw more than 30 summer days more than normal.

There were also more tropical nights (TR) than normal in 2019 over most parts of the RA VI domain. However, the anomaly values for TR are smaller than for SU with mostly up to 20 tropical nights more than normal. Largest anomalies with 40-60 tropical nights more than normal occurred along the Mediterranean coast. Locally, there were also less than normal tropical nights throughout the RA VI Region.

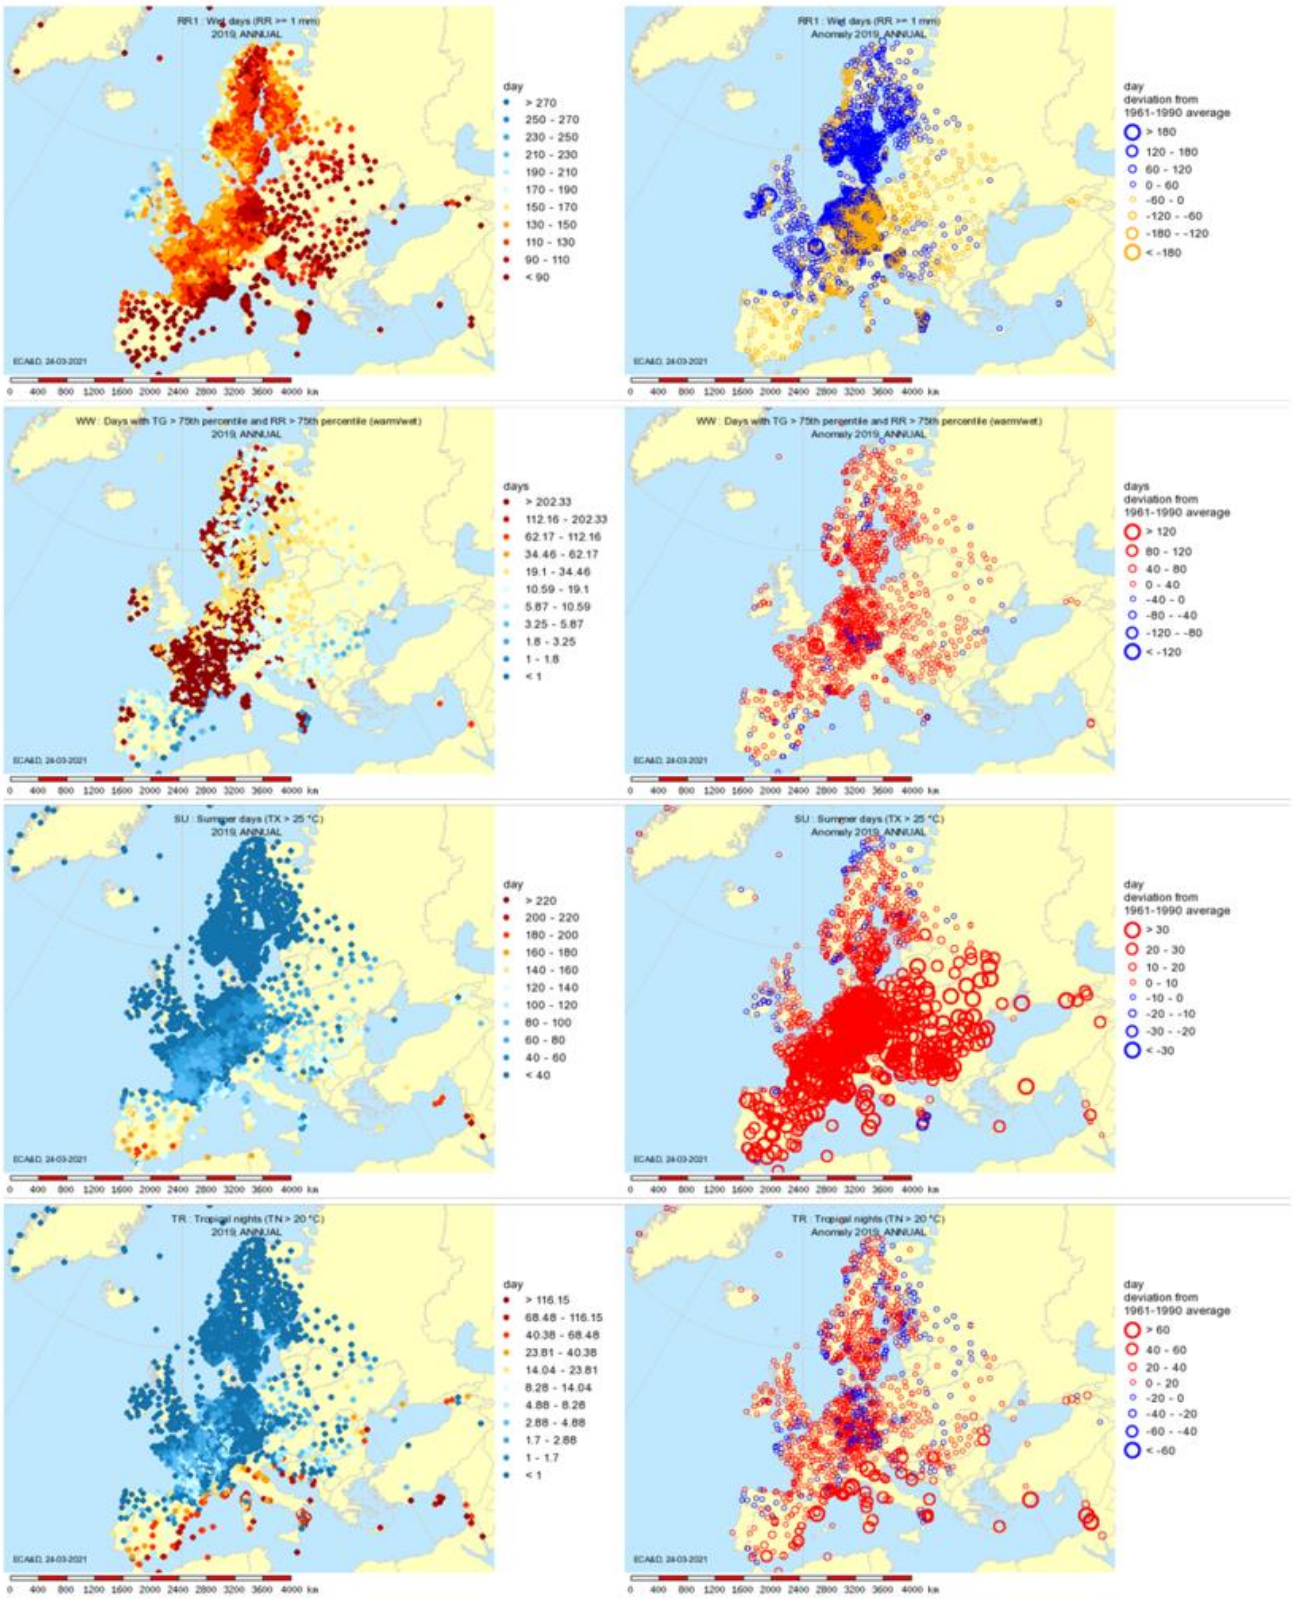

Figure 2-9: Selected Climate Indices for 2019 (left) and their anomalies (right) with respect to the 1961 to 1990 reference period (Source: ECA&D, http://www.ecad.eu).

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2019 with anomalies related mainly to the normal period 1981-2010 for the following selected climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1 Seasonal averages and anomalies of selected climate variables

3.1.1 Sea level pressure and circulation indices

Pressure distribution in **winter 2018/2019** shows that both circulation centres, the Icelandic Low and Azores High, were stronger than normal with anomalies of -4 to -6 hPa and up to +6 to +8 hPa respectively. That winter the North Atlantic Oscillation (NAO) was positive, but with 1.08 not very pronounced; the Arctic Oscillation (AO) was in a neutral phase (-0.08). The dominant circulation patterns were the East Atlantic/ West Russia Pattern (EA/WR) and the Polar/ Eurasia Pattern (POL), with values of -1.55 and -1.89 respectively.

In **spring,** pressure was lower than normal over the entire RA VI Region except for Scandinavia. The Icelandic low was shifted south. Largest negative anomalies occurred southwest of Ireland and over Russia.

In **summer** the pressure anomalies were mostly only slightly positive or negative (within -2 to +2 hPa). Larger negative anomalies occurred tough over the Arctic including Iceland.

The circulation centres in **autumn** were well pronounced with a core pressure between 1000 and 1005 hPa around Iceland and between 1020 to 1025 hPa around the Azores. The latter formed part of high pressure belt extending further across southern and central Europe to western Kazakhstan with one maximum around the Azores and the second one over Eastern Europe. Above-normal pressure anomalies occurred over northeastern Europe, with largest anomaly values in the range of +4 to +6 hPa over the Baltic countries. All circulation patterns were in a neutral phase except for the NAO which was positive with a value around 1.

Table 3-1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference. Blue and yellow colors indicate index values lower and greater than zero respectively

season	NAO	EA	EA/WR	SCA	POL	AO
Winter 2018/2019	-0.16	0.18	-0.12	0.25	0.29	0.77
Spring 2019	-0.17	-0.38	-0.22	-0.34	0.35	-0.07
Summer 2019	-0.74	-1.27	1.1	-0.12	-0.98	-0.54
Autumn 2019	-0.63	-0.29	0.98	-0.11	0.36	0.24

Note that all values are standardized with the reference 1981 to 2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**:ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

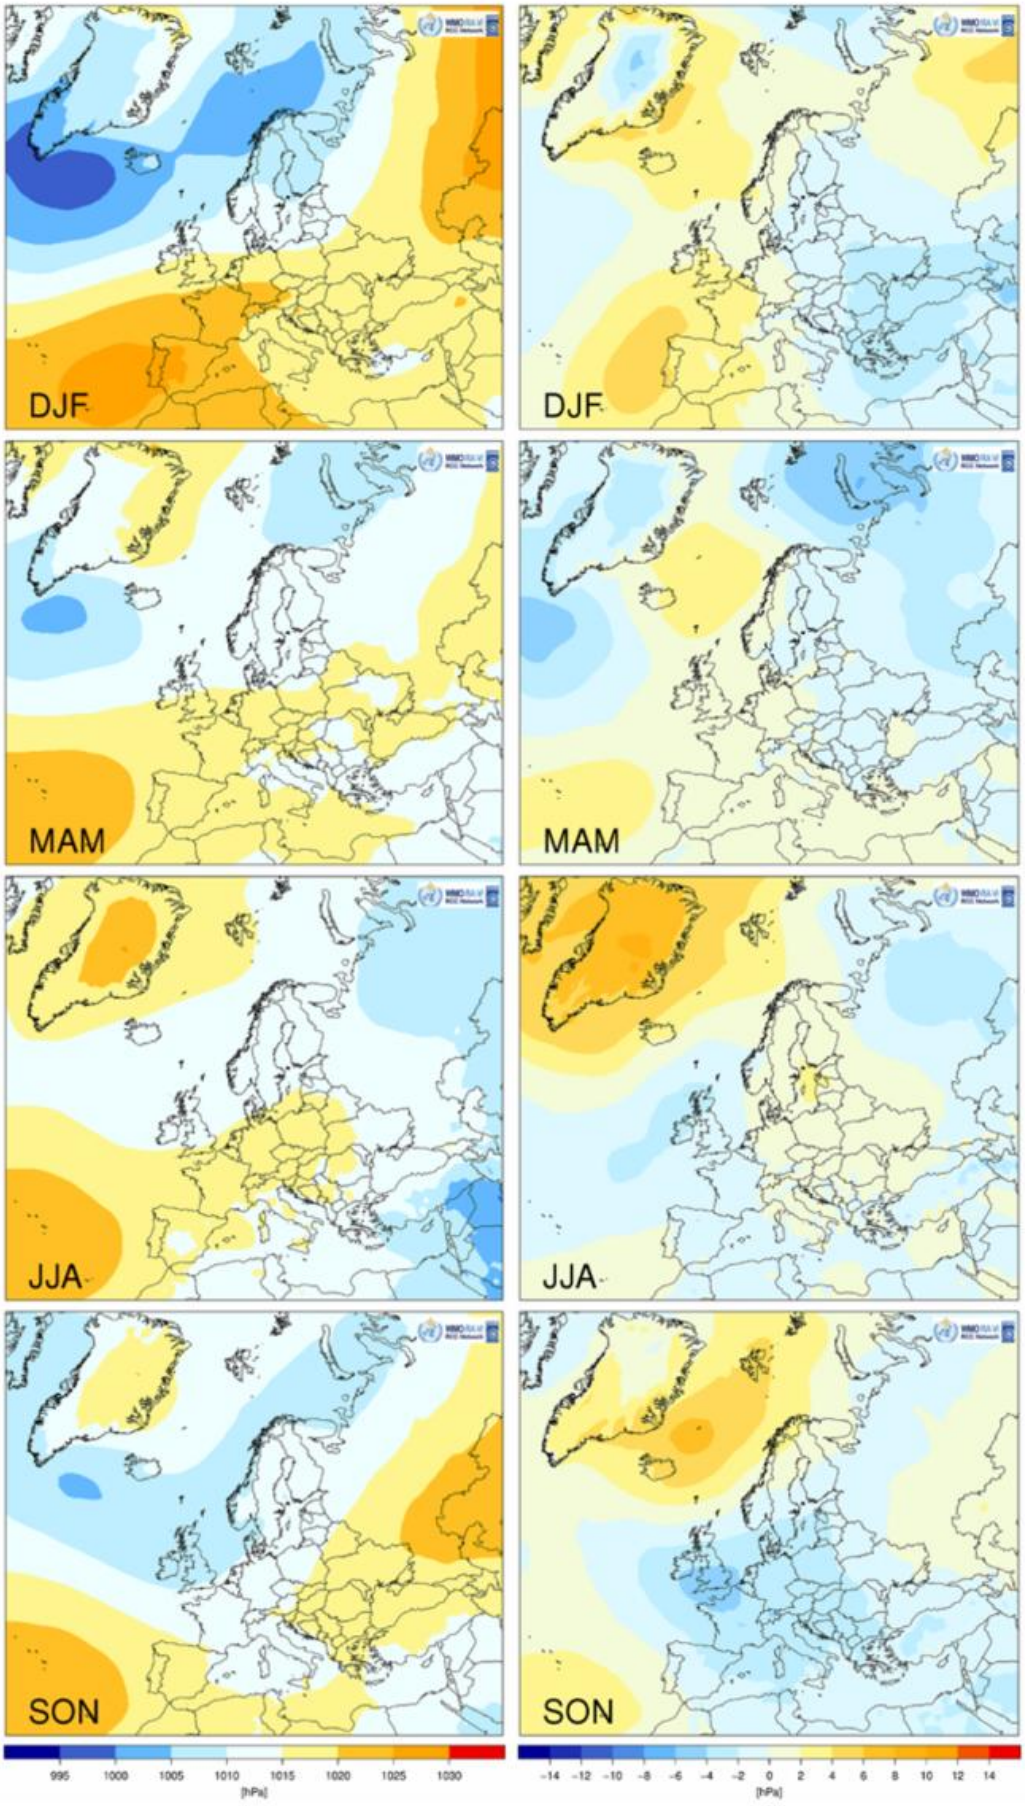

Figure 3-1: *Seasonal sea level pressure (left, in hPa) and anomalies (right, in hPa) in 2018/2019, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).*

3.1.2 Temperature

In 2019, mean annual temperatures were higher than normal (w.r.t. 1981-2010) over the whole RA VI Region which is reflected by positive anomalies in all sub-regions ranging from +0.69 °C over Iberia to +1.51 °C over Eastern Europe (see Table 3-2). Temperatures were not only higher than normal on an annual basis but also in all seasons except for the summer season over Eastern Europe which was normal with an anomaly value very close to zero (0.1).

Table 3-2: Seasonal and annual average of temperature anomalies over land areas in °C for each sub-region in the year 2019 (reference period: 1981-2010; definitions of the sub-regions see Figure 1-1)

region	year	winter	spring	summer	autumn
Central and Western Europe	1.33	0.91	0.59	1.94	1.06
Nordic und Baltic Countries	1.46	0.78	1.78	1.28	1.36
Iberia	0.69	0.34	0.56	0.63	0.66
Med. Italian and Balkan Peninsula	1.43	0.38	0.55	1.79	2.26
Eastern Europe	1.51	1.26	1.73	0.09	1.27
Middle East	1.17	0.85	0.79	1.06	1.19

Meteorological **winter 2018/19** (December 2018, January and February 2019) was mild in much of Europe (Fig. 5) with a NAO index of 1.16. Winter 2018/19 in Ireland was the warmest winter on record (since 1900). February was exceptionally warm (anomalies of +2.0 °C to +4.0 °C in Eastern Europe, and even higher in places) due a strong southwesterly airflow of moist and mild air from the East Atlantic.

In **Western Europe**, the winter was very mild (United Kingdom +1.4 °C above normal (eighth warmest), Netherlands +1.8 °C, Luxembourg +1.8 °C, France +1.3 °C, Ireland +1.8 °C above normal (warmest on record)) due to a very warm December 2018 and an exceptionally warm February. The United Kingdom reported the second warmest February on record (+2.4 °C above normal), Luxembourg and Ireland its third warmest (+3.7 °C and +2.4 °C respectively). In France, the countrywide average of maximum temperature was +4.1 °C above normal making it the second warmest February after 1990. Similarly in Ireland it was the warmest winter on record for many stations and more than half of the stations set new monthly maximum temperature records in February on the 25th and 26th. Other countries in Western Europe reported new records as well in late February (see below in section "Notable events"). Winter was mild in **Central Europe** with anomalies between +1.0 °C and +2.0 °C. Germany reported the ninth warmest winter with an anomaly of +1.9 °C. February, with an NAO index of 1.9, was unusually warm with anomalies of +2.0 °C and above (Austria +2.0 °C, Slovakia +2.9 °C, Czech Republic +2.6 °C, Hungary +3.0 °C, Germany +3.1 °C). In **the Nordic and Baltic countries**, the winter had well-above-normal temperatures. Denmark reported the seventh warmest winter on record with an anomaly of +2.9 °C. January, however, was colder than normal in most of the region, especially in Finland where temperatures were -3.0 °C to -4.0 °C below normal in the north. February, in contrast, was very mild with anomalies of +4.0 °C to +5.0 °C in the Baltic countries and Finland, resulting in many new monthly records of maximum temperature. On February 26th, 15.8 °C was measured at Tirstrup in

Djursland (Denmark), tied with the previous record of 24 February 1990 measured in Copenhagen. In Sweden, a new record was measured at Karlshamn with 16.7 °C on the same day. In Latvia, at Kolka, a new record of 13.4 °C was set on 16 February for the highest winter maximum temperature. Estonia reported the seventh warmest February on record with an anomaly of +4.3 °C, Latvia the eighth warmest (+4.5 °C above normal), Lithuania sixth warmest (+4.4 °C above normal). In **Iberia**, winter was generally warmer than normal. Spain reported an anomaly of +0.8 °C and Portugal +0.4 °C. After the year started with colder-than-normal temperatures in January (-0.1 °C anomaly) it continued with a very warm February ending the season with +1.2 °C above normal in Spain. In the north of Portugal, about 30 % of the stations registered new maximum temperature records for February. Concerning the **Mediterranean, Italian and the Balkan peninsula**: except for Greece (anomaly -0.2 °C) the winter season was warmer than normal for the region between +0.6 °C above normal for Italy and Serbia up to +1.3 °C above normal for Slovenia and Turkey. January was colder than normal for some western parts of the region. Serbia and Greece reported January anomalies of -0.9 °C, Italy -0.7 °C. The season ended with a warmer-than-usual February except for Sicily and Malta, the latter reporting its second coldest February on record. Slovenia reported +3.1 °C, Serbia +2.1 °C, Italy +1.4 °C and Greece +0.7 °C above normal. Over **Eastern Europe**, the year started with below-normal temperatures in January for most of Eastern Europe with anomalies of 1.0 °C in Belarus, -0.7 °C in Moldova and -0.5 °C in Ukraine (NAO of -0.36). February was extremely mild with anomalies ranging from +3.2 °C above normal to above +4.0 °C in Russia (+4.1 °C) and Ukraine (+4.4 °C) (NAO of +1.9). The **Middle East** experienced a warmer-than-normal winter, though anomalies in January and February exceeded +1.0 °C only locally. Winter was exceptionally mild in the **South Caucasus**. The whole region experienced anomalies above +2.0 °C and in Armenia even close to +3.0 °C. During all winter months, the anomalies were above +2.0 °C.

Above-normal temperatures continued with the start of **spring,** and only at the end of the season temperatures from Italy to the Nordic countries dropped to below normal by -2.0 °C to -3.0 °C in many regions, making it one of the coldest Mays in a long time for many countries. In **Western Europe,** spring was mild with anomalies ranging from +0.3 °C in France, over +0.7 °C in the Netherlands to +0.8 °C in the United Kingdom. Only May had below-normal temperatures with anomalies below -1.0 °C in the Benelux countries, eastern and southern France. In **Central Europe**, spring was just slightly warmer than normal for Switzerland and Austria (+0.1 °C and +0.2 °C above normal) and between +0.5 °C in Germany and +0.7 °C for the rest of the countries in the region. While March and April brought widespread temperatures up to +3.0 °C above normal, May was far colder than normal due to northwesterly circulation and below average solar radiation with anomalies between -2.2 °C and -2.6 °C ranking among the 10 coldest Mays for most countries. In **the Nordic and Baltic countries**, spring temperatures were above normal by more than +1.0° in most of the region (Norway +0.8 °C, Finland +1.15 °C, Denmark +1.5 °C and Latvia +1.5 °C above normal). April was especially warm with Finland and Norway reporting their second warmest April on record (+2.5 °C above normal) and Latvia the third warmest (+2.1 °C above normal) May was the only month of the season, which was colder than normal in the whole region except for Lithuania and Latvia, where May was slightly warmer than usual. Over **Iberia**, spring started with a warmer-than-usual March and anomalies of around +0.7 °C. While April was close to normal, May proved to be warm again especially in Portugal, which reported its 7th hottest May since 1931, and southern Spain.

Table 3-3: Seasonal rank statistics for temperature (2018/2019) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the to time series.

Country	Anomaly	Reference period	Rank /Start of time series
		winter	
Ireland	+2.18	1961-1990	1
		spring	
Latvia	+1.6	1981-2010	4
Lithuania	+1.5	1981-2010	5

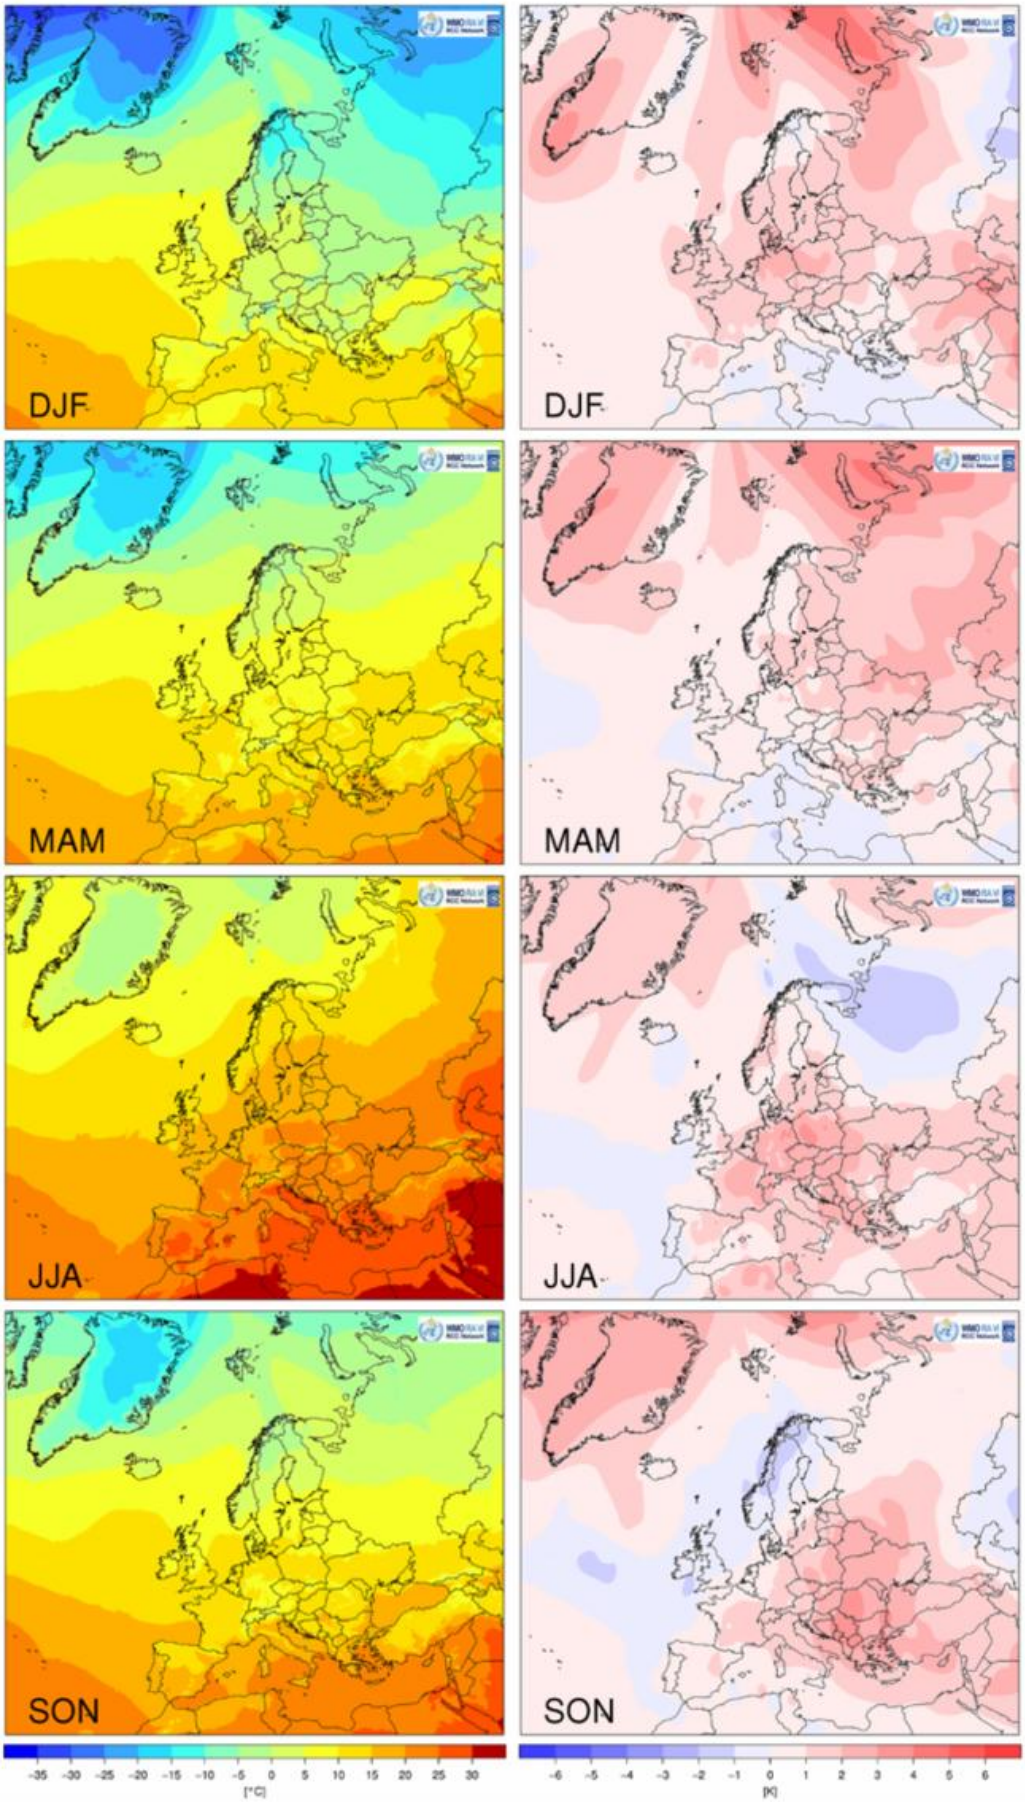

Figure 3-2: *Seasonal mean temperature (left, in °C) and anomalies (right, in K) in 2018/2019, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).*

Concerning the **Mediterranean, Italy and the Balkan states**, overall spring anomalies were +0.5 °C for Spain and +1.03 °C for Portugal. Spring was warmer than normal for almost the entire region. Anomalies mainly ranged from +0.2 °C to +0.7 °C r. The end of the season, due to northwesterly circulation and below-average solar radiation, was unusually cold in Italy and the Balkans. Slovenia reported one of the coldest May's on record (anomaly -2.8 °C), Italy the sixth coldest (anomaly -1.45 °C), Serbia the eighth coldest (anomaly -2.1 °C), and Malta and Greece reported anomalies of -1.5 °C and -0.5 °C respectively. Over **Eastern Europe**, well-above-normal temperatures continued in spring. Russia and Ukraine reported their eighth and seventh warmest spring each with an anomaly of +2.3 °C. Belarus and Moldova reported their fourth and fifth warmest spring (anomalies of +1.7 °C and +1.4 °C). March with an NAO of 2.39 was especially warm with anomalies of +2.9 °C (in Belarus) to +3.9 °C (in Ukraine) and ranked in the top ten of the warmest March months for all countries of the region. In the **Middle East**, after a slightly-colder-than-normal March (anomalies down to -1.0 °C for most of the region) and an April with well-below-normal temperatures (anomalies below -1.0 °C), a warmer-than-normal May followed with anomalies above +2.0 °C in parts of Israel and Jordan. Israel reported its warmest May for at least 50 years. During a prolonged heat spell starting in mid-May, multiple Sharav events (hot and dry winds coming from desert regions) brought very high temperatures, most notably between 22 and 24 of May when maxima of 43 °C to 45 °C were reached in the coastal plain and up to 47 °C in the Dead Sea region. Overall, spring season was closer to normal except for Cyprus where temperatures were +0.7 °C above normal. In the **Middle East**, in spring, above-normal precipitation (>125 % of normal) was received in northern and western Syria and in the Lebanon. Southeastern Syria and eastern Jordan had an early start of the dry season and received less than 10 mm in the whole spring. In May, precipitation was scarce in the whole region. The dry season continued until September. Spring started with a close-to-normal March in the **South Caucasus** followed by a colder-than-normal April with anomalies below -1.0 °C in Armenia. However, due to well-above-normal temperatures in May (anomalies above +2.0 °C in the whole region) the season overall was warmer than normal.

Summer was warmer than normal in much of Europe. June proved to be a month full of records for many countries with widespread anomalies of +2.0 °C to +4.0 °C. Summer in **Western Europe** was close to normal (+0.4 °C) in Ireland and only slightly warmer in the United Kingdom (anomaly of +0.8 °C, twelfth warmest). For Belgium (+1.5 °C), Luxembourg (+2.4 °C) and France (+1.7 °C) it was the third warmest summer on record and in the Netherlands the fourth warmest at De Bilt with an anomaly of +1.4 °C. June was very warm for most of Europe. It was the warmest June in the Netherlands, second warmest in Luxembourg (anomaly +3.6 °C) and fifth warmest in France (anomaly +1.8 °C). Ireland was below normal with anomalies of -0.3 °C. Although it was only the 4th warmest July on record for France (+2.2 °C), many records of daily maximum temperature were broken especially on 25 July (see "notable events" and sidebar for more details). Summer in **Central Europe** was exceptionally warm. Slovakia and the Czech Republic reported their warmest summer on record with anomalies of +2.4 °C and +2.5 °C, Hungary and Austria reported their second warmest (+2.2 °C and +2.7 °C above normal), and Germany and Switzerland their third warmest (+2.1 °C and +2.3 °C). All summer months were warmer than normal in the region but June in particular was the warmest month on record for all countries except for Switzerland where it was second warmest. Anomalies in June were well above +3.0 °C, and close to +5.0 °C in places. Many highest temperature records were broken. In Germany, the previous countrywide record of 40.3 °C, measured at station Kitzingen in summer 2015 was beaten by 14 different stations during the peak

of the heat wave on 25 June. Austria reported new June records at more than half of the 269 stations of ZAMG. In the **Nordic and Baltic countries**, summer was warmer by above +1.0 °C in the northern countries (Estonia +1.6 °C (warmest since 1961 together with 2015), Denmark +1.6 °C, Norway +0.9 °C, Latvia +1.0 °C, Finland +0.29 °C). Some new records were set, for example a new high minimum temperature of 26.1 °C observed at station Sømna – Kvaløyfjellet (Nordland, Norway) on 28. July. Never before a higher minimum temperature had been recorded in Norway. At the Swedish station Markusvinsa a new record of maximum temperature at 34.8° was measured on 26 July. This was the highest temperature ever reported north of the Arctic Circle in Sweden. On June 13, a new seasonal record with a temperature of 33.0 °C was set in Riga. Many other stations broke their monthly maximum temperature record during June. Contrasting to the warm June, July was colder than normal in the Baltic countries and Finland with anomalies slightly below -1.0 °C (Finland -1.1 °C, Latvia -1.2 °C, Lithuania -1.0 °C, Estonia -1.0 °C). In **Iberia**, the summer was warmer than usual by +0.8 °C for Spain, contrary to the situation in Portugal where temperatures were below normal by -0.3 °C. During a heat wave in the last days of June (26 June to 01 July) the highest measured temperatures reached well above 40.0 °C, for example 43.4 °C in Lleida and 43.2 °C at Zaragoza Airport, each on 29 June, and 43 °C at Girona Airport on 28 June. Seven main stations in Spain recorded a new daily maximum temperature record for the season during this heat wave. Concerning the **Mediterranean, Italian and Balkan Peninsula**: during the summer season, especially the Balkan states experienced widespread temperatures of more than +2.0 °C above normal. Slovenia and Italy reported the second warmest summer on record with an anomaly of +2.5 °C and +2.9 °C, respectively, Greece the fourth warmest (+1.3 °C above normal) and Serbia the fifth warmest (+1.8 °C above normal). June and August featured very high temperatures. It was the hottest June on record for Malta (+2.45 °C above normal), the second warmest for Slovenia (+4.2 °C above normal) and Italy (+3.9 °C above normal) and the fourth warmest for Greece (+1.5 °C above normal). August was reported the fourth (+1.7 °C) and fifth (+2.7 °C) warmest on record by Greece and Italy. Over **Eastern Europe**, during summer, the month of June was exceptional. Belarus, Ukraine and Moldova reported their warmest June on record with anomalies of +4.5 °C, +4.7 °C and +3.6 °C above normal, respectively. Records were broken at several stations. In Belarus, temperatures up to 34.7 °C were recorded during daytime while temperatures at night often did not fall under 21.0 °C in the period of 11 to 26 June. Locally, anomalies reached up to +7.0 °C. On 2 July, the 1929 highest maximum temperature record was broken at station Voznesensk in the Ukraine with a temperature of 39.0 °C. In the **Middle East**, summer was warmer than normal by more than +1.0°. In June, anomalies in the Middle East were close to and, in Jordan, even above +2.0 °C, ranking the season amongst the warmest five for all countries in the region. Summer in **South Caucasus** was characterized by a record June (in Georgia the warmest since 1960) with anomalies of +3.0 °C to +5.0 °C for the whole region, while in July the western parts of Georgia were slightly colder than normal and the other parts of South Caucasus had slightly-above-normal temperatures. This reversed in August when anomalies were below normal in Azerbaijan and above normal in Georgia and Armenia.

Autumn also was warmer than normal except for the Nordic countries, Ireland and the United Kingdom. The Balkan states were particularly warm with anomalies well above +2.0 °C.

Western Europe: While autumn brought below-normal temperatures to Ireland (anomaly -0.4 °C) and the United Kingdom (anomaly -0.3 °C) and near-normal temperatures in the Benelux countries (Netherlands +0.2 °C, Belgium +0.3 °C, Luxembourg +0.7 °C above normal), France reported its

sixth warmest autumn since 1900 with an anomaly of +1.0 °C. December 2019 was mild with anomalies of 0.8 °C in Ireland, around +1 °C in the United Kingdom and +2 °C in Benelux and France. **Central Europe** experienced a warmer-than-usual autumn, especially for the southeastern parts of the region. Hungary (+2.4 °C anomaly), Slovakia (+2.1 °C) and the Czech Republic (+1.6 °C) reported their warmest autumns, while for Austria (+1.6 °C) it was the fourth warmest, Switzerland (+1.1 °C) the sixth warmest and Germany, with 1.0 °C above normal, the 10th warmest. December 2019, too, was a mild month with anomalies ranging from about +1 °C in western Germany and +3 °C in eastern Poland. In the **Nordic and Baltic countries**, autumn was colder than normal in Norway (-0.9 °C below normal), Sweden and Finland (-0.16 °C below normal), while the Baltic countries and Denmark reported above-normal temperatures (Latvia +1.6 °C anomaly, eighth warmest together with 1949; Lithuania +1.9 °C, Estonia +1.1 °C, Denmark +0.7 °C). On 14 November, daily maximum temperature records were broken at many stations in Estonia, for example at coastal station Kunda the temperature rose to 12.5 °C (the previous record was recorded on 14 November 1938). December 2019 was generally mild, with anomalies ranging from below +1 °C in Iceland to above +5 °C in easternmost parts of the region. In **Iberia**, with an anomaly of +0.7 °C, Spain had a warm autumn. Only November had close to normal temperatures (anomaly +0.1 °C) while September and October were warmer than usual with anomalies of +0.7 °C and +1.3 °C for Spain. December, too, was a mild month with anomalies above +2 °C in central parts of Spain. For the **Balkan states**, an extremely warm autumn followed. For Croatia (+2.1 °C), Serbia (+2.9 °C) and Greece (+1.9 °C) it was the warmest autumn on record while for Slovenia it was the second warmest with +1.9 °C above normal, and Turkey and Italy reported their third warmest autumn with +1.9 °C above normal. December, too, was very mild with anomalies mostly between +1 °C and +3 °C, highest in northeastern Balkans and eastern Turkey. Over **Eastern Europe**, all three autumn months were warmer than normal for all countries in Eastern Europe except West Kazakhstan, which was repeatedly touched by a northerly inflow of cold air. Belarus reported the second warmest (+2.2 °C), Moldova the third warmest (+2.6 °C) and Ukraine the eighth warmest (+2.4 °C) autumn. It was the warmest October in Belarus since records began (anomaly of +2.87 °C). Abnormally warm weather between 14 and 22 October with anomalies up to +10.0 °C was observed in the whole country. The season ended with a warmer-than-normal November ranking fifth warmest in Belarus (+3.2 °C) and Moldova (+3.8 °C) while for the Ukraine it was only the 12th warmest (+3.1 °C). December, too, was extremely mild with highest monthly anomalies between +8 °C and +10 °C in the Arkhangelsk region in northwestern European Russia and many new daily records of daily maximum temperature especially in the period 18-23 December. It was the second warmest air temperature anomaly in December for the European part of Russia on average (+5.25 °C). In the **Middle East**, the warmth continued in autumn and December with anomalies of well above +1.0 °C in much of the Middle East in all four months September to December. In the **South Caucasus** region, autumn was warmer than usual in Georgia and Armenia while temperatures in Azerbaijan were close to normal. While temperatures were unusually high in October with anomalies above +2.0 °C in the whole South Caucasus region (3rd warmest October since 1960 in Georgia), cold air in the east caused a drop to slightly-below-normal values in November in its eastern parts. Warm air came again in December, and anomalies increased notably to around +3 °C.

3.1.3 Precipitation

Many parts of Western Europe received only 60 % to 80 % of normal precipitation that **winter** (Fig. 6), and only 20-60 % in parts of the Iberian Peninsula, while in the south of Central Europe, Eastern

Europe and parts of the Eastern Mediterranean precipitation was 125 % to 250 % of normal. During the winter season, precipitation was close to normal or below normal for **Western Europe**. The United Kingdom and Ireland reported 77 % and 66 % of normal precipitation, respectively. In the Benelux countries and most parts of France, precipitation was close to normal and only some western, central and southern parts of France recorded below-normal precipitation down to 60 % of normal. In **Central Europe**, the year as a whole was close to normal or drier. Some places in eastern Germany and Poland even received less than 80 % of normal precipitation. In **Central Europe**, the winter season was wetter than normal. Germany, Slovakia and Hungary reported about 110 % and the Czech Republic 148 % (eighth wettest) of normal precipitation. While January was wetter than normal with widespread precipitation between 125 % and 167 % of normal, February was drier than normal especially in Germany with most of the country receiving between 20 % and 60 % of normal precipitation. In the **Nordic and Baltic countries**, winter was wetter than normal in Denmark with 105 % and Norway with 115 % of normal precipitation. Precipitation in Norway, however, was distributed inhomogeneously. While some stations in the east received 200 % to 300 % of normal, several stations in the west received only about 50 % of normal. Finland was close to normal with countrywide precipitation of 102 % of normal. Estonia and Latvia were drier than normal with about 60 % to 80 % of normal precipitation, western Iceland was even drier, while southern Lithuania recorded locally above 125 % due do some low pressure systems coming from Central Europe. In **Iberia**, it was the fifth driest winter in Spain with 49 % of normal rainfall. Portugal had 42 % of normal, the fourth driest winter since 2000. Only in January did northern parts of Spain receive above-normal precipitation. In February, precipitation on the entire Iberian Peninsula was widely 20 % to 60 % of normal. With a countrywide average of 28 % of normal precipitation, Spain recorded the fourth driest February since 1965 and the driest in the 21st century. Concerning the **Mediterranean, Italian and Balkan peninsula**, winter was drier than normal in Italy (63 % of normal), Slovenia (68 % of normal) and Croatia (77 % of normal) while it was wetter for Serbia (120 % of normal), Turkey (146 % of normal), and for Greece it was the fifth wettest winter on record (155 % of normal). January was particularly wet in almost all parts of the region with Greece reporting the wettest January on record with 244 % of normal precipitation. Over **Eastern Europe**, the winter was generally wetter than normal with up to 126 % of normal precipitation in places. January in particular brought a precipitation surplus and was reported the fifth wettest by Russia (132 % of normal) and Moldova (231 % of normal). February, on the other hand, was the fourth driest in Belarus with locally just 20 % of normal precipitation. Ukraine reported 46 % of normal precipitation while Moldova was close to normal (94 %) and Russia reported above-normal precipitation with 132 % of normal, mainly in the north. In the **Middle East**, during January, Cyprus, Lebanon and the western parts of Syria received above-normal precipitation while in Israel and Jordan precipitation was below normal. February was wet again except for some parts in the east of Syria. In the **South Caucasus** region, the winter season was wet in Azerbaijan and Armenia, which received 125 % -250 % of normal precipitation and more than 250 % in places. Georgia received below-normal precipitation, below 80 % of normal in places.

Many parts of France and the Iberian Peninsula were drier than normal in spring with precipitation of 60 % to 80 % while in the rest of Europe it was closer to normal or wetter (125 % to 167 % of normal in Scandinavia and Italy/ northern Balkans). In **Western Europe**, Ireland and the United Kingdom reported slightly above-normal totals for the spring season. March was very wet in both countries. The United Kingdom reported the eighth wettest March since 1910 (136 % of normal). The Benelux countries were slightly drier than normal in spring with around 90 % of normal

precipitation. Parts of France remained dry with deficits as low as 50 % to 80 % of normal. In **Central Europe**, for Germany (98 %), Switzerland (102 %) and the Czech Republic (103 %) spring was close to normal while for Slovakia (121 %) and Hungary (112 %) the season was wetter than normal. For Hungary, March was the 10th driest on record with only 28 % of normal precipitation. During April, the precipitation deficit shifted to Germany, the Czech Republic (60 % of normal and the ninth driest) and northern parts of Poland where precipitation reached only 20 % to 40 % of normal.

Table 3-4: Seasonal and annual average of precipitation anomalies over land areas in % for each sub-region in the year 2019 (reference period: 1981-2010; definitions of the sub-regions see Figure 1-1)

region	year	winter	spring	summer	autumn
Central and Western Europe	96	95	94	85	113
Nordic und Baltic Countries	94	103	89	95	89
Iberia	89	57	83	87	101
Med. Italian and Balkan Peninsula	106	97	111	104	102
Eastern Europe	107	120	107	100	100
Middle East	99	130	113	119	63

Table 3-5: *Seasonal rank statistics for precipitation (2018/2019) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the to time series.*

Country	Anomaly	Reference period	Rank /Start of time series
		winter	
Jordan	86.6mm	1981-2010	4th wettest since 1981
Italy	-93 mm	1961-1990	5th driest since 1961
Spain	-101 mm (50% of normal)	1981-2010	5th driest since 1965
		autumn	
Georgia	-99.4 mm	1981-2010	5th driest since 1960

Spring again was wetter than normal for the **Nordic countries** except Iceland (Norway 122 %, Denmark 130 %, Finland 118 % of normal) while the **Baltic countries** reported below-normal precipitation (Latvia 82 %, Lithuania 76 % of normal). Especially April was extremely dry in the whole region. Latvia reported only 9 % of normal precipitation making it the driest April on record. Finland only received 42.8 % of normal, ranking fourth driest, and Denmark reported only 36 % of normal precipitation. In **Iberia**, spring started with a very dry March when precipitation ranged from 20 % to 80 % of normal in most parts of the Iberian Peninsula. After a very wet April with 148 % of normal precipitation, ranking the fourth wettest for Spain, the season ended with an extremely dry May. Almost the whole Iberian Peninsula received only 20 % to 60 % of normal precipitation, with large parts of Spain below even that, making it the fourth and sixth driest May on record for Spain and Portugal, respectively. Over the **Mediterranean, Italian and Balkan peninsula**, most of the region experienced a wetter-than-normal spring, only Turkey was close to normal and Greece reported slightly-below-normal precipitation of 93 %. May was very wet in many countries of the region with

the exception of Greece and Turkey. Croatia and Slovenia reported 195 % of normal precipitation, the latter even reported the wettest May on record. For Serbia, it was the sixth wettest (192 % of normal) and Italy reported 185 % of normal precipitation. Over **Eastern Europe**, spring was wetter than normal in Russia and Ukraine while Belarus and Moldova received below-normal precipitation. March was rather dry in Romania, Moldova and Ukraine. Moldova even reported the second driest March on record with a countrywide average of only 1 mm, which is 3 % of normal precipitation, and Ukraine on countrywide average received 64 % of normal precipitation. In Belarus, it was only slightly drier than normal (91 % of normal) and the European parts of Russia reported a precipitation surplus of 115 % of normal. April was drier than normal in all countries of the region but driest in Russia, which reported the sixth driest April with 66 % of normal and Belarus even recording the driest April on record with only 18 % of normal precipitation. The season ended wet for the whole region with precipitation of 124 % to 161 % of normal, the latter being reported by Ukraine as the sixth wettest May. In the **South Caucasus** region, during spring, Azerbaijan again recorded above-normal precipitation of 125 % or more while precipitation in Georgia and Armenia was closer to normal.

Except for the eastern Mediterranean, the United Kingdom, Ireland and southern parts of Norway, summer was drier than normal with 60 % to 100 % of normal precipitation. In **Western Europe**, summer was predominantly characterized by low pressure leading to a rather wet season in Ireland and the United Kingdom. The United Kingdom reported its 10th wettest summer with 138 % of normal precipitation as well as some broken records - 425.4 mm in South Yorkshire, which is double the average for the season. In contrast, summer was drier than normal in France and the Benelux countries with only 80 % to 90 % of normal precipitation. In **Central Europe**, the summer was drier than normal for the whole region. Germany reported 73 %, Slovakia 84 %, Czech Republic 76 %, Hungary 91 % and Switzerland 95 % of normal precipitation. June in particular was very dry for Austria, which reported its driest June since the beginning of measurements in 1767 with only 43 % of normal precipitation, and Poland where the southern parts only received 20 % to 40 % of normal precipitation. In the Czech Republic, the precipitation deficit was 67 % of normal and thus it was the eighth driest June on record. Germany and Switzerland received 72 % and 88 % of normal precipitation during June. The summer season was drier than normal for all **Nordic and Baltic countries** except for Denmark (115 % or normal) and Norway (110 % of normal). Finland received only 67 %, Latvia and Lithuania a bit more than 80 % and Estonia 78 % of normal precipitation. Especially July was extremely dry in Finland (48 % of normal, ranking the fifth driest in history), Sweden (52 % of normal), most of Norway (74 % of normal) and Estonia (78 % of normal). Over **Iberia**, the summer started with a dry June, ranking seventh driest for Spain (58 % of normal) and Portugal reporting that 98 % of its territory was under meteorological drought (30 % in severe or extreme drought). While July brought above-normal precipitation of 120 % to Spain (enough to make it the 11th wettest July), the drought situation in Portugal increased with precipitation of only 20 % to 80 % of normal in the south and locally even less. In August, precipitation was distributed heterogeneously in Iberia. Locally there was more than 250 % of normal due to heavy rain. In Portugal, the drought was slightly relieved only in northern and central parts by above-normal precipitation while the south stayed dry. Overall, Portugal ended the season with 77 % of normal and Spain with 86 % of normal precipitation. Concerning the **Mediterranean, Italian and Balkan peninsula**, in summer, it was wetter than normal around the Aegean Sea and in Turkey, while Italy and the Balkans had around-normal precipitation or less. Serbia was only slightly wetter with 102 % of normal, Turkey and Greece reported 136 % and 131 % of normal precipitation, respectively. For

Italy, Slovenia and Croatia, precipitation was between 77 % and 84 % of normal. June in particular was notably dry for these countries with only 34 % of normal in Italy, 50 % of normal in Slovenia, 67 % of normal in Croatia, and Malta reporting no precipitation at all for only the fourth June in the last 70 years. In **Eastern Europe**, over the summer, precipitation was below normal except for the European parts of Russia with 108 % of normal, mainly in the north. It was close to normal in Belarus (97 % of normal). Ukraine and Moldova only reported 68 % and 87 % of normal precipitation. Precipitation was distributed inhomogeneously in the summer months as locally extreme amounts of precipitation were observed. At several stations in southern and central Ukraine (Kherson, Mykolaiv, Kirovohrad) new daily maximum record sums were set on 3-5 June with 76 mm to 104 mm, which is equal to 150 % to 200 % of the monthly normal. In the **Middle East**, in spring, above-normal precipitation (>125 % of normal) was received in northern and western Syria and in the Lebanon. Southeastern Syria and eastern Jordan had an early start of the dry season and received less than 10 mm in the whole spring. In May, precipitation was scarce in the whole region. The dry season continued until September. In the **South Caucasus** region, summer was drier than normal, with the highest deficits in eastern Azerbaijan and totals of only 40 % of normal. The dryness persisted more or less during all three summer months, only Georgia received above-average rain in June and particularly July.

For Eastern Europe, Turkey and southwestern Iberia, autumn was rather dry while Central and Western Europe mostly received above-normal precipitation between 100 % and 167 % of normal.. In **Western Europe**, autumn was wetter than normal in the Netherlands and Luxembourg with precipitation of around 115 % of normal. Belgium reported 95 % of normal. France, with 130 % of normal, had its fifth wettest autumn (since 1959), though France recorded a countrywide average of only 60 % of normal during September. December 2019 was wetter than normal in western Scotland, southern England and France, partly more than 125 % of normal, while the Netherlands received only around 80 % of normal. In **Central Europe**, autumn was close to normal in the Czech Republic (99 % of normal), Germany and Hungary (both 104 % of normal), while for Slovakia (130 %), Switzerland (115 %) and Austria (129 %) it was a wetter-than-normal season. December was drier than normal in Germany, western Poland and western Czech Republic (60-100 %), but wetter in the Alps, and in eastern and southeastern parts of Central Europe, locally exceeding 125 % of normal. Concerning the **Nordic and Baltic countries**, autumn season was rather wet in southern Finland and Sweden, southeastern Norway and Denmark. Denmark even reported autumn as the wettest on record with 153 % of normal precipitation. While some stations in eastern Norway received 150 % to 200 % of normal, several in the western parts reported less than 50 % of normal. Sweden received 141 %, Finland 124 %, Estonia 123 %, Latvia 118 %, and Lithuania slightly below-normal (95 %) precipitation. December was again a wet month for much of the Nordic countries (partly above 125 % of normal, locally above 250 % in northern Finland), but closer to normal or drier in the Baltic countries and scarce of snow. In **Iberia**, in the autumn, Spain reported a countrywide average of 115 % of normal precipitation. Double the normal precipitation was registered in some areas in Spain, for example between Granada and Jaén and Murcia while southwestern parts of Iberia were drier than normal with only around 60 % of normal precipitation. December was mainly wetter than normal, with 150 % of the long-term average falling in places. Other parts were drier, but only southern Spain recorded monthly totals below 80 % of normal. Concerning the **Mediterranean, Italian and Balkan Peninsula**, it was the sixth driest autumn on record for Serbia with 55 % of normal precipitation. Turkey also reported well-below-normal precipitation for autumn (63 % of

normal). All other countries of the region received above-normal precipitation, except for Malta, which was near normal. For Italy and the Balkan states only the last month of the season brought a surplus of precipitation while for Turkey only September was wetter than normal in southwestern and northeastern parts. December had a very heterogeneous distribution of precipitation. It was particularly dry in Sicily, North Macedonia and Bulgaria (40-80 % of normal in parts), but very wet in southern Turkey (above 250 % of normal in places). In **Eastern Europe**, autumn was drier than normal in the southern parts and wetter than normal in northern parts. Belarus reported 79 %, Ukraine 67 % and Moldova only 27 % (sixth driest) of normal precipitation for the season. For Ukraine and Moldova all three autumn months were drier than normal. Especially in Moldova, September (19 % of normal, 11th driest) and November (only 15 % of normal, fifth driest) were outstanding. December had a similar distribution with above-normal precipitation in northern European Russia (up to 250 % of normal), but drier than normal in the south (40-80 % of normal in large parts), although heavy showers were observed at the Black Sea coast on individual days. In the **Middle East,** the autumn season was much drier than normal with parts of Syria and Isreal receiving only 40% or less of normal precipitation. For Israel is was the 7th driest November in the past 80 years. In the **South Caucasus** region, autumn started with a wet September with heavy rain in places, particularly in central Georgia and eastern Armenia. Locally, monthly totals exceeded 125 % of normal, especially in Armenia. October and November, on the other hand, were drier than normal in the whole region with only 20 % to 60 % of normal precipitation, and below 20 % in places. The deficit continued in December, except for some places, particularly in Armenia, which experienced heavy rain. Due to abnormally dry conditions in December, snow cover in Georgia persisted up to 18-20 days only in the high-mountainous zone with recorded maximum snow depth up to 10-15 cm. The average snow depth at winter resorts (Bakuriani, Gudauri) was two to three times lower than in previous years.

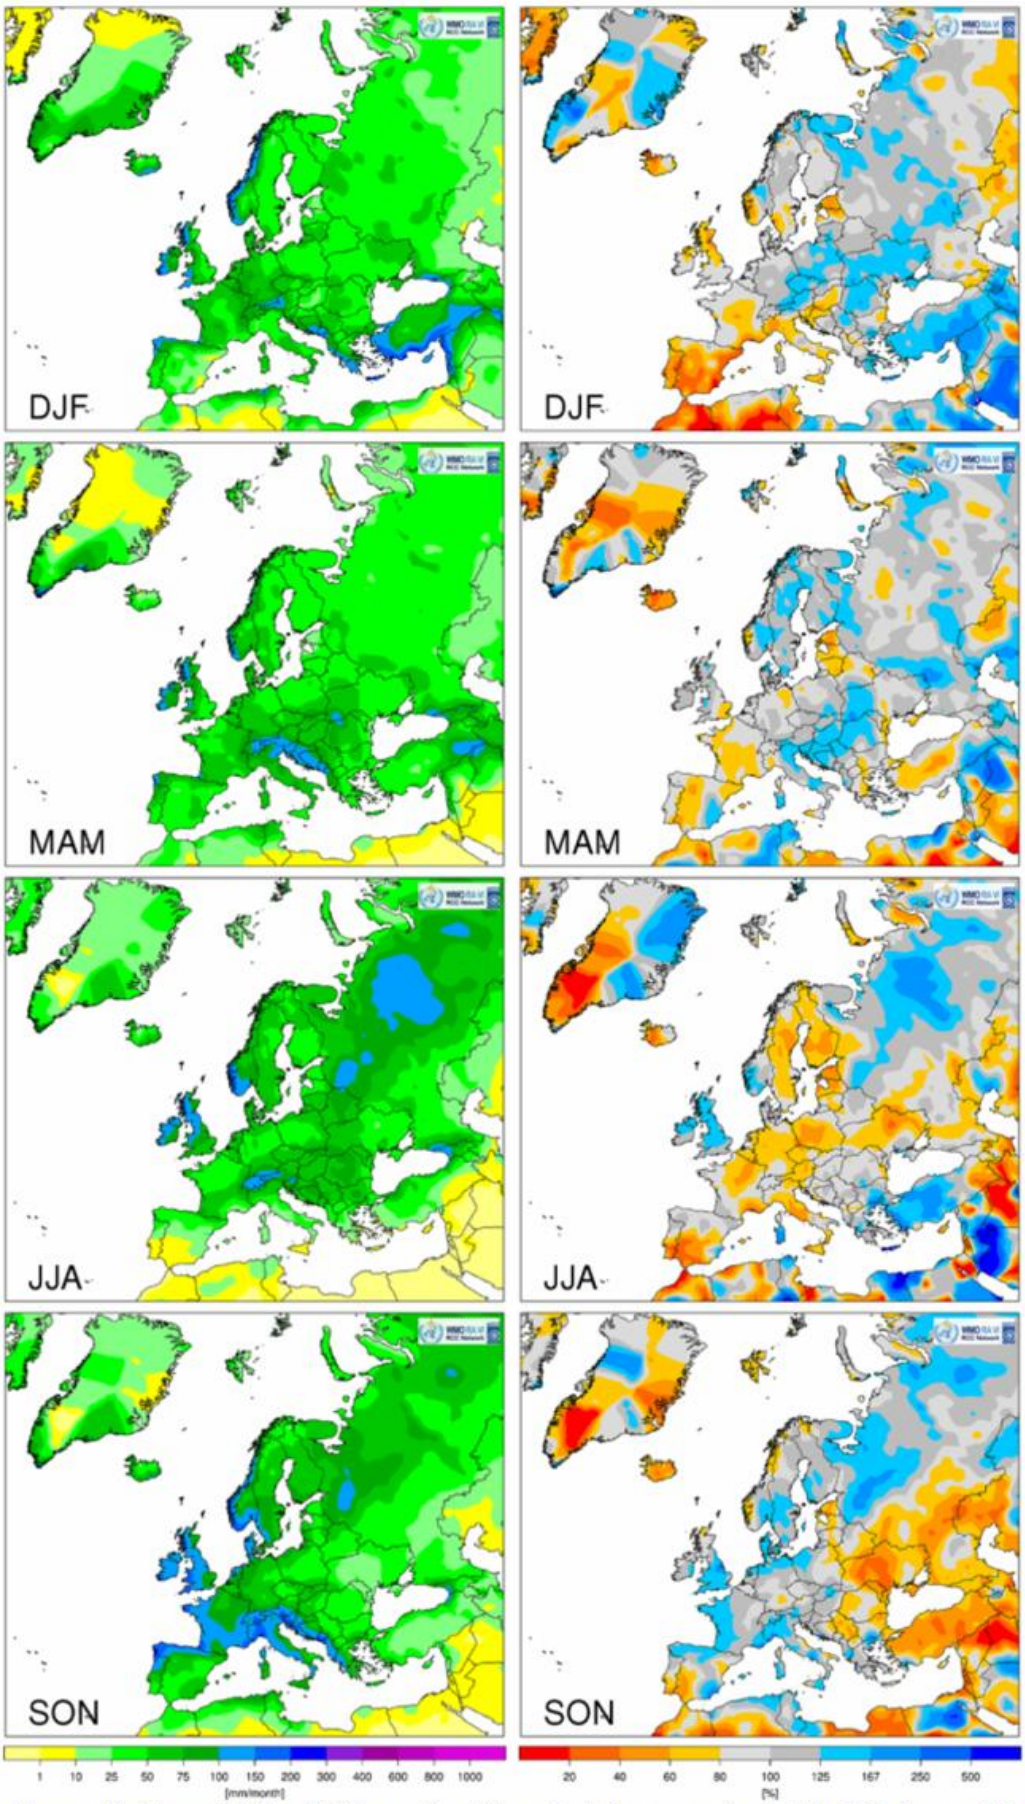

Figure 3-3: *Seasonal total precipitation (left, in mm/month), and relative anomalies (right, in % of normal) in 2018/2019, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).*

3.1.4 Sunshine duration

The year 2019 as a whole was more sunny than normal over most parts of the RA VI Region and even exceptionally sunny with annually accumulated sunshine hours above the 90th percentile over large parts of Central and Eastern Europe as well as over Iberia, which saw 200 to 500 hours (in relative terms up to 125 %) more sunshine hours than normal (see section 2.1.4). This surplus of sunshine hours stems in case of Iberia from seasonal surpluses in winter and spring, which saw over large parts of the area more than 100 sunshine hours more than normal. In case of Central and Eastern Europe the summer and the spring season, respectively, contributed most to the large annual surplus.

During **winter 2018/19** most parts of the RA VI Region recorded above-normal durations of sunshine generally up to 100 hours more than normal, over Iberia even 100 to 200 hours more. Especially northern and eastern parts of the RA VI Region received over large parts less sunshine than normal (up to 100 hours).

Spring brought surplus in sunshine hours to most of the RA VI Region with generally up to 100 hours more sunshine than normal. Over northern parts of Iberia, Belarus and southern Russia the surplus even exceeded 100 hours. Parts of the Italian and Balkan Peninsula, on the contrary, saw a less sunny than normal spring season with a deficit of up to 100 hours.

In **summer**, largest surpluses of sunshine hours were recorded over large parts of Central and Western Europe with more than 100 sunshine hours more than normal.

In **autumn**, the western part of the RA VI Region saw less than normal sunshine hours whereas the eastern part reported a surplus in sunshine duration. Largest surplus in sunshine hours occurred over parts of southern Russia and northern Turkey (between 100 and 200 hours more than normal).

Table 3-6: Seasonal and annual average of sunshine duration anomalies over land areas in hours for each sub-region in the year 2019 (reference period: 1961-1990; definitions of the sub-regions see Figure 1-1)

region	year	winter	spring	summer	autumn
Central and Western Europe	154.2	57.3	18.2	93.3	-9.7
Nordic und Baltic Countries	25.2	21.6	27.2	11.5	-15.7
Iberia	154.7	100.4	86.4	1.0	-14.1
Med. Italian and Balkan Peninsula	97.9	36.6	-1.0	44.9	28.4
Eastern Europe	149.0	24.1	73.3	18.6	46.3
Middle East	110.6	39.7	17.6	0.0	59.4

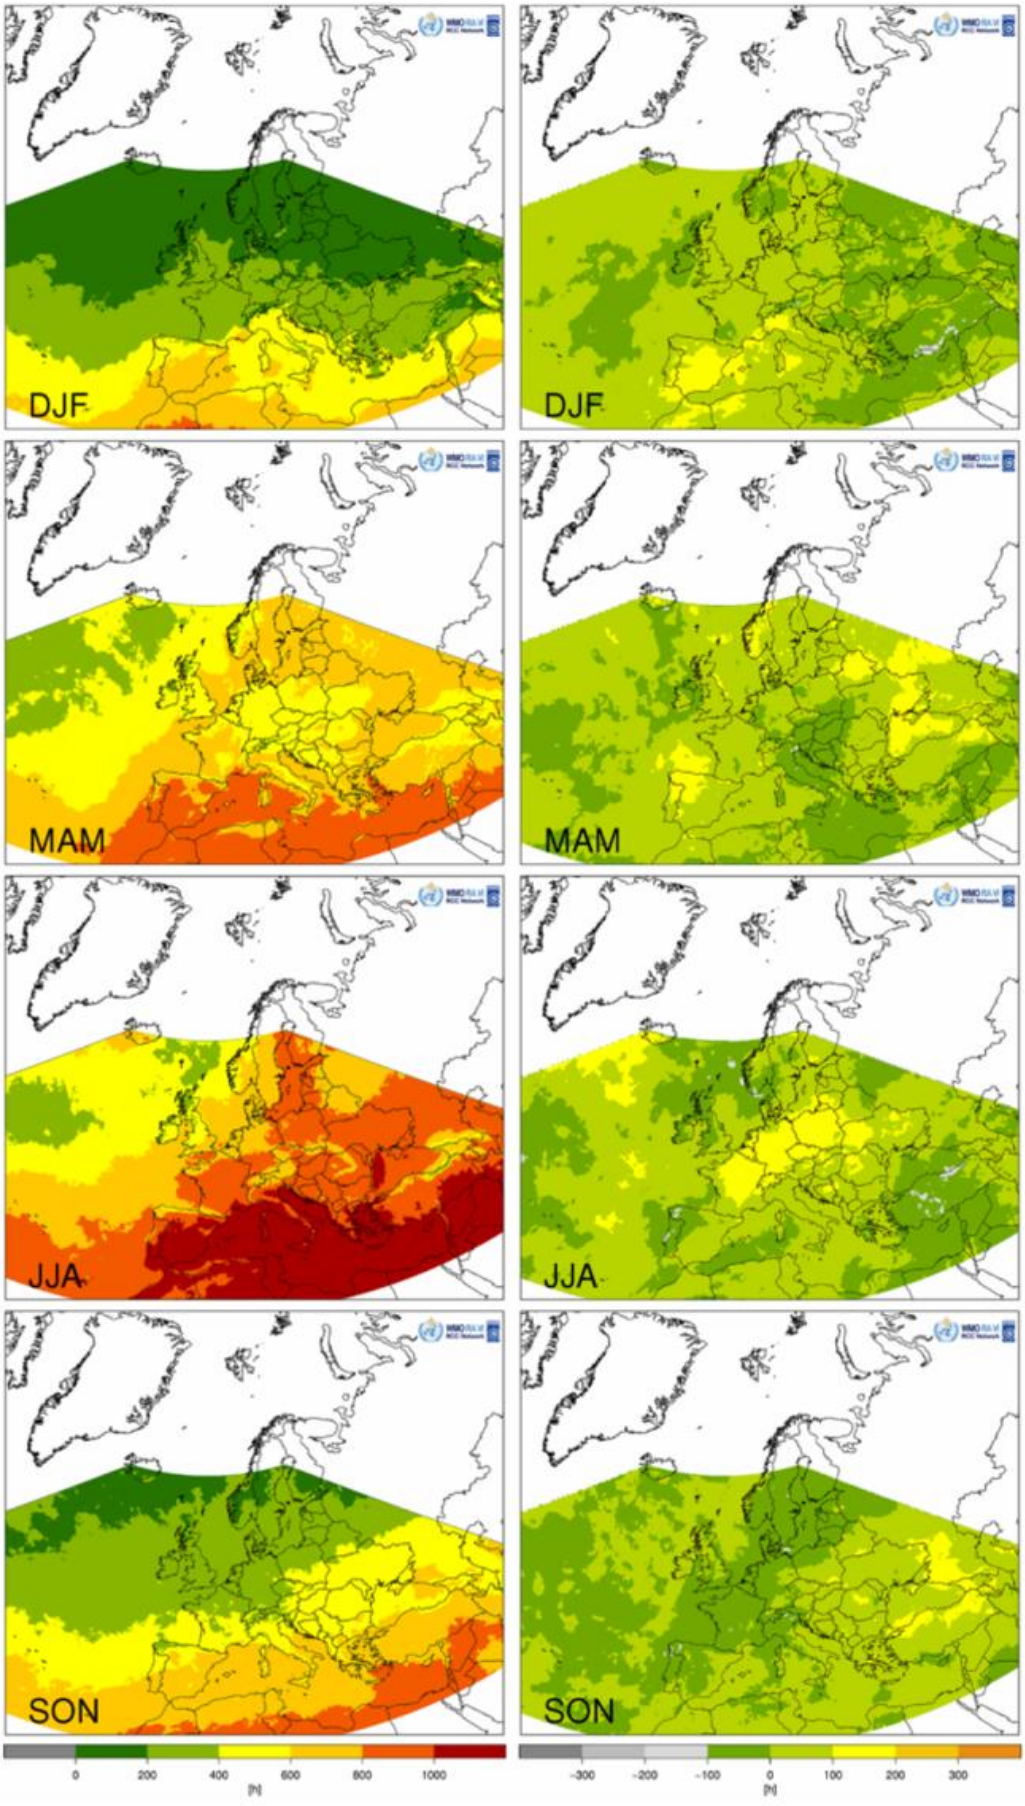

Figure 3-4: *Seasonal sunshine duration (left, in hours), absolute anomalies (middle, in hours) and percentage of mean (right, in %) in 2018/19, reference period 1961-1990 (Source: http://www.dwd.de/rcc-cm).*

3.1.5 Drought

In **winter 2018/19**, precipitation deficits were most severe in Spain, southern France and northern Italy where partly even less than 40 % of normal precipitation amounts were recorded. These are also the regions for which the GPCC-DI indicates moderate (partly even severe) drought conditions with values lower than -1.5. In Spain February was very dry in the whole of Spain. Its average precipitation was 72 % below normal value, and it represented the driest month in the 21st century and the fourth driest month since 1965. Mild drought conditions (with GPCC-DI values between 0 and -1) occurred over parts of Western, Northern and Eastern Europe, which also received less-than-normal precipitation. The rest of the RA VI Region experienced mildly wet conditions, except for Turkey and the Middle East where GPCC-DI reaches values above 1, partly even above 1.5 indicating moderately wet to severely wet conditions.

In **spring** mild drought conditions continued over Spain and France and smaller parts of Central and eastern Europe. Lowest GPCC-DI values occurred over Iceland (-1 to -1.5) indicating a moderate drought level. Over the rest of the RA VI Region wetter than normal conditions prevailed mostly mildly wet according to the GPCC-DI, only southeastern Turkey saw moderately wet conditions.

In **summer**, most of RA VI Region, experienced mildly wet conditions, only over northern parts of Russia moderately up to extremely wet conditions occurred. But dry conditions continued over Spain and France and extended further towards Italy. In this region mild drought occurred prevailed, locally GPCC-DI values dropped below -1.5 indicating severe drought, partly even up to extreme drought (in Spain). Over Iceland, moderate drought conditions from spring continued in early summer, especially in the South and the West. No precipitation was recorded in Stykkishólmur for 37 consecutive days, from 21 May to 26 June. This is the longest drought on record in Stykkishólmur since 1856.The drought conditions in Western, Central and Northeastern Europe intensified particularly during the first strong heat wave in late June 2019 and continued during the whole month of July. Weeks of dry weather since the heat wave in late June 2019 had left more than 80 of French departments facing water restrictions. Plants and wildlife were stressed. More than 20 departments were in the critical red category that restricts water use to only essential needs. The dry weather also hit parts of Spain, the Netherlands, Germany, Poland, the Czech Republic and Scandinavian countries. Soil moisture in the first week of July in northern and eastern Germany was lowest since at least 1961. Drought Indices (e.g. SPI) indicated extreme drought conditions for these areas. Water levels of major rivers in eastern Central Europe (e.g. Elbe, Odra) fell below mean low water levels, causing restrictions for ship traffic. Also in northern Italy, the Po River recorded low water. This month, Lithuania declared an emergency, with drought expected to cut its harvests by half. Due to too dry soils, there were fires in fields and forests in many parts of Europe and Middle East.

In **autumn**, drought conditions stopped for the southeastern parts, which mostly experienced mildly wet conditions. Over Italy and in the regions along the Atlantic coast of Spain, France and the UK moderately and partly even severely wet conditions occurred. Moderately wet conditions also prevailed in a band stretching from the Benelux countries over northern Germany, Denmark and Sweden into northern Russia. The southeast of the RA VI Region saw mostly drier-than-normal conditions, locally even moderate drought (e.g. Ukraine and southern Russia).

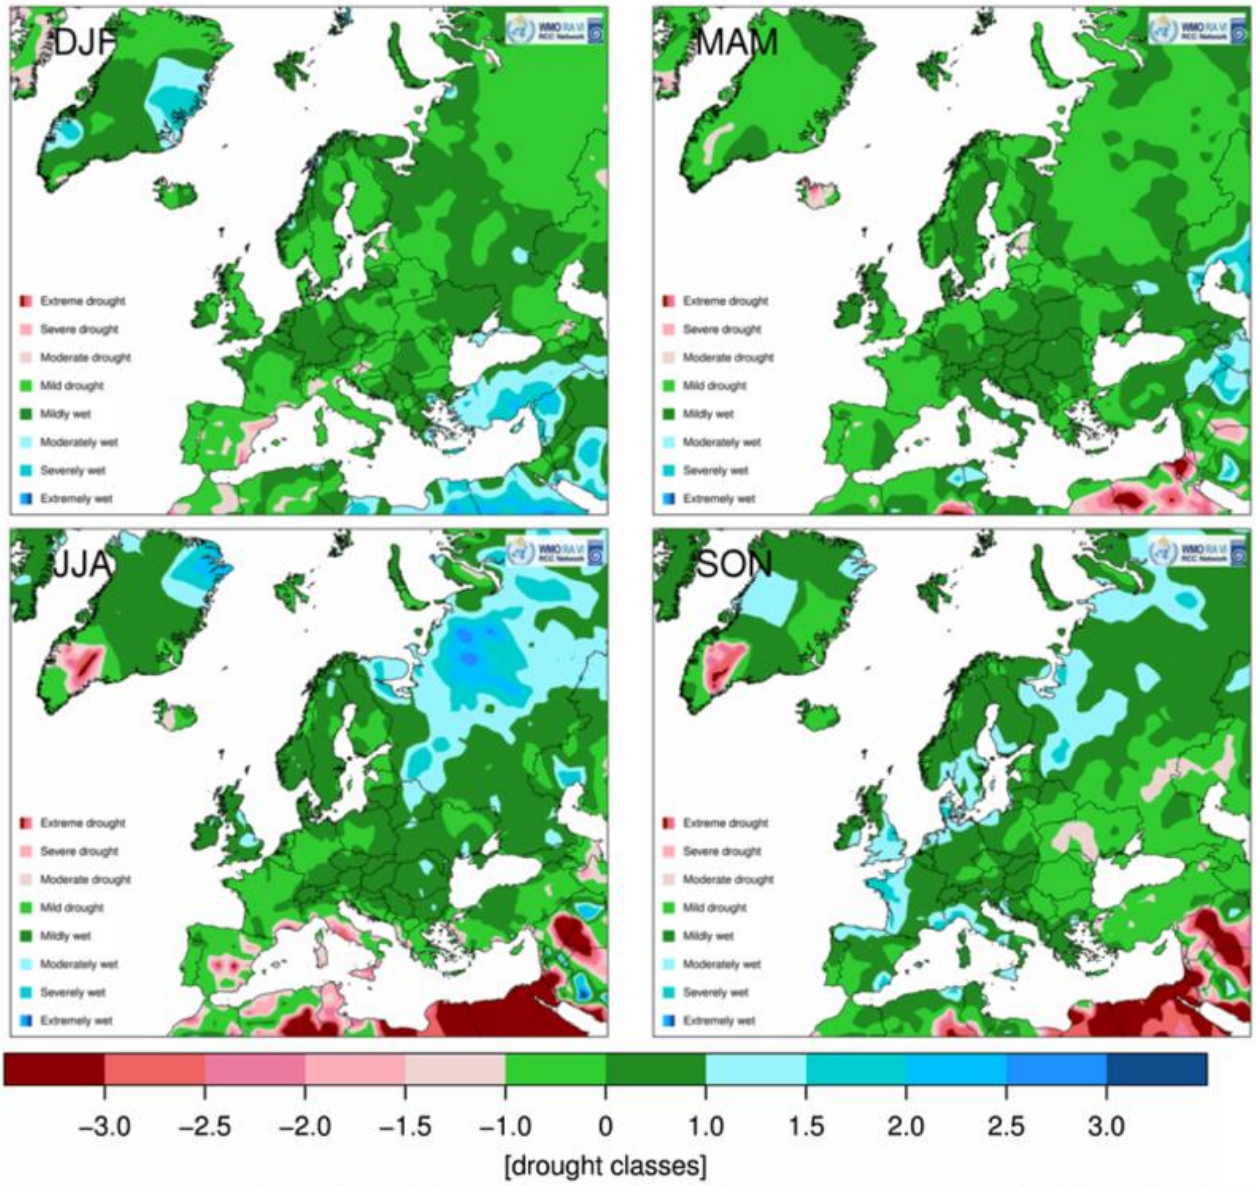

Figure 3-5: *Seasonal GPCC-DI (GPCC-Drought Index, in drought classes, reference period 1961-1990) in 2018/2019 (Source: http://www.dwd.de/rcc-cm).*

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2019 on the Climate in WMO Region VI - Europe and Middle East (available on http://www.dwd.de/rcc-cm). It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each month as well as monthly overviews of extremes and notable events.

4.1 Sea surface pressure and circulation indices

This chapter about atmospheric circulation provides information on selected northern hemisphere teleconnection indices relevant for WMO RA VI and discusses influences of circulation patterns upon anomalies and outstanding events. The information is based on the "Monthly Bulletins on the Climate in WMO RA VI" and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/ upper troposphere not shown here. (See http://www.ncdc.noaa.gov/teleconnections/ and http://www.cpc.ncep.noaa.gov/products/CDB/index.shtml)

Table 4-1: Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981-2010 reference including the Arctic Oscillation, for January to December 2019.

year	month	AO	NAO	EA	EA/WR	SCA	POL

North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: ftp://ftp.cpc.ncep.noaa.gov/wd52dg/data/indices/tele_index.nh and http://www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/monthly.ao.index.b50.current.ascii.table)

In **January**, the Azores High was more intense than normal and extended far to the north, causing mostly drier-than-normal conditions in Western Europe. The Icelandic Low, on the other hand, was weaker than normal. This resulted in a slightly positive NAO phase, which persisted almost the whole month and led mild air to Europe. However, in other parts of the Northern Hemisphere the circulation was less zonal in times as revealed by a below-normal AO index on monthly average. This also included the European continent, where two main low-pressure centers dominated, one over Scandinavia, the other one over the central Mediterranean. The extension of the blocking Russian

High is close to normal. Warm air was advected over Eastern Europe far to the north on average, but the circulation was very variable within the month, with several warm and cold spells and temporary cut-off lows with heavy rain, partly snow in central and eastern parts of RA VI.

In February, the Azores high was more intense than normal and extended very far into the European continent, causing above-normal temperature and low precipitation over large parts of Europe. The Icelandic low also was very intense but shifted to the southwest. The resulting NAO index was slightly positive, but due to the relocation of the pressure centres, it remained weak throughout the month and within the standard deviation. Anyway, a strong southwesterly airflow of moist and mild air from the East Atlantic took place over Northwestern Europe and southern Scandinavia to northern parts of central European Russia, where the temperature anomalies were largest. The Russian high, on the other hand, was less extended to Europe, leading to more cyclonic circulation and high precipitation particularly over northern European Russia. It was also more cyclonic than normal over the Eastern Mediterranean where some heavy rain events occurred. The AO was clearly in a positive phase in the second and last third of the month, which implies relatively low influence of cold Arctic air on the middle latitudes.

In March, both the Icelandic Low and the Azores High were more intense than normal in March 2019. The Azores High was also more extended to the north and to the east. This resulted in an enhanced zonal airflow from the North Atlantic over Ireland and the United Kingdom to Central Europe and even further to Eastern Europe because the Russian High was less extended to Europe than usual. This airflow brought mild and moist air with frequent precipitation to these parts of the Region. In the north, an intense low was located north of Scandinavia and affected Northern Europe with above-normal precipitation. Southern Europe, from Iberia to the Black Sea region, was mainly under high-pressure influence, causing mostly dry and sunny weather with warm days, but partly cold nights, the latter especially in Southwestern Europe. The eastern Mediterranean region including the Middle East, eastern Turkey and sometimes up to Greece, was cyclonic on average with some heavy rain events and partly below-normal temperatures due to missing sunshine.

In April, high-pressure influence extended over Northern Europe and parts of Central Europe, causing high temperatures, very little precipitation and much sunshine there. The high-pressure zone extended even far west and north to Iceland and the Arctic region between Greenland and Svalbard. The Icelandic Low had its normal position for April, but was quite intense and much extended to the southeast. The Azores High, on the other hand, was only slightly more intense than normal, but less extended to the north. Consequently, cool and moist Atlantic air masses mainly affected Iberia and the Mediterranean region, while a warm airflow reached Iceland and the Arctic region. The Middle East and Turkey, too, were under cyclonic influence with cool and partly rainy weather. The NAO showed large fluctuations within the month, implying much air pressure variability over the North Atlantic, occasionally extending to Europe causing changeable weather. The AO had a strong negative phase mainly in the first half of the month, which explains the Arctic warming.

May had mostly a very meridional circulation structure. Much of Europe was under cyclonic influence, while high pressure prevailed over the eastern North Atlantic and Russia. Consequently, cold air flowed over Scandinavia, Central Europe down to the western and central Mediterranean, while warm air from the south came to the eastern Mediterranean and Eastern Europe. High pressure caused much sunshine, prevailing warm and dry weather in western Iberia. The cyclonic area over much of the rest of Europa was characterized by cloudy and rainy weather, including some

heavy rain especially in Central and Southeastern Europe. The NAO index was negative during the whole month following the meridional pattern, most at the beginning but weakening to the end of the month, when a westerly weather type developed over Europe. Similar the AO, causing an arctic air flow to Europe, except the last week of May 2019.

A very pronounced high pressure zone near Greenland was present in June, which blocked the flow of weather systems circulating the Northern Hemisphere. This resulted in weaker zonal winds and more meridional flow instead. A negative NAO is often an indicator of a Greenland block as it is the case this month with negative daily NAO values during the whole month and a monthly NAO value of -1.09. The AO, which often shares the phase with the NAO also stayed negative almost the whole month and finished with a monthly value of -0.601. During the first half of the month low pressure situated over Ireland and UK brought cool and unsettled weather with heavy and thundery showers over the western part of Europe. During the second half an upper-level trough was positioned over the eastern Atlantic, west of France together with a high pressure over the continent and another low pressure system over southeastern Europe formed an omega block which led to a plume of very warm air from North Africa being transported to Europe. It thereby caused a short but severe heat wave to Western and Central Europe with many all-time station and country-wide records being broken. This distribution was due to the main location of the upper trough over low pressure, from the British Isles towards western Iberia, and high pressure over the continent.

In July, both AO and NAO were negative during almost the entire month with just a brief period above zero around 18–20 July and 22–25 July respectively. As a result, NAO and AO monthly mean values for July were both negative with values of -1.43 and -0.89 respectively. The negative phase of both indices was primarily due a very pronounced high pressure zone over Greenland which was already present in June. Together with low pressure systems developing over the North Atlantic and over western Russia and high pressure over the European continent during the second decade of July, this led to hot air masses from North Africa being transported over western Europe up to Scandinavia, causing again (like in June) a short but severe heatwave.

In August, the daily NAO was strongly negative for the first half of the month and then near-neutral for the second half. The daily AO was negative during almost the entire month with just a brief period above zero around August 23–27. The negative phases of both NAO and AO were primarily due to the ridge over Greenland along with the troughs over the Northeast Atlantic (and Northwest Pacific). The primarily negative daily values resulted in negative monthly values of both NAO and AO with respective values of -1.17 and -0.722. NAO and AO thus continue their prolonged negative phase that started back in May.

In September, the general situation was driven by the Azores High, which was stronger and more widespread than usual, and the Icelandic Low, which was deeper than normal. Pressures were higher than normal over much of Europe pushing the westerly flow further north over the northern British Isles and Scandinavia. The daily NAO was weak but positive for the first half of the month and then increasingly negative during the second half resulting in a monthly mean near zero (-0.16). The circulation during the first half of September looked like a classic positive NAO with an enhanced trough over Greenland and enhanced ridging over the northeast Atlantic. These patterns reversed during the second half of the month. The AO was weak but generally positive during most of September, finishing with a monthly value of 0.306.

In **October,** the general situation over Europe was driven by the Icelandic low positioned further south than normal and the Azores high weaker than normal as well as by a persistent high pressure area over Greenland. Pressures over most of the RA VI Region were mostly slightly lower than normal (up to -2 hPa), over Russia up to -6 hPa. The daily NAO was negative for almost the entire month, and moderately negative (-1.4) for the monthly mean. The negative NAO was primarily due to the persistent high pressure over Greenland and the low pressure over the central North Atlantic. The AO was positive for the first half of October and negative for most of the second half, resulting in neutral conditions for the month as a whole with a monthly mean value of -0.082.

In **November,** the general situation over Europe was driven by the Icelandic low positioned much further south than normal and by the Azores high, which was stronger than usual. As a result, pressures were much lower than normal over western and central Europe but higher from Iceland to northern Scandinavia and Russia. The daily NAO was weakly positive for most of the month before turning negative in the final week. The positive values early in the month were largely due to high pressure over the central North Atlantic, but it was likely weakened by the lack of low pressure over Greenland. In the final week of the month, high pressure area shifted northward over Greenland and was replaced by low pressure over the North Atlantic. The AO was negative for almost the entire month, primarily in association with the high pressure over Greenland and low pressure near northwestern Europe.

The meteorological situation in **December** was characterized by a more intense than normal Icelandic low with its core stretching from Greenland towards the north coasts of Scandinavia and a more intense than normal Azores high extending over the entire southern part of the RA VI Region into Kazakhstan. Compared to the climatological mean the monthly mean surface pressure was lower than normal over the entire RA VI Region due to the frequent passing of low-pressure systems. This situation is also reflected in the circulation indices. Due to the low pressure near Greenland, the daily NAO was strongly positive for the first half of the month. For the second half it turned neutral resulting in a monthly value of 1.2. The daily AO was also positive for the first half of December, but then negative for the second half until the final days of December when it returned to positive. Averaged over the month, it was moderately positive.

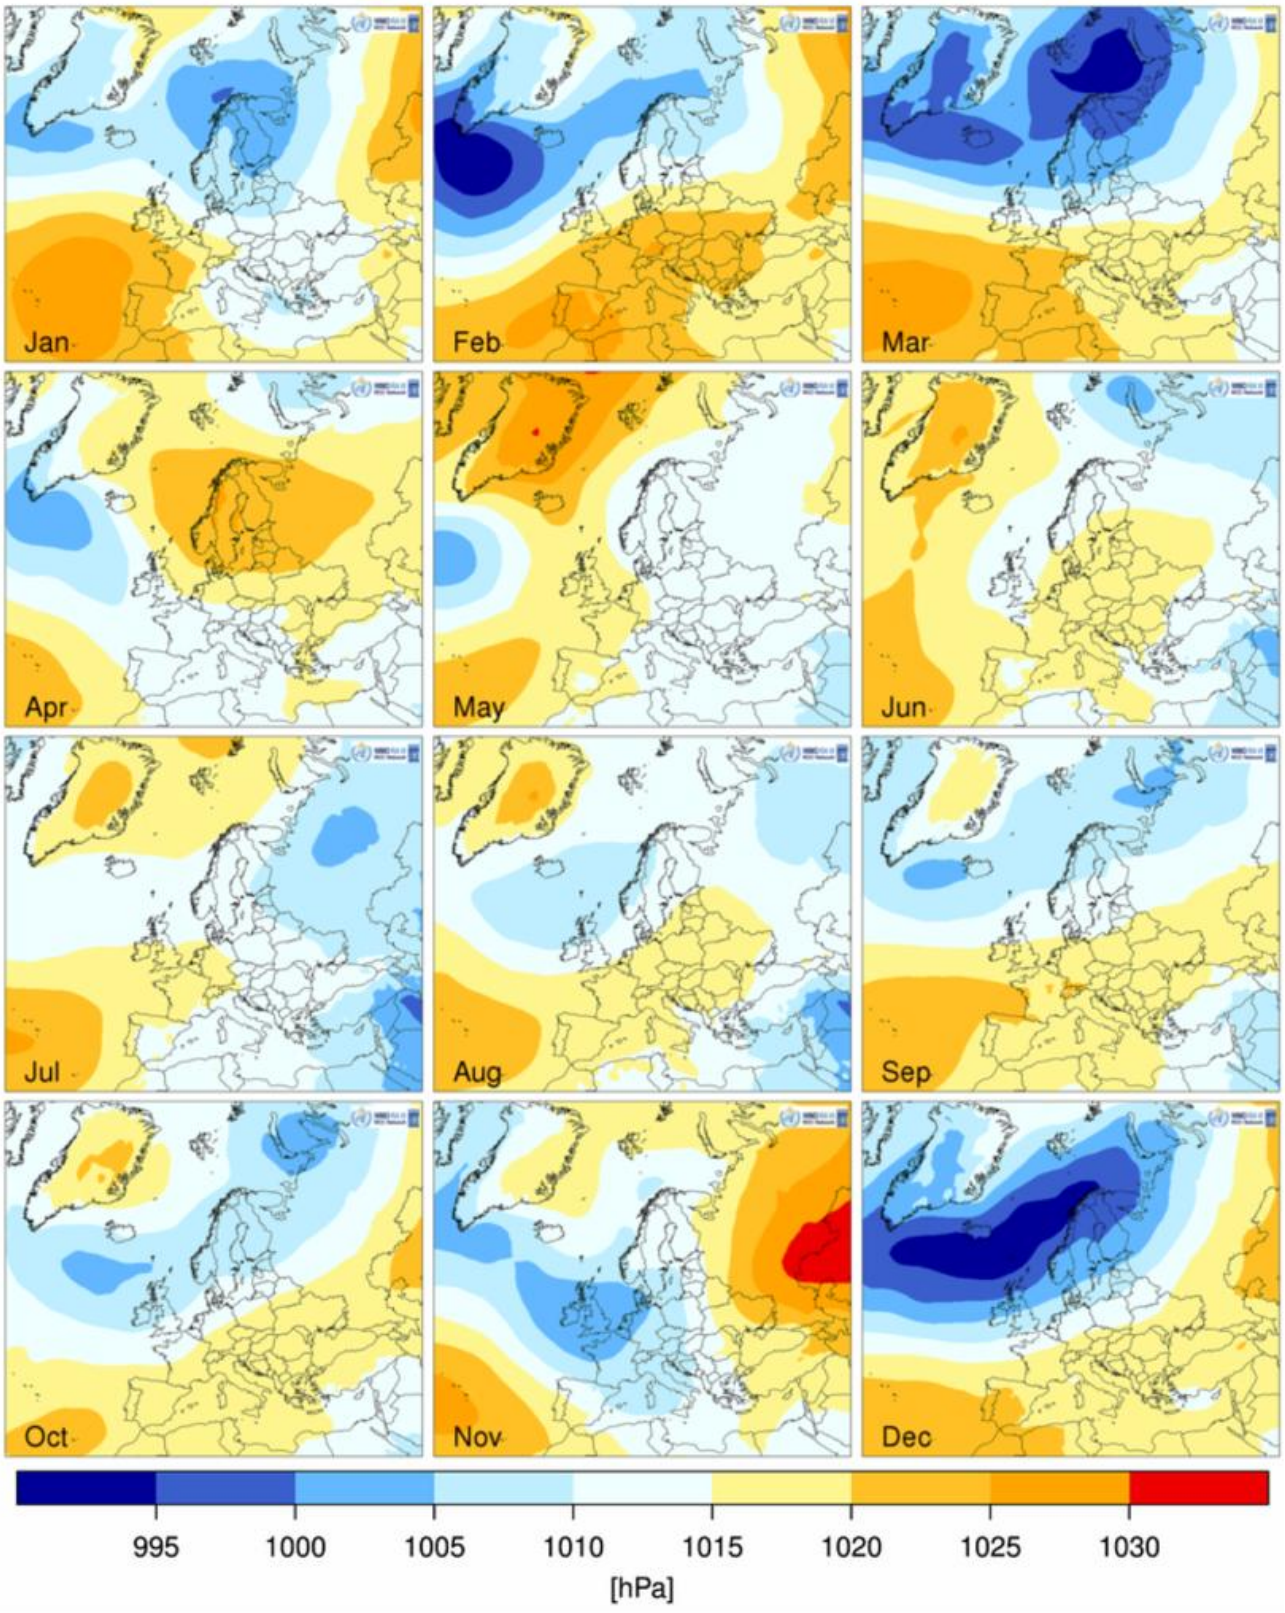

***Figure 4-1**: Monthly mean sea level pressure in hPa for the year 2019 (reference period 1981-2010).*

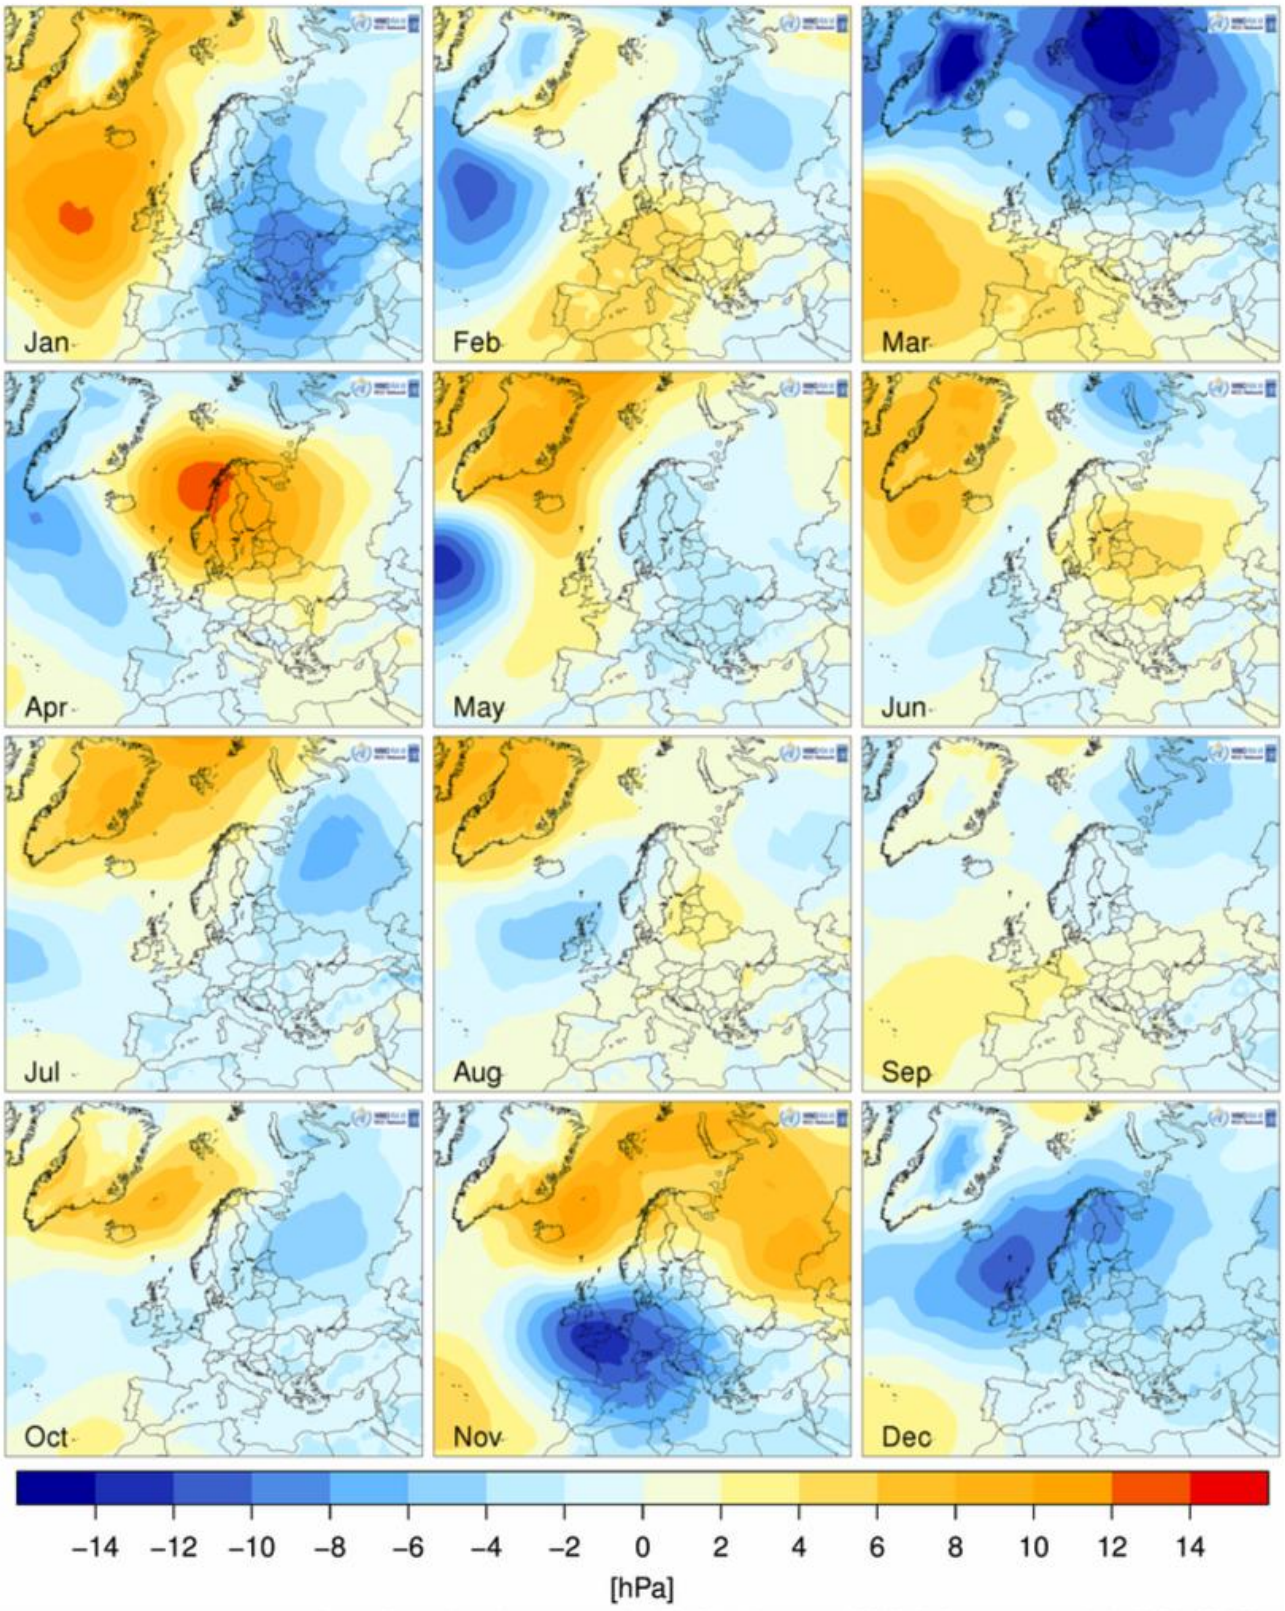

***Figure 4-2**: Monthly anomalies of sea level pressure in hPa for the year 2019 (reference period 1981-2010).*

4.2 Temperature

In most of the months and sub-regions it was warmer than normal as can be seen from Table 4-2, with February and March being the only two months with temperatures below normal in some regions, namely Central and Western Europe, Iberia and Eastern Europe. Largest anomalies with anomaly values exceeding +4 °C occurred in Eastern Europe in January and over Central and Western Europe as well as over the Mediterranean, Italian and Balkan Peninsula in April.

Table 4-2: Monthly and annual area average temperature anomalies in °C for each sub-region in the year 2019 (reference period: 1981-2010; definitions of the sub-regions see Figure 1-1).

Region	Year	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
Central and western Europe	1.33	0.02	2.70	2.00	1.10	-1.35	3.03	1.28	1.50	0.83	1.31	1.04	2.45
Nordic und Baltic Countries	1.46	-0.11	2.50	0.07	3.70	1.57	2.09	0.74	1.03	1.27	1.29	1.53	1.91
Iberia	0.69	-0.14	1.20	0.69	-0.10	1.13	0.12	1.00	0.76	0.75	1.10	0.13	1.68
Med., Italian and Balkan Peninsula	1.43	-0.48	1.60	2.11	0.80	-1.26	2.65	0.90	1.81	1.52	1.92	3.33	2.29
Eastern Europe	1.51	0.05	3.80	2.30	1.20	1.65	2.42	-1.67	-0.46	0.48	1.45	1.89	5.09
Middle East	1.17	1.13	1.40	0.61	-0.70	2.46	2.70	0.18	0.31	0.76	2.27	0.55	2.32

Most of the RA VI Region had around-normal temperatures (1981-2010 anomalies within +/-1 °C) in January 2019. Anomalies were highest in in the Arctic region (up to +3 °C in southern Greenland) and in the South Caucasus region (+4 °C in Armenia). It was colder than normal in northern Scandinavia (<-3 °C anomaly), locally in Eastern Europe and generally in the Mediterranean region (<-1 °C). On mountain sites of the northern Alps in Switzerland and Austria it was the coldest January for more than 30 years (below 4 °C anomaly in places), while the Southern Alps were very mild. High mountains in Slovenia, too, were noticeable colder than normal (e.g. Kredarica -3.8 °C anomaly). Monthly mean temperature averaged over Europe was close to the 1981-2010 normal, only slightly cooler than normal. Anyway, it was the first colder-than-normal month after nine consecutive warmer-than-normal months since April 2018, also on national average, e.g. in Austria, Italy or Latvia. The warming trend for January since 1910 is +1.25 °C/ 100 years and the January 2019 average corresponds well to the warming trend. However, temperature variability was high during the month. Especially in parts of Northern and Eastern Europe, periods of freezing weather alternated with thaws. In Scandinavia and much of European Russia, mild temperatures characterized the first half of the month, in Iceland even exceptionally high, but the second part of the month was much colder and especially the last few days. Sweden reported 9 days in a row with daily minimum temperatures below -30 °C. On the other hand, Denmark only had 3 ice days (Tx<0 °C) on average (normal is 8.6 days in 1961-1990), the Netherland 2 ice days (normal: 3), Ljubljana in Slovenia 1 ice day, most of Serbia 1-7 ice days. In Central Europe, wintry temperatures dominated the early days of January, while the rest of the month was mostly milder. High-pressure influence in the second half of the month resulted in cold nights even in lowlands. A markedly cold episode occurred between 19 and 25 January in the Czech Republic, at some stations in Slovakia, in Hungary, and even in Slovenia.

During this period, the surface air temperature in the Czech Republic remained below the freezing point throughout the day. In northern Greece and the southern Balkans, temperatures were particularly low in the first decade of the month with daily minima falling down to -20 °C or below. Over the western Mediterranean, the cold spell came down to Malta, minimum temperatures reached 4.1 °C on 5 January.

It was a mild February with above-normal temperatures in almost the entire RA VI Region. The highest anomalies of above +6 °C (1981-2010 reference) had been recorded in northern European Russia. Only a small part of northern Scandinavia (Lapland) and some places in southeastern Spain, southern Italy (Sicily) and Malta had below-normal temperatures. In the Middle East, temperatures were close to average.

According to Copernicus gridded data, the European-average temperature was +2.75 °C higher than normal, making it the seventh warmest February since 1979. Based on the NOAA dataset, February 2019 was the sixth warmest February since 1910. The warmest February on record was by far 1990.

After a cold start of February 2019, the second half the month became very mild, especially in Northern/Northwestern Europe. Svalbard airport in the Arctic region registered again above-normal temperatures, continuously since December 2010. The highest daily maximum at Norwegian Arctic stations that month was 5.0 °C on Jan Mayen Island. On continental Norway, the highest maximum was 18.7 °C in Landvik, a new record for the province Aust-Agder (southern Norway). Sweden even had a new national February record (16.7 °C in Karlshamn). In Denmark, the highest temperature registered in February 2019 (15,8ºC) was record breaking high (together with February 1990). Ireland recorded highest local absolute February maxima at over half of its stations. The United Kingdom recorded its second highest February mean since 1910 behind 1998, which had higher daily minima, but February 2019 had the highest mean maximum temperature on record. The Netherlands and Belgium noted national records above 20 °C (Netherlands: 20.5 °C in Arcen, Belgium: 22.8°C in Houyet on 27 February). This was only the second time since 1901, when a Dutch station measured more than 20 °C in February. France, too, noted maxima above 20 °C with local records on several stations during this month, in the south even above 27 °C. The number of days in February with the temperature exceeding 20° in Paris was also record-breaking. Luxemburg was very close to this threshold with 19.8 °C at Findel Airport, but a local record since 1947. Minima were high in Denmark, where no ice days (daily maximum <0 °C) occurred at all. The Netherlands had only one ice day at a few stations. In contrast, severe frost (< -15 °C) occurred in southeastern Germany on 4-7 February, but maxima also exceeded 20 °C at the end of the month, also with local records.

In the Alps, Switzerland recorded its warmest or second warmest February on record at some mountain sites. It was +5.1 °C warmer than the 1981-2010 average on Jungfraujoch (3580m a.s.l.). A north foehn in the valleys on the southern side of the Alps brought daily maxima around 23 °C in the lowlands on 22 February. Several other Swiss stations had new local records on 26-28 February. Austria had a new national February record at 24.2 °C on 28 February, Slovakia recorded up to 20.6 °C the same day, the Czech Republic up to 18.8 °C. Croatia also had some local monthly February records.

Spain recorded monthly temperature maxima up to 28.3 °C in Murcia, and several other places had above 25 °C at the end of the month, resulting in new local February records. Andorra recorded up

to 26.1 °C, also a new local February record. Monthly mean maxima in Spain, Andorra and Portugal were generally high, while minima were lower than normal due to cold cloudless nights. Thermal inversions occurred frequently.

Malta started the month relatively warm with a maximum of 19.4 °C on 2 February, but late in the month (23-24 February) cold winds from northeast let the temperature drop to a minimum of 3.7 °C, which resulted in a below-normal temperature on monthly average.

At the Black Sea coast of Turkey, the temperature was almost two months ahead in the annual cycle and resulted in too early blossoming of plums, which had never been observed in winter before.

Russia was particularly warm in its European part throughout the month. New records of daily maximum temperature were reached in the south of the Krasnodar region in the first decade. Estonia was especially warm in the second decade of the month, a new record of mean temperature for that decade since 1961. Similarly warm was Latvia, where Kolka station reached a new local record of monthly absolute maximum temperature for February at 13.4 °C on 16 February. Lithuania noted two national daily records of maximum temperature on 16 and 19 February at 10.7 °C and 10.4 °C, respectively. In contrast, Kiev in the Ukraine had its warmest day on 28 February like in Central Europe (11.2 °C daily maximum). Altogether, February 2019 was the warmest winter month in Kiev over the past 139 years.

March 2019 was mostly 1-3 °C warmer than the 1981-2010 normal throughout the Region. Highest anomalies up to above +3 °C (locally above +4 °C) were at the eastern border of RA VI, but also in a secondary maximum over eastern Central Europe, western parts of Eastern Europe and the Balkans. Only a few areas had below-normal temperatures: in the north from eastern Greenland (-3 °C anomaly) to northern Scandinavia, in places in Ireland, Spain and Hungary, in the Middle East, and in small areas over the North Atlantic and the Mediterranean. More than half of the stations in Ireland reported air and ground frost. Denmark reported 5 frost days on average, much below the 1961-1990 normal of 15. De Bilt in the Netherlands had 3 frost days (normal: 8), Uccle in Belgium 1 frost day, Ljubljana in Slovenia 2 frost days (highest number on March record was 26 days in March 1958). In the south, Cyprus recorded 7 frost days in mountainous areas. Soils were frozen in Lithuania and Belarus at the beginning of the month, but thawed until mid-March. Later in the month, there was only a short period of ground frost in these countries. Monthly mean European surface air temperature was +1.7 °C above normal according to Copernicus data. March 2019 was the 7th warmest March since 1979 on European average. According to NOAA data, March 2019 was the 6th warmest since 1910. The warmest March was in 2014. According to a Russian analysis, Europe had the 5th warmest March in history of observations.

In Russia (whole territory), 2019 had the third warmest March, but much of its contribution came from outside of RA VI. The European part of Russia mostly was warmer than normal too, but with weaker anomalies. There were some exceptions: The Russian North was colder than usual in the first decade of the month (with -35 °C frosts on the Kola Peninsula). Cold spells at the end of the month were quite untimely in southern Russia. They reached -3 to -5 °C in the nighttime in the Stavropol and Krasnodar Territories, and -10 °C in the early morning hours in Karachay-Cherkessia (North Caucasus).

April 2019 was particularly warm in the Arctic region with anomalies up to + 5-6 °C in Greenland and Svalbard. Over Iceland, temperatures were also exceptionally warm, making April 2019 the warmest April on record in Reykjavík, Stykkishólmur, Bolungarvík, Grímsey, Akureyri and Hveravellir. Temperature anomalies decreased to the south, but Central Europe and the Balkans were mostly still + 1-2 °C warmer than the 1981-2010 normal. Southern parts of the RA VI, from the Azores over Iberia, the Mediterranean to Turkey, the South Caucasus and the Middle East were mostly slightly colder than normal, in easternmost parts even with anomalies < -1 °C. Especially the first two decades of the month were colder than normal in Greece, but that was overcompensated by a warm third decade. Sea surface temperatures in the Mediterranean were normal or slightly above normal, in the north the Northern, Baltic and Barents Seas were much warmer than normal (up to > +2 °C anomalies). On European average, April 2019 was +1.0 °C warmer than normal and the 7th warmest April since 1979 according to Copernicus data, the 8th warmest since 1910 according to NOAA. The warmest April was in 2018 in both data sets and by far warmer than in 2019. For Germany, Austria and Hungary, April 2019 continued a series of 13 successive warmer-than-normal months (1981-2010 reference), which never occurred before in measurement history. In much of Northern, Western, Central and Eastern Europe, however, the month was characterized by a strongly changing weather picture, with a few cold days with frost in the lowlands down to the middle latitudes and the Balkans, and (wintry) showers alternated by sunny periods with warm summer days. However, the warm periods were prevailing. It was the second warmest April on record in Norway since 1900 (after 2011) and in Iceland (after 1974), the third warmest in Latvia. Some stations noted new local April records in Iceland, Norway, Sweden, Finland, Latvia and Russia (Kaliningrad Region), Latvia reported a new national record of the highest absolute April daily maximum at 28.9 °C. Anomalies in European Russia were mostly lower than in many other parts of Europe because mainly the first decade of the month was warm there, but it became colder in the rest of the month, culminating in night frosts even in Moscow region. In Western and Central Europe and even in Latvia and Lithuania, maxima reached above 25 °C several times locally, in Hungary even 30 °C. Ireland reported its highest monthly April maximum in 44 years at 22.9 °C. Ljubljana in Slovenia recorded 10 summer days that month, the highest number in April since at least 1951. The monthly maximum temperature in Andorra was 23.5 °C and was lower than in February and March there, southern Spain recorded up to slightly above 30 °C, also Serbia in the Balkans.

May 2019 was colder than normal over much of Europe, from Scandinavia over Central Europe down to the western and Central Mediterranean. At many stations in western Norway and northern and eastern Iceland, May 2019 was colder than April 2019, in Hungary only the first 3 weeks of May 2019 were colder. Coldest anomalies were over the Alps, colder than -3 °C, in Austrian highlands -5 °C. In the southern Alps (Dolomites Mountains in Italy), many records of low minimum temperatures were broken. Eastern parts of the RA VI, in contrast, were warmer than normal with local anomalies up to +3 °C. Furthermore, the west of RA VI from Greenland / western Iceland over the eastern North Atlantic to western and southern Iberia also was warmer than normal, up to +4 °C anomaly in northwestern Greenland. Averaged over Europe, the temperature was almost identical to the 1981-2010 average (-0.003 °C anomaly) after Copernicus data. According to NOAA data, May 2019 was the 41st warmest May of the series starting in 1910, which means a little bit more than one third of this series was warmer than May 2019. The warmest May was by far May 2018. To find a month of May, which was colder than in 2019 (and colder than normal), we need to go back to 2004.

In the UK, May 2015 was last colder than 2019, in France and Belgium May 2013, in Germany 2010. In Switzerland, Austria, the Czech Republic, Hungary, Slovenia and even at some stations in Italy (Rome, Pisa, Modena), it was the coldest May since 1991.

Only the middle of the month was relatively warm in Northwestern and Northern Europe, while the beginning and the end of month were rather cold, therefore the monthly mean was very close to normal there (-0.4 °C anomaly in Norway and Sweden, -0.3 °C in the UK, 0.0 °C in Finland). Finland recorded 6 summer days (maximum >=25 °C), 3 more than usual in May. In Southwestern Europe, Portugal and Spain experienced several heat waves with maxima up to above 35 °C at several stations.

France and Spain reported some local records of lowest minima and widespread frost at the beginning of the month. In Central and Southeastern Europe, especially the first half of the month was cold. The cold air and partly frost caused a slowdown of the vegetation development in Central and Southeastern Europe. Most of Austria did not have any summer days at all, the first time for 30 years in a month of May. Other countries, especially on the Balkan Peninsula had higher maxima at the end of the month, partly close to or even exceeding 30 °C (Bosnia-Herzegovina, Albania, North Macedonia, Greece).

Eastern countries were generally warmer than normal this month. May 2019 was the hottest month in Turkey in the last 49 years, many local maximum temperature records were broken. Cyprus had two heat waves at the end of the month with maxima above 40 °C. The highest maximum in Cyprus in May 2019 (42.1 °C) was the highest May maximum since 1983.

Over most of the RA VI Region, the average monthly temperature in June 2019 was above normal (that is the 1981-2010 average), particularly over central and eastern Europe with anomalies around +6 °C. In Eastern and central Europe warm temperatures dominated for the month as a whole, but these regions additionally experienced short but intense heat waves. Around the middle of the month during a first heatwave hit for example in Poland over much of the country, temperatures exceeded 30 °C during several days. At the end of the month the western and central parts of the continent experienced a short but even more intense heatwave, with daily average temperatures up to 10 °C higher than normal and daily maximum temperatures above 40° in France and Spain. In France, the all-time temperature record at Gallargues-le-Montueux, Gard, near the city of Nîmes was even broken on June 28 with a new record of 45.9 °C. For many countries including Austria, the Netherlands, Czech Republic as well as Germany June 2019 finished up as the warmest June on record. Other regions with temperatures substantially above normal include Greenland with anomalies between +2 and +4 °C. Lower-than-normal temperatures in the month of June are only found over western Iberia and parts of the British Isles. This temperature distribution was due to the main location of the upper trough over low pressure, from the British Isles towards western Iberia, and high pressure over the continent. Monthly mean temperature averaged over Europe was 2.34 °C above the 1981-2010 normal according to the Copernicus Climate Change Service (based on ERA5), making it the warmest June on record also for Europe as a whole since 1979,

Over large parts of the RA VI Region the average temperatures in July 2019 were higher than the 1981-2010 average for July, especially over Western, Central and Southern Europe and over Greenland. Compared to June, which was the warmest June on record in several European countries with anomalies around +6 °C, the July anomalies were in general lower in magnitude.

Largest anomalies occurred over France with monthly mean temperatures of +2 to +3 °C above normal. There were also regions with lower-than-normal temperatures in July, namely the southwestern edge of the Iberian Peninsula and northeastern Europe (Finland, Baltic countries, Belarus, western Russia) where monthly mean temperatures of -2° to -4 °C below normal occurred. The monthly mean temperature averaged over Europe was +1.35 °C above the 1910-2000 normal, making it the 13th warmest July for Europe as a whole according to the State of the Climate for July 2019 published by NOAA National Centers for Environmental Information[4].

During a short but severe heatwave occurring over the western part of Europe on 24 and 25 July daily maximum temperatures exceeded 40 °C in many places and many station records were broken. New country-wide records were set in the UK (in Cambridge Botanic Garden: 38,7 °C), the Netherlands (Gilze-Rijen: 40,7 °C), Luxemburg (Steinsel: 40,8 °C) and Belgium (Begijnendijk: 41,8 °C) (see list for RA VI with highest maximum-temperature[5]). In Belgium and the Netherlands temperatures exceeded 40 °C for the first time since the beginning of meteorological recording. Because the area of high pressure extended far to the north, even Scandinavia experienced new temperature records. In Helsinki Kaisaniemi for example temperatures reached 33.2 °C on 28 July exceeding the previous record (31.6 °C) from 1945 by 1.6 °C. In Sweden maximum temperature values exceeded 32 °C, in Norway even 34 °C.

Over largest parts of the RA VI Region averaged temperatures in **August** were above normal temperature, with anomalies mostly up to +2 °C, over eastern/southeastern parts of Europe (Poland down to Greece) even up to +4 °C. Below-normal temperatures occurred over in the northeastern part of Europe, over Western Russia, Portugal and Ireland. In the last third of the month a persistent high pressure zone caused a long warm spell especially in parts of central and southeastern Europe which lasted more than a week. The monthly mean temperature averaged over Europe was 1.9 °C above normal relative to 1910-2000 making it the 3rd warmest August since 1910 for Europe as a whole according to the State of the Climate for August 2019 published by NOAA National Centers for Environmental Information (published online September 2019, retrieved on 08 November, 2019 from https://www.ncdc.noaa.gov/sotc/global-regions/201908).

Over large parts of the RA VI Region the average temperatures in **September** 2019 were higher than the 1981-2010 average for September, especially southeastern Europe and over the South Caucasus region where temperatures were +2 to +3 °C above normal. There were also regions with lower-than-normal temperatures in September, namely European Russia and Kazakhstan in the east as well as Ireland and parts of Scandinavia (Norway and Sweden) in the west. Here monthly mean temperatures of up to 2 °C below normal occurred. The monthly mean temperature averaged over Europe was +1.29 °C above the 1910-2000 normal, making it the 8th warmest September for Europe as a whole according to the State of the Climate for September 2019 published by NOAA National Centers for Environmental Information (retrieved from NOAA website[6]). The European-average temperature for September 2019 was 0.7 °C warmer than the average September from 1981-2010 based on ERA5 (Copernicus Climate Change Service/ECMWF).

Temperatures in October were above normal for most of the RA VI Regions with largest anomalies occurring in the East (Russia and Belarus) where it was 3 to 4 °C warmer than normal. Cooler-than-normal temperatures occurred over the British Isles and Scandinavia where anomalies of up to -1 °C and between -1 and -3 °C were recorded respectively. The monthly mean temperature for Europe as a whole was 1.87 °C above normal relative to 1910-2000 making it the 5th warmest October since 1910 according to the State of the Climate for October 2019 published by NOAA National Centers for Environmental Information (https://www.ncdc.noaa.gov/).

In November, temperatures were above normal over most parts of the RA VI Region. The monthly mean temperature for Europe as a whole was 1.76 °C above normal relative to 1910-2000 period making it the 7th warmest November since 1910 according to the State of the Climate for November 2019 published by NOAA National Centers for Environmental Information (https://www.ncdc.noaa.gov). Largest anomalies occurred over the Balkan Peninsula where is was 3 to 4 °C warmer than normal, locally even more.

Monthly mean air temperature values were higher than the 1981-2010 average for December over the entire RA VI domain. Largest anomalies occurred over Eastern Europe, where temperatures were more than 3 °C above normal, over Russia anomalies exceeded even +6 °C. The temperature in Moscow rose to 6.2 °C on 22 December, a new local record in a series of about 140 years. The monthly mean temperature averaged over Europe was +2.73 °C above the 1910-2000 average, making it the 2nd warmest December for Europe as a whole according to the NOAA National Centers for Environmental Information (https://www.ncdc.noaa.gov). According to the Copernicus Climate Change Service/ECMWF, December over Europe was 3.2 °C warmer than the average for 1981-2010 (based on ERA5), making it, by a narrow margin, the warmest December on record for Europe since 1979.

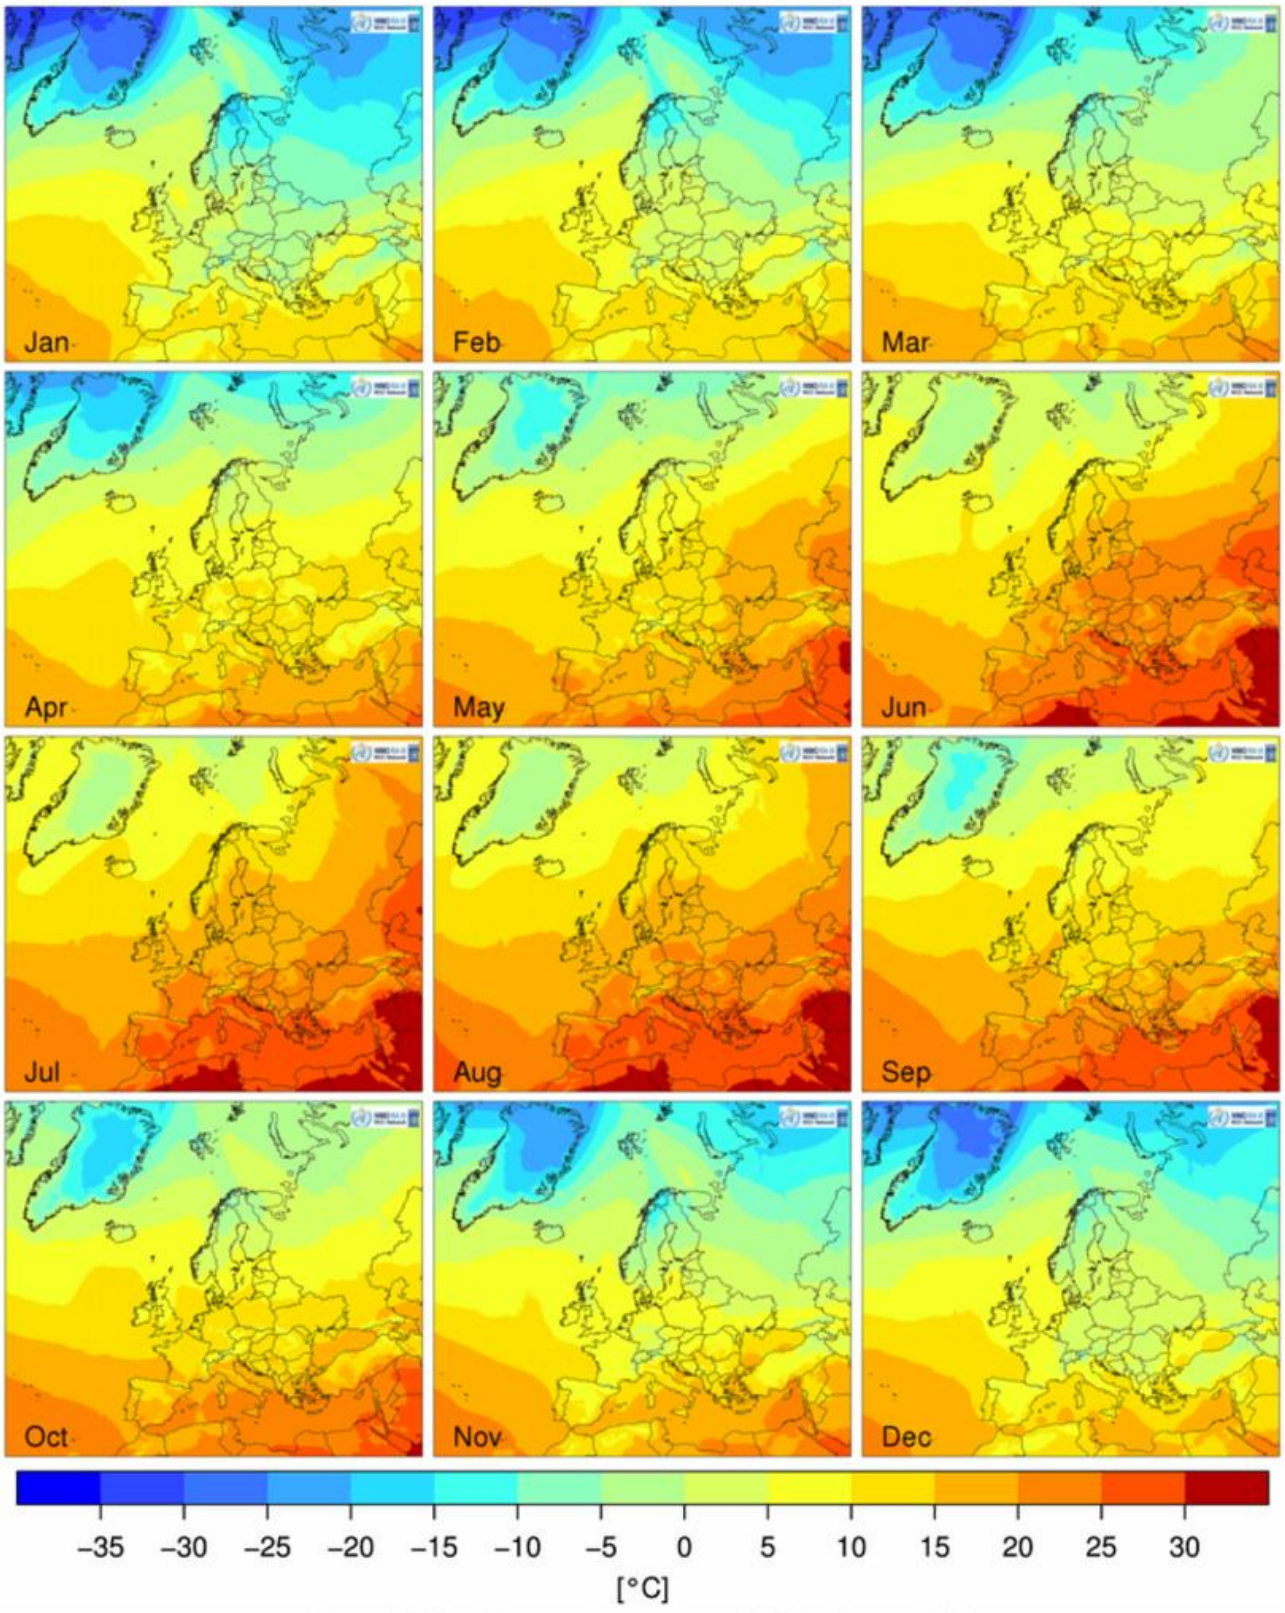

Figure 4-3: Monthly mean temperature (in °C) for the year 2019.

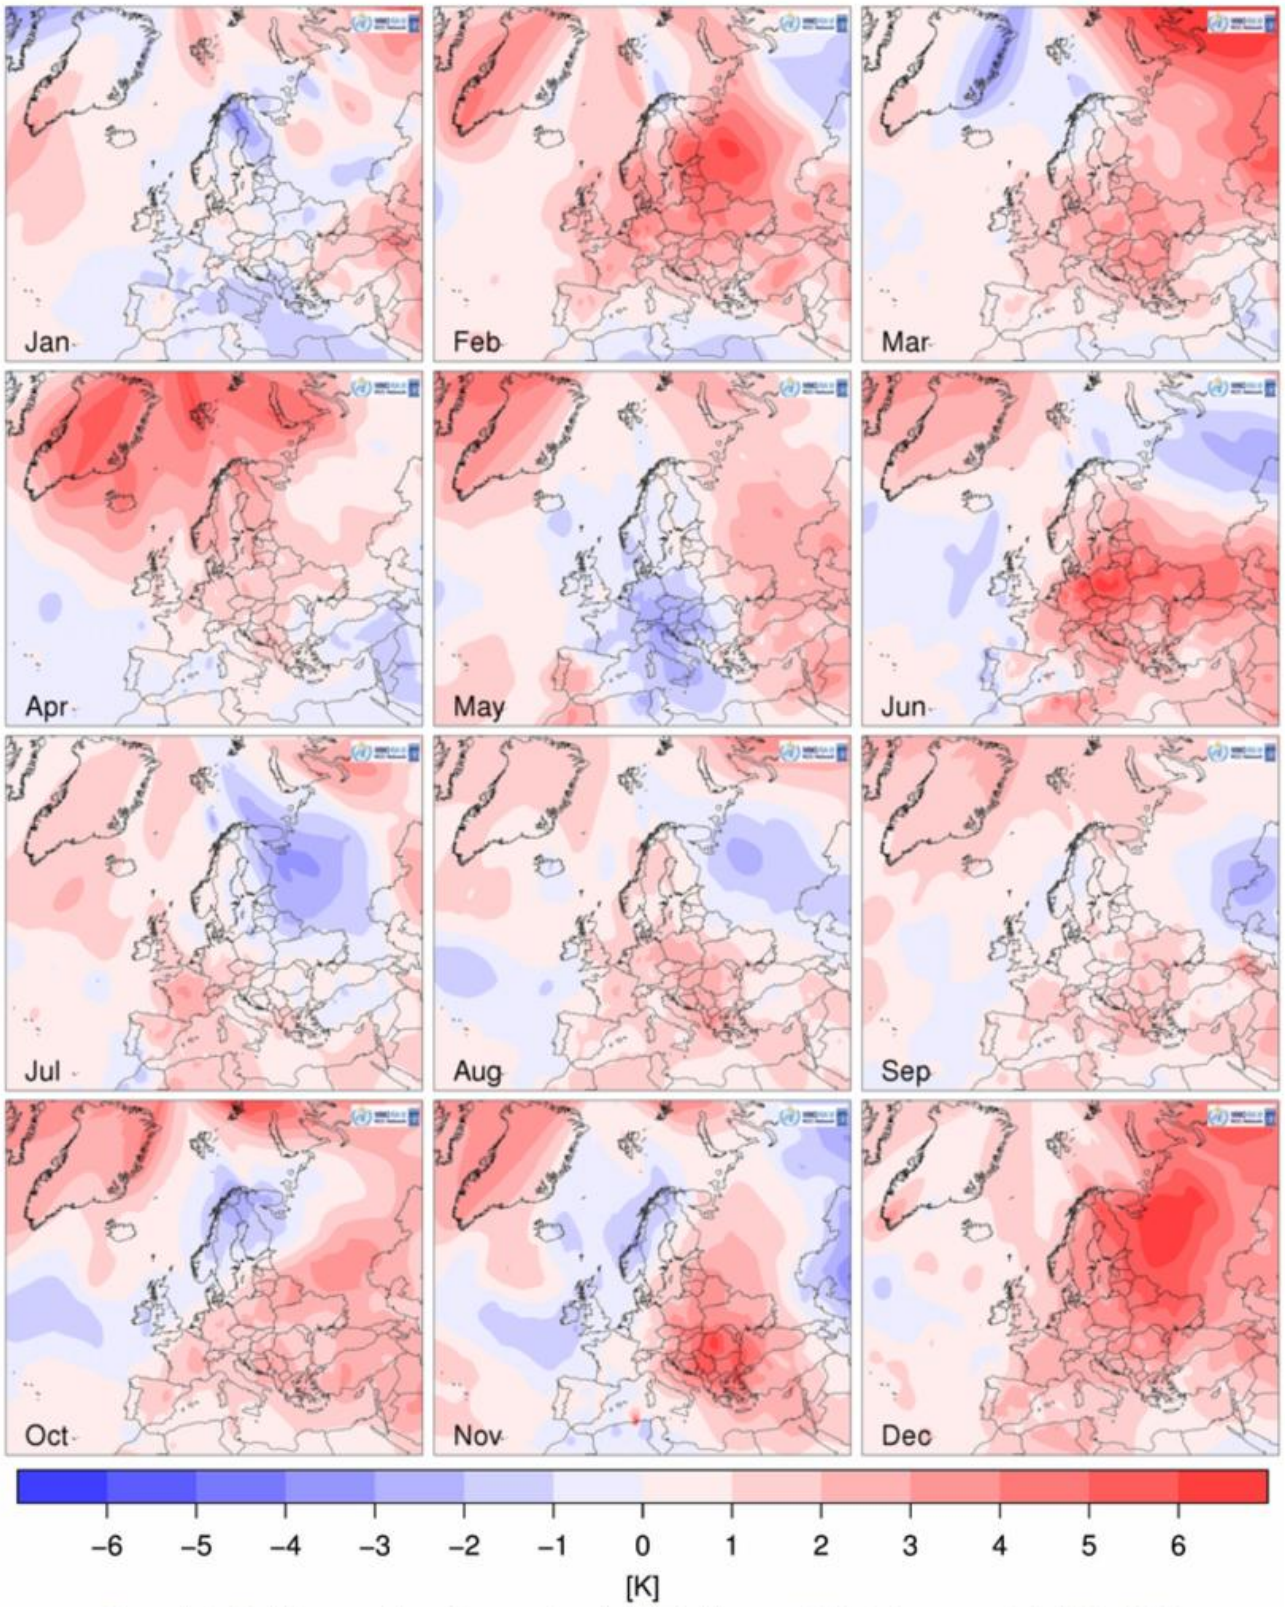

Figure 4-4: *Monthly anomalies of temperature (in °C) for the year 2019 (reference period: 1981-2010).*

4.3 Precipitation

Table 4-4: Monthly and annual area average precipitation anomalies in % for each sub-region in the year 2019 (reference period: 1981-2010; definitions of the sub-regions see Figure 1-1).

Region	Year	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
Central and western Europe	96	97	69	100	73	109	86	75	93	97	116	126	105
Nordic und Baltic Countries	94	125	85	117	68	83	108	55	123	107	79	80	103
Iberia	89	79	51	60	146	43	52	102	106	103	79	121	130
Med., Italian and Balkan Peninsula	106	149	70	46	123	163	89	148	76	67	64	174	107
Eastern Europe	107	137	119	120	71	129	82	121	97	80	125	95	108
Middle East	99	85	102	146	141	54	123	123	111	77	78	34	112

In January, precipitation anomaly distribution shows a notable west-east dipole. It was drier than normal particularly in Western Europe and parts of Scandinavia, though with locally heavy precipitation e.g. in northern Spain / southwestern France and in Norway. It was the driest January in the United Kingdom since 2006. The southern Alps were dry as well, with less than 10 % of normal in some areas of southern Switzerland, while the northern Alps were very wet with new local records, e.g. 279 mm in Kufstein. Eastern parts of RA VI were mostly wetter than normal as well, particularly around the Black Sea and near the eastern Mediterranean, locally above 250 % of the normal, e.g. in Romania, Moldova, Bulgaria, near the Aegean Sea, in southern Turkey and Cyprus. In Turkey, it was the highest January total in the last 15 years in the Aegean region and the last 37 years at the Mediterranean coast. Especially Greece and Cyprus recorded several heavy rain events with flooding and landslides. Malta, too, was wet, recording the wettest January since 2011, much contributed by 6 thunderstorms (more than 3 are rare in January), partly with hail. In Serbia, the stations Valjevo, Kragujevac and Pozega observed record-breaking numbers of days with precipitation (23-25 days, series since 1925, which means that the above-normal monthly totals came from high frequency of precipitation. In eastern Central Europe (e.g. Czech Republic, Slovakia), most of the precipitation fell in the first half of the month, also in the Middle East (e.g. Israel).

In February, precipitation was below normal in most of the RA VI Region from Western Europe to southern parts of Eastern Europe. Only the first third of the month was stormy and rainy in Western and Central Europe, but turned to anticyclonic conditions with little precipitation afterwards, especially the last third was mostly dry. Some places had severe or even extreme drought, particularly in northeastern Spain, France and Germany. Especially parts of Spain, eastern Ukraine, southern European Russia and west Kazakhstan received less than 10 mm or less than 20 % of the 1981-2010 normal that month. It was the driest month in the 21st century in Spain so far. The Netherlands had 45 mm, but these fell almost all in the first third of the month, similar in Belgium.

It was relatively wet particularly in northern European Russia, above 250 % of normal fell locally. Parts of Scandinavia recorded above-normal precipitation as well (locally above 300 % of normal in Norway). Some stations in Norway (Nordland province) received around 300-350 mm that month and reached new local February records. Places in the Southern Alps had a precipitation excess due to some heavy rain events, much of them within a few days in early February. Near the eastern Mediterranean, too, some heavy rain events took place, e.g. on 25 February in western Crete (Greece), when Chania station recorded 374 mm of daily rainfall, a new record for Crete, and also Cyprus reported several events, resulting in a monthly total of 139 mm or 171 % of normal. Israel, too, had a lot of rain. From 5 February to the end of month, it rained almost every day in any part of the country, including on three heavy precipitation events throughout the month.

In **March**, there was a clear contrast between north and south with respect to precipitation. While the northern half of the RA VI Region was mainly wetter than normal (except Iceland and the Arctic region), much of the southern half was drier than normal. European Russia also was mainly wet, and so was also the southeast of the Region from Azerbaijan to parts of the Middle East and the eastern Mediterranean including the southern Greek island Crete. The difference between north and south was extreme since much of the precipitation in the north was above the 90th percentile and in the south below the 10th percentile with locally less than 20 % of the normal and totals of less than 10 mm or even zero for the whole month. Some stations in Serbia (Palic, Crni Vrh, Sombor) recorded their driest March on record. For Italy, it was the driest month countrywide for at least 15 years. The Turkish Black Sea region received the lowest precipitation since 1995.

A few stations in Norway recorded 3 times the normal precipitation. Sweden even registered local records of monthly precipitation in the southwest with totals up to 179 mm. Finland reported totals occurring less frequently than once every 30 years in places. Some stations in Ireland experienced their wettest March since 2008. For Denmark, it was the wettest March countrywide since 1874 with 106 mm on spatial average. Some parts of European Russia received more than twice the normal monthly precipitation, the same in Israel. Latvia had its third wettest March in the 21st century and its first month since April 2018 with above-normal rainfall; thus, it ended a long drought period. In northern and parts of central Israel, it was the rainiest March since 2003.

March's weather in Northwestern, Western and Central Europe was dominated by westerly and northwesterly winds, mild temperatures and frequent rain belts moving in off the North Atlantic until the 17th-18th. Named storms Freya and Gareth (UK names) brought spells of particularly wet and windy weather. Zurich in Switzerland recorded 6 days of strong wind (gusts >75 km/h), which did not happen before since 1995, also France had more windy days than normal. From the 19th onwards, it was often dry and sunny in Northwestern, Western and Central Europe with cold nights, due to high-pressure influence.

Large areas from Spain to the Ukraine had at least moderate drought conditions, partly severe and locally extreme. Monaco and southern Andorra had just 1 day of rain in the whole month. In Hungary, rainfall exceeded 1 mm only on 3 days on national average

Much of the northern half of Europe was very dry in **April,** especially large parts of Scandinavia, Poland, the Baltic countries, Belarus and adjacent parts of western Russia, which all received less than 10 mm of precipitation in the whole month and thus experienced mostly severe or extreme drought conditions. The totals were mostly below the 10th percentile and less than 20 % of normal

in large parts. Water levels fell considerably in rivers and lakes, e.g. in Lithuania and Belarus. It was the driest April on record in Latvia since 1924 with not more than 2 days with at least 1 mm of daily precipitation anywhere, and the driest in Belarus in the post-war period. Norway saw the second driest April on record (after 1918). Sweden had some local records of low precipitation with below 1 mm over the whole month at several stations. Uppsala station received 1.6 mm; to find a lower value there, we need to go back to 1813. Also in many places in Finnish Lapland, the rainfall in April was the lowest in recorded history. The dryness led to wildfires, especially in southern Finland during the latter half of April and in Belarus during the last five days of the month. In the Russian plain, no similar dryness was observed in April for almost 50 years. Other areas such as parts of the United Kingdom and Central Europe had a moderate, locally also severe drought, most rain in Central Europe came mainly in the last week of the month. Uccle in Belgium recorded only 8 days with precipitation compared to 15 on 1981-2010 average. Highest precipitation this month with totals above 100 mm (locally much more) was mostly in the south, especially in much of Iberia, the southern Alps, Monaco, southern Italy, western Balkans and southeastern Turkey, locally 2-3 times the normal and above the 90th percentile. Monaco recorded its rainiest April on record since 1969 with 212.6 mm (about 300 % of the normal), Spain the second wettest in the 21st century after 2008 with local records.

In May, much of Europe was wetter than normal, from Scandinavia over Eastern / eastern Central Europe to the Balkans and Italy, locally with more than 250 % of the normal, in Norway 300-400 %, Sweden and Finland even had record-wet places with monthly totals above 100 mm. Some places in Austria recorded the second wettest May on record. It was the third rainiest May in Hungary, where also a new record of daily precipitation in May (141.2 mm) was noted. Hungary recorded 18 rainy days, 7 times more than average. Slovenia recorded its wettest May? since start of measurements in 1961 with monthly totals above 400 mm in some places in the Julian Alps. Dubrovnik in Croatia had its highest number of rainy days that month since start of measurements. Serbia reported both local record-breaking monthly precipitation totals (177.9 mm at Zrenjanin station) and number of precipitation days (23 days at Kikinda) for May. Montenegro had a new local monthly precipitation record at 321.4 mm in Herceg Novi. Northern Italy, too, recorded widespread totals above 300 mm, also partly with new records (e.g. Belluno, Modena) and high number of rainy days (16-18 compared to 12-14 normally). Malta recorded 6 thunderstorm that month (normal is 1), the highest number since 1951.

Western Europe (except Scotland) and most parts of western Central Europe were drier than normal and also the eastern Mediterranean region. Places in Ireland saw their driest May since 1991. Especially most of Iberia, but also southern Greece and southern Turkey, and Iceland/ Greenland received less than 40 % of the normal, partly even less than 20 %. It was the second driest May in the 21st century in Spain after 2015 and the third driest since 2000 in Portugal after 2006 and 2003. Turkey was dry especially in the Mediterranean region, the driest May in the last 20 years. Cyprus received only 1.6 mm the whole month (8 % of normal). The Middle East was in the dry season anyway. Over Russia, precipitation had a high spatial variability due to much convective rain.

In June, due to the main influence of high pressure over the continent dry conditions dominated over southwestern, central and also eastern Europe. Large parts only received less than 40 % of the normal precipitation amounts for example parts of Spain, Italy, Poland, the Baltic countries, Finland

and southeastern Russia. In Spain, Italy and Russia precipitation sums did not even reach 20 % of normal. At the same time, both western Europe and southeastern Europe experienced heavy precipitation events due to the eruption of heavy thunderstorms in the first week of June locally resulting in flooding. Turkey experienced a precipitation surplus of 70 %. In France, active disturbances, often stormy, followed one another. Violent thunderstorms locally accompanied by hail and gusts exceeding 100 km/h occurred over the north of the country on the 4th and 5th. The storm "Miguel" swept over a large part of France on the 7th. Then on the 9th, there were numerous thunderstorms over the south-east quarter.

The dry conditions present already in June continued in **July** over large parts of Europe. In Ukkel, Belgium, the dry period that had started on 16 June continued till 11 July, resulting in a total of 26 days in a row without precipitation. Last time Ukkel had seen such a long period without rain was back in 1995. Precipitation sums were exceptionally below normal in western and central Europe as well as over Scandinavia and parts of eastern Europe (< 10th percentile). In France and over Scandinavia the GPCC precipitation index regionally dropped below -1.5 indicating severe drought conditions. In Finland, it was particularly dry in the western parts of Northern Ostrobothnia and in southwestern Lapland where the monthly amount of precipitation was less than 10 millimetres. It rained least in Siikajoki, where the monthly amount of precipitation was only 2.3 millimetres. This is the lowest amount of precipitation recorded for July in the history of the observation station. Wetter conditions occurred in July particularly over southern and eastern Europe with exceptionally above precipitation sums over Russia, the Balkan Peninsula, Turkey but also over the United Kingdom. In southeastern Europe these resulted from severe storms hitting for example Italy, Croatia, Serbia, Bosnia and Herzegovina as well as Greece between 7 and 10 July and producing violent hailstorms. In the United Kingdom, flash floods occurred after torrential rain causing severe damage in northern and central England on 30 and 31 July.

Drought conditions were a very prominent feature again in **August.** There were two main zones of continued dryness: one extending from France over Central Europe to the Baltic countries and Finland and the other one from the Balkans to Ukraine/ Russia. In between the two zones there was a zone with more than average precipitation. Largest monthly deficits with monthly sums lower than the 10th percentiles were recorded over Ukraine, southwestern parts of Russia and parts of Greece as well as over Baltic countries. GPCC precipitation indices regionally dropped below -1.5 for Greece, Ukraine, southern France indicating severe drought conditions (for August). The monthly precipitation deficit was locally above 40 mm so that some places received less than 40 % of the usual August total. Even more serious was the long duration of periods without rain for parts of central and northern Europe and as well as for the Baltic where accumulated summer precipitation amounts stayed exceptionally below the average (< 10th percentile) of the reference period 1951 to 2010. The summer months were exceptionally wet (> 90th percentile considering the reference period 1951 to 2010) over northern UK, Norway, Russia and Turkey. Several heavy precipitation events partly going along with severe storms and floods contributed to these exceptionally wet summer conditions (see also “Selected Significant Events” reported by the National meteorological and hydrological services for this and precious months).

Precipitation sums for **September** were below normal over large parts of the RA VI Region, especially over Eastern Europe, Turkey and France where the monthly totals were partly only 40 % or less of normal. In these regions, the drought index dropped to values below -1.5 for September

indicating severe to extreme drought. In the Ukraine, the south only received 10 mm or less which is 75 % less than normal (w.r.t. 1981-2010). Exceptionally above average precipitation, amounts due to several cyclonic systems were registered over the northwestern part of Europe, for example over the UK, Netherlands, Denmark, but also over southeastern Spain. In Vega Baja del Segura, the area most affected in Spain, the accumulated rainfall in a few hours (from the morning of the 12th to the morning of the 13th) was almost equivalent to the amount normally accumulated over a whole year. Maximum values, accumulated during the period from 10 to 14 September, in the network of AEMET stations were registered at Gaianes with 482.8 mm (more than 350 mm of that fell in the last 24 hours).

In October, the regions receiving more sunshine than normal correspond also to those experiencing below normal precipitation. In parts of Italy and along the western coast of the Balkan peninsula the accumulated amounts were even exceptionally below normal (< 10th percentile). Exceptionally above normal precipitation amounts occurred, on the contrary, over northern Russia and along the Atlantic coast of western Europe affecting France, the UK and the Netherlands. Southern France, the northeast of Spain and the north of Italy were hit by excessive rainfall events during 21 to 24 October caused by a depression over the Mediterranean Sea. They resulted in severe flooding and landslides. The frontal system moved westward from Italy towards Spain between the 22 and 24 October. On the east side of the depression a south to southeasterly wind brought warm and humid air from the Mediterranean Sea causing excessive rainfall and heavy thunderstorms along the Mediterranean coasts. In Italy, most precipitation fell on 22 October. The province of Alessandria in Piedmont was among the worst hit areas. Piedmont Regional Agency for Environmental Protection (ARPA) reported that on 22 October as much as 253 mm of rain fell in 12 hours in Casaleggio Boiro. In France, most precipitation fell on the 22 and 23 October. In southern France, precipitation amounts of 100-200 mm were recorded over a large area, but locally even more than 200 mm. This is the amount of rainfall normally accumulated over three months. The largest rainfall amounts were reported in the Languedoc and the Roussillon regions, for example at the station Puechabon 271.5 mm. The Spanish Meteorological Service of Catalonia (Meteocat) recorded on 23 October at several locations in the northeast of Spain more than 200 mm in 24 hours, among them Prades, Baix Camp, with 287.4 mm. The northern part of Russia also experienced very intense precipitaion with up to 30-50 mm per day and often in the form of snow already. In many regions monthly precipitation normals were exceeded by two or more times.

Monthly accumulated precipitation amounts differed a lot within the RA VI Region in November. The eastern part saw below normal precipitation amounts which were even exceptionally below normal (thus < 10th percentile) over Turkey, Southern Russia, Ukraine and Kazakhstan. In Russia, the monthly precipitation totals in the areas down to the Caucasian Ridge amounted to less than half the normal values, and were altogether zero in some areas of the Trans-Volga Region. A severe drought was observed in the Krasnodar Territory where sizeable rains fell on the last day of November only.

The regions neighbouring the northern Mediterranean as well as the Atlantic coast regions of Spain and France, on the contrary, experienced exceptionally above normal precipitation (>90th percentile). The rainfall amounts accumulated over the whole month are very impressive in these regions. In Italy, monthly precipitation values were in some areas double (for example in the Po basin) or even triple to quadruple (for example in south Tyrol) the normal amounts (that is the average over the reference period). For Italy, November 2019 finished as the rainiest November

ever. In France, rainfall was particularly frequent and abundant in the west and south of the country. France as a whole registered a surplus of precipitation of 90 %, making November 2019 the third wettest November since 1959. Over the western half of France and Corsica there were 15 to 27 days of rain, 5 to 14 days more than normal. Over the South-West as well over the South-East (of France), monthly precipitation totals reached double or even triple to quadrule the normal amounts. Records were broken at several stations including Lanvéoc (Finistère) with 246.4 mm, Ajaccio (Corse-du-Sud) with 284.3 mm, Cambo-les-Bains (Pyrénées-Atlantiques) with 531.5 mm and Saint-Martin-de-Hinx (Landes) with 534 mm. The heavy rainfall generated significant floods in Aquitaine on 16 and 17 November and in the Provence - Alpes - Côte d'Azur region on 22 and 23 November. In Slovenia, precipitation amounts exceeded the long-term averages everywhere. The largest surplus was reported in the northwest of Slovenia, in Gornja Radovna where 327 % of the normal precipitation fell. At lower altitudes, these large amounts of precipitation fell as rain, at higher altitudes as snow. In Kredarica, 29 days with snow cover were reported and the thickness of the snowpack reached 295 cm, which is the thickest snow cover in November ever observed in Kredarica. In Austria, the weather conditions in November brought an extraordinary amount of precipitation in the southern and southwestern parts of the country. In these regions the anomalies of precipitation were 200 to 440 % of normal. Many weather stations in these regions set new monthly precipitation records. In Austria it was the third wettest November (+100 %) since 1858.

These abundant precipitation amounts were due to several Mediterranean Storms occurring between 12 and 24 November. First, Medicane Trudy developed on 12 November from the low pressure area Detlef. Trudy brought heavy rain especially to Italy and the Balkan coasts. In Italy up to 90 mm of rain fell on 12 November, on the Balkan coasts up to 78 mm. In the southern Alps Trudy brought fresh snow quantities of more than 1m as well as strong winds. As soon as Medicane Trudy had left, low Heiner started heading towards Italy and the Alps. This time, largest amounts of precipitation occurred mainly in the south and east of Austria. Almost 140 mm accumulated in 24 hours. At lower altitudes, these fell as rain, at higher altitudes as snow, resulting in floods and enormous amounts of fresh snow. Furthermore, the strong air pressure gradient in Austria caused widespread strong winds and gale force gusts. In the night from 22 to 23 November, Luis II moved across the Bay of Biscay and reached the coast of southwestern France on 23 November. Especially along the Atlantic coast of the Iberian Peninsula, stormy winds and abundant precipitation occurred. Several stations in France and Spain recorded more than 100 mm in 24h. But also parts of Italy experienced again heavy precipitation exceeding 100 mm in 24h at several places (on 24 November).

Monthly precipitation totals were also exceptionally above normal in the northeast, namely over Russia and Finland. In Russia, up to 50 mm of precipitation fell per day in some locations in the Novgorod Region and more than twice the normal monthly amount accumulated in the first decade of November. Such abundance of rains led to a rapid rise of river levels. Water flooded roads, bridges and even in parts the city of Veliky Novgorod. In the Volgograd Region, the situation was similar, while in the Kostroma Region, heavy rains were followed by ample snowfalls. In Finland, in the area extending from Satakunta to Koillismaa, the precipitation was 1.5 to 2 times more than in an average November. In parts, even location-specific precipitation records for November were measured. The month's highest overall amount of precipitation, 134.4 mm, was measured in Niinisalo, Kankaanpää.

At the same time, this was the highest November precipitation in the 80-year history of the observation station.

Monthly precipitation totals for **December** were below normal mainly in the eastern, southeastern and central parts of the RA VI domain with for example less than half the normal precipitation amounts in southern parts of European Russia. Around the Caspian Sea no or only very little precipitation was recorded. More than normal precipitation, on the contrary, was observed among others over northern Europe. In Finland, for example, it rained twice as much as usual in Central Lapland. In Vuotso (Sodankyla), the highest amount of precipitation in the station's measurement history for December was recorded with 98.7 mm. The highest amount of precipitation was recorded in Koivuniemi in Virolathi with 116.8 mm. Wetter than normal conditions also prevailed in western parts of Europe as well as over the eastern Mediterranean region resulting from several winter storms passing over Europe during December. A first storm occurred over Iberia in early December and caused flooding in France and Spain. In southern France (Var region) 187 mm fell in 24 hours on 2 December, the second highest daily total on record behind 3 October 2015. In mid-December another storm caused flash floods in parts of the Murcia region in southern Spain. Gusts of 130-140 km/h were measured in several places in France and Germany (mainly coastal or mountain sites), in Corsica (France) even 173 km/h on 13 December and on the peaks of the Alps up to 158 km/h (Jungfraujoch) on 14 December. In Portugal, 115.8 mm were accumulated in 24 hours on 16 December and in France a gust of 173 km/h was registered on December 13. Between 19 and 22 December several fast-running low-pressure systems reached Western and Central Europe causing stormy winds, mild temperatures and heavy precipitation. Strongest gusts occurred over Iberia and southwestern France with wind speeds up to 150-180 km/h at several stations in Portugal and Spain. In the eastern Mediterranean region, after a very dry autumn, December finally brought above-normal precipitation over almost in the whole region except for southern Israel and southern and eastern Jordan. A weak low-pressure system caused heavy precipitation in Israel (on 25-28 December) and Lebanon. Monthly totals up to above 250 % were recorded particularly in various parts of Syria and Israel.

Table 4-5: Rank statistics, monthly average precipitation (mm) and anomalies (mm or %) from several countries of the RA VI for the individual months in 2019 including countries with rankings among the top 5 (ranks 1–5) since start of the to time series. Ranks refer to monthly values being sorted from wettest to driest if not indicated differently.

Country	Rank	Anomaly [mm] (1961-1990)	Anomaly [mm] 1981-2010	start of time series
January				
Moldova	5	-	+47	1891

In January, large parts of the RA VI Region were **sunnier** than normal, especially in southwestern Europe and in the Middle East. On the other hand, particularly parts of France, the Alpine region, Southeastern Europe and Turkey were relatively dull. The station Kragujevac in Serbia measured 26.4 hours of sunshine duration, the lowest ever recorded in January there.

Due to prevailing anticyclonic conditions, February was mostly sunny, particularly in Southwestern, Western and Central Europe with over 50 hours more than usual in Spain, France, Germany and parts of eastern Central Europe. It was Germany's sunniest February since 1951 and the UK's second sunniest February in a series from 1929, just behind 2008. De Bilt in the Netherlands recorded the third sunniest February on record. Basel and Geneva, both in Switzerland, registered their sunniest February since start of measurements in 1886 and 1897, respectively, with each 169 hours, more than twice the 1981-2010 normal. Northeastern France, too, had twice as much sunshine compared to the long-term average (1991-2010), and several places in France had new records (including Toulouse in the south with 189 hours, highest since 1948). Similarly, Germany's stations Bad Kissingen and Constance were more than twice as sunny compared to normal. Even southeast Sweden received much sunshine; Karlskrona station registered a new February record at 122 hours since start of measurements in 2009.

For March, there was a contrast between north and south concerning sunshine duration. Some parts of the north, particularly northern Central Europe, but also the Middle East had more than 20 hours sunshine deficit. Conversely, much of the south was sunnier than normal with partly more than 50 additional sunshine hours that month compared to the normal. Some places noted new local records in monthly sunshine duration for March, e.g. Nice in France since 1991 with 283 hours. However, also parts of the north were at least slightly sunnier than normal, e.g. Sweden, Denmark. The United Kingdom was sunny especially in the last week of the month; the monthly total also was higher than normal. In Switzerland, several stations reached the maximum possible sunshine duration on many days in the last third of the month.

In **April**, much sunshine occurred over large parts of Northern Europe within the high-pressure zone, but also most of the middle latitudes of Europe were sunnier than normal. Several stations in Sweden noted new April sunshine records and also the national April record for Sweden was surpassed (Borlänge in Dalarna 335 hours; there, the sun shone at least 10 hours (of a maximum of 14-15 hours) per day from 10 to 30 April). For Denmark, too, it was the sunniest April on record (since 1920). Southern parts of RA VI mostly had around-normal sunshine, partly also duller, especially in the most rainy areas.

In **May**, sunshine duration and global radiation show a very similar distribution like precipitation. The wet areas were also mainly the dullest with deficits down to -100 hours. However, the southern slopes of the Alps often had sunny days due to north foehn. Western and southern Spain had the sunniest places in May 2019 with up to above 400 hours of sunshine, more than 50 hours above normal. Cork Airport in Ireland had its sunniest May since 2007. In contrast, Uccle in Belgium recorded only 182 hours, less than in April 2019. Austria recorded its dullest May since 2010, Slovenia since 1961. Serbia notes some new local records of dullest May.

Due to the strong high-pressure area and corresponding significant subsidence in **June**, there is also a strong positive anomaly (>100 % of normal) of sunshine duration over much of central and eastern Europe. Over an area reaching from western Iberia over England to Norway a zone with negative anomalies in radiation can be clearly distinguished as a result of the frontal systems passing along the western edge of Europe.

In **July** it was generally more sunny than normal (the average calculated from the climatological period 1986 to 2015) over most parts of the RA VI Region with largest anomalies over France and Scandinavia. Over France, we also find the largest surplus of radiation for July whereas negative anomalies in radiation are visible over the southern and the northeastern part Europe as well as over the United Kingdom.

In **August** it was generally more sunny than normal (with respect to the average calculated from the climatological period 1986 to 2015) with anomalies of 5-25 % over most parts of RA VI. The largest radiation surplus in August is found over Eastern Europe (Balkan Peninsula, Ukraine) whereas southern parts of Sweden, Norway, Turkey received below-normal radiation amounts.

In **September** it was generally more sunny than normal (the average calculated from the climatological period 1986 to 2015) over most parts of the RA VI Region with largest anomalies over Eastern Europe, France and Italy with a surplus of 20 to 50 sunshine hours. Over Eastern Europe, we also find the largest surplus of radiation for September (up to 40 W/m² more than normal) whereas negative anomalies in radiation are visible over southern Iberia as well as over the southern Caucasus (up to 30 W/m² less than normal).

In **October** it was more sunny than normal (with respect to the average calculated from the climatological period 1986 to 2015) over the southern and eastern part of the RA VI Region. The largest surplus in sunshine hours is found over Eastern Europe (Balkan Peninsula), over Italy and over the South Caucasus region, which received 50 to 100 hours extra sunshine. Scandinavia and France, on the other hand, experienced fewer than normal sunshine hours (up to 50 hours less) corresponding to a radiation deficit of up to 20 W/m².

Sunshine duration was in November over most parts of the RA VI Region below normal with up to 100 hours less sunshine hours than normal occurring for example over Portugal. Turkey, southern Russia and the Middle East region, on the contrary, experienced above-normal sunshine duration with 50 to 100 hours more sunshine hours than normal corresponding to a surplus of radiation in the range of +20 to +40 W/m².

The month of December was over most parts of the RA VI domain more sunny than normal. Anomalies were mostly small though (only up to +20 sunshine hours). Largest anomalies occurred over the southeastern part, which experienced 50 to 100 more hours of sunshine than normal. This corresponds to a surplus in radiation of 10 to 20 W/m².

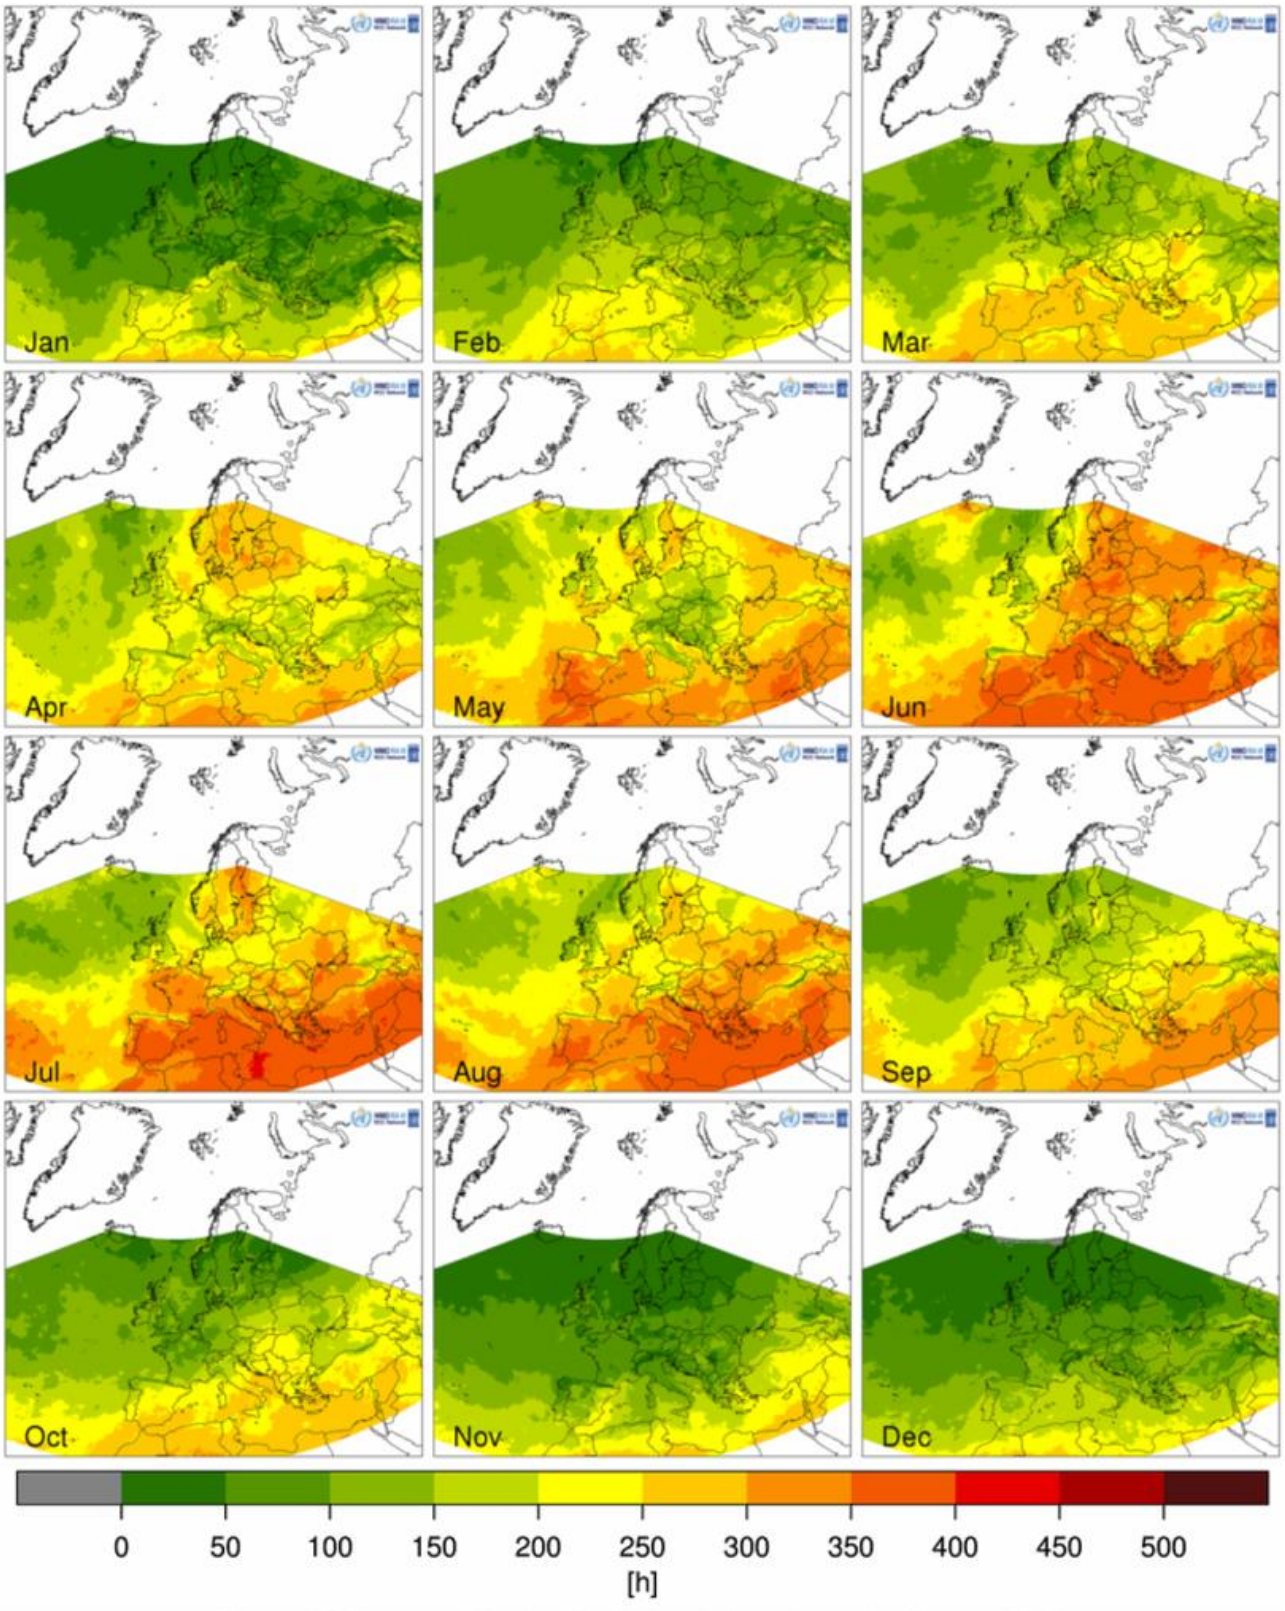

Figure 4-7: *Mean sunshine duration (in hours) for each month of the year 2019.*

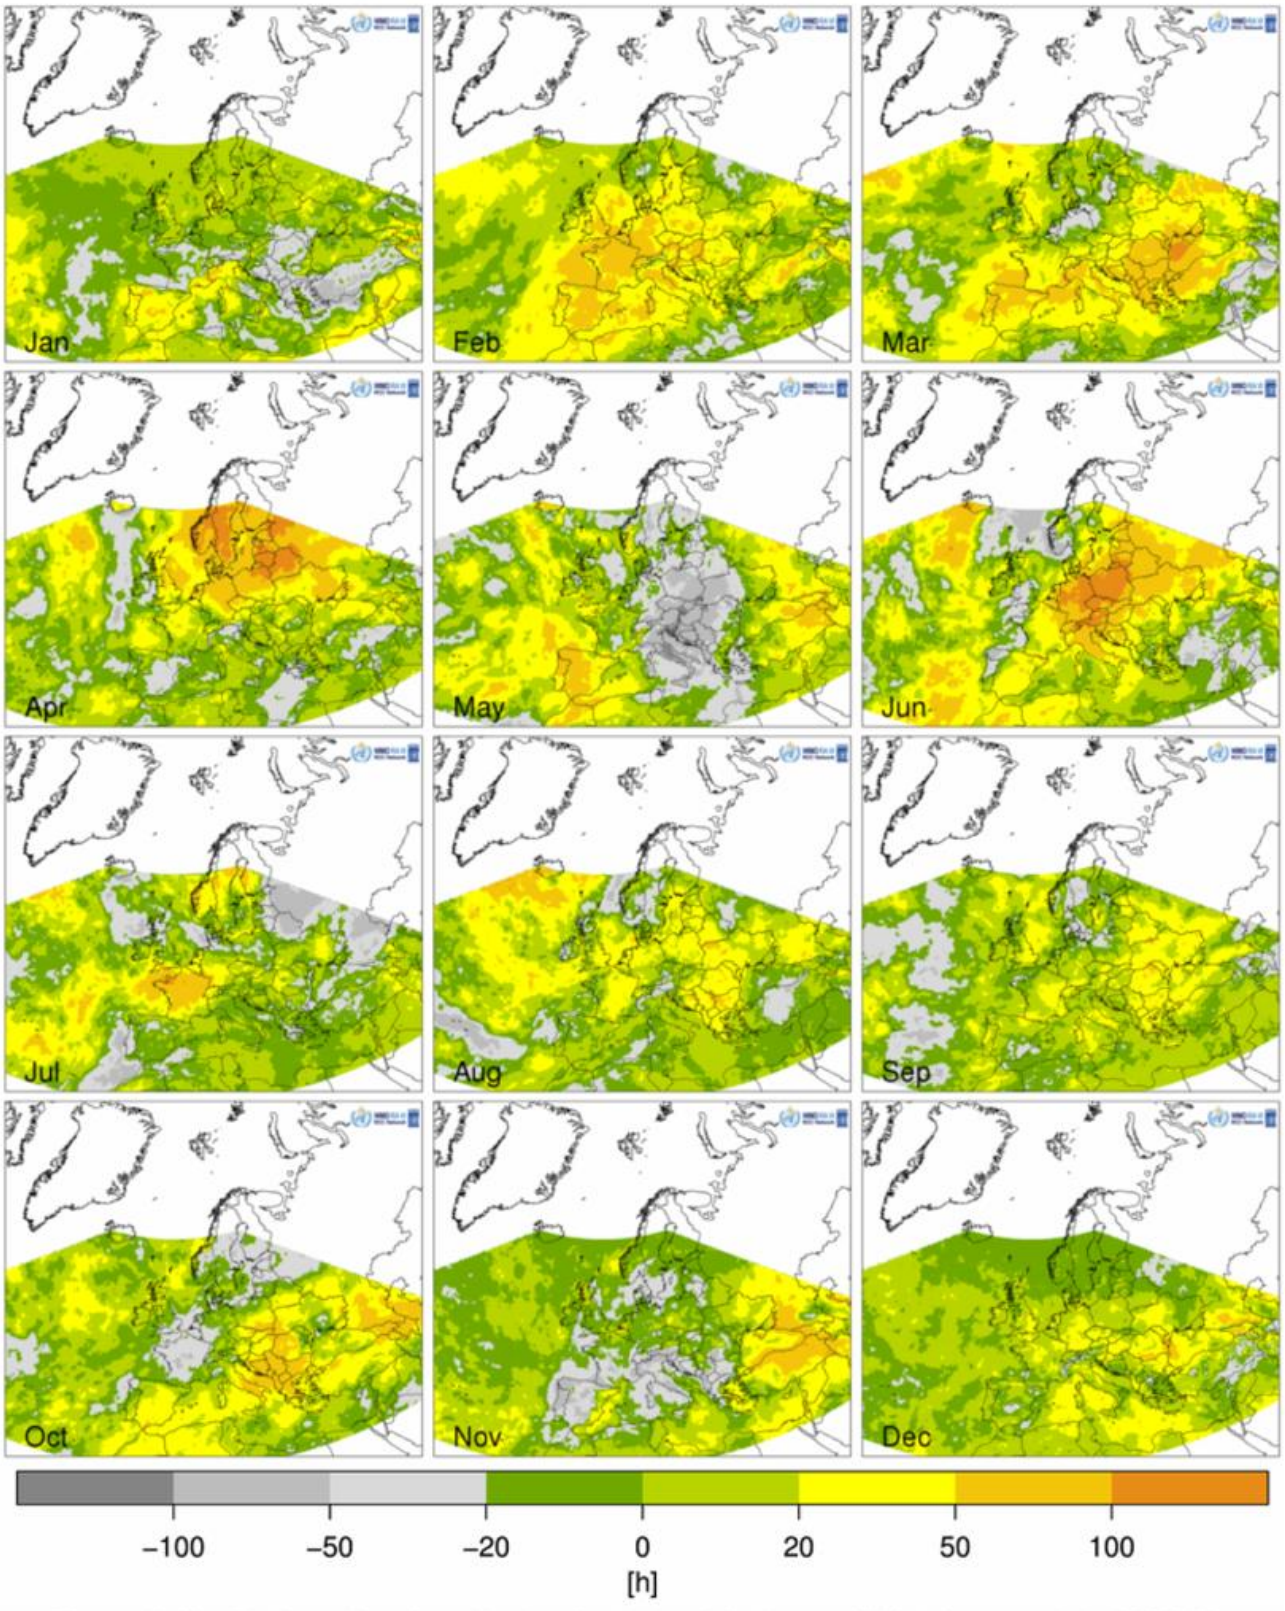

Figure 4-8: *Monthly Anomalies of sunshine duration (in hours) for the year 2019 (reference period 1986-2015).*

4.5 Maps of monthly significant climate anomalies and events

The following maps are based on different data (as noted in the legends in parentheses), and are meant to summarize weather conditions in each month of the year 2019. The Monthly Event Maps contain information about significant anomalies of temperature, precipitation and wind gusts. Dots represent anomalies of climate indices calculated based on station data, for example the number of very warm days and cold days and the locations of strong wind gusts (>=32 m/s). The dot is subdivided into several different colours in case more than one anomaly value needs to be depicted. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

January

Monthly mean temperature averaged over Europe was close to the 1981-2010 normal in January, but temperature variability was high during the month. Especially in parts of Northern and Eastern Europe, periods of freezing weather alternated with thaws. In Scandinavia and much of European Russia, mild temperatures characterized the first half of the month, in Iceland even exceptionally high, but the second part of the month was much colder and especially the last few days. Sweden reported 9 days in a row with daily minimum temperatures below -30 °C. On the other hand, Denmark only had 3 ice days (Tx<0 °C) on average (normal is 8.6 days in 1961-1990), the Netherland 2 ice days (normal: 3), Ljubljana in Slovenia 1 ice day, most of Serbia 1-7 ice days.

Eastern parts of RA VI were mostly much wetter than normal in January, particularly around the Black Sea and near the eastern Mediterranean, locally above 250 % of the normal, e.g. in Romania, Moldova, Bulgaria, near the Aegean Sea, in southern Turkey and Cyprus. In Turkey, it was the highest January total in the last 15 years in the Aegean region and the last 37 years at the Mediterranean coast. Especially Greece and Cyprus recorded several heavy rain events with flooding and landslides. Malta, too, was wet, recording the wettest January since 2011, much contributed by 6 thunderstorms (more than 3 are rare in January), partly with hail. In Serbia, the stations Valjevo, Kragujevac and Pozega observed record-breaking numbers of days with precipitation (23-25 days, series since 1925, which means that the above-normal monthly totals came from high frequency of precipitation. In eastern Central Europe (e.g. Czech Republic, Slovakia), most of the precipitation fell in the first half of the month, also in the Middle East (e.g. Israel).

Between 7 and 14 January, the Alps and other mountainous regions in Central Europe experienced extreme snowfall under the influence of north-westerly or northerly flow. Up to 100 mm of precipitation fell in 72 hours in the Ore Mountains (Germany) and northern Alps. On 13 January, Central Europe was within the warm air sector of Low FLORENZ, which made the snow line temporarily rise to 1200 m. Rainfall of up to 109 mm/24h increased the weight of the snow cover dramatically and thus the danger of collapsing buildings or trees. New monthly records of 24h precipitation were registered in Saxony (eastern Germany) on 9 January and new records of snow depth in southern Germany on 11 January. Switzerland recorded up to 160 cm of fresh snow on the northern slopes and wind gusts of up to 180 km/h.

Wintry storms ravaged parts of the north. In Sweden, winds of 111 mph (179 km/h) were recorded as Storm Jan (named "Donald" in Central Europe) ravaged Stekenjokk near the Norwegian border on 11 January. The storm made roads impassable in Sweden and Norway. In Finland, a record 10min average wind speed of 32.5 m/s was measured in the Gulf of Bothnia, and wave heights were close to previous records. The storm was estimated to have caused damage of 10-20 million Euros in forests and due to power outages.

February

At the beginning of February, three storm lows moved over Central Europe and Germany. Low STEFAN launched the storm series on 06/07 February 2019 and brought gusts up to 117 km/h, especially in the UK. THOMAS (named "Erik" in UK and Ireland) followed on 08/09 February, causing storms in Ireland, the UK (with the strongest gust of 138 km/h recorded at Capel Curig in North Wales) and northern Germany. Large waves were observed at exposed coasts and falling trees, causing at least two fatalities when trees fell on cars. Bridges and roads were partially closed. Some flights, ferry and rail services were also affected by the strong winds. In the Republic of Ireland, 2500 people were left without power.

After a cold start of February 2019, the second half of the month became very mild. During a warm spell lasting from 21-27 February, exceptionally mild weather brought record high temperatures with many areas in Central Europe exceeding 20.0 °C. Many local monthly and winter records of maximum temperature were reached or broken even at stations with time series spanning more than 100 years. For Austria, Slovenia, Hungary even countrywide records for February were reported. At Kew Gardens in London, 21.2 °C was reached on the 26th. This was the first time that a temperature above 20 °C had been recorded in winter in the UK. Achnagart (Highland) set a new highest daily minimum temperature record for the UK with temperatures not dropping below 13.9 °C on 23rd. In France, more than half of the 150 measurement stations broke maximum temperature records for February, for example Istres with 23.4 °C on 28 February (previous record 23.3 °C on 27 February 1960) and Cazaux with 26.2 °C on 27 February (previous record 26.0 °C on 23 February 1929). A new record was also set at the station De Bilt in the Netherlands 20.5 °C on the 27th, also breaking the monthly and winter record for all stations. In Belgium, the 26 February was an extremely early first spring day (here defined as daily maximum temperature above 20 °C) in Uccle, making it the first winter with a spring day in history.

March

At the beginning of March, several storm lows swept across Europe in succession. Especially the United Kingdom, Ireland, northern and eastern France, the Benelux countries, Germany and Czech Republic were affected. One of the storms even spread far to the south down to Spain. The storm episode with strong winds, mild temperatures and heavy rain lasted two weeks until 17 March. Storm gusts reached above 200 km/h in exposed places. While the northern half of the RA VI Region was therefore much wetter than normal, much of the southern half was drier than normal and some regions even experienced severe drought conditions.

April

Due to the inflow of moist and warm air from the south, heavy thunderstorms developed along a cold front over Romania. On 30 April a large tornado about 110 km east of Bucharest damaged homes, agricultural fields and vehicles. At least 7 people were injured, most of them after the twister turned over a bus with 39 people inside. Ten houses were left without their roofs. Sahara dust affected Albania in the last few days of April and also Malta during 6 days.

May

In May, much of Europe was wetter than normal, from Scandinavia over Eastern / eastern Central Europe to the Balkans and Italy, locally with more than 250% of the normal (in Norway up to 300-400% of normal), Sweden and Finland even had record-wet places with monthly totals above 100mm. In Italy, the Emilia Romagna region experienced an exceptional wet month. Due to heavy precipitation, severe thunderstorms, hail and snowfalls, total monthly precipitation (average over Emilia Romagna) reached 228 mm, which is 40 % higher than the previous record (164 mm in 1984) and three times the 1961-1990 climatological average of 73 mm. Consequently, flooding and landslides were observed and around one hundred people displaced. In Georgia, heavy rain and hail affected the Kakheti Region, mainly Lagodekhi, Akhmeta, Telavi and Dedoplistskaro municipalities on 4-5 May 2019. The heavy rain of up to 150 mm/24h in Lagodekhi flooded entrances, basements and first floors of many buildings. Furthermore, infrastructure, such as roads and bridges connecting the villages, riverbank protections, as well as agricultural lands, vineyards and fruit trees were destroyed. Supplies of drinking water and electricity were interrupted for a short period. In total 5,088 people were affected by this disaster.

Large parts of the RA VI Region saw more warm days than normal. Especially over the eastern parts and in the southwest monthly temperatures were warmer than normal due to episodes of anomalously hot weather. Across southern and western parts of the Iberian Peninsula, for example, a heat wave occurred mid of May. Alcácer do Sal, Barrosinha (southern Portugal) reached 38.1 °C on 13 May. Daily maxima at many stations in Portugal, western and southern Spain exceeded 30°C. These are extremely high temperatures for this period, being 12-15 °C hotter than average in places. In Israel, a prolonged heat spell occurred from 12 May until the end of the month, most noticeably in the interior parts of the country, during which there were several Sharav events. The most significant one was on 22 to 24 May with temperatures of 43-45 °C in the Coastal Plain, the Negev and the Northern Valleys and 45-47 °C at the Dead Sea and the Arava. Two stations in the area were even warmer – En Gedi (Dead Sea) with 48.0 °C and Hazeva with 47.9 °C. At many stations the maximum temperatures measured during this heat wave are ranked as the 2nd-4th warmest on record since measurements began. In some cases they are the warmest since 1970 or even before. Fires broke out in many areas across Israel on 23 May and continued until the following day. Fortunately there were no casualties, yet dozens of homes were destroyed and thousands of dunams of forests, bush land and open space were burnt. From May 5 to 14, anomalously hot weather was also observed in the eastern regions of European Russia. On average, during this period, the temperature exceeded the climatic norm (1981-2010) by 8-10°C. Many temperature records were broken, both daily highs and absolute for the entire first half of May. The average temperature for the first half of May was 6–7°C above normal (which also corresponds to the highest values in the history of observations).

June

Heatwave conditions affected western, central and northeastern Europe, and particularly in the last week of June with some new national and numerous local records of maximum temperature broken. The heatwave has resulted in at least eight deaths so far. The reason for the heatwave was the shift and spread of the Azores high over Europe and strong warm air advection, which transported the hot air masses of Africa over the Mediterranean to Europe. In the Ukraine the heat wave lasted from 6 June to 10 July and brought record high temperatures making it the hottest June since 1961. The average monthly temperature for June was +4.5 °C to +5.5 °C above normal and the maximum air temperatures exceeded 30 °C in most parts of the country on 30-35 days. For 1-6 days, even 35 °C was exceeded. In Italy, the heat wave lasted from 8 June to 9 July (32 days) and maximum temperatures exceeded 30 °C across wide areas and even 40 °C in some places. At some locations, new records were set for the highest June minimum temperature (e.g. 27.5 °C on 27 June in Milan). In Florence, the maximum temperature exceeded the 90th percentile on 12 consecutive days, the second longest heat wave since 1955. A three-day heat wave in Lithuania starting on 11 June brought an absolute maximum temperature record of 35.7 °C in the city of Kaisiadorys. In Germany, June 2019 was the warmest June since the beginning of observations. The hot air masses from the Sahara and the high solar radiation led to many new June temperature records at DWD stations, highest on 30 June with 39.6 °C. For Germany, June was also the start of an exceptional three-month drought/dry spell affected Western, Central and Eastern Germany. Soil moisture in large areas was below long-term minimum values causing economic losses due to crop failure. On several major rivers low water levels hindered river navigation. It was the second major drought period after that in the year 2018, which was even longer than in 2019. The month of June was also very dry in Estonia. Countrywide only 30 % or less of the monthly normal precipitation was received. The monthly total for Kihnu on Kihnu Island, southwest of Estonia, was only 0.3 mm, which is 1 % of the month's normal and a record low in a series starting in 1932.

Unusually strong storms for this time of year battered parts of Spain, France, United Kingdom, Benelux, Germany, Switzerland, Poland, Hungary during almost the whole month of June. Exceptionally intense hailstorms with hailstones larger than 6.5 cm hit southern Germany on 10-11 June. At least six people were injured; cars, trees and houses were damaged in Munich and Bavaria more widely. Accompanying heavy precipitation led to flooding of homes. In Berlin and surrounding areas, thunderstorms brought daily totals of 60 mm to 70 mm on 11 and 12 June. Roads needed to be closed. Similarly, the northern areas of Poland (including Sopot, Gdynia and Gdańsk) reported heavy winds and precipitation causing flooding, uprooted trees and power outages for thousands of households on 10 June. Record large hailstones of 12 cm were reported in Gorzów Wielkopolski-Ustronie and Wojcieszyce (western Poland). Thunderstorms caused wind damage and flash floods in Hungary starting on 16 June. On that day, a daily total of 144.4 mm of precipitation was measured in Rakamaz, nearly twice the normal monthly mean for June (73.5 mm). On 20 June, a new daily record of 117.8 mm of rain fell in 24 hours, beating the previous record high for this date of 101.3 mm set in Szőlősardó in 1956. On 23 June, the daily total of precipitation was 154.9 mm at Terpes, the highest total in this place / in Hungary? recorded in 2019. Southeastern Europe and Turkey, too, were hit by heavy rain and severe flooding the same time.

July

Short but intense heatwave which set many new temperature records across Western, Central and Northern Europe. Hot air moving from the Sahara region caused temperatures to rise. Like other heat waves, it was caused by a so called Omega weather type with high pressure over Europe and low pressure each over the North Atlantic and west Russia (looking like the Greek letter Omega). In the westerly parts of Germany (Rhine-Main via Lower Rhine to Emsland) maximum temperatures exceeding 40 °C on three consecutive days (24 – 26 July 2019) occurred for the first time since the beginning of meteorological recordings. On 25/07/2019, 25 stations reported maximum temperatures of 40 °C or more. The previous record temperature for Germany (40.3 °C) was exceeded at 14 stations. Four stations recorded temperatures above 41 °C. For Germany, summer 2019 was the third warmest summer season since 1881. In Israel, a daily maximum temperature of 49.9 °C was measured in Sedom (southern Dead Sea region) during an extreme Sharav event on 17 July. This was the highest temperature on record in Israel for more than 70 years (the highest temperature ever measured in Israel was 54 °C in Tirat Tzvi on 21 June 1942).

Severe storms affected southern parts of the RA VI Region (Spain, Italy, Romania, Balkans, Greece, and Turkey) during 5-10 July with strong winds and heavy precipitation events causing floods and landslides over large parts. Northern Greece was hit by very strong winds, tornadoes and violent hailstorms on 10 July 2019. Such severe weather is extremely unusual in Greece for this time of year, which is normally mostly calm and dry. Trees were uprooted and roofs collapsed after a storm with wind gusts up to 100 km/h (62 mph) hit the area, claiming lives of 7 people and injuring more than 100. According to the network of automatic meteorological stations of the National Observatory of Athens / Meteo.gr, the highest wind gusts were recorded in the areas: Klidi Viotia 101 km/h (62.7 mph) and Stratoni Chalkidiki 100 km/h (62 mph). Floods and landslides occurred in north-western Turkey in many districts in Düzce Province on 17-18 July 2019 after heavy rainfall: 84.7 mm of rain fell in Akçakoca district on 17 July, 75 mm in Cumayeri district, 72 mm in Çilimli district and 161.7 mm on Kardüz Plateau.

August

August was exceptionally wet due to heavy rain events (partly associated with storms) especially in UK, Ireland, Italy, Turkey and Spain causing floods and landslides in many places. Flash floods hit Rize Province in the Black Sea Region of Turkey on 04 August 2019 after 120mm of rain had fallen in 4 hours, flooding areas around the city of Rize, inundating roads and buildings. A major tornado occurred on 9 August across northeastern France and south-western Luxembourg. It brought wind speeds between 178 km/h and 217 km/h and caused considerable damage. Almost 500 buildings were damaged in communities of Pétange and Käerjeng, Luxembourg and 30 in the province of Meurthe-et-Moselle, France. Trees were knocked down, roads blocked, cars damaged and 19 people in Luxembourg were reported injured. On 5 August, heavy rain accompanied by a sea storm occurred in Adjara-Guria (south-western part of Georgia) causing infrastructure damage.

September

Record heavy rainfall was observed in southeastern Spain in the first half of September. Due to an almost stationary cut-off low, torrential rainfall and strong winds were observed over the period 10-15 September. The most affected areas included Valencia, Alicante, Murcia, Albacete, Almería and Malaga provinces. Some areas of Valencia region, especially the Vega Baja del Segura plain, got

over 400 mm of rain over 48 hours. The highest total was 521 mm, measured in Orihuela (Alicante province). Six stations reported new records of 24-hour precipitation. At Ontinyent, 296.4 mm of rain was recorded in 24 hours, which equates to about half the yearly average. This is the second highest daily rainfall total on record, behind the 316.0 mm which fell on 04 November 1987. On average for the affected area, the equivalent of a year's rain accumulated on just one day (from the morning of the 12th to the morning of the 13th). The storm was exceptional due to the lack of similar precedents in at least the last 100 years in the Vega Baja del Segura, the area most affected by the rainy season. Consequently, rivers broke their banks in several locations, flash floods damaged several roads and cars were swept away. Flights, railway and ship traffic was disturbed and at least six people died, around 3500 were displaced, including 2000 residents of the town of Santomera.

Northwestern and southeastern parts Europe were hit by several cyclonic systems from mid to end of the month. Upland areas in the western UK recorded more than 200 mm of rain from 21 to 30 September. Western Norway was hit by a series of intense storms mid of September, with trees uprooted, downed power lines, floods, landslides and the closing of several roads. In Bergen, 75 mm of rain was recorded in 24 hours. Albania also experienced severe thunderstorms and heavy rain in September which caused flash flooding in some areas.

October

Very intense precipitation over the northwestern part of the European Russia with up to 30 to 50 mm per day and often in the form of snow already. Normal precipitation amounts were exceeded by two or more times in many regions.

On 3 and 4 October, a low-pressure system passed over Ireland and the United Kingdom as the post-tropical cyclone Ex-Lorenzo, bringing disruptive winds and heavy rain. Lorenzo was still a powerful and very large cyclone. Hurricane-force winds extended outward up to 240 km from the center and tropical-storm-force up to 630 km. On the following days, it moved over Central Europe with rapid weakening, bringing some more rain, but less severe. Finally, LORENZO disappeared after becoming a shallow Low west of the Black Sea on 6 October. Some areas of northwest Ireland saw between 50mm and 100mm of rain.

In mid and late October, deep troughs and a cut off Low over Spain and later the Mediterranean caused heavy rain and thunderstorms. Spain, France and Italy were particularly affected by the torrential rainfall and even several tornadoes. Since warm air was advected from the subtropics and the temperatures of the Mediterranean Sea were still very high, about 23°C at this time, the air masses could absorb a lot of humidity. Due to a ridge over Central and Eastern Europe, the Low and its fronts were almost stationary, resulting in extreme rainfall totals over this area, especially near mountains such as the Pyrenees and the Massif Central.

Starting on 13 October, more than 100 forest fires broke out across central-western (south of Beirut) and northern Lebanon. Over 1,200 hectares of land were burned. At least 72 people were injured. In the districts of Chouf and Nakkar, people were displaced after fires extended to populated areas. Twenty landmines exploded because of the fires. On 15 October, Lebanon requested assistance through the EU Civil Protection Mechanism for aerial forest firefighting capacities.

Northern parts of Northern Europe saw a sudden and outstanding cooling at the end of the month with much snow and low temperatures for that time of year. In Sweden, the temperature dropped

below -20 °C for the first time in 2019. At its lowest, it was -21.1 ° in the well-known cold hole Nikkaluokta in northern Lapland.

November

Above-normal temperatures occurred over most of the RA VI Region in November, especially over the southeastern part. In Israel, for example, November was warm - daytime temperatures in November were 2-3 °C warmer than normal. Night-time temperatures were 1-2 °C warmer than normal. November was one of the warmest in terms of maximum temperatures. The highest temperatures occurred mainly during the first half of the month with temperatures 4-5 °C above normal. In the Coastal Plain, the Northern Negev, and the Northern Valleys maximum temperatures were as high as 28-30 °C, and in the Jordan Valley and the Arava – 30-35 °C. Such a sequence of warm days in November is unusual. In the past 70 years there were similar sequences only in 1962 and 2010. Records of the few stations that operated even further in the past reveal that in 1933 there was a similar warm sequence in the Coastal Plain and the Negev, and in Jerusalem, where measurements date back to the mid-19th century, there were such events in 1878 and 1922.

Several major storms passed over the Mediterranean region during almost the whole month of November 2019, bringing heavy precipitation and devastating impact due to landslides, heavy snow and flooding in various countries, especially at steep coasts and near mountain chains. Already at the beginning of the month on 3 November, a storm affected parts of France, Italy and Spain. In France, gusts up to 163 km/h (Cap Ferret, Gironde) brought down trees and power lines. That gust was only slightly lower than the highest ever measured November gust near the French Atlantic coast (169 km/h in November 1996). Several stations in western France had new local November records of wind gusts since start of data in 1981, including Bordeaux with 120 km/h. Coastal waves up to 15m had been observed. In Italy, local rainfall of 57mm in one hour was recorded (Sestri Levante, Liguria) and waves of over 4 metres were reported along the Ligurian coast. Several families were evacuated, also further south in the Campania Region. Northern parts of Spain also were affected by gusts up to above 150 km/h; Santander airport, too, had a new November record at 130 km/h. Heavy precipitation occurred in Galicia and the Pyrenees.

The Medicane Trudy developed from a cut off low and brought heavy rains to Italy and the Balkan coasts mid of November. In Italy, 90mm came on November 12-13, at the Balkan coasts up to 78mm with heavy thunderstorms. Storm gusts up to 130 km/h occurred in the south of Italy and over the Adriatic Sea. This resulted in a high storm surge and high tide peaks, which led to heavy flooding especially on the Adriatic coasts of Italy and Croatia. Due to high water temperatures of around 23°C, Trudy was able to take up enormous amounts of water vapour and finally developed into a Medicane with a very pronounced eye. The pressure dropped to 990 hPa.

November brought exceptionally wintry conditions to Scandinavia. An exceptional snow depth in Tromsö (northern Norway) had been measured on 6 November. Even the downtown area registered a depth around 70cm. The last time when so much snow was seen in Tromsö so early in the autumn was in 1922. It occurred within a period of the season's first major snowfall, and sub-freezing temperatures affected the whole country including the south and caused many accidents due to slippery roads. The snowfall came along with remarkably low temperatures. In Bardufoss, located 70km south of Tromsö, a daily minimum of -29.8°C was registered on 11 November. The lowest reading at Synop stations in Norway that day, however, was in Kautokeino, also located in the north,

with -34.4°C. A daily minimum temperature of -34.6°C was measured in Nikkaluokta in northern Sweden the same day. There were only three days in the last 75 years before with similar or lower temperatures in Sweden in early November: 4 November 1952 (-39°C in Nikkaluokta), 3 November 1968 (-35.0°C in Vittangi), and 8 November 1971 (-34.1°C in Vittangi).

December

Several storms hit Western, Central and Southern Europe bringing strong winds and heavy rain causing flash floods. A first storm (named Olaf in Central Europe) occurred over Iberia in early December with flooding in France and Spain. In Cannes, southern France, 109mm of rain fell in 3 hours and 187mm in 24 hours which was the second highest daily total on record behind 3 October 2015. In Spaini, the station San Javier recorded more than 120mm of rain in 24 hours on 2-3 December. Waves up to 4 metres and more than 300mm rainfall in 48 hours (2-4 December) were observed in Valencia region. In Mallorca, 123mm of rain fell in 12 hours in Santa Maria del Cami (northwest Mallorca) and gusts of 90 km/h were recorded in Puig de Alfabia (Mallorca highlands, 1067m elevation). Storm Atiyah brought gusts of hurricane force, rough sea and heavy rain across Ireland and the UK on 8 and 9 December and also touched northern France with gusts reaching up to 130 km/h in Brittany (Pointe du Raz, Finistère). End of December a winter storm hit Portugal and Spain with gusts up to 150-180 km/h and heavy precipitation events.

Northern and Eastern Europe were hit by several winter storms as well with gusty winds and record warm temperatures. Parts of Iceland saw heavy snowfall and hurricane-force gales up to nearly 190 km/h on 10-11 December, resulting in snow depths up to 9m near buildings. The Baltic States, too, were affected by this storm. On 18 December, severe storm gusts up to 98 km/h were recorded at the coast of Latvia (Ventspils). Trees fell down, power outages had been reported. The water level of the southern gulf of Riga increased to a dangerous level, warning was issued for the lowlands. The storm also brought warm air, and a new country record for December maximum temperature was reached in Riga at 10.7°C the same day. Temperature in Moscow rose to 6.2°C on 22 December, a new local record in a series of about 140 years. There was no snow that time; trucks with artificial snow were sent. On normal average, Moscow has a snow cover of 16cm at the beginning of the third decade of December.

1. Introduction

The Annual Bulletin on the Climate in WMO Region VI (Europe and Middle East with 51 Members) provides an overview of climate characteristics and phenomena in Europe and the Middle East for the preceding year. It is mainly based on dedicated national reports from RA VI National Meteorological and Hydrological Services (NMHSs) as well as general climate monitoring information from their official websites. The Bulletin provides an excellent example of international collaboration across cultural and political borders since its first publication in 1994. The Bulletin is seen as a regional contribution to WMO's climate system monitoring, complementing and detailing well-known regular global assessments, such as WMO's annual "State of the Global Climate" and the "State of the Climate" published in the Bulletin of the American Meteorological Society (BAMS). The evolution of the RA VI Regional Climate Centre Network (RCC Network) allowed adding a couple of RA VI-wide maps in order to provide a certain degree of consistency across the information and the national borders. Otherwise, basic methodologies for, and operations of, climate monitoring activities still differ among the various RA VI NMHSs. Maps and information compiled in this Bulletin are the result of a selection process and are mainly taken from reports, maps and statistics provided by the NMHSs, websites of NMHSs as well as the webpages of the RA VI RCC Network (RCC website) which provide useful additional information and regularly produced maps etc. The Bulletin is intended to serve primarily NMHSs in the RA VI Region but it might also be interesting for public institutions, research institutes, universities and others.

This annual bulletin includes three parts: the annual, seasonal and monthly survey of the state of the climate in 2020. The long time series of temperature, precipitation and sunshine duration provided by NMHSs in order to illustrate long-term variability up to 2020 (previously presented in section 5) will be made available on the RA VI webpages.

Notes:

Maps of the RA VI RCC Network are based on the following data sources:

- Temperature: CLIMAT data and ship observations provided by the Global Collecting Centre (GCC), operated by the Deutscher Wetterdienst
- Precipitation: Global Precipitation Climatology Centre (GPCC; Schneider et al. 2018), operated by the Deutscher Wetterdienst
- Sunshine: Meteosat satellite data (introduced in 2018).
- Anomaly maps of climate indices are provided by the RCC De Bilt Node on Climate Data Services (RCC Node-CD) via the European Climate Assessment & Dataset project (ECA&D) run by the Royal Netherlands Meteorological Institute (KNMI)

1.1. Definition of subregions

The following subregions are used in this bulletin:

Central and Western Europe (14 countries):

Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxembourg, Monaco, Netherlands, Poland, Slovakia, Switzerland, and United Kingdom

Nordic and Baltic Region (9 countries/territories):

Denmark, Estonia, Finland, Greenland, Iceland, Latvia, Lithuania, Norway, and Sweden

Iberia (2 countries):

Portugal, and Spain

Mediterranean, Italian and Balkan Peninsula (12 countries):

Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, Italy, Malta, Montenegro, North Macedonia, Serbia, Slovenia, and Türkiye

Eastern Europe (5 countries):

Belarus, European Russia, Moldova, Romania, and Ukraine

Middle East (9 countries):

Armenia, Azerbaijan, Cyprus, Georgia, Israel, Jordan, Lebanon, Syria, and western Kazakhstan

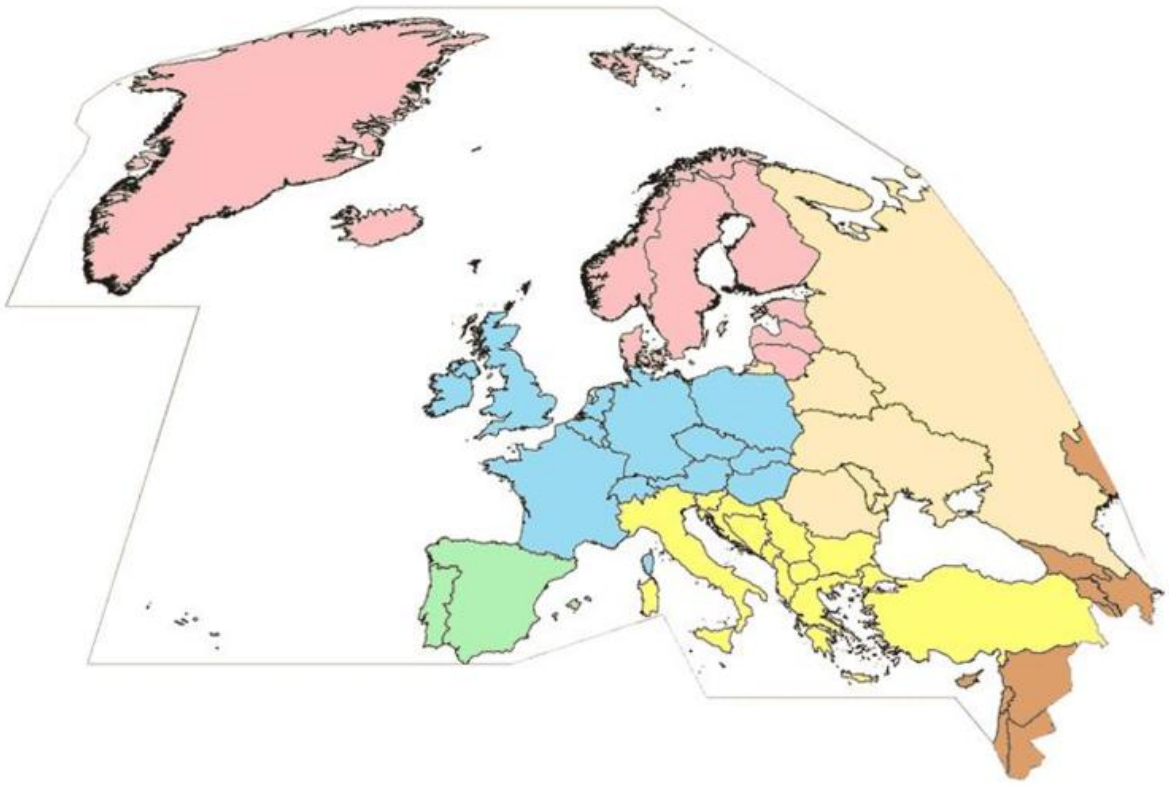

Figure 1-1: *Definitions of the 6 subregions used in this bulletin.*

1.2. The climate in 2020 – Overview

1.2.1. Anomalies

Temperature

Based on both the E-OBS (van der Schrier et al. 2013) and the Global Historical Climate Network (GHCN) v4.0.1 dataset (Menne et al. 2018), 2020 was the warmest year since start of the time series in 1951 and 1900 respectively with annual anomalies of +1.75 °C and +1.6 °C (relative to the 1981–2010 period). For the RA VI Region, temperatures were 1.66 °C above the 1981–2010 average. Largest anomalies occurred in the northeast with anomalies larger than +2 °C (for example Finland, Baltic countries and northern European Russia). All seasons were warmer than normal in all subregions. Especially the winter of 2019/2020 was warm over the RA VI Region with an anomaly of +3.2 °C. Highest seasonal temperature anomaly was +5.31 °C in Eastern Europe during winter.

Precipitation

Precipitation amounts across the RA VI Region were mostly close to normal in 2020. For the RA VI land areas as a whole, the annual precipitation was slightly above normal (w.r.t. 1981–2010). In eastern and southeastern parts of the RA VI Region, the year was characterized by a precipitation deficit which was as low as 40%–60% in wide regions around the Black Sea as well as in west Kazakhstan. Germany and most parts of France and the Iberian Peninsula also received below normal precipitation which reached as low as 60%. The northern parts of Europe on the other hand received above-normal precipitation mostly up to 125% of normal. Similarly, the eastern parts of the Iberian Peninsula as well as many countries east of Germany reported above-normal precipitation. During the year, there was significant variation between seasons. After a mostly wet winter and spring season, autumn and summer 2020 saw mostly drier than normal conditions. The Mediterranean and Balkans for example received only 66% of the normal rainfall during autumn.

Sunshine Duration

Most of the RA VI Region received more sunshine than normal during 2020 (w.r.t. 1986–2015). Central and Western Europe as well as the Mediterranean and the Balkans region recorded the highest surpluses in terms of sunshine duration (about 170 hours). In case of Central and Western Europe this surplus was due to a very sunny spring season with 155 hours more sunshine than normal.

1.2.2. Events

- Stormy start into 2020, February was an extraordinary stormy month
- Warm winter (see above)
- Dry conditions over the RA VI Region during summer and autumn (see above)
- Cold wave in April and May affecting Western, Central Europe, Mediterranean and Balkans
- Period of heat waves between May and September over the RA VI Region especially in the Middle East, Eastern Europe and Türkiye
- Extreme weather events (thunderstorms, flooding, etc.) during summer due to heat waves

2. Annual survey

The climate of 2020 was characterized by a broad range of spatial and temporal anomalies outlined in section 1.2. This section presents an overview of the spatial patterns of mean annual climate conditions in 2020 and anomalies of the selected climate variables: sea level pressure, surface air temperature, precipitation, sunshine duration and snow. Throughout this report, 1981–2010 is the baseline reference period used unless otherwise specified. Long-term trends in temperature and precipitation indices are presented in section 2.2. Section 3 and 4 present the seasonal and monthly patterns and statistics for selected climate variables including also reports from individual countries. The long time series of temperature, precipitation and sunshine duration provided by NMHSs in order to illustrate long-term variability up to 2020 (previously presented in section 5) will be made available on the RA VI webpages.

2.1 Annual averages and anomalies of selected essential climate variables

2.1.1. Sea level pressure

Generally, mean annual sea level pressure distribution in 2020 over the WMO Region VI (RA VI) was dominated on one hand by a band of low pressure with the minimum pressure extending from southern Greenland over Iceland until the Barents Sea. On the other hand, there was a high-pressure belt with maximum pressure in the area of the Azores (Azores High) extending further across Southern and Central Europe into Russia.

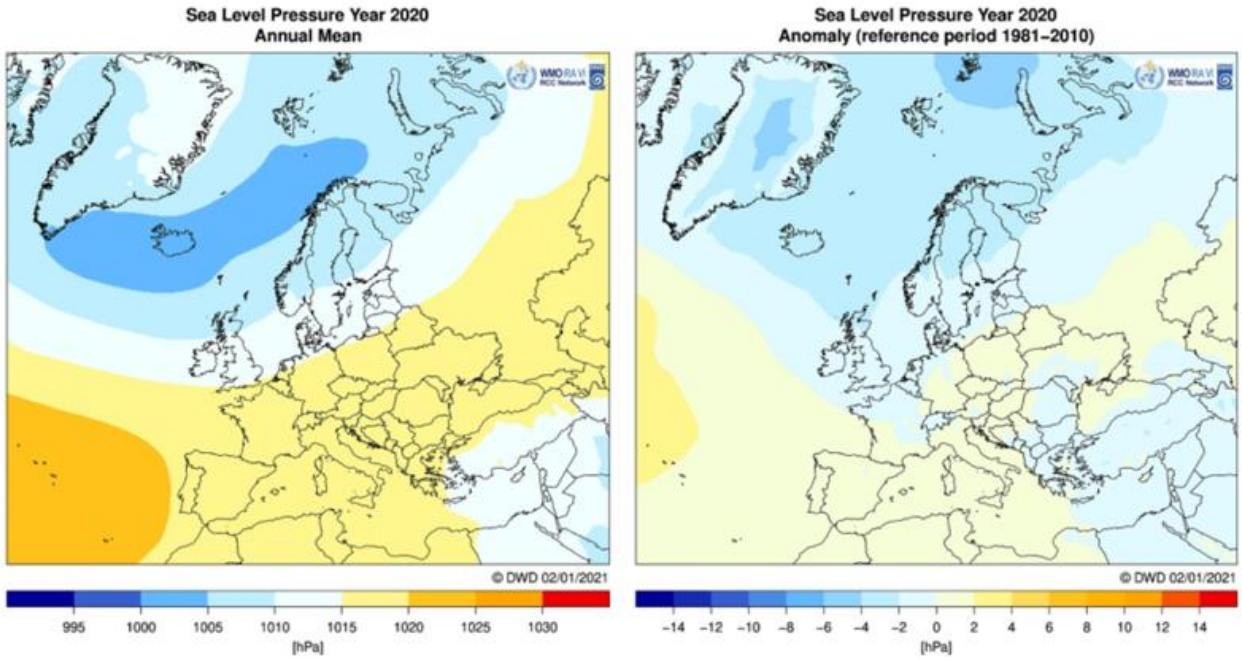

Figure 2-1: *Annual mean sea level pressure in hPa (left) and anomalies in hPa relative to 1981–2010 (right) for the year 2020. Source: RCC-CM website.*

Over most parts of the RA VI Region the mean sea level pressure in 2020 was around normal with anomalies between −2 hPa and +2 hPa. Larger differences only occurred over northern parts of Scandinavia, Iceland and especially Greenland, with negative anomalies as low as −4 hPa to −6 hPa. The Azores High was slightly more intense than normal on annual average.

2.1.2. Temperature

Mean annual temperatures in 2020 were higher than normal (w.r.t. 1981–2010) over almost the whole RA VI Region. Temperature anomalies varied mostly between +1 °C and +3 °C. Largest annual anomalies occurred in Eastern Europe, where temperatures were 2.18 °C above normal, followed by Scandinavia and the Baltic States (+1.55 °C), the Middle East (+1.46 °C), Central and Western Europe (+1.43 °C) and the Mediterranean and Balkan Peninsula (+1.34 °C). The annual average anomaly of +1.01 °C was recorded over the Iberian Peninsula. For the European region as a whole, 2020 was the warmest year since at least 1950 considering the E-OBS data set (van der Schrier et al. 2013) and the Global Historical Climate Network (GHCN) v4.0.1 datasets (Menne et al. 2018; Bissolli et al. 2021) with an overall anomaly (with respect to the base period 1981–2010) of +1.75 °C (**Figure 2-3**) and +1.6 °C respectively. For many countries the year proved to be the warmest on record: Latvia, +2.4 °C; Belgium, +1.6 °C; Belarus, +2.1 °C; Estonia, +2.4 °C; Lithuania, +2.3 °C; Luxembourg, +1.5 °C; Kazakhstan, +1.9 °C; Spain, +1.0 °C; Norway, +1.8 °C; Ukraine, +2.8 °C (w.r.t 1961–1990); (European) Russia, +2.86 °C (w.r.t. 1961–1990); Moldova, +2.6 °C (see also Table 2-1).

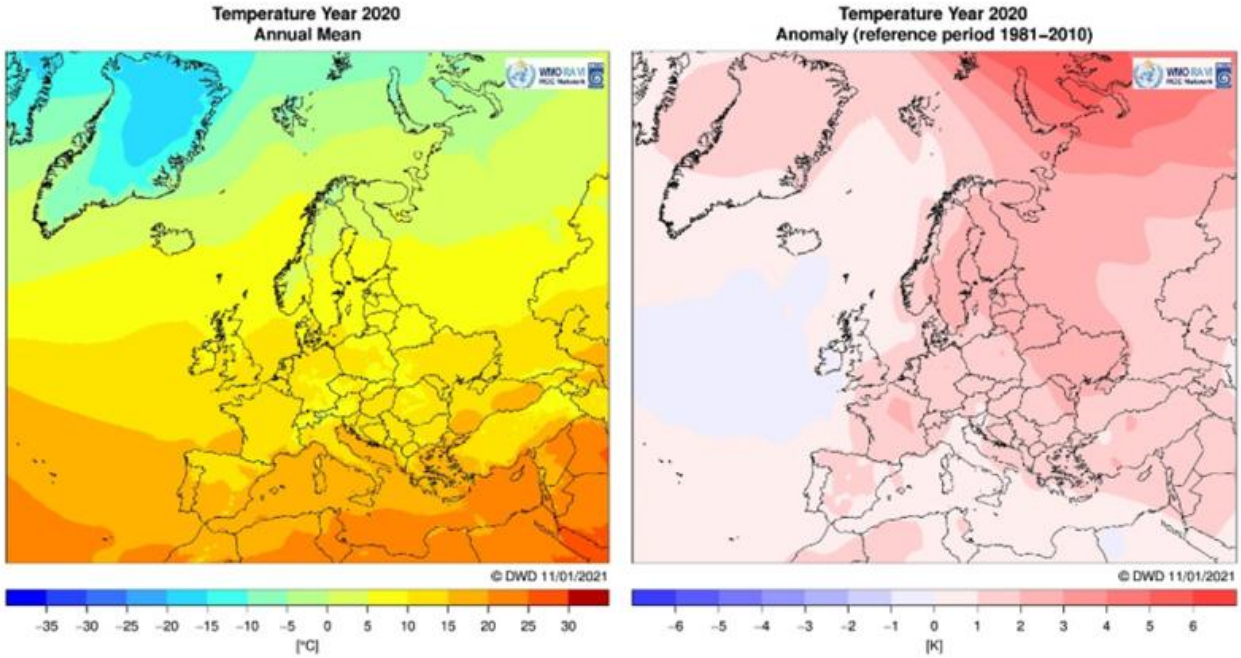

Figure 2-2: *Annual mean temperature in °C (left) and anomalies in °C relative to 1981–2010 (right) for the year 2020. Source: RCC-CM website.*

In 2020, all subregions within the RA VI Region showed positive anomalies ranging from +1.0 °C over the Iberian Peninsula to +2.18 °C over Eastern Europe. The only area with slightly negative annual anomalies was over the central North Atlantic.

The annual mean temperature over **Western and Central Europe** was 10.93 °C and thus 1.43 °C warmer than normal. Some countries showed even higher anomalies and reached new heat records. In Belgium (+1.6 °C) and Luxembourg (+1.5 °C) it was the warmest year since start of the measurements. For Denmark (+1.5 °C), Germany (+2.2 °C) and in Poland (+1.7 °C) 2020 was the second warmest year.

Scandinavia and the Baltic States recorded an anomaly of +1.55 °C. High positive anomalies were measured in Sweden, Finland and the Baltic States. Lithuania reported its warmest year on record with 2.3 °C above normal as well as Estonia with an anomaly of +2.4 °C.

The **Iberian Peninsula** saw the smallest anomalies among the subregions with temperatures being 1.01 °C above normal. However, 2020 was still the warmest year for Spain (+1 °C) since 1961 and the fourth warmest for Portugal (+0.96 °C) since 1931.

The **Mediterranean and the Balkan** countries also recorded warmer than normal temperatures. The anomaly for this subregion was +1.34 °C. The year 2020 was among the top five of the warmest years in Bulgaria (second warmest, +1.9 °C), Cyprus (third warmest, +1.1 °C), Italy (fifth warmest, +1.54 °C), Türkiye (third warmest, +1.5 °C) and Slovenia (fifth warmest, +1.23 °C).

In **Eastern Europe,** 2020 was exceptionally warmer than normal (+2.18 °C). Especially high anomalies were recorded in Russia with 2.86 °C above normal followed by the Ukraine (+2.8 °C) and Moldova (+2.6 °C).

The **Middle East** had an overall warm year as well. It was 1.45 °C warmer than normal. Kazakhstan (+1.9 °C) observed a new annual record with 2020 being its warmest year since 1936.

Globally, 2020 was one of the three warmest years on record (WMO 2021, Dunn et al. 2021). The past six years, including 2020, have been the six warmest years on record. The global mean temperature for 2020 was around 0.6°C above the 1981–2010 average (Dunn et al. 2021) and 1.2 ± 0.1 °C above the 1850–1900 baseline (WMO 2021).

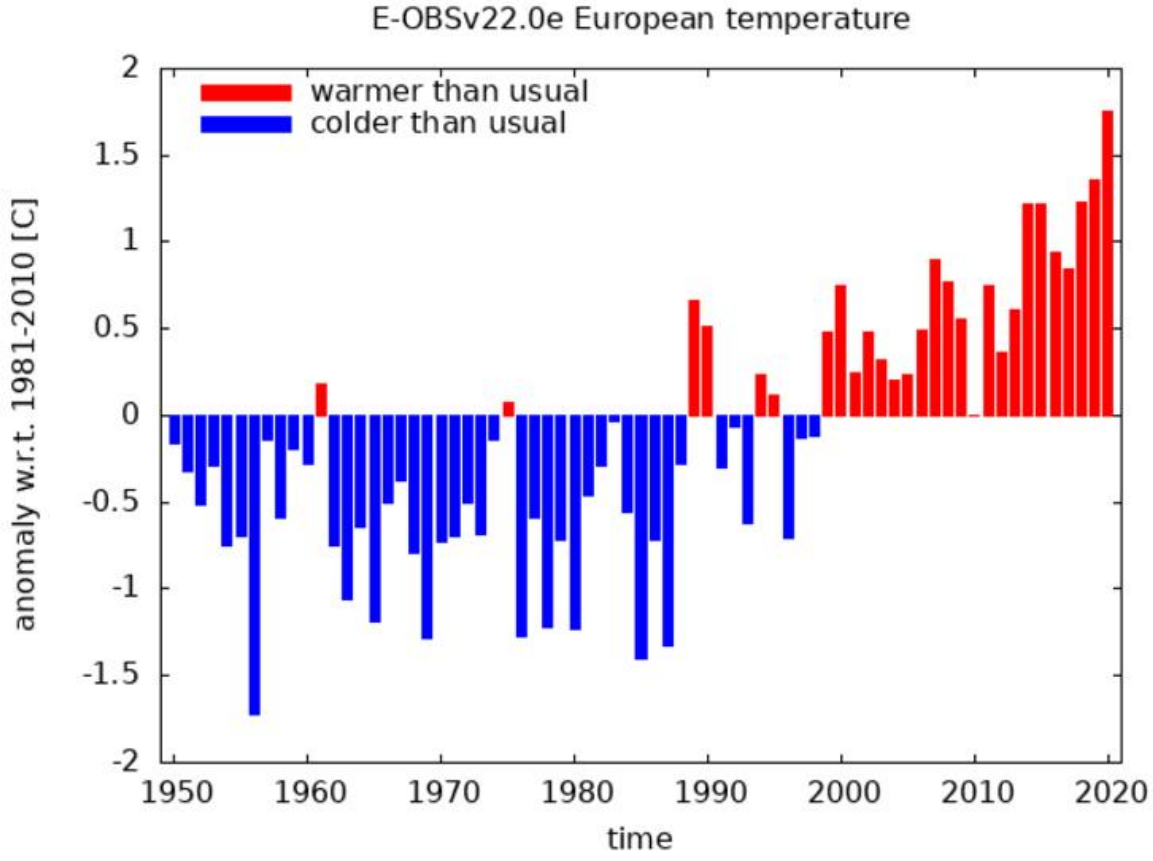

Figure 2-3: *Annual temperature anomalies in° C relative to 1981–2010 for the years 1950–2020 for Europe (land area; 34°N–71°N and 25°W–40°E; based on the E-OBS dataset). Source: Royal Netherlands Meteorological Institute Netherlands, KNMI.*

United Kingdom	3	+0.8	1981–2010	1884

2.1.3. Precipitation

For the RA VI land areas as a whole, precipitation in 2020 was near average (w.r.t. 1981–2010). For large parts of Iberia, France, Germany and especially the Southeast and the Baltic states, the year was characterized by below-normal conditions. Exceptionally dry conditions (< 10th percentile), with deficits as low as 20% to 60% were recorded in wide regions around the Black Sea as well as in parts of the Baltic countries and the Middle East. Conversely, northern parts of Europe, northeastern Spain, some regions of Italy as well as many countries east of Germany received above-normal precipitation, mostly around 125% of normal, some parts even up to 167% of normal.

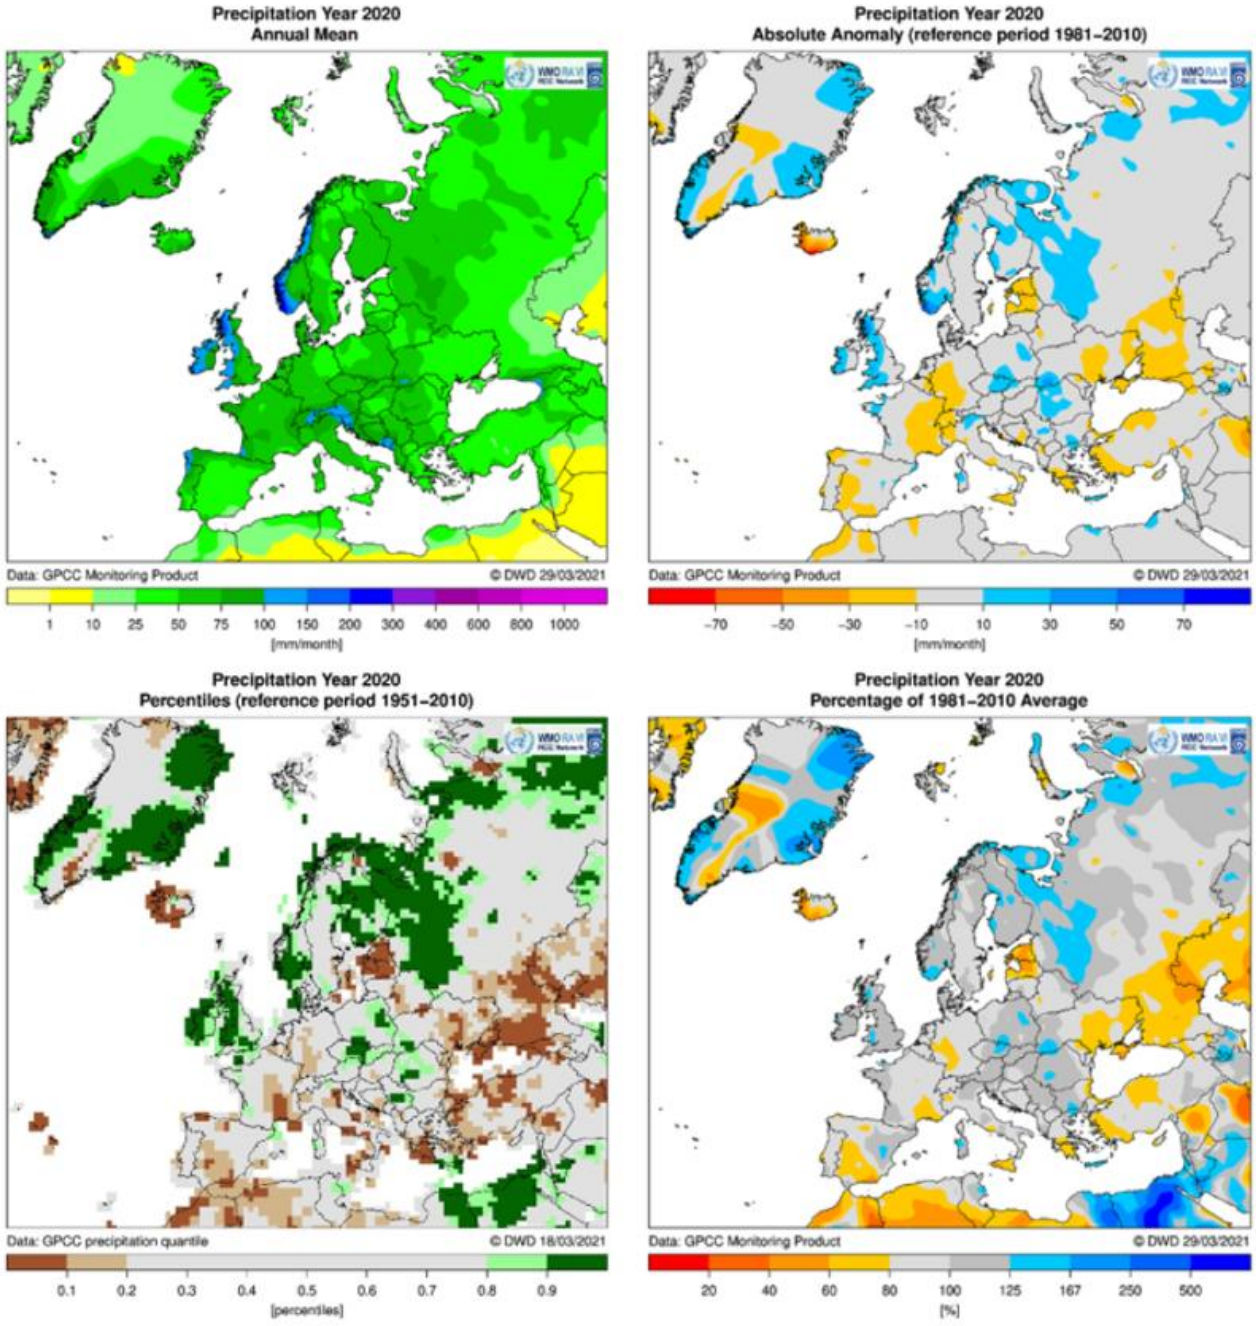

Figure 2-4: *Annual total precipitation (left, top), precipitation anomalies in mm per month relative to 1981–2010 (right, top) and percentiles relative to 1951-2010 (left, bottom) as well as percentage of precipitation in % (right, bottom) relative to1981–2010 for the year 2020. Source: RCC-CM website.*

Across **Central and Western Europe,** precipitation for the year was close to normal (99% of normal precipitation). United Kingdom and Ireland, however, saw much wetter-than-normal conditions with 116% and 121% of normal precipitation respectively, making 2020 United Kingdom's fifth and Ireland's third wettest year on record.

The subregion **Scandinavia and the Baltic States** showed the largest precipitation surplus with 118% of normal precipitation. Norway reported +293 mm more than normal ranking 2020 the second wettest year on record. All Baltic States, however, experienced drier than normal conditions. For Lithuania, 2020 was the seventh driest year with a deficit of 40 mm.[1]

The **Iberian Peninsula** saw slightly lower than normal precipitation (93% of normal). Spain recorded regionally only 60%–80% of normal precipitation but for the country as a whole precipitation amounts were near-normal.

The **Mediterranean and the Balkans** received also slightly lower than normal precipitation amounts. Several countries saw wetter than normal conditions with anomalies mostly up to 125% of normal amounts. Other countries recorded negative precipitation anomalies, for example Bosnia and Herzegovina received 171 mm less precipitation than normal.

In the **Middle East,** there were countries with both drier and wetter than normal conditions as well. Kazakhstan had its seventh driest year since 1936 with 71 mm less rain than normal. Syria also saw drier than normal conditions with regionally less than 60% of normal precipitation. In Israel, Jordan and Lebanon wetter conditions prevailed. For the region as a whole 112% of normal precipitation was recorded.

Eastern Europe as a whole saw close to normal conditions with 97% of normal precipitation. Largest deficits were observed in the areas around the Black Sea and in southern European Russia.

[1] The RCC annual precipitation anomaly map for 2020 shows large negative anomalies for Estonia and slighly negative anomalies for Lithuania. It turned out that these anomalies do not correctly represent the anomalies reported by the respective NMHSs included in Table 2-2. The issue is likely related to incorrect decoded real-time data used for the grid generation. As a result, these grid point values may deviate considerably from actual precipitation totals.

Table 2-2: Rank statistics and anomalies of annual precipitation anomalies in 2020 as reported by the National Meteorological and Hydrological Services (NMHSs).

Country	Rank	Annual Anomaly [mm][2]	Reference period	Start of time series
Europe (35°–75°N, 25°W–40°E, E-OBS)	-	-	-	-

Moldova	-	+13.0	1981–2010	1891
Montenegro	-	−139.0	1981–2010	1949
North Macedonia	17 (driest)	−144.0	1981–2010	1981
Norway	2 (wettest)	+293.0	1981–2010	1900
Poland	16	+45.2	1981–2010	1966
Portugal	-	−131.0	1971–2000	1931
Romania	-	+24.4	1981–2010	1961
Russia	42 (wettest)	+3.6	1961–1990	1936
Serbia	18 (wettest)	+64.3	1981–2010	1951
Slovenia	25 (driest)	+24.6	1981–2010	1961
Spain	24 (driest)	−35.0	1981–2010	1961
Sweden	17 (wettest)-	+36.0	1981–2010	1880-
Switzerland	58 (driest)	91% of normal	1981–2010	1864
Türkiye	-	−73.9	1981–2010	1971
Ukraine	39 (driest)	−59.0	1961–1990	1891
United Kingdom	5 (wettest)	116% of normal	1981–2010	1862

[2] By default anomalies are given in mm unless otherwise specified.

2.1.4. Sunshine duration

The year 2020 was sunnier than normal over most parts of the RA VI Region (w.r.t. 1986–2015). Especially Central and Western Europe, Scandinavia and Eastern Europe recorded positive anomalies with between 200 and 500 more hours of sunshine. Deficits of up to 200 hours less sunshine than normal were observed in parts of Portugal, Spain, Russia, Belarus and the Middle East. Some central parts of the North Atlantic saw particularly little sunshine in contrast to the European continent with a duration below the lowest decile. Annual and seasonal average anomalies of sunshine duration are shown in **Table 3-6**.

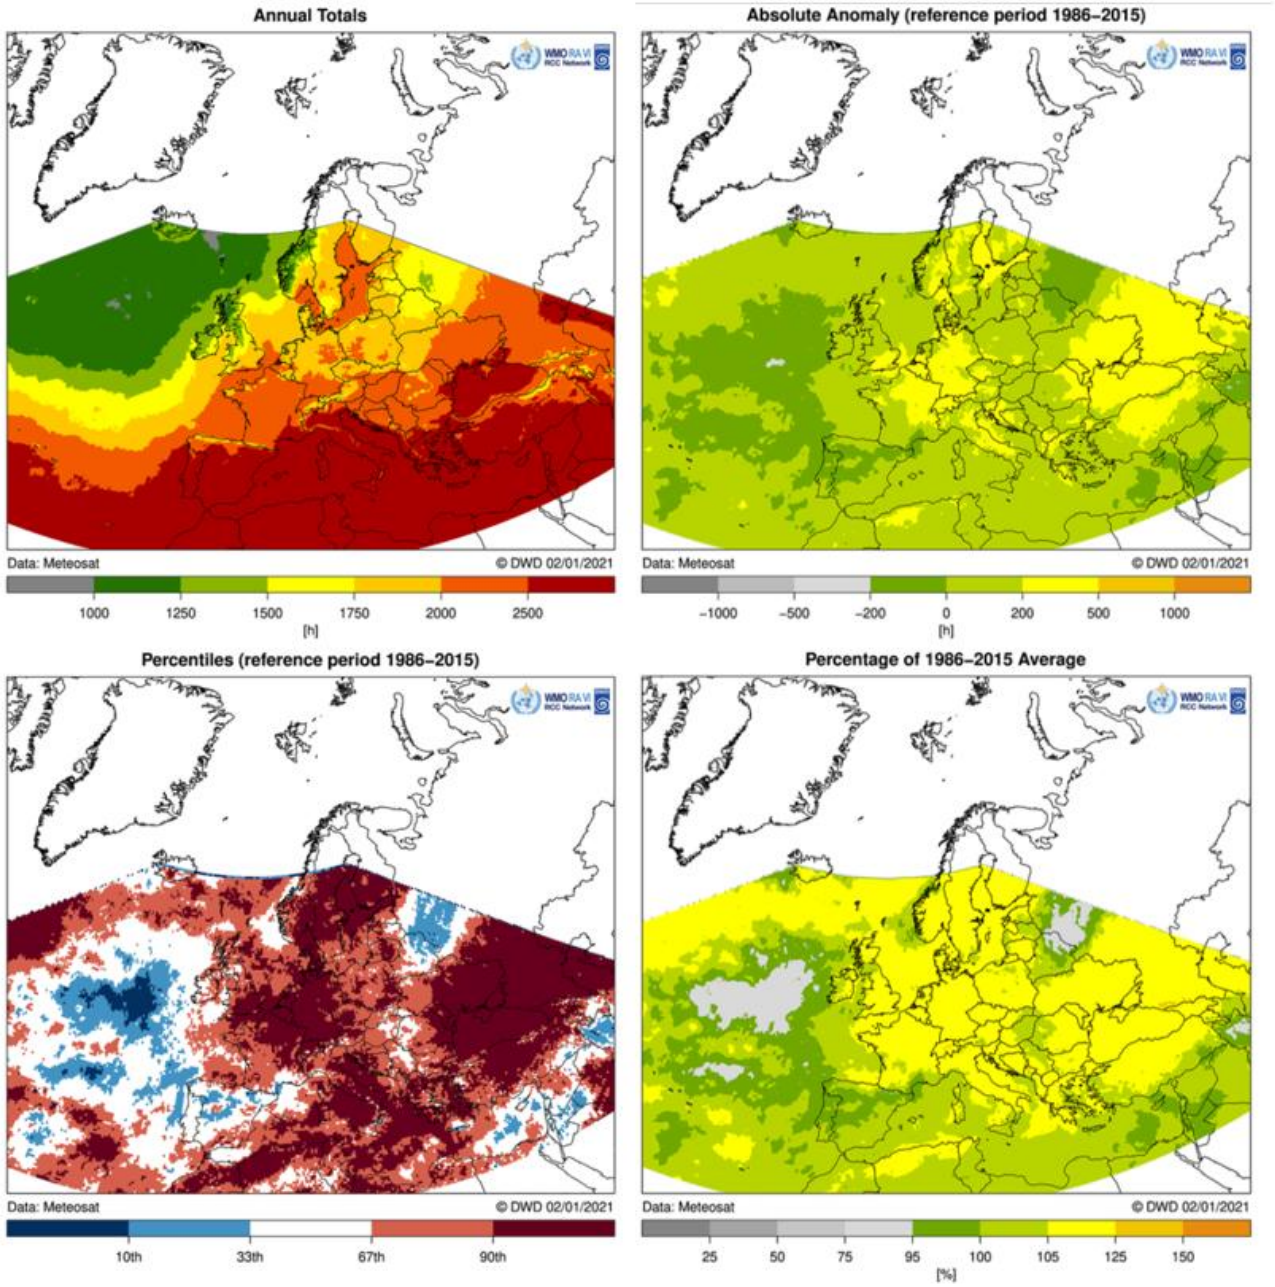

Figure 2-5: *Annual sum of sunshine duration in hours (upper left) as well as absolute anomalies in hours (upper right), percentiles (lower left) and percentages of the long-term mean (lower right) relative to 1986–2015 for the year 2020. Source: RCC-CM website.*

Central and Western Europe received the largest sunshine surplus with 177 hours more sunshine than normal. This was mainly due to a very sunny spring (surplus of 155 sunshine hours).

The **Mediterranean and the Balkans** saw sunnier than normal conditions as well, with around 173 hours more sunshine than normal. Here all seasons, except for the summer, contributed to the overall sunshine surplus. **Eastern Europe** received a surplus of 106 hours of sunshine. All seasons were sunnier than normal with surpluses between 20 and 40 hours of sunshine. Lowest surpluses for sunshine duration were observed over the **Iberian Peninsula** with an average surplus of only 7 sunshine hours. A deficit of 60 hours was observed during summer, the other seasons were slightly sunnier than normal. The **Middle East** received above-normal sunshine hours as well with 78 hours more sunshine than normal. The parts of **Scandinavia and the Baltic States** covered by the maps experienced mostly surpluses of sunshine duration up to 125%. The areal means are not representing the entire subregion but only the parts covered by the product (see **Figure 2-5**).

2.1.5. Drought situation

When looking at the Global Precipitation Climatology Centre Drought Index (GPCC-DI, Ziese et al. 2014) as a metric for characterizing meteorological drought, the values for the year as a whole ranged mostly between −1 and 1 (see **Figure 2-6**). Most regions with large precipitation deficits (for example areas neighbouring the Black Sea and the Baltic countries, see also 2.1.3) appear here with values between 0 and −1 indicating mild drought conditions on annual average. Over parts of Spain and the Middle East the drought situation was even classified as moderate drought with values as low as −1.5 (Spain) or lower (Syria, Israel). For some countries, this year's total precipitation ranked among the top 10 of the driest years.

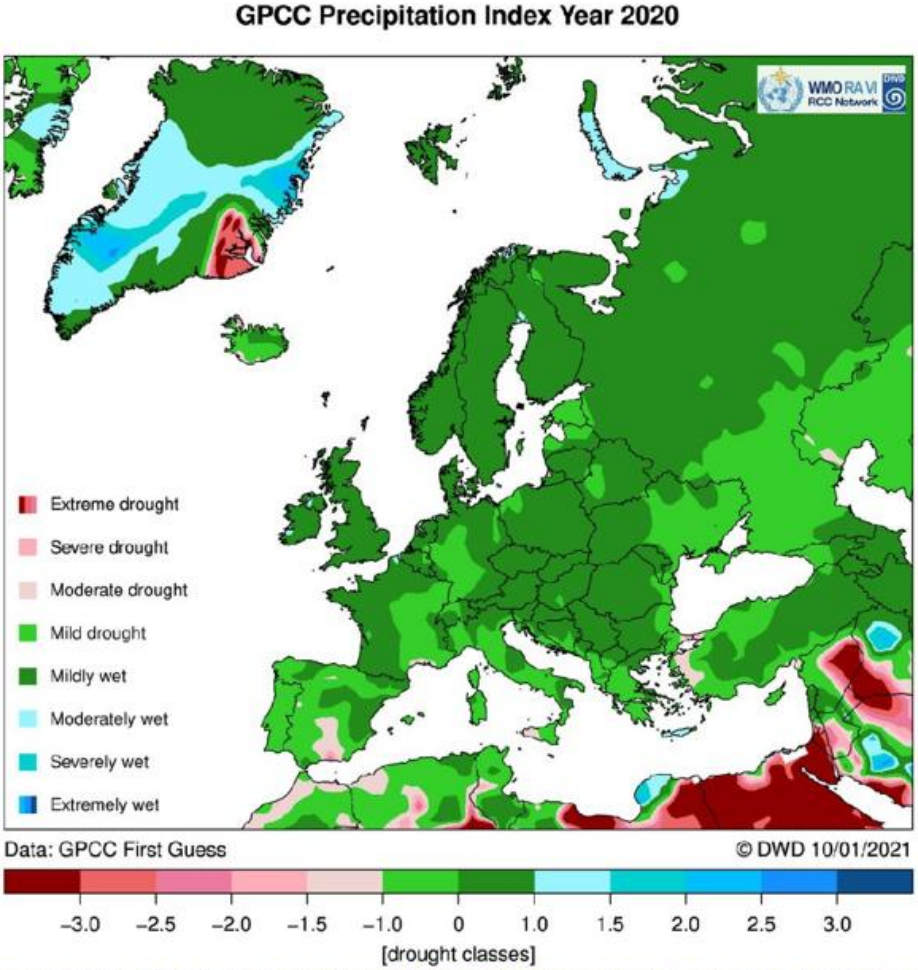

Figure 2-6: *Annual GPCC –DI (GPCC-Drought Index) in drought classes relative to 1961–1990 for the year 2020. Source: RCC-CM website.*

2.1.6. Snow cover

In January, there was considerable snow in Iceland, Scandinavia and Eastern Europe as well as the Alps. These regions were covered by snow for the whole month. Altai is a good example for the high amount of snow in Russia, where snow piles were above human height. In the North Caucasus, the amount of snow reached up to 30 mm per day. In Nur-Sultan, the capital of Kazakhstan, no such abundance of snow has been seen for more than 50 years in January. Due to the high-pressure influence from the Atlantic Ocean and high temperatures, there was no snow in the west, the south and most parts of Central Europe.

In February, there was considerable snow in Iceland, the north of Scandinavia and northeastern Europe as well as the Alps. These regions were covered by snow for almost the entire month. In Finland and Sweden, the country was split into two parts: the southern part experienced exceptionally low (or no) snow coverage, whereas in the northern part, an unusually high snow depth of up to 120 cm was measured. Due to the extended high-pressure influence from the Atlantic Ocean into the European continent and high temperatures, there was no snow in Western, Southern and most parts of Central Europe.

In March, due to warm temperatures and sparse snowfall in the preceding winter there was consequently a less extended snow cover in spring. While snow covered much of Norway and the northern parts of Sweden and Finland during almost the entire month of March, the southern end of each of these countries saw less than 15 days of snow cover, southern Sweden was even completely snow-free.

In April, parts of northern and central Finland received record-breaking amounts of snowfall. At Sodankylä, the Tahtela weather station reported 1.25 m of snow on 14 April, breaking the previous record of 1.19 m set on 6 April 2000. Northern Norway saw extreme snowfall as well. At the official station in Tromsø, 30 cm of snow fell within one day on 5 April. In other parts of the town, a daily accumulation of almost 1.2 m was reported the same day. Over the whole snow season, 6.5 m of snow had fallen, the highest snowfall since the 1999/2000 snow season. The snow depth on 6 April was 160 cm, just 13 cm away from the highest depth on record in 1997. In Ystnes, Finnmark, the snow was 2.8 m high on 1 April, which was the highest snow depth registered in the lowland areas of Troms and Finnmark. In Iceland, up to 1.5 m of snow fell on 4–5 April. Switzerland, on the contrary experienced its mildest winter since observations started and, as a consequence, there was hardly any snow at that time.

In November, the dry high-pressure weather brought Austria one of the ten Novembers with the least precipitation in measurement history. For Austria as a whole, there was 74% less precipitation than normal. This also had an impact on the snow situation. Below 1 000 m above sea level, this November remained almost snow-free. In the high mountains, the snow cover from October remained partly intact, but the total daily amount of new snow was significantly below the average. For example, at the Rudolfshütte weather station, at 2 317 m above sea level in the Hohe Tauern in Salzburg, only 34 cm of snow fell in November 2020. In an average November, 178 cm of new snow fall here.

December brought heavy snow to the Alps. Up to 3 m of snow fell in parts of Austria (particularly eastern Tyrol) and 2 m in Italy (South Tyrol) from 4 to 6 December in elevations above 2 000 m. In Austria, 72-hour totals of fresh snow also had new records in places, e.g. 80 cm in Umhausen (Ötztal

Province, 1 030 m altitude, measurements since 1956). In Switzerland up to more than 140 cm of snow fell in elevations above 1 200–1 500 m in three days on 4–7 December. Total depths were around twice as large the normal at this time of year.

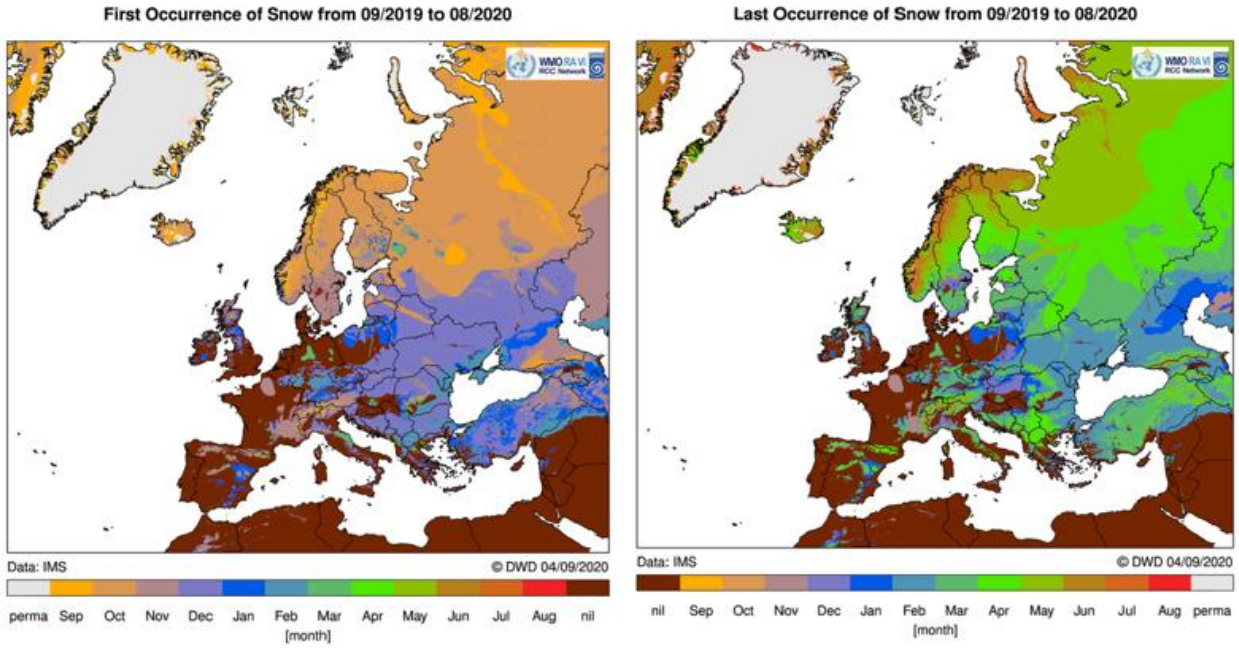

Figure 2-7: First occurrence (left) and last occurrence of snow (right) during the snow season 2019/2020 from /2019 to 08/2020. Source: RCC-CM website.

2.2. Selected climate indices for 2020

This section presents selected temperature and precipitation indices calculated using the station-based ECA&D (European Climate Assessment & Dataset; https://www.ecad.eu) dataset. Annual climate index maps are shown as well as anomaly and trend maps. The following climate indices are considered:

1. **RR1, Number of wet days**: count of days where RR (daily total precipitation) ≥ 1 mm; precipitation below 1 mm/day has no effect on vegetation because it normally evaporates on the same day and is locally affected

2. **WW, Number of warm and wet days**: days with TG (daily mean temperature) > 75th percentile and RR > 75th percentile

3. **SU, Number of summer days**: count of days where TX (daily maximum temperature) ≥ 25 °C

4. **TR, Number of tropical nights**: count of days where TN (daily minimum temperature) ≥ 20 °C

The maps showing the number of wet days (RR1, uppermost left panel in Figure 2-9) clearly depict the dry conditions prevailing in 2020 over southern, central and eastern parts of Europe with less rainy days than normal. The northern and northwestern parts of Europe, on the contrary, experienced more than normal wet days, in Northern Europe up to 60 days more.

The maps showing the number of warm and wet days (WW) reveal above-normal numbers of these days across Europe. Most parts show a surplus up to 30 days of warm and wet days. Only a few negative anomalies of 10 days less were recorded for example in Germany.

Another climate index is the number of summer days that are shown in the map below. The entire region received more summer days than normal in reference to 1961–1990. Northern parts saw up to 20, the southern parts more than 30 summer days more than normal. Negative anomalies with up to 10 summer days less than normal only occurred over Ireland and the northern part of Scandinavia.

There were also more tropical nights (TR) than normal in 2020 over most parts of the RA VI domain. The southern part of the RA VI Region experienced up to 60 tropical nights more than normal. Especially over central parts and Scandinavia, there were also less than normal tropical nights reported in many places.

Figure 2-10 shows the trend maps for the selected climate indices based on the years 1951–2020. In Northern, Northwestern, Central and Eastern Europe, most stations showed an increase in the annual number of wet days (RR1) for the last 69 years (mostly greater than 3 days per year per decade) while in Southern Europe a decreasing trend prevails. The decreasing and increasing trends at neighbouring stations, however, indicate inhomogeneities in the time series. The number of warm and wet days (WW) has increased over almost whole Europe by more than 1.5 days per year per decade. The annual numbers of summer days (SU) have increased in Central and Southern Europe and partly in Eastern Europe, while stations in northwestern and northern Europe do not indicate any significant trend. Annual numbers of tropical nights (TR) show an increasing trend in the southeastern part of Region VI but values are mostly small with 0–2 days per year per decade. In the northwestern part no significant trends are found.

3. Seasonal survey

This section presents an overview of the spatial patterns of seasonal mean climate conditions in 2020 and anomalies related mainly to the normal period 1981–2010 of the following selected climate variables: sea level pressure, circulation indices, surface temperature, precipitation and sunshine duration.

3.1. Seasonal averages and anomalies of selected climate variables

3.1.1. Sea level pressure and circulation indices

The pressure distribution in **winter 2019/2020** shows that both circulation centres, the Icelandic Low and Azores High, were stronger than normal with anomalies up to −14 hPa and between +2 hPa and +6 hPa respectively. As a result, the North Atlantic Oscillation (NAO) and the Arctic Oscillation (AO) were positive with mean values of 1.02 and 2.08. The other dominant circulation pattern next to the positive NAO and AO was the East Atlantic Pattern (EA) with a mean seasonal value of 1.31, indicating that the pressure gradient over the North Atlantic was largest close to Europe.

Table 3-1: Seasonal mean values of selected northern hemisphere teleconnection indices standardized to the 1981–2010 reference. Blue and yellow colours indicate index values lower than −1 and greater than 1 respectively.

Season	AO	NAO	EA	EA/WR	SCA	POL
Winter 2019/2020	2.08	1.02	1.31	0.25	−0.8	−0.22
Spring 2020	1.18	−0.31	0.18	0.61	−1.59	0.36
Summer 2020	−0.30	−0.33	0.65	−0.68	−1.09	−0.28
Autumn 2020	0.88	1.15	0.59	−0.89	0.29	−0.42

Note that all values are standardized with the reference 1981–2010. North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: NOAA CPC Indices and NOAA CPC Monthly AO Index)

In **spring**, a high-pressure area extended from the Azores far to the east until southern Russia and Kazakhstan resulting in higher than normal pressure over large parts of the RA VI Region, especially over the northwest (United Kingdom, Ireland). The Icelandic Low was shifted westward. Lowest surface pressures and also largest negative anomalies occurred over the northeast in the Barents Sea. As a result, the Scandinavian Pattern Index (SCA) was strongly negative with −1.59.

In **summer**, the pressure anomalies were mostly slightly negative (within 0 hPa and −2 hPa). Positive anomalies occurred over northern European Russia and Greenland (up to +4 hPa). The negative SCA pattern continued.

The circulation centres in **autumn** were well pronounced with a core pressure between 1 000 hPa and 1 005 hPa around Iceland and between 1 020 hPa and 1 025 hPa around the Azores. The latter formed part of high-pressure belt extending far to the east across Southern and Central Europe till western Kazakhstan with one maximum around the Azores and the second one over southern parts of Russia and Kazakhstan. That is also where the largest positive anomalies (> +4 hPa) occurred. All circulation patterns were in a rather neutral phase or only weakly pronounced except for the NAO which was positive with a value around 1.

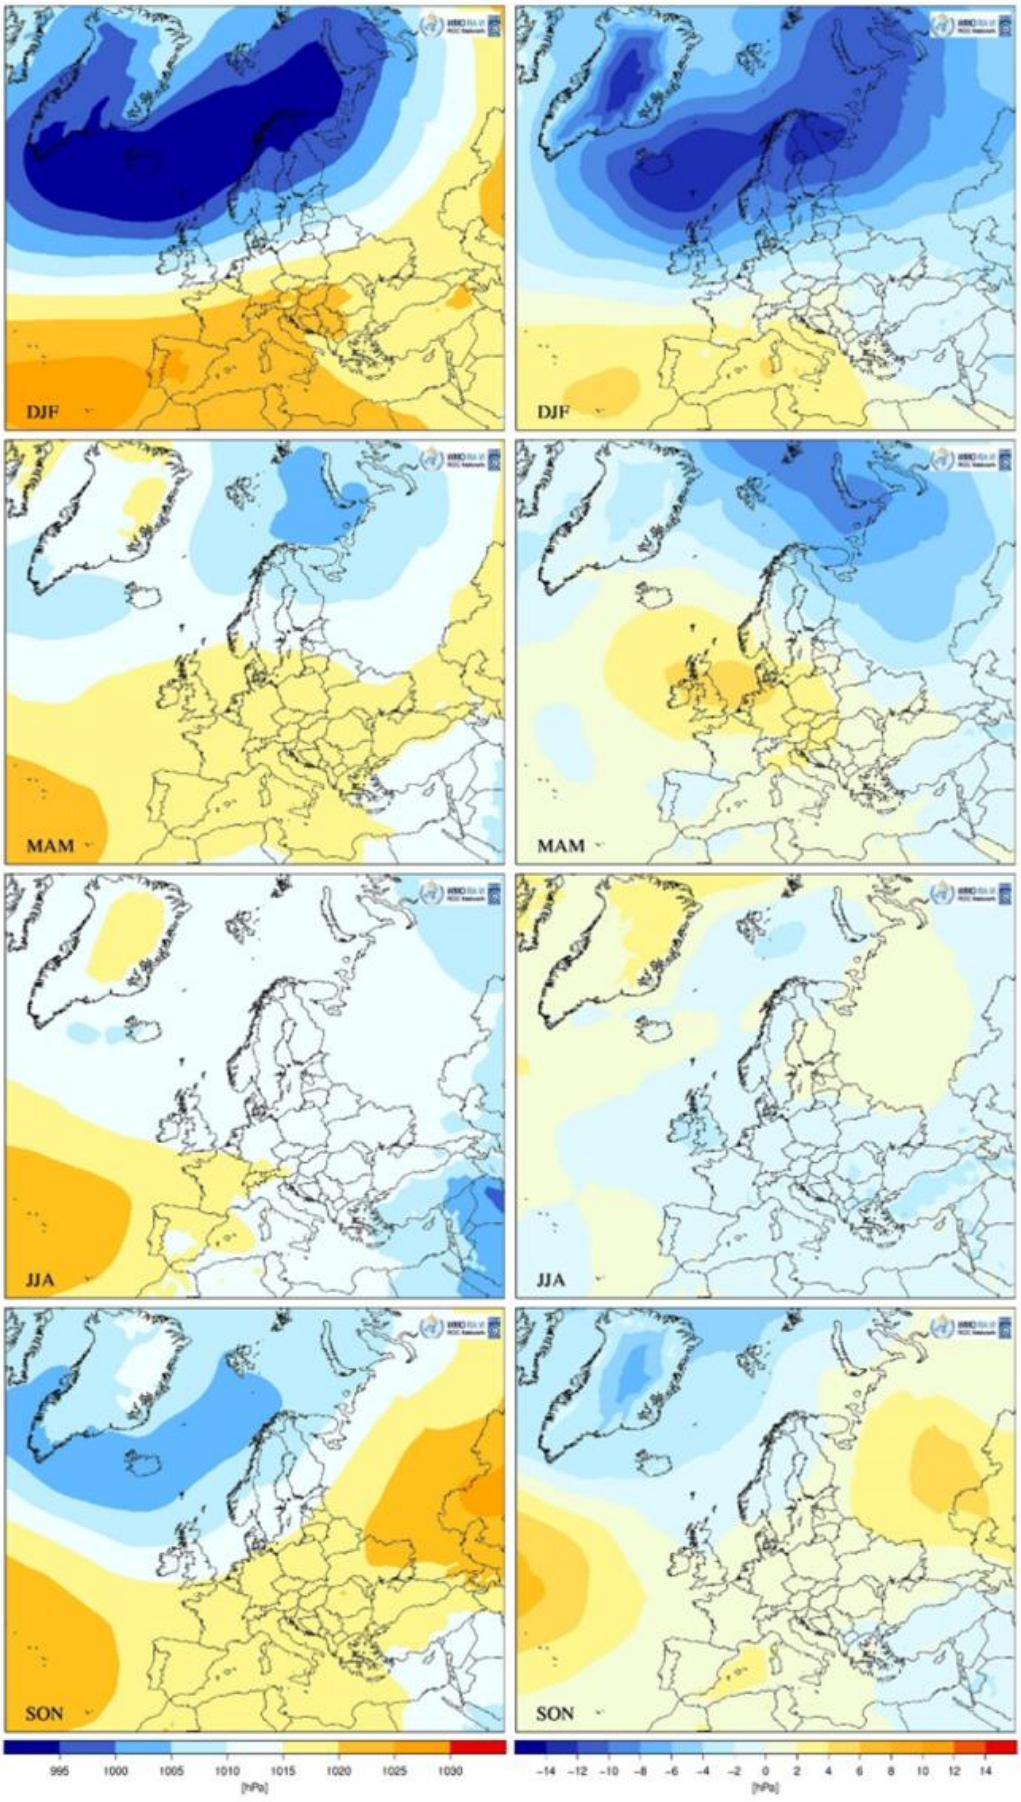

Figure 3-1: *Seasonal sea level pressure in hPa (left) and anomalies in hPa relative to 1961–1990 (right) for winter (DJF), spring (MAM), summer (JJA) and autumn (SON) 2020. Winter values relate to December 2019 – February 2020. Source: RCC-CM website.*

3.1.2. Temperature

In 2020, mean annual temperatures were higher than normal over the whole RA VI Region which is also reflected in the positive anomalies in all subregions ranging from +1.01 °C over the Iberian Peninsula to +2.18 °C in Eastern Europe. All subregions show positive anomalies in all seasons.

Table 3-2: Seasonal and annual average of temperature anomalies over land areas in °C for each subregion in the year 2020 (reference period: 1981–2010; definitions of the subregions see Figure 1-1).

Region	Year	Winter	Spring	Summer	Autumn
Central and Western Europe	+1.43	+2.87	+0.97	+0.98	+1.19
Eastern Europe	+2.18	+5.31	+0.95	+1.06	+2.68
Iberian Peninsula	+1.01	+1.72	+1.45	+0.88	+0.45
Mediterranean and Balkans	+1.34	+1.76	+0.97	+0.69	+1.91
Middle East	+1.46	+1.96	+1.10	+0.96	+2.31
Scandinavia and the Baltic States	+1.55	+2.29	+1.54	+0.86	+1.17

Winter 2019/2020 was remarkably warmer than normal. The entire RA VI Region showed positive anomalies. Mean anomalies of the subregions ranging from +1 °C to +2 °C occurred over Iberia, the Middle East, as well as over the Mediterranean and Balkans region. Larger anomalies were observed in Central and Western Europe (+2.87 °C), Scandinavia and the Baltic States (+2.29 °C). Largest positive temperature anomalies of +5.31 °C occurred in Eastern Europe. Even larger anomalies were recorded on country scale, for example in European Russia (+6.8 °C), Belarus (+5.5 °C) and all Baltic States (from +5.4 °C to +5.8 °C). These and many other countries reported their warmest winter on record (see **Table 3-3**).

Temperature anomalies in spring were also positive, but smaller compared to the winter. The mean anomalies were close to +1 °C in most subregions but higher in southwestern Europe (+1.45 °C in Iberia) and Scandinavia and the Baltic States (+1.54 °C). Locally negative anomalies occurred. Temperature anomalies of up to 1 °C below normal occurred for example in parts of Poland, Belarus and Norway.

Temperature anomalies for summer were again positive in all subregions but stayed below or close to +1 °C. In Ukraine and European Russia, temperatures were locally up to 3 °C above normal. Ireland, the United Kingdom and Italy were the only countries that partially recorded negative anomalies of up to −1 °C.

Autumn also saw above-normal temperatures in all subregions. Largest regional anomalies occurred over Eastern Europe (+2.68 °C) and the Middle East (+2.31 °C). The subregion with the lowest anomalies was the Iberian Peninsula (+0.45 °C). The arctic regions and northern European Russia saw the largest positive anomalies with temperatures being up to 6 °C warmer than normal. Positive anomalies up to +5 °C were also recorded in Türkiye. Several countries reported their warmest autumn on record (see **Table 3-3**).

Table 3-3: *Seasonal rank statistics for temperature (2019/2020) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the time series.*

Country	Rank	Anomaly [°C]	Reference period

3.1.3. Precipitation

In 2020, average precipitation amounts across the RA VI Region were mostly within 80%–125% of normal. Regional averages were close to normal except for the Middle East and Scandinavia and the Baltic States where average precipitation amounts were larger than normal with 112% and 118% respectively.

Winter 2019/2020 saw higher than normal precipitation anomalies in most subregions of the RA VI except for the Iberian Peninsula and the Mediterranean and Balkans region, which registered around normal precipitation. Winter was especially wet in Scandinavia, European Russia, Türkiye, the Middle East, the United Kingdom, Ireland and parts of Greenland and Spain with precipitation totals of 125%–250% of normal amounts. Large parts of Eastern, Central and Western Europe showed around normal values. The Mediterranean and Balkans region, the Baltic States, western Iberia, parts of Greenland and Kazakhstan experienced drier than normal conditions with 20%–40% less precipitation than normal. Even less precipitation was recorded in Sicily (partially 80% less than normal precipitation).

Table 3-4: Seasonal and annual average of precipitation anomalies over land areas in % for each subregion in the year 2020 (reference period: 1981–2010; definitions of the subregions see Figure 1-1)

Region	Year	Winter	Spring	Summer	Autumn
Central and Western Europe	99	115	71	107	98
Eastern Europe	97	113	119	93	83
Iberian Peninsula	93	96	141	76	86
Mediterranean and Balkans	95	99	104	113	66
Middle East	112	124	132	85	59
Scandinavia and the Baltic States	118	117	116	98	132

Spring was wetter than normal for Eastern Europe due to Arctic troughs extending into that area, with many areas receiving precipitation well above 125% of normal, some even more than 167% of normal. Wetter than normal conditions also prevailed over the Iberian Peninsula and the Middle East, with precipitation anomalies of 141% and 132% respectively. Conversely, Central and Western Europe and parts of the Scandinavian and Baltic states and the Balkans were drier than normal, due to more high-pressure influence that contributed to the third spring with a precipitation deficit on a row, after 2018 and 2019. These areas only received 40%–80% of normal precipitation amounts. Northwestern Germany, the Benelux, and southern United Kingdom partially received precipitation as low as 20% of normal.

The distribution of precipitation during the summer months was very inhomogeneous. The central Mediterranean region and the Balkan states, the United Kingdom, and eastern parts of Central Europe received above-normal precipitation with anomalies ranging from 125%–167% of normal precipitation in most parts. Scandinavia and the Baltic states, influenced by higher than normal pressure, as well as the southern parts of the Iberian Peninsula, which were strongly influenced by dry subtropical air from northern Africa, were drier than normal. Largest precipitation deficits occurred over Iberia and the Middle East with average precipitation totals as low as 76% and 85% of normal

precipitation respectively on regional level. For many areas north of the Black Sea, precipitation was well below 60% of normal amounts.

In autumn, the dry conditions over the RA VI Region continued. Over the Eastern Europe and Iberian Peninsula received on regional level only 83% and 86% of normal amounts, respectively. Largest deficits were observed in the Middle East and the Mediterranean and Balkans region which saw only 59% and 66% of normal precipitation amounts, respectively. Over Iceland, Syria, Kazakhstan, Ukraine, Greece and Türkiye partially only 20%–60% of normal precipitation amounts were registered. Ireland, the United Kingdom, the Benelux, and the Scandinavian countries, on the contrary, experienced normal or slightly wetter than normal conditions in autumn.

Table 3-5: Seasonal rank statistics for precipitation (2019/2020) as provided by the NMHSs including countries with rankings among the top 5 (ranks 1–5) since start of the time series.

Country	Rank	Anomaly [mm][3]	Reference period
		winter	
Denmark	2 (wettest)	+100.4	1981–2010
Estonia	5 (wettest)	+37.9	1981–2010
Sweden	1 (wettest)	+63.0	1981–2010
		spring	
Hungary	4 (driest)	−58.0	1981–2010
Lithuania	4 (driest)	−80%	1981–2010

		summer	
Armenia	4 (driest)	−14.7	1961–1990
Ireland	4 (wettest)	+133.7	1981–2010
Serbia	2 (wettest)	+11.3	1981–2010
		autumn	
North Macedonia	2 (driest)	−66.2	1981–2010

[3] By default anomalies are given in mm unless otherwise specified.

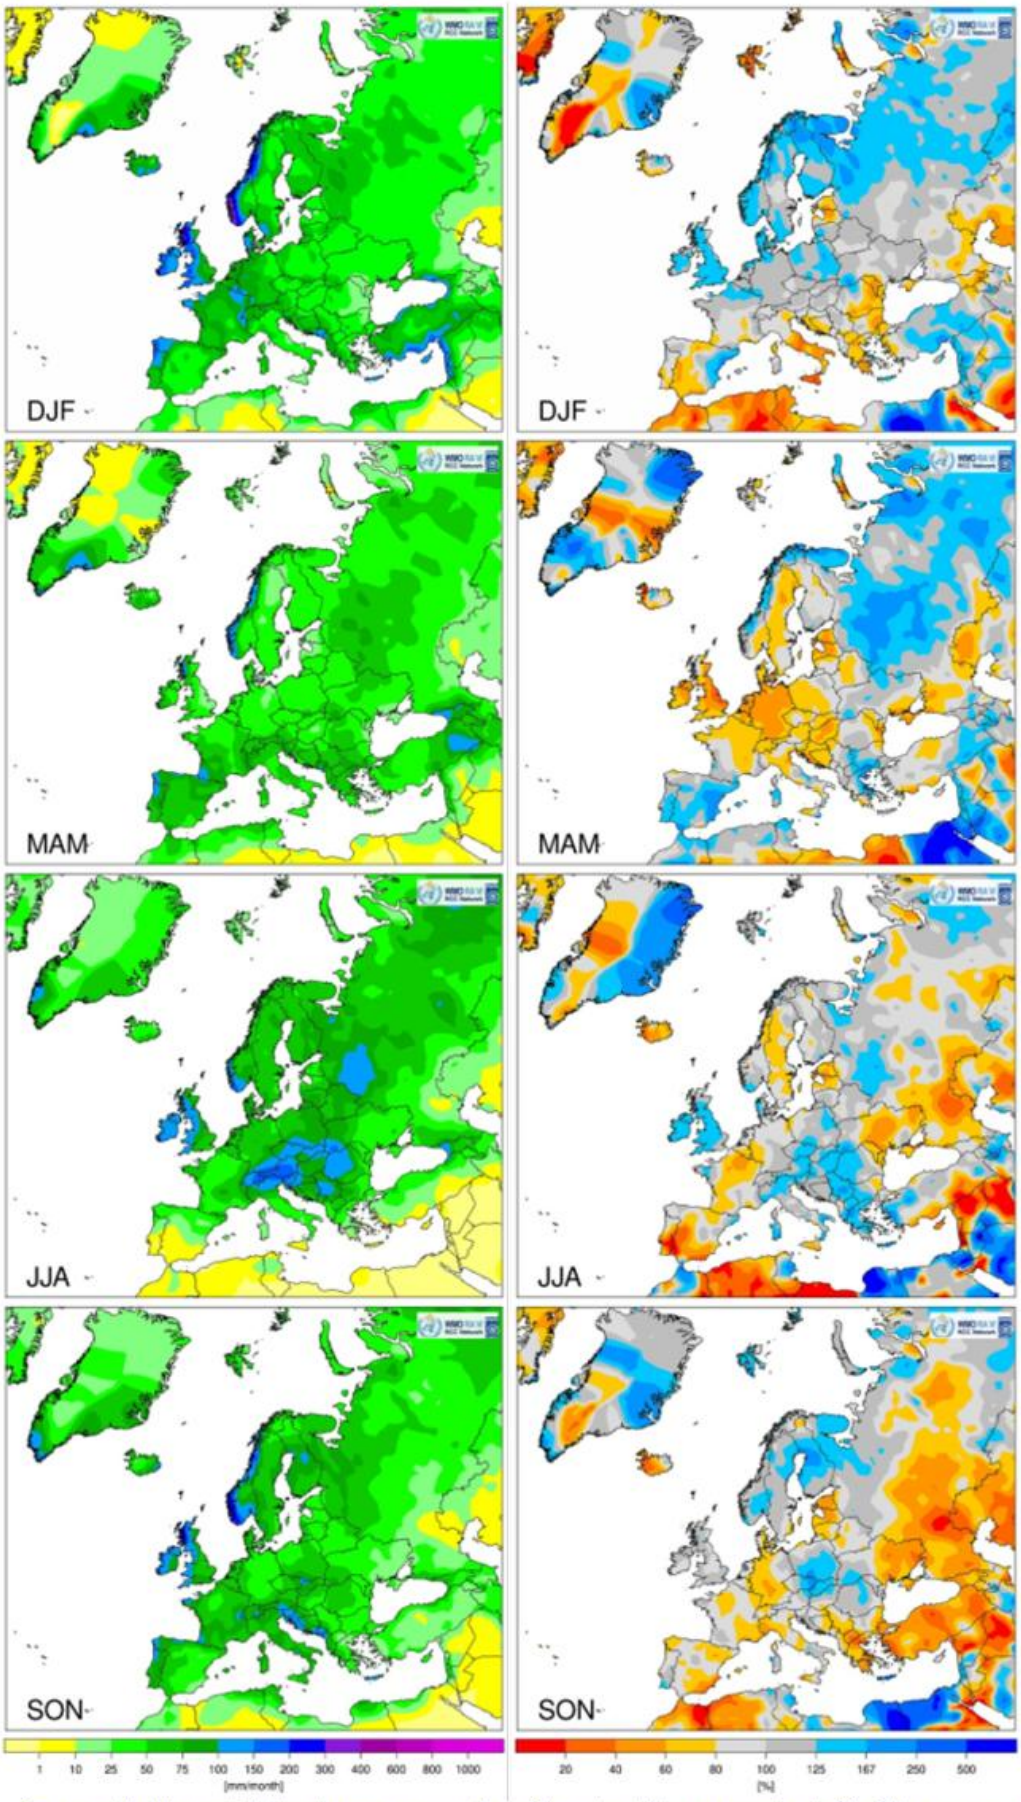

Figure 3-3: *Seasonal total precipitation in mm per month (left), and relative anomalies in % of the average for 1981–2010 (right) for winter (DJF), spring (MAM), summer (JJA) and autumn (SON) 2020. Winter values relate to December 2019 – February 2020. Source: RCC-CM website.*

3.1.4. Sunshine duration

The year 2020 as a whole was sunnier than normal (w.r.t. 1986–2015) over most parts of the RA VI Region with surpluses of up to 500 hours in some parts. On regional scale, largest surpluses were observed in the Mediterranean and the Balkans region as well as in Central and Western Europe with mean anomalies exceeding 170 hours more sunshine than normal.

Table 3-6: Seasonal and annual average of sunshine duration anomalies over land areas in hours for each subregion in the year 2020 (reference period: 1986–2015; definitions of the subregions see Figure 1-1).

Region	Year	Winter	Spring	Summer	Autumn
Central and Western Europe	+177	+40	+155	+3	+5
Eastern Europe[1]	+106	+20	+39	+22	+29
Iberian Peninsula	+7	+32	−61	+11	+30
Mediterranean and Balkans	+173	+57	+58	−2	+65
Middle East	+78	+11	+25	+5	+31
Scandinavia and the Baltic States[4]	+39	+5	+24	+21	−8

In winter 2019/2020, all subregions of the RA VI Region were on average sunnier than normal. With about 57 hours more sunshine than normal, the Mediterranean and Balkans region was the region with the largest surplus. Lowest anomalies occurred in the Middle East with only about 11 hours more sunshine than normal and in Scandinavia and the Baltic States (+5 hours), but due to the low absolute sum in Northern Europe, relative anomalies were large there.

Spring brought a lot of sunshine to Central and Western Europe with a surplus of 155 hours. For Germany, it was the sunniest spring since 1951. In Switzerland, Basel registered the second sunniest spring since the beginning of measurements in 1886 with 718 hours of sunshine. Uccle (Belgium) saw a new spring record for sunshine duration with 741 hours instead of 464 hours (time series started in 1887). Less sunny than normal conditions prevailed over the Iberian Peninsula with around 61 hours less sunshine than normal. Less sunshine was also received in parts of Russia, Belarus and Sicily.

In summer, all subregions registered normal to slightly above-normal sunshine. Eastern Europe (22 hours more sunshine) and Scandinavia and the Baltic countries (21 hours more sunshine) had the largest positive anomalies. Parts of Scandinavia, Russia and Ukraine recorded even surpluses of 100–200 hours sunshine hours compared to normal. Largest deficits occurred over Ireland and the United Kingdom with up to 200 hours less sunshine than normal.

The sunniest subregion in autumn was again the Mediterranean and the Balkans region with an average surplus around 65 sunshine hours. At country level, Russia and Türkiye experienced even larger surpluses with up to 200 hours more sunshine hours than normal. For Russia, it was the sunniest autumn since 1961. Less sunshine hours than normal occurred over northwestern and northern parts and over parts of Central Europe with up to 100 hours less sunshine than normal.

[4] This subregion is not fully covered, therefore the values are not representing the entire region (see maps).

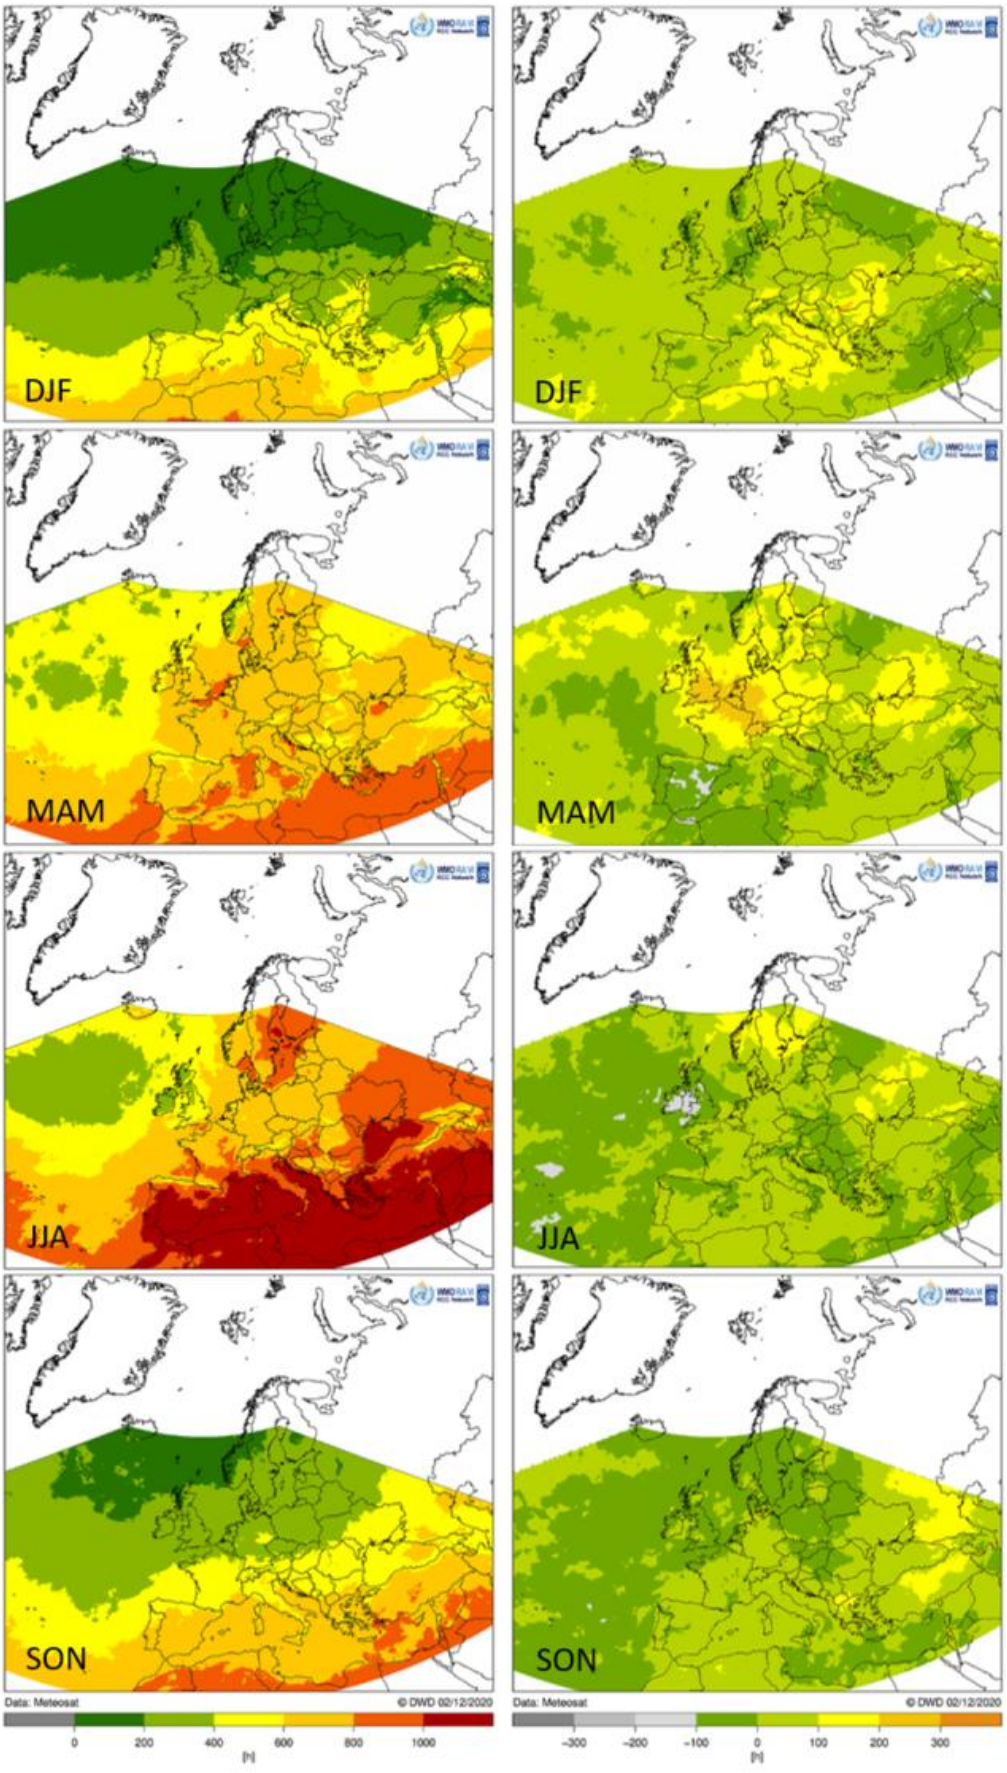

Figure 3-4: *Seasonal sunshine duration in hours (left) and absolute anomalies in hours relative to 1986–2015 (right) for winter (DJF), spring (MAM), summer (JJA) and autumn (SON) 2020. Winter values relate to December 2019 – February 2020. Source: RCC-CM website.*

3.1.5. Drought

In 2020, most regions in the RA VI showed mildly dry to mildly wet conditions on average. Severe to extreme drought signals only appeared in the Middle East, parts of Spain and Greenland. However, some more pronounced drought conditions were observed on seasonal scale.

In **winter 2019/2020**, most parts of the RA VI Region saw mildly dry to mildly wet conditions with GPCC-DI values ranging between −1 and 1. In Romania, the Mediterranean and Balkans, the Iberian Peninsula and Greenland, even drier conditions occurred. For southern regions of Portugal (Baixo, Alentjo, Algarve) January was the start of a prolonged drought situation. Extremely dry conditions in Greece were the determining factor for January 2020 to be one of the top ten driest Januaries on record.

The precipitation deficits occurring in **spring** over Central and Western Europe, Scandinavia and the Baltic countries mostly only led to mildly dry conditions in these areas. In some parts, however, these deficits caused even moderate to severe drought (GPCC-DI values between −1 and −1.5), namely in northern Germany, the Netherlands and parts of the United Kingdom. In the Netherlands, a record high precipitation deficit was observed in the months of April and May, which was 160 mm for De Bilt. In the United Kingdom, spring was the fifth driest on record.

Summer saw wet conditions in most parts of the RA VI Region, especially in the eastern and northeastern parts. Only in the southwest and southeast dry conditions prevailed. The Iberian Peninsula, parts of Türkiye and the Middle East experienced partially even extremely dry conditions (GPCC-DI values up to −3).

Mildly dry to mildly wet conditions prevailed in **autumn** over most of the RA VI Region, except for the Middle East, parts of European Russia and the eastern Mediterranean where locally medium to extremely dry conditions occurred.

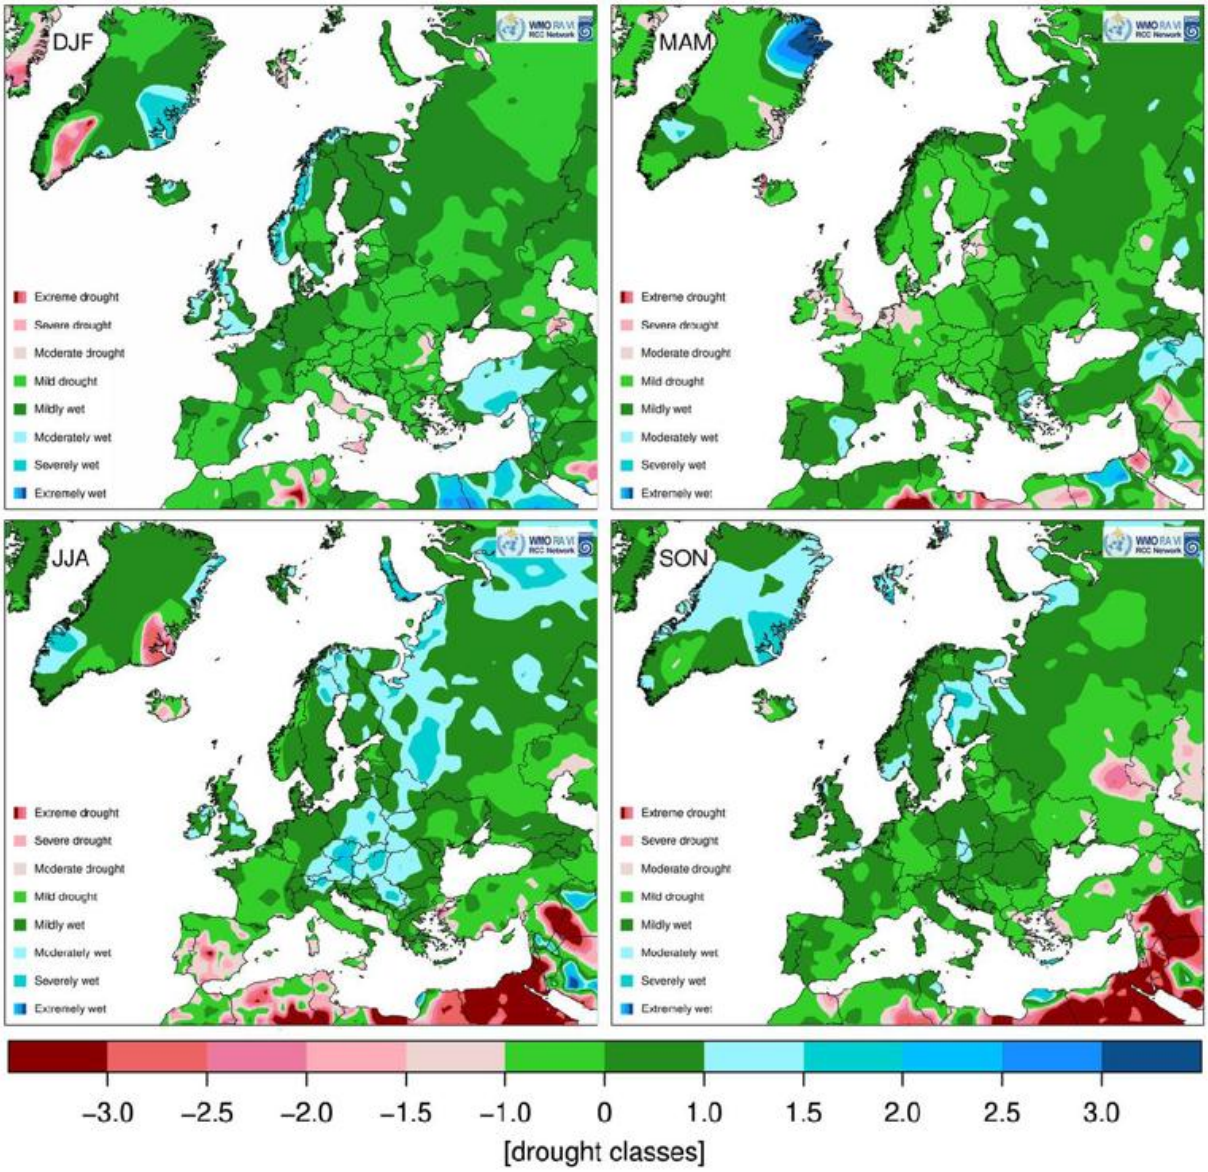

Figure 3-5: *Seasonal GPCC-DI (Drought Index) in drought classes relative to 1961–1990 for winter (DJF), spring (MAM), summer (JJA) and autumn (SON) 2020. Winter values relate to December 2019 – February 2020. Source: RCC-CM website.*

3.1.6. Selected contributions by NMHSs

3.1.6.1. Stormy and very wet conditions during summer in Bulgaria

(Contribution from the National Institute of Meteorology and Hydrology, Bulgaria)

Severe thunderstorms, accompanied by torrential rains, hail and stormy winds, leading to local floods, road damage and broken electricity pools, were registered mainly in western and central parts of the country in May, June, July, and the first half of August.

In May, thunderstorms with hail and heavy rainfall caused significant damage to many settlements, mainly in northwestern Bulgaria. The thunderstorm caused several fires in the Vidin region. In the evening of 20 May, a large hailstorm with hailstomes similar to the size of chestnuts lasted over 10 minutes and caused material damage in the districts of Sofia, Vidin and Montana. Egg-sized hailstones fell in the municipality of Godech on 21 May. It was accompanied by strong wind and rain and caused great material damage, for example broken windows of houses and cars, damaged roofs, and destroyed agricultural areas.

In June, powerful thunderstorm, accompanied by intense rain and hail, led to damages in many parts of the country. More than 30 houses in the village of Kazichene, Sofia District, were flooded. As a result of the heavy rains, dozens of flooded houses and significant damage to the Veliko Tarnovo District's road infrastructure had been reported. Due to the huge amount of water poured into the region, a landslide formed on the road that connects the city with several other neighbouring villages.

In July, a powerful thunderstorm, accompanied by torrential rain, hail, and strong wind, caused serious damage in various regions of Sofia. The disaster lasted about two hours, as the measured amount of rain in some stations in the southwestern part of the capital exceeded 50 mm. Subways, shops, streets, ground floors of administrative and residential buildings were flooded. The Vladayska, Slatinska and Perlovska rivers overflowed. The Evlogi and Hristo Georgievi Boulevard became a canal, as the wave dragged dozens of cars. Strong winds felled nearly 70 trees.

3.1.6.2. Scorching heat in Romania in summer

(Contribution from Meteo Romania)

In order to assess the agrometeorological conditions in the time period with maximum water demands of the crops (June–August), data was processed concerning the intensity and duration of the scorching heat phenomenon. Scorching heat characterized through its intensity (Σ maxT ≥ 32 °C per scorching heat units) and duration (number of days with scorching heat units). **Figure 3-6**, reveals that in time period from 1 June to 31 August, both the sum of the units and the number of days when the scorching heat occurred was small (0–10 scorching heat units per 0–10 days) in Transylvania and Maramureş, most parts of Crişana and Banat, locally in the north, west and east of Moldavia, northern and western Oltenia and in eastern and southeastern Dobrudja. There was moderately intense scorching heat (11–30 scorching heat units in 11–20 days) locally in western and

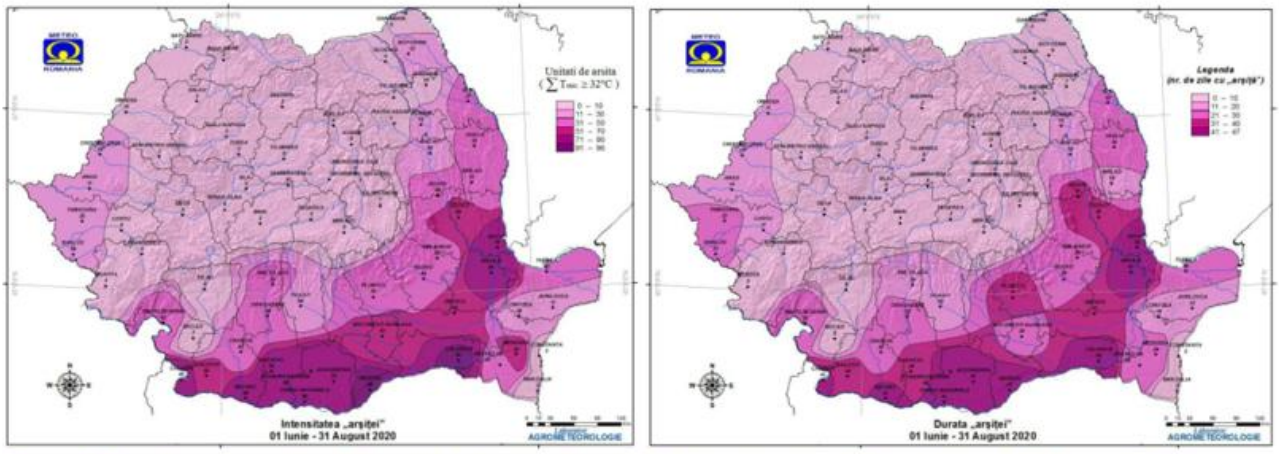

Figure 3-6: *Intensity (on the left) and duration (on the right) of "scorching heat" from 1 June to 31 August 2020. Source: Meteo Romania.*

southern Crișana, northern and western Banat, central and eastern Dobrudja, in central and sparsely in northern Moldavia, also in western Wallachia. Locally, in eastern and southern Moldavia, in northern Wallachia, in eastern, northeastern, central and sparsely in western Oltenia, and in northern and southwestern Dobrudja, the intensity of the scorching heat was high (31–50 scorching heat units in 21–30 days). Locally, in eastern, southern and central Wallachia, in southern Oltenia, in the south and southeast of Moldavia and sparsely in central Dobrudja, 51–96 scorching heat units accumulated per 31–47 days, which made the scorching heat severely intense.

4. Monthly survey

The following monthly survey integrates relevant information from the Monthly Bulletins 2020 on the Climate in WMO Region VI - Europe and Middle East (available on RCC-CM website). It contains highlights, means and anomalies of sea level pressure, temperature, precipitation and sunshine duration for each month as well as monthly overviews of extremes and notable events.

4.1. Sea level pressure and circulation indices

This chapter about atmospheric circulation provides information on selected northern hemisphere teleconnection indices relevant for WMO RA VI and discusses influences of circulation patterns upon anomalies and outstanding events. The information is based on the "Monthly Bulletins on the Climate in WMO RA VI" and was completed by reports of the NMHSs. The discussion partly refers to atmospheric circulation patterns in the mid-/upper troposphere not shown here (see NOAA NCEI Products and NOAA CPC Products).

Table 4-1: *Monthly values of selected northern hemisphere teleconnection indices standardized to the 1981–2010 reference including the Arctic Oscillation, from January to December 2020.*

Year	Month	AO	NAO	EA	EA/WR	SCA	POL
2020	1	2.42	1.05	1.74	0.66	−0.55	0.16

North Atlantic Oscillation (NAO); East Atlantic Pattern (EA); East Atlantic/West Russia Pattern (EA/WR); Scandinavia Pattern (SCA); Polar/Eurasia Pattern (POL); Arctic Oscillation (AO)
(**Sources**: NOAA CPC Indices and NOAA CPC Monthly AO Index)

The daily NAO and AO were strongly positive for almost the whole of January, showing a decreasing tendency. The Azores High was more intense than normal in January 2020 and extended far to the east. The Icelandic Low was also more pronounced than normal, but split into two centres, one over Iceland and another one over northern Russia. This situation resulted in a stronger-than-normal westerly flow over the eastern North Atlantic bringing exceptionally mild air to Europe. Central and Southern Europe were under high-pressure influence the entire month, associated with a lack of precipitation and above-normal sunshine. Around 15 January there was an important change in the European Weather type after Hess/Brezowsky which caused a significant decrease especially of the

AO. Except for the last few days the primarily strong positive daily values resulted in positive monthly values of both NAO and AO with respectively values of 1.05 and 2.42.

The daily NAO and AO were strongly positive for almost the entire month, especially between 7 and 25 February. Around 3–5 February both indices reached their monthly minimum, which is still above normal (1961–1990) for the AO, but below normal for the NAO. On 10 and 21 February the AO reached its maximum value which was 6. The primarily strong positive daily values resulted in positive monthly values of both NAO and AO with respectively values of 0.98 and 3.42. The Azores High was more intense than normal in February 2020 and extended to the east, with its core over Southwestern Europe. The Icelandic Low was more pronounced than normal and extended almost over the whole of Northern Europe from Greenland to eastern Russia. This situation resulted in a stronger-than-normal westerly flow over the eastern North Atlantic bringing exceptionally mild and humid air to Europe.

The daily NAO was neutral at the beginning and end of March and moderately positive in between. The daily AO was strongly positive until the last days of the month when it became neutral. The monthly averages of both indices are positive with values of 0.66 for NAO and 2.64 for AO and thus continue the positive phase of the two previous months. The positive AO/NAO values were due to an anomalous low-pressure area near the North Pole favoured by a strong polar vortex and a well pronounced Azores high. The high-pressure area reached further north than normally and extended over the large parts of the European continent. This positive AO/NAO setup resulted in a strong zonal jet stream which kept much of the frigid air in the Arctic, leaving the mid-latitudes warmer and generally less snowy than normal, but which also brought stormy weather which especially affected northwestern Europe.

The daily NAO was negative at the beginning of April and weakly positive to neutral during the second half of the month. The monthly average was weakly negative (−1.26). The negative NAO was primarily driven by an anomalous trough in the North Atlantic, which was strongest early in the month and high-pressure extending far north and east till south of Iceland and Central Europe. This resulted in higher than normal pressure from Iceland to Southeastern Europe and lower than normal surface pressure over the Azores. The daily AO was mostly positive with two weak negative episodes around 3 and 21 April. The monthly average was positive (0.93). The positive AO was primarily driven by the high-pressure over Western Europe combined with an anomalous trough near the North Pole which extended till northern Russia.

The daily AO was weakly negative for most of the first half of May and then weakly positive later in the month. The monthly average was near zero (−0.27). The daily NAO was also weak but positive for most of the month except for the second week of May when it was strongly negative. With a value of −0.33 it was slightly negative when averaged over the month. Accordingly, the Azores High was weaker than normal in May 2020 but extended far to the northeast until Iceland in the north and Poland in the east, with a second core over the British Isles. The Icelandic low was a bit more intense than normal but split into two cores with the second core situated south of Spitsbergen. This situation resulted in a lower-than-normal westerly flow, with the high-pressure centred over the eastern North Atlantic bringing exceptionally mild and humid air to the northwestern part of Europe.

With a negative NAO index the Azores high and the Icelandic low were weakly pronounced in June. The westerly flow was weak and blocking formed with stable weather conditions. Atmospheric

blocking came up with long-lasting large-scale weather events like the heat wave in the Arctic region. In northern Europe and parts of the Arctic, an area of unusually high-pressure developed, that caused extremely high temperatures. The high-pressure anomaly caused little precipitation in Northern Europe, whereas further south there was more precipitation due to cyclonic influence. The AO was negative most of the month too. The NAO decreased significantly at the end of the month.

The daily NAO and AO indices were mostly negative during the whole month and as a result NAO and AO monthly mean values for July were also both negative with values of −1.19 and −0.41. In July 2020, the Azores High was a little bit more intense than normal and also the Icelandic Low was in its centre more intense, but south of Greenland the sea level pressure was higher than normal. This situation led into north-west flow, which brought cold and wet air to Northern Europe. During the month, the northwesterly flow changed to a southwesterly flow which caused a transport of warm air masses to East Europe. Central and Southern Europe were under high atmospheric pressure influence which led to a lack of precipitation and above-normal sunshine. Due to low atmospheric pressure influence over northern Europe there was above-normal precipitation and lower temperature.

Both NAO and AO were rather weakly pronounced during August resulting in monthly mean values close to zero: 0.03 for NAO and −0.38 for AO. During the first half of August, the daily NAO was moderately positive which was primarily associated with a trough over Greenland early in the month. But then the pattern changed and a blocking pattern built up across Western, Central, Eastern, and Southwestern Europe which is also reflected in the daily NAO values which changed to negative values by mid of the month. This blocking brought an intense heatwave to much of Western Europe. During the second half of the month, the atmospheric situation changed to more cyclonic patterns bringing largely above-normal precipitation to the British Isles, and a band extending from the Alpine region over eastern parts of Central Europe till northwest Russia. On a monthly basis, the pressure was lower than normal over the Atlantic, Western Europe and the Mediterranean, mostly up to 2 hPa below normal, over the North Atlantic even up to 6 hPa below normal. From northern Ukraine to southern Scandinavia, pressures were slightly higher than normal.

The daily NAO was neutral at the beginning of September, then strongly positive during 7 to 21 September and turned strongly negative by the end of the month. The daily AO was positive during most of the month with the strongest values around 10 and 21 September. Monthly averages of both indices were positive, 1.11 and 0.63 for NAO and AO respectively, reflecting the persistent trough near Greenland and the ridge over the North Atlantic throughout the month. The high-pressure extended further to the north than normal and also in the east pressure was larger than normal. The Icelandic Low was also stronger than normal with the lower than normal pressure area reaching even Spitsbergen and Scandinavia. This resulted in a stronger than normal west wind drift shifted towards the north affecting Scandinavia and the British Isles with heavy rain.

Both daily NAO and daily AO were generally negative until around 20 October and positive thereafter. The negative values early in the month were stronger for the NAO than the AO, so the monthly mean NAO for October was negative whereas for AO the monthly mean value was near zero. As visible from the monthly pressure maps, October 2020 was characterized by higher than normal surface pressure around Spitsbergen extending towards the east of the RA VI domain as well as by low pressure in the south of Iceland. The low pressure was more pronounced than usual over Europe, resulting in negative anomalies over practically the whole European continent except

for the Iberian Peninsula and northern Scandinavia. Additionally, a persistent ridge over the North Atlantic favoured stronger than normal westerly winds which dominated especially at the end of the month (positive NAO).

Both daily NAO and AO were strongly positive for nearly the entire month, and the respective **November** means were thus also strongly positive with 2.54 for NAO and 2.09 for AO. The strongly positive signals were associated with a persistent trough near Greenland and a ridge over the North Atlantic. These features were prominent throughout most of November. As a result, November 2020 was characterized by higher than normal mean sea level pressure over most parts of the European continent and lower than normal pressures north of the Arctic Circle. These unusual anticyclonic conditions resulted in very dry, warm and sunny weather conditions over large parts of the RA VI Region.

The daily AO was negative for most of **December** with strongly negative values in mid-December and at the end of the month. The monthly mean was strongly negative (−1.74). The daily NAO was weak but negative during most of December, and the monthly mean NAO was slightly negative (−0.37). The negative values of both indices were associated with a ridge near Greenland. The NAO's amplitude was reduced, however, because that ridge extended southward into the North Atlantic. During a typical negative NAO phase, a trough would have been located to the south of the Greenland ridge. The higher than normal mean sea level pressure extended from Greenland far to the north and east where a pronounced high was located over Russia. Below normal sea level pressure was found over the northwestern parts of Europe which resulted in a pronounced low-pressure area with its core located between Iceland and the British Isles. These patterns led to a southerly flow in between the low-pressure to the west and the high-pressure to the east bringing exceptionally warm conditions even to the Arctic.

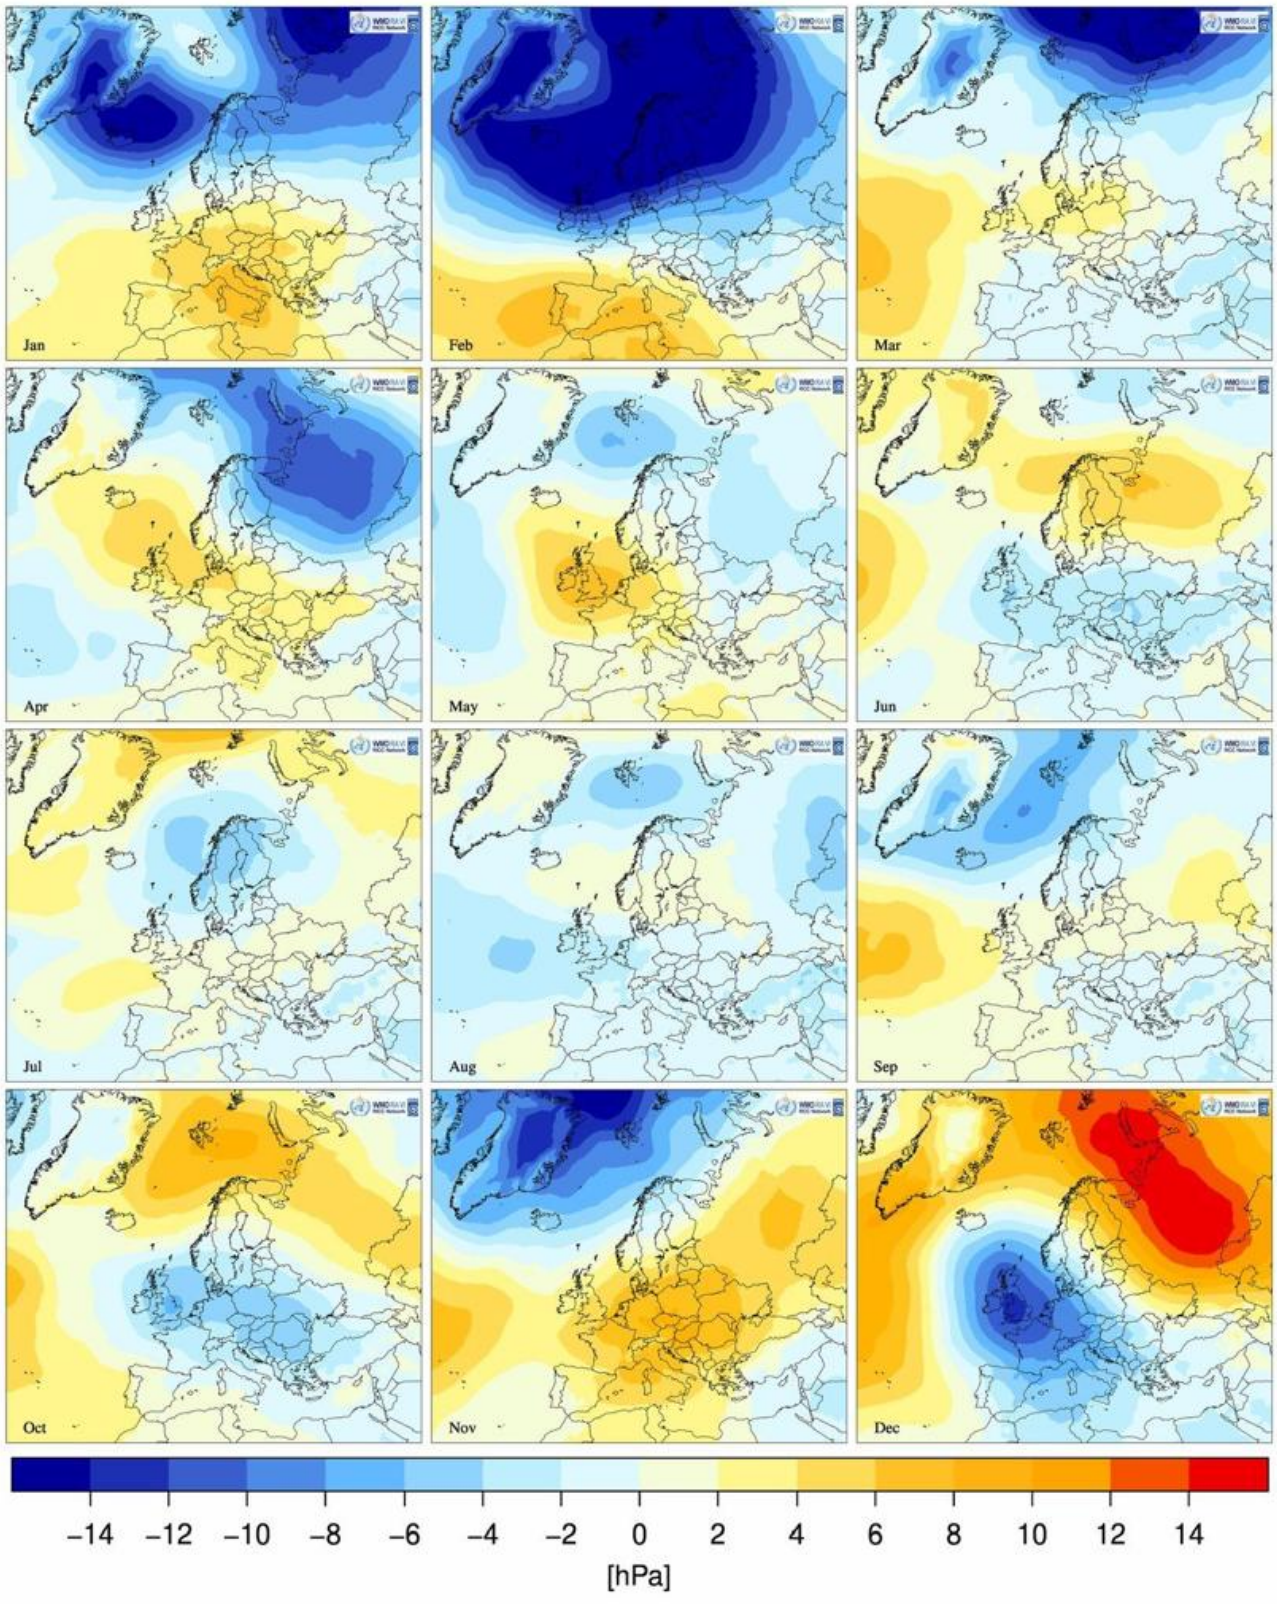

Figure 4-2: *Monthly anomalies of sea level pressure in hPa relative to 1981–2010 for each month of the year 2020. Source: RCC-CM website.*

4.2. Temperature

In most of the months and subregions it was warmer than normal as can be seen from **Table 4-3**, with April, May and October being the only months with below normal temperatures in some regions, namely Iberia and Eastern Europe. Largest anomalies with anomaly values exceeding +4 °C occurred in Eastern Europe from January to March.

Table 4-2: Monthly area average temperature anomalies in °C for each subregion in the year 2020 (reference period: 1981–2010; definitions of the subregions see Figure 1-1).

Region	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

In January 2020, most of the RA VI Region reached higher temperatures than normal (reference period: 1981–2010) due to steady high-pressure influence. Anomalies were highest in the east of Europe (between +6 °C and +7 °C in the Baltic States, +9.1 °C in Northern European Russia) and in Scandinavia (+9 °C in Norway, +10 °C in Sweden). In Norway, the highest maximum temperature, 19.0 °C, was recorded on 2 January at Sunndalsøra III (Sunndal, Møre and Romsdal). This is a new Norwegian heat record for January. In Trøndelag and Troms and Finnmark, county records were set. In many countries, this month was one of the three warmest in history (see **Table 4-3**). It was colder than normal in the south of Greenland with anomalies around −2 °C. The monthly mean temperature averaged over Europe was +3.27 °C above the 1981–2010 average according to Copernicus data. This anomaly was almost as high as in December 2019. The warming trend for January since 1910 is +1.38 °C per 100 years. January 2020 was the second warmest January since 1910, straight after January 2007 with 3.33 °C above the 1910–2000 average according to NOAA NCEI (National Centers for Environmental Information).

In February 2020, most of the RA VI Region saw higher temperatures than normal (reference period: 1981–2010) due to a powerful and continuous (south-)westerly flow. Most of Central and Southwestern Europe registered anomalies between +2 °C and +4 °C. Anomalies were highest in the east of Europe (for example +7.3 °C in European Russia, +6.2 °C in Estonia and +5.9 °C in Latvia) and in Scandinavia (+6 °C in Norway). In many countries, this month was one of the three warmest on record (see **Table 4-3**). It was colder than normal in the seas around Greenland with anomalies between −1 °C and −3 °C, whereas over land Greenland itself registered mostly negative

anomalies, but temperatures equal to or above the normal level (1981-2010) was also measured (between -6.2 °C and +3.4 °C). Italy recorded not only one of its warmest Februaries since 1800, but also its second warmest winter after 2006/2007 due to positive anomalies in all winter months (December 2019: +1.9 °C, January 2020: +1.9 °C, February 2020: +2.9 °C). The monthly mean temperature averaged over Europe was 3.86 °C above the 1981–2010 average according to Copernicus data. According to NOAA NCEI, for Europe as a whole, February 2020 was the second warmest since 1910, straight after February 1990 with an anomaly of +4.11 °C.

As the polar vortex stayed strong during **March**, it continued to keep much of the frigid air in the Arctic, leaving the mid-latitudes with warmer than normal temperatures. Over the RA VI Region, temperature anomalies for March 2020 (w.r.t. the 1981–2010 average) increased from west to east, with lowest values over Western Europe (up to +2 °C) and largest anomalies over parts of European Russia, where temperatures were more than 5 °C above normal. Over European Russia, the average temperature in each decade of the month exceeded the normal value even by 8 °C to 12 °C or more in various regions. New maxima of air temperature were recorded among others in the northwestern part, Northern Caucasus and Siberia. March 2020 became the warmest in the history of meteorological observations in European Russia and the second warmest in Russia as a whole – outranked by March 2017 only. In Moscow, the monthly-averaged air temperature in March was +3.8 °C, and the anomaly was +6.0 °C. This March was the second warmest in the meteorological chronicle of the capital, only March 2007 being even warmer, by 0.6 °C. The monthly mean temperature averaged over Europe was 2.48 °C above the 1910–2000 normal, making it the sixth warmest March for Europe as a whole according to NOAA NCEI. According to the same reference, the period from January to March as a whole was the warmest on record with an anomaly of +3.19 °C.

For **April**, monthly mean temperatures were warmer than normal over western, central and southern parts and colder than normal in the east of the RA VI Region. Largest positive anomalies occurred over France and Greenland with anomalies greater than +3 °C (w.r.t. 1981-2020). For France, April 2020 ranks as the third warmest April since 1900, behind April 2007 (+3.6 °C) and April 2011 (+3.3 °C). Largest negative anomalies occurred over Russia with temperatures between 1 °C and 2 °C below normal. The European-average temperature for April 2020 was among the 12 warmest on record according to the ERA5 (Copernicus) and the NOAA NCEI data (retrieved from NOAA CAG) with anomalies of +0.6 °C (w.r.t. the 1981–2010 average) and +1.49 °C (relative to 1910–2000) respectively.

The monthly mean temperature in **May** was warmer than normal over western and southern parts of the RA VI domain with largest anomalies occurring over the Iberian Peninsula, where it was, in some places, more than 3 °C warmer than normal. In Spain, the month of May was extremely warm with an average temperature of 19.3 ºC, which is 2.7 ºC above the average for this month (reference period: 1981–2010). This was the warmest May since the beginning of the time series in 1965, having surpassed May 2015 by 0.2 ºC, which was until now the warmest in the series. The largest thermal anomalies, close to +4 ºC, were observed in inland areas of Galicia and the northwest of Castilla y León, as well as in some parts of the Pyrenees of Huesca and Lleida. At 28 stations, the average temperature in May was the highest for a month of May since the beginning of the time series. Colder than normal temperatures, on the contrary, occurred over the central, northern and eastern parts of the RA VI domain with largest negative anomalies over Poland, Belarus and the Ukraine where

temperatures were 2 °C to 3 °C below normal. The monthly mean temperature for May averaged over Europe was 0.47 °C above the 1910–2000 average according to the NOAA NCEI data (retrieved from NOAA CAG) and 0.3 °C below the 1981–2010 average according to the Copernicus Climate Change Service at ECMWF (based on ERA5).

In June, the temperatures in Northern Europe were well above average, but below average or around normal in the south. Overall, this was the second warmest June in Europe on record according to Copernicus data and the third warmest according to NOAA NCEI data (+0.92 °C anomaly, 1910–2000 reference). Due to the influence of high pressure at the beginning of June, Russia and Scandinavia experienced a particularly warm airflow causing high temperatures in the Arctic Cycle. At a station in Russia, located at 66.7° N, 30.3 °C were recorded, which is more than 20 °C warmer than normal. In Russia as a whole, June 2020 was marked as the third warmest in the meteorological chronicle, colder than June 2012 and June 2016 only. The unusually high air pressure over Scandinavia and Russia brought numerous heat anomalies in other places of Northern Europe too. In the middle of the month, new temperature records were reached in Scandinavia: In Sweden, the highest maximum of the month (34 °C) reached the highest ever-measured June temperature in Sweden since 1970. June was hot or very hot in most places and in parts of central Sweden, also record warm. Norway experienced the highest heat anomaly within RA VI this month with 6 °C above normal in Trøndelag. The monthly temperature for the whole country was 3.2 °C above normal, making June the second warmest June since 1900. There were also numerous heat anomalies in Spain (with a maximum temperature of 43 °C), France, Germany, Eastern Europe and the Middle East. Highest monthly mean sea surface temperatures of June were reached in the Mediterranean Sea, in the region of Israel and Lebanon, with temperatures between 24 °C and 26 °C.

In July 2020, the average temperatures were higher than the 1981–2010 average for July in large parts of the RA VI Region due to high pressure influence, particularly over Eastern and Southern Europe with anomalies between +1 °C and +3 °C. Also, along the western coast and southern tip of Greenland, the average temperature was between 1 °C and 2 °C higher than the average for July, for example, in the south of Europe: Portugal experienced the warmest July since 1931 with an anomaly of +2.91 °C and with three periods of heatwaves, which led to severe drought in some regions. France, Cyprus and Spain experienced also several heat waves in July with a maximum daily temperature over 40 °C. In Spain, it was the third warmest July since 1965. In contrast, lower than normal temperatures occurred over Northern Europe, especially in Norway, Finland, Russia, Sweden and Ireland, where the anomalies ranged between −1 °C and −3 °C because of low pressure influence over these regions. In Sweden, the lowest minimum temperature (−3.3 °C) was recorded in Latnivaara, which was the lowest measured temperature in July since 1976. The monthly mean July temperature averaged over Europe was 0.2 °C above the 1981–2010 normal according to Copernicus data. July 2020 was the thirteenth warmest July since 1910, which was just as warm as the year before.

In August, average temperatures were higher than the 1981–2010 average for August over large parts of the RA VI domain, with largest temperature anomalies occurring over France, the Benelux countries, Germany and Poland with values above +2 °C. These large anomalies resulted mainly from an intense heatwave developing during the first half of the month due to a blocking pattern associated with a strong upper ridge expanding across much of the European continent. Peak

daytime temperatures were measured over France, reaching almost 40 °C in the southwestern parts. The heat wave from 6 to 13 August was in terms of cumulative heat – also called severity – very close to the heat waves that France experienced in June and July 2019, but far behind 2003 and 2006, and a little below the episode of the summer of 2018. On 9 August, the maximum temperature reached 39.1 °C in Paris and 40.4 °C in Saint-Maur (Val-de-Marne). Monthly records for maximum temperatures were broken, for example 39.6 °C in Nantes (Loire- Atlantic) on 7 August, 37.1 °C in Lille (North) on 8 August and 39.3 °C in Creil (Oise) on 9 August. In the Netherlands, August was very hot with an average temperature of 20.4 °C in De Bilt compared to a normal of 17.5 °C. This makes August 2020 the second warmest August since the start of observations in 1901 (after August 1997). Large temperature anomalies occurred as well over the Arctic. Svalbard Airport was the warmest station with an average temperature of 7.2 °C (2.5 °C above normal). This is, together with 2013, the third highest mean temperature measured at that station in August (since 1975). For the summer season 2020, the average temperature at Svalbard Airport was 7.2 °C, which is 3.0 °C above normal, and the highest recorded average summer temperature. The old record was 6.7 °C from 2015. The monthly mean temperature averaged over Europe was 2.02 °C above the 1910–2000 average, making it the third warmest August for Europe as a whole according to the NOAA National Centers for Environmental Information (retrieved from NOAA CAG). According to the Copernicus Climate Change Service/ECMWF, August was, over Europe, 1.1 °C warmer than the average for 1981–2010 (based on ERA5), making it the fifth warmest on record for Europe.

September 2020 was warmer than the 1981–2010 average for September over most parts of the RA VI domain especially in countries bordering the Black Sea and in the Middle East with anomalies above +3 °C, in Türkiye locally even +5 °C. New high temperature records were reported for Türkiye, Israel and Jordan. In Eilat, in southern Israel, 48.9 °C were measured on 4 September, which was not only a record for September, but also an all-time record in an over 70-year time series. In Jerusalem, a September record was broken on 3 September with 41.2 °C in a long data series of 118 years. Israel as a whole experienced its warmest September on record, and the intensity and length of the September heatwave in Jordan was exceptional. In European Russia, the air temperatures averaged for the first decade of September exceeded the normal values by 2 °C to 5 °C or more in the southern parts. In the third decade, the whole of European Russia experienced abnormally warm temperatures with decade-averaged temperature anomalies reaching +5 °C and more. New temperature maxima were recorded in the northwest of Russia at that time. The average temperature of September in Moscow was 13.9 °C, implying an anomaly of +2.9 °C. This was the fourth highest temperature for September in the history of meteorological observations in the capital. It was also generally warmer than normal over the Arctic Ocean (except for the Greenland Sea and the Norwegian Sea). Together with the warm spring and early start of snow melting period, this made the Arctic Sea Ice shrink to the second lowest extent (behind September 2012) since modern record-keeping began in the late 1970s. In contrast, it was colder than normal over Greenland and Iceland. The European-average temperature for September 2020 was the highest on record for September according to both ERA5 (Copernicus) with an anomaly of +1.8 °C (w.r.t. the 1981–2010 average) and the NOAA NCEI data with an anomaly of +2.33 °C (relative to 1910–2000).

Monthly mean air temperatures in October were below the long-term means in the western and southwestern parts with anomalies up to −3 °C (w.r.t. 1981–2010) and above normal in the eastern parts of the RA VI domain with largest anomalies occurring over the Ukraine and central parts of

Türkiye with anomalies larger than +3 °C. In Belarus, the average monthly air temperature ranged between 9 °C and 12 °C, which is 3 °C to 5 °C higher than the climatic norm. October 2020 was the warmest on record during the post-war period. Prior to that, the warmest October was in 1967 with the national average temperature of 9.7 °C. In Russia, in the Central Russia District, the average air temperature broke the previous record by 0.5 °C. It was set over a century ago in 1896. In Türkiye, the temperature in October 2020 was 3.2 °C higher than the long-term average (of 1981–2010) making it the warmest October of the last 50 years. The European-average temperature for October 2020 was the highest on record for October according to both ERA5 (Copernicus) with an anomaly of +1.6 °C (w.r.t. the 1981–2010 average) and the NOAA NCEI data (retrieved on 4 December 2020 from NOAA CAG) with an anomaly of +2.17 °C (relative to 1910–2000).

The monthly mean temperature of November was warmer than normal over most parts of the RA VI domain with the largest anomalies occurring in northern Scandinavia and Russia and the Arctic Ocean. In the southern and central parts of Finland, station-specific monthly average temperature records were measured in several places. The deviations from the reference period ranged between +4 °C and +6 °C, with largest anomalies occurring in Lapland. In Sweden, many places in Götaland and southern Svealand experienced their warmest November on record. The cliff in Blekinge had a monthly average temperature of 9.1 °C, which is a new Swedish November record. Previous records were 8.8 °C at Måseskär in 2006 and Falsterbo in 1938. An extremely warm first week in November contributed strongly to the very high monthly average temperature. Especially on 2 and 6 November, new November records were set to a rarely seen extent. One of the most notable ones was 18.4 °C in Gladhammar on 6 November. This is similar to the Swedish heat record for November from Ugerup in Skåne on 2 November 1968. Other station records for November set on 2 November include the old observatory series in Lund (17.1 °C, start year 1753), Stockholm (15.1 °C, start year 1756) and Uppsala (15.7 °C, start year 1739). In Norway, the monthly temperature for the whole country was 4.1 °C above normal, and the month was, together with 2011, the warmest month of November recorded in a series dating back to 1900. Largest anomalies were recorded in Troms and Finnmark, with temperatures between 6 °C and 7 °C above normal. Three stations with measurements dating back to 1867 – namely Torungen lighthouse, Lista lighthouse and Utsira lighthouse – set new records for the warmest November. In Arctic Norway, Bjørnøya was the warmest station with an average temperature of 0.5 °C (3.1 °C above normal). At Hopen, the monthly temperature was −0.5 °C, which is 6.1 °C above normal. Svalbard Airport had −2.9 °C on average for the month, which is 5.3 °C above normal. Jan Mayen had a monthly temperature of −1.0 °C, which is 0.7 °C above normal. Ny-Ålesund got an average temperature of −3.5 °C, which is 4.6 °C above normal. The highest maximum temperature of the month was measured on 12 November on the Reindal Pass with 9.4 °C. This was the highest ever measured temperature on Svalbard in November. The old record was 7.8 °C measured in Ny-Ålesund on 6 November 2011. For Europe as a whole, the temperature for November 2020 was the second highest on record according to both ERA5 (Copernicus) and the NOAA NCEI data (NOAA CAG) with an anomaly of +2.2 °C (w.r.t. the 1981–2010 average) and +2.15 °C (relative to 1910–2000) respectively. When looking at the seasonal average (September–November), it turns out that the average temperature for Europe was even the highest on record with 1.9 °C above the 1981–2010 norm according to the ERA5 data (Copernicus) and 2.24 °C above normal with respect to the 1910–2000 average according to the NOAA NCEI data.

In **December**, monthly mean temperatures were above normal over most of the RA VI domain, with largest anomalies occurring in Scandinavia and Southeastern Europe with temperatures up to 4 °C above normal (w.r.t. 1981–2010). Monthly mean air temperatures below the long-term mean occurred around the Caspian Sea (Kazakhstan, Russia) and over Ireland. In Finland, the largest anomalies occurred in the western part of Finnish Lapland, where temperatures were about 7 °C above normal. In Sweden, December 2020 was warmer than normal with the largest temperature anomalies occurring in the northern half of the country. December 2020 was record-breaking, for example at Luleå Airport. The monthly temperature for Norway was 4.1 °C above normal. The month was the fourth warmest December in a series dating back to 1900. In Innlandet, Viken and Troms and Finnmark, some stations had deviations of 7 to 8 °C above normal. In the Arctic region, Jan Mayen was the warmest station with an average temperature of −1.6 °C (2.0 °C above normal). At Hopen, the monthly temperature was −3.8 °C, which is 6.4 °C above normal. Svalbard Airport had −7.0 °C on average for the month, which is 4.3 °C above normal. Bjørnøya reported a monthly temperature of −1.8 °C, which is 3.5 °C above normal. Ny-Ålesund got an average temperature of −7.5 °C, which is 3.3 °C above normal. Also, Romania saw large deviations of the average air temperature from the median of the standard reference period (1981–2010) in December 2020 which exceeded the value of 3 °C in most regions. The highest value of the positive deviation was 5.4 °C, measured at the Sibiu meteorological station. For Europe as a whole, the temperature for December 2020 was the fifth (NOAA) highest on record according to ERA5 (Copernicus) and the fourth highest according to NOAA NCEI data with anomalies of +2.3 °C (w.r.t. the 1981–2010 average) and +2.43 °C (relative to 1910–2000) respectively.

4.3. Precipitation

Annual precipitation in 2020 was near normal over most parts of the RA VI Region. The individual months reveal a lot variability in the course of the year (see **Table 4-4**) that started with mostly wetter than normal conditions in the winter months. These were followed by dry conditions in spring over large parts of the domain. Autumn brought even drier conditions especially to Central and Western Europe and the Mediterranean and Balkans.

Table 4-4: *Monthly area average precipitation anomalies in % for each subregion in the year 2020 (reference period: 1981–2010; definitions of the subregions see Figure 1-1).*

Region	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Central and Western Europe	71	180	87	44	75	135	70	113	91	157	47	111
Eastern Europe	98	152	99	90	157	94	102	83	77	94	81	80
Iberian Peninsula	108	19	170	139	91	68	69	92	70	81	92	82
Mediterranean and Balkans	67	99	119	83	107	129	82	113	69	86	48	112
Middle East	131	90	149	93	76	39	111	105	108	26	158	50
Scandinavia and the Baltic States	115	105	120	98	132	114	111	111	101	137	141	134

Table 4-5: *Rank statistics, monthly average precipitation (mm) and anomalies (mm) from several countries of the RA VI for the individual months in 2020, only including countries with rankings among the top 5 (ranks 1–5) since start of the time series.*

Monthly accumulated precipitation amounts differed a lot within the RA VI Region in January 2020. The central and southern parts of Europe as well as Northern Greenland saw below normal precipitation amounts, which were even exceptionally below normal over Greece, the southern part

of Italy and Romania. In Greece, only 1 mm of precipitation was recorded in Thessaly, which is 31 mm less than normal. Several Greek stations reported new drought records for January: Kerkyra (second driest since 1901) in the Northern Ionian Sea, Kakmata (fifth driest since 1901) in southern Peloponnese, Andravida in western Peloponnese (second driest since 1959) and Larisa in Thessaly (second driest since 1949). In contrast, regions in the north and east of Europe (especially along the west coast of Norway) as well as in the south of Greenland and the east of Spain experienced exceptionally above-normal precipitation (> 90th percentile). The rainfall amounts accumulated over the whole month were very impressive in these regions: In Norway, the monthly precipitation was 170% of normal, and the month was the wettest in the series going back to 1900. A couple of stations in Norway received more than four times the normal rainfall amounts. In the east of Spain, a major flooding event was caused by both major storm surge (from severe winds) and excessive rainfall amount, triggered by cyclone Gloria from 20 to 22 January. Some areas received more than 300 mm of rain within this 48-hour period.

Monthly precipitation anomalies differed a lot within the RA VI Region in February 2020 as well. The Mediterranean region and Northern Greenland saw below-normal precipitation amounts, which were even exceptionally below normal over Spain and Italy. The south of Italy received less than 20% of normal precipitation and the Maltese Islands only 0.6 mm of rain, making it the driest February on record. Spain also reported its driest February on record with an average precipitation of only 9 mm, which is only 17% of the normal value for the month (w.r.t. 1981–2010). In contrast, regions in northern, eastern and central parts of Europe, especially the United Kingdom, the north of France and regions around the North Sea coast experienced exceptionally above-normal precipitation. In Denmark, the monthly precipitation was 285% of normal (1981–2010), corresponding to an anomaly of +88.2 mm, making it the wettest February in the series going back to the 19th century. In Estonia, about 223% of normal precipitation was recorded. Around Paris and near the river Somme, the amount of rainfall was even more than 3 times higher than usual. In Ireland, February 2020 was the wettest February on record (since 1941).

Precipitation totals for March 2020 were below normal (1981–2010) in a band extending from the British Isles in the west towards western Kazakhstan in the east with largest deficits occurring in regions neighboring the Black Sea with precipitation sums lower than 20% of normal (and < 10th percentile). In Kazakhstan, monthly precipitation totals amounted even to several millimetres only. Over the southern parts of European Russia, the GPCC drought index reached values of −2 and lower, indicating extreme drought conditions. Wetter than normal conditions, on the contrary, prevailed over southern parts of Europe and northern parts of European Russia. The normal precipitation amounts in the Russian North-West Federal District were exceeded by about 1.5 to 2 times, locally even more. The monthly precipitation totals set new records in Karelia and the largest values for the last 25 years were recorded in Saint Petersburg. Heavy rains poured in the north of the central region, bringing up to half the normal monthly amount of precipitation per day in the second decade. Also, Iberia experienced more precipitation than normal, especially the eastern part of Spain. Some Spanish regions experienced 3 times the normal amounts. The largest daily amounts were observed on 31 March with 150 mm in Castellón-Almassora which set a new daily record for March. Additionally, several new monthly records were set as well, among them Castellón-Almassora with 205 mm as well as Logroño/Agoncillo and Teruel, both with 105 mm. Parts of Norway experienced exceptionally above-normal precipitation amounts. Norway as a whole

registered 155% of normal precipitation which resulted in March 2020 being the fourth wettest since 1900. Largest precipitation amounts occurred in Lurøy (Nordland) with 560.9 mm (265% of normal); Takle (Gulen, Vestland) with 444.6 mm (152% of normal) and Hovlandsdal (Fjaler, Vestland) with 432.9 mm (166% of normal).

Large parts of the RA VI Region experienced below normal precipitation in April, especially in western, central and large parts of eastern Europe where the observed precipitation amounts were even exceptionally below normal (< 10th percentile) with locally less than 20% of normal. The precipitation index in these regions reached values below −1.5 indicating severe to extreme drought conditions. Germany experienced its second driest April since 1901, Hungary experienced the third driest since 1901, and the Netherlands experienced the sixth driest since 1906. For France, April 2020 was not exceptional on a national scale, but the province Alsace experienced the second driest April on record behind April 2007. Monthly precipitation totals above the long-term means, on the contrary, were observed over the Iberian Peninsula, western Norway and over Russia. In these regions, precipitation totals were partly even exceptionally above normal (> 90th percentile). In Spain, for example, there was abundant rainfall throughout the month, on many occasions accompanied by storms. It was extremely wet in the interior of Castilla y León and along the Catalan coast. Rainfall exceeded 3 times the normal values on the Mediterranean coast in the provinces of Girona and Barcelona, to the southwest of Cáceres and in some parts of the Balearic Islands. In terms of total precipitation for the month, two observatories also exceeded the previous highest value in their long time series: Barcelona/airport with 264 mm and Valladolid with 114 mm. In addition, several main observatories recorded the highest number of rain and thunderstorm days in the corresponding series for the month of April. In France, rainfall totals often reached 1.5 to 3 times the normal amounts in eastern Corsica and Languedoc-Roussillon and up to 4 times normal locally in the Pyrénées-Orientales with 291.7 mm at Amélie-les-Bains (opened in 1977), a monthly record. As a result, the province Pyrénées-Orientales experienced the fourth wettest April on record behind April 1969.

Monthly precipitation totals in May were below the long-term means in the northwestern and northern part of the RA VI domain, whereas above-normal precipitation amounts were observed in the eastern part, especially over Russia and the Ukraine which saw even exceptionally above-normal precipitation totals (> 90th percentile). Largest precipitation deficits occurred, on the contrary, over southern United Kingdom and the Benelux countries, which saw less than 20% of normal amounts corresponding to drought indices lower than −3 over the United Kingdom indicating extreme drought conditions. Over the United Kingdom as a whole, only 47% of average rainfall was recorded on national level with exceptionally dry conditions over most of England and Wales. In Belgium, the station in Uccle reported only 5.4 mm of precipitation (norm: 66.5 mm) fallen on 6 days (norm: 16.2 days). This low amount is a new record for the current reference period (1981–2010). Looking at the entire period since 1833, only the first May in this series was drier. In May 1833, only 1.4 mm of precipitation fell. In the Netherlands, May was a very dry month as well with a national average of 15 mm compared to the normal 61 mm. In most places, there were at least 24 dry days.

The highest amount of total monthly precipitation within the RA VI Region in June fell in the alpine region between Germany, Austria and Italy (between 200 mm and 300 mm) and in the border region of Poland and the Czech Republic (> 200 mm). Lowest monthly precipitation amounts were recorded in eastern Germany, Scandinavia, Spain, eastern Türkiye, the Middle East and near the Caspian

Sea. Below-average June precipitation fell in Scandinavia, Spain, Portugal, Iceland, parts of Greenland and in large areas of Russia and other eastern parts of RA VI.

The monthly accumulated precipitation differed a lot within the RA VI Region in July. In Central Europe, especially in France and Germany, and in the east of Europe and southern Greenland, the precipitation sums were well below normal (< 10th percentile). In France, Germany, Türkiye and in eastern European Russia the GPCC precipitation index regionally dropped below −1.5, and in some parts below −3, which indicated severe or extreme drought conditions. In France, the national deficit exceeded 70% and with a country average of less than 20 mm precipitation, it was the driest month in the period of 1959–2020. In Germany, it was the sixteenth driest month since 1901. In contrast, due to the main influence of low pressure over the regions in Northern Europe, especially Finland, Sweden, the west of Russia and in northeastern Greenland, the regions experienced exceptionally above-normal precipitation (> 90th percentile) in July. The GPCC precipitation index in Northern Europe increased up to above 2, which indicated severely wet conditions. In some Swedish regions, there was 3 times more precipitation than normal, which led to some local storm surge at the coast of Gothland. In Norway, it was the seventh wettest month since 1900. In Ireland and the United Kingdom, the high precipitation caused some floods in the southwest of Ireland and also in Wales and in Cumbria. Some flooding events were also reported in western Georgia, in Bulgaria (Sofia) and in northeast Türkiye, caused by heavy rain.

Precipitation sums were exceptionally or much above the 1981–2010 average for August over parts of France, Italy, Switzerland, southern Germany, Austria, as well as Spain. Over most parts of Scandinavia, but also over northern Germany, on the contrary, drier than normal conditions prevailed. For several countries in Europe, the hot spell of the first half of the month ended with thunderstorms and torrential downpours, leading to widespread disruption including flooding after the weather situation had turned to a more westerly flow situation. Above-normal precipitation was observed especially in western parts of Europe. At the end of the month, Atlantic low-pressure areas with frontal systems led to widespread above-normal precipitation, especially over Ireland and the United Kingdom and in a band from the Alpine region across eastern Central Europe to northwestern Russia. In the east, on the contrary, August was over large parts drier than normal, especially in the countries neighbouring the Black Sea, where the precipitation sum was exceptionally below normal (< 10th percentile) leading to severe or even extreme drought conditions (for example in the Ukraine and Türkiye).

Precipitation sums were exceptionally below the 1981–2010 average (< 10th percentile) for September in the east and southeast of the RA VI domain. No or almost no precipitation fell in the northwest of the Caspian Sea. Monthly totals above the long-term means were reported in parts of the Mediterranean region, Northeastern and Northern Europe, and locally over the northern Iberian Peninsula. These totals were largely caused by heavy precipitation events. Storm Aila swept for example from the North Atlantic to Scandinavia. It was initially quite weak, but had a strong development, when it came to Finland on 16 and 17 September. Regions in central and southwestern Finland experienced storm gusts up to 125 km h^{-1}, high waves up to 5.8 m in Rauma and heavy rains up to 66 mm in 24 hours in Kajaani, which was equivalent to the area's average rain for the whole September month. The Western Mediterranean, but also the Central and Eastern Mediterranean were affected by intense storms in September as well, mainly due to the warm seawater (temperatures around 27 °C). The most outstanding event in that region was a medicane

over Greece which caused incalculable damage in parts of the Ionian Islands and Thessaly. The medicane made land fall in Kefalonia and wind gusts up to 135 km h^{-1} reaching hurricane strength. Rainfall estimations derived from combined satellite, station and model data resulted in 186 mm over the Ionian Sea and 123 mm over western Greece mainland in 32 hours (17–18 September). In Mouzaki 254 mm of rain was recorded on 18 September and 227 mm in Ithaca for 17–18 September.

Monthly precipitation totals in October were below the long-term means in the east and in the Mediterranean coastal areas of Spain and France as well as over Iceland, and the western slope of the Scandinavian Mountains, while being around or above normal elsewhere. In Türkiye, the deficit in precipitation exceeded 90% in the eastern and southeastern Anatolia Regions, both regions experienced the lowest October precipitation in the last 40 years. In eastern Anatolia, the average rainfall in October was only 4.5 mm which corresponds to a 91% decrease in precipitation compared to normal (which is 50.9 mm). In southeastern Anatolia, the average rainfall of the region in October was 0.3 mm, which is a 99% decrease in precipitation compared to normal (36.8 mm). In the United Kingdom, on the contrary, October was a generally unsettled month with rain crossing the country at frequent intervals and some heavy and persistent falls of rain at times. Storm Alex brought rain and strong winds to much of England and Wales on 2 October, and a very wet day followed for much of the United Kingdom on 3 October. Later on, storm Barbara caused some impacts, with flooding on the Glasgow to Ardrossan/Largs railway line on 19 October. Storm *Alex* also brought exceptionally wet and windy weather to France. Monthly records for the number of days with more wind than 60 km h^{-1} were beaten with 8 days in Lons-le-Saunier (Jura), 9 days in Poitiers (Vienne), 13 days in Saint-Nazaire (Loire-Atlantique) and 16 days in Brest (Finistère). Same for the records of the number of days with higher wind speeds than 100 km h^{-1} which were beaten with 2 days in Aurillac (Cantal) and 3 days at the tip of Socoa (Pyrénées-Atlantiques). The rainfall for France in October was on average 40% higher than normal on national level, but over northern Brittany and the Manche département as well as over the southern Lot aux Landes rainfall was 2 to 3 times the normal: 289.2 mm was recorded at Cavan (Côtes-d'Armor), 307.8 mm at Bricquebec (Manche), 413.5 mm at Saint-Martin-de-Hinx (Landes) and locally more than 580 mm in the Alpes-Maritimes. Conversely, the regions of Roussillon to the south of the Ardèche and Provence, as well as the east of Haute-Corse, experienced a deficit of more than 50%, even 75% on the Rhone delta as well as locally in the Gard and Hérault. Only 14.2 mm were observed at Marsillargues (Hérault), 16.8 mm at Aigues-Mortes (Gard) and 17 mm at Marseille (Bouches-du-Rhône). In Switzerland, storm low *Brigitte* caused wind speeds up to 181 km h^{-1}. In addition, the cyclone caused torrential precipitation, especially along the Alps. In 24 hours, more than 250 mm occurred in some regions of the Alps, especially in Switzerland. In the Czech Republic, October was strongly above normal in terms of precipitation, with a monthly total precipitation of 90 mm, representing 209% of the 1981–2010 normal. Most precipitation (174 mm) fell in the Zlín Region. It also rained more than 100 mm in the Liberec (107 mm), Pardubice (105 mm), Olomouc (129 mm) and Moravian-Silesian (158 mm) regions.

As a result of the unusual anticyclonic conditions dominating in November, monthly precipitation totals were below the long-term means nearly everywhere in the RA VI domain except for Scandinavia, western Russia and some parts of the Mediterranean region. No or almost no precipitation fell in some southern parts of the RA VI domain, for example in Anatolia, the Balkans

and south of the Alps. France reported a precipitation deficit of more than 60%. Records were observed with only 18.1 mm in Biscarrosse (Landes), 15.4 mm in Nevers (Nièvre) or 6.8 mm in Romorantin (Loir-et-Cher). In France, November 2020 ranks among the three driest November months over the period 1959–2020, without reaching the record of November 1978 with a deficit of 80%. In Switzerland, precipitation in November was widely less than 10% of normal from the Valais via the southern side of the Alps to Graubunden and in some areas even less than 5% of the 1981–2010 norm. The other areas of Switzerland mostly received only 20% to 50% of the norm. In Romania, large parts received less than 50% of normal precipitation, most parts less than 20 mm. In Moldova, the monthly precipitation amount over half the territory was equal to 5–25 mm (15%–65% of the norm), in the rest of the territory between 28 mm and 45 mm (75%–115% of the norm). Precipitation during the month fell predominantly in the form of rain, at the end of the month in the form of sleet and snow. In Germany, a deficit of 46.3 mm was observed, corresponding to 69.1% less precipitation than the average for the period 1981–2010. November 2020 was thus the seventh driest November in Germany since 1901 and the eighth driest since 1881, making it one of the very dry November months in terms of precipitation. In Saxony-Anhalt and Thuringia less than 10% of the average precipitation fell locally: Erfurt/Weimar (7%) and Magdeburg (8%) registered the lowest monthly total with 3 mm each. In Austria, the dry high-pressure weather also brought one of the ten Novembers with the least precipitation in history of measurement. For Austria as a whole, there was 74% less precipitation than normal. This also had an impact on the snow situation. In Türkiye, a 49% decrease in precipitation compared to normal was observed in November, in the north and west of the Aegean, Marmara and Central Anatolia, the deficits exceeded even 80% in places. In Greece, the station Aktio only reported 9 mm (only 5.3% of the normal value referring to 1971–2000) precipitation, making it the driest November on record. Both, the northwestern part of Europe and the Mediterranean region, on the contrary, were hit by several heavy rain events along with strong winds. Due to the heavy rains widespread flooding occurred.

December: Monthly precipitation totals were below the long-term means, especially in the eastern parts of the RA VI domain, but also in Western Scandinavia, Central Europe, over the south of the Iberian Peninsula, and the Baltics. No or almost no precipitation fell in some parts around the Caspian Sea and the southern coast of the Iberian Peninsula. Exceptionally dry conditions (< 10th percentile) occurred over Türkiye, Baltic countries and parts of European Russia with less than 40% of normal precipitation. Above-normal precipitation totals, on the contrary, occurred in the central Mediterranean region, Northwestern Europe and parts of Scandinavia with partly even exceptionally above-normal amounts (> 90th percentile), affecting for example the United Kingdom, France, the northern coast of Spain, and Italy. In the United Kingdom, rainfall was 135% of average overall, with parts of eastern Scotland, East Anglia and Gloucestershire seeing more than twice the normal rainfall. In Norway, the monthly precipitation was 115% of normal for the country as a whole, but in Agder, Vestfold and Telemark and Viken there were stations that received between 400% and almost 500% of normal: for example, Senumstad (Birkenes, Agder) 595.1 mm (416% of normal), Bøylefoss (Froland, Agder) 559.8 mm (491% of normal) and Nelaug (Åmli, Agder) 517.7 mm (493% of normal). The highest daily precipitation was 100 mm, and was registered at Godal (Skien, Vestfold and Telemark) on 28 December. In Romania, the deviation of the precipitation amount in December 2020 from the median of the standard reference interval (1981–2010), was positive in most regions of the country. High values, between 100% and 300%, were recorded in the northeast, east, central and west of Muntenia, central and southern Moldova and on the coast. The largest positive deviation,

391.5%, was registered at the Râmnicu Sărat meteorological station. In Croatia, precipitation anomalies for December ranged from 77% of the multi-annual average in Sisak, where 53.6 mm of precipitation fell, to 347% in Makarska (443.1 mm). Very wet and extremely wet conditions occurred in the southernmost part of the country.

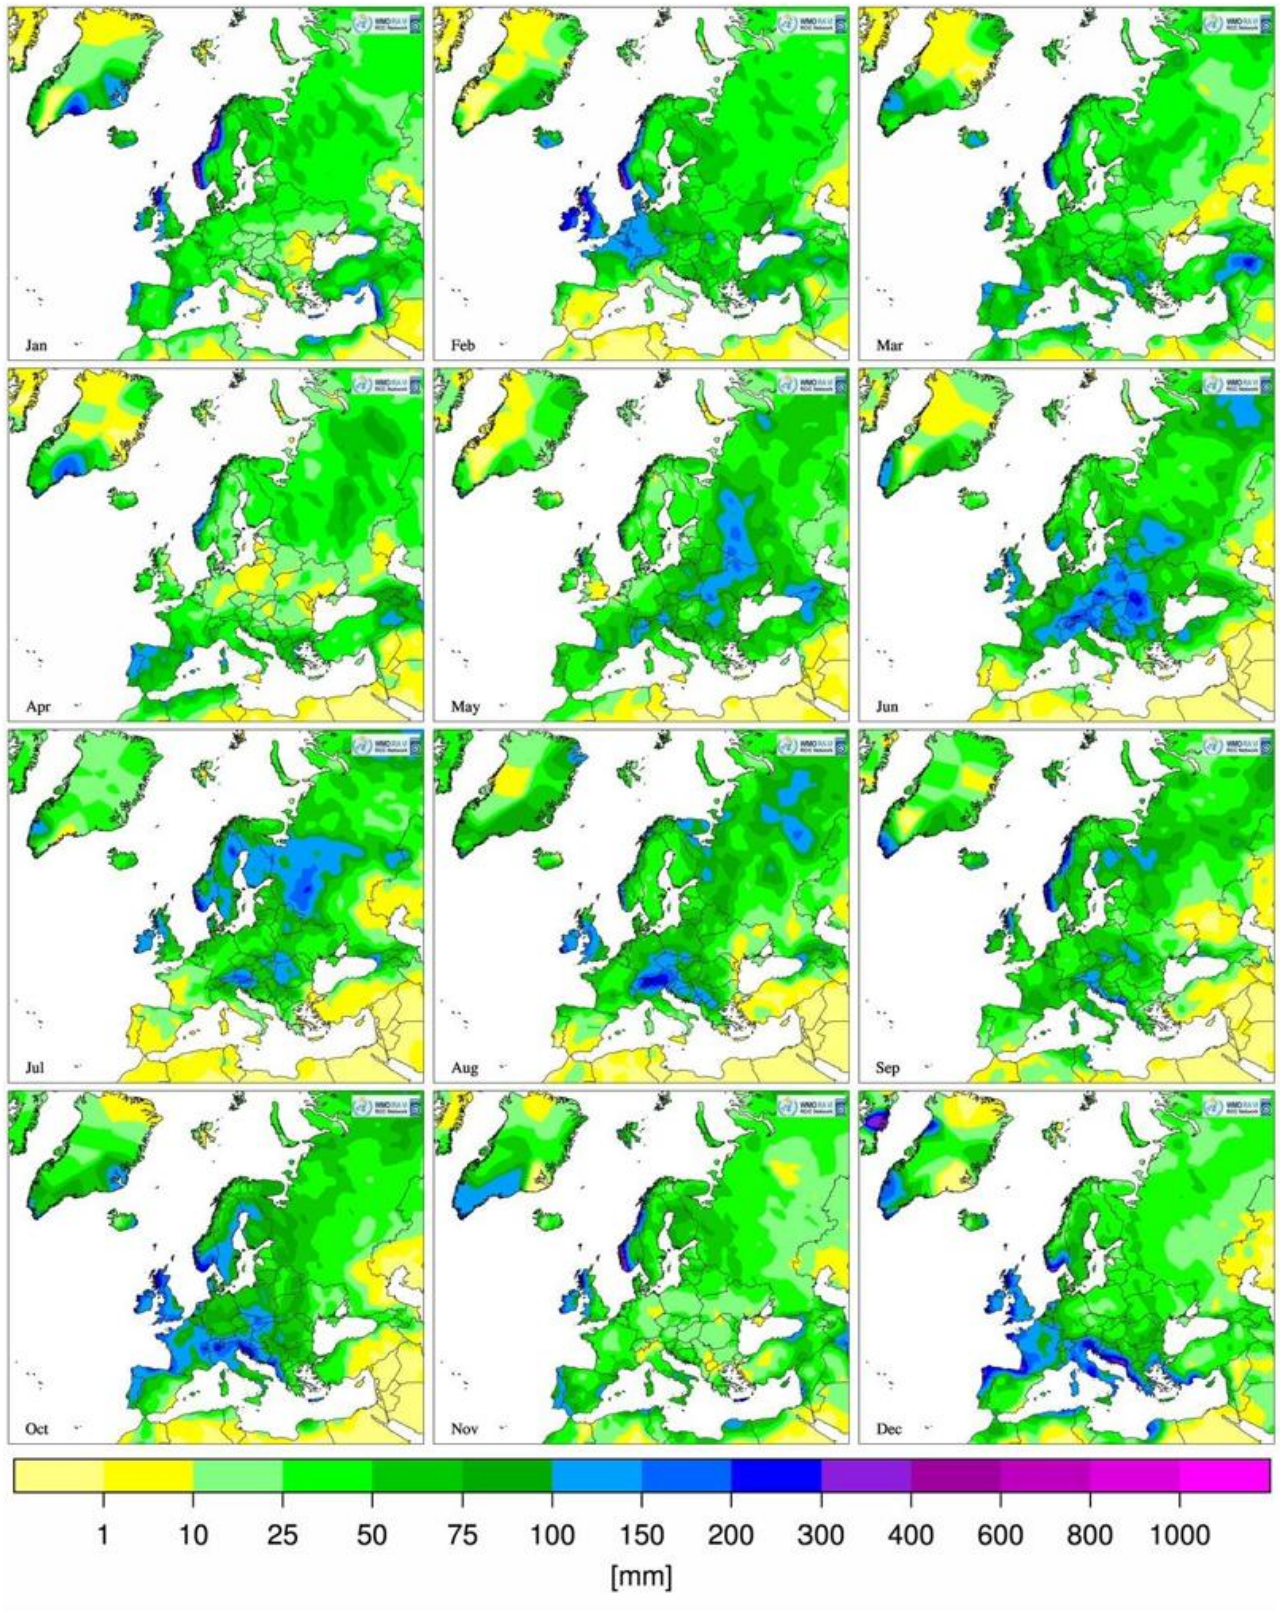

Figure 4-5: *Monthly mean precipitation in mm/month for each month of the year 2020. Source: RCC-CM website.*

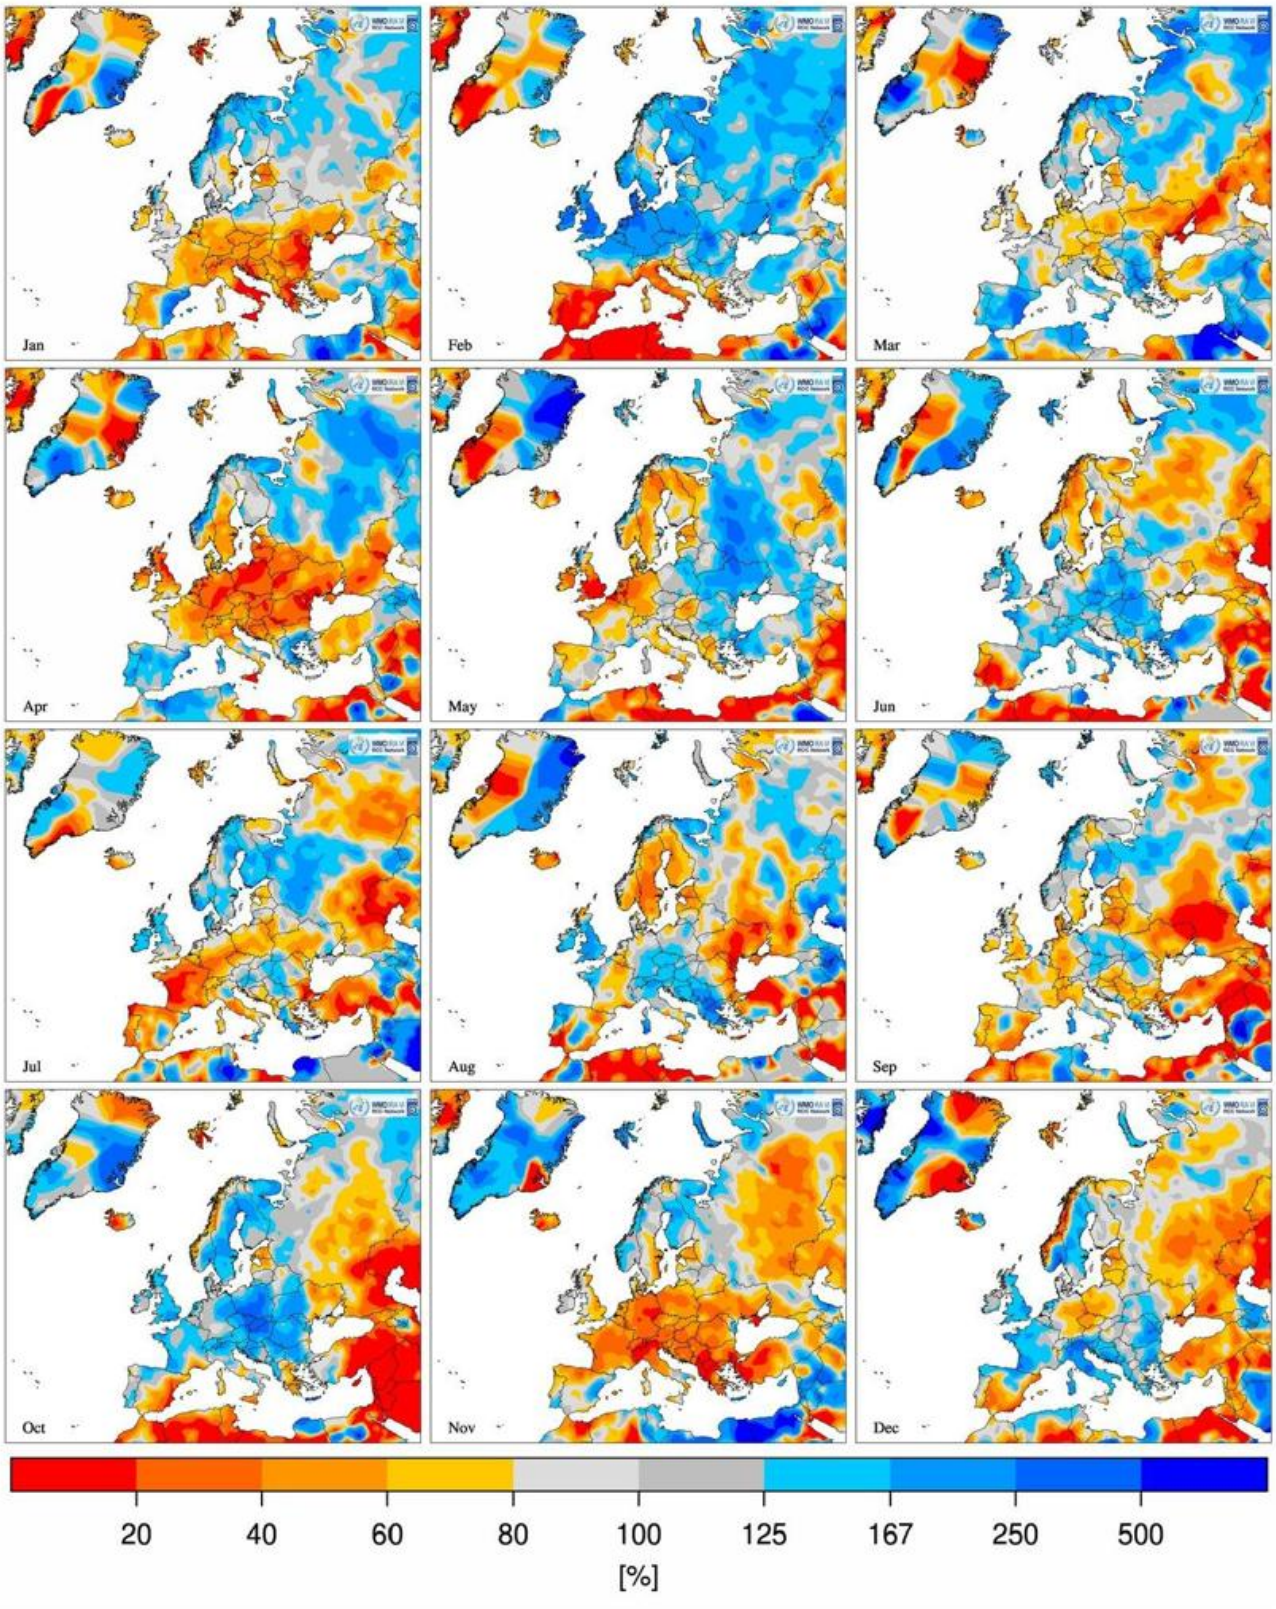

Figure 4-6: *Monthly precipitation anomalies in % of the average for 1981–2010 for each month of the year 2020. Source: RCC-CM website.*[5]

[5] Similar to the RCC annual precipitation anomaly maps shown in 2.1.3, the RCC monthly precipitation anomaly maps for March, April, June and July show deficits for Estonia which turned out to not correctly represent the anomalies reported by NMHS of Estonia (indicating above normal precipitation amounts). The issue is likely related to incorrect decoded real-time data used for the grid generation. As a result, these grid point values may deviate considerably from actual precipitation totals.

4.4. Sunshine duration

Table 4-6: Monthly area average sunshine duration anomalies in hours for each subregion in the year 2020 (reference period: 1981–2010; definitions of the subregions see Figure 1-1).

Region	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Central and Western Europe	+14	+11	+37	+80	+38	−16	+16	+3	+30	−44	+18	−11
Eastern Europe	+4	+9	+36	+32	−29	+8	0	+15	+32	0	−3	+3
Iberian Peninsula	−2	+36	−26	−61	+26	−5	+13	+3	+6	+20	+4	−8
Mediterranean and Balkans	+30	+20	+7	+43	+7	−13	+7	+4	+17	+24	+25	+2
Middle East	0	+3	+4	+6	+15	+11	−8	+2	+3	+38	−9	+14
Scandinavia and the Baltic States[6]	+1	+4	+6	+8	+9	+17	−7	+10	−1	−6	−1	−2

In January 2020, sunshine duration was above normal over most parts of the RA VI Region, with a surplus up to 100 hours more than normal occurring over Italy and the Balkans, corresponding to a surplus of radiation in the range of +10 W m^{-2} to +30 W m^{-2}. Spain, the United Kingdom and the northeast of Europe, on the contrary, experienced anomalies of 50 hours less sunshine than normal. As for the whole month of January, the sun shone in Moscow for eleven hours only, 3 times less than normal. Such a deficiency of sunshine was observed for the first time in this century.

In February 2020, sunshine duration was above normal over major parts of the RA VI Region (reference period 1986–2015), with a surplus up to 20–100 hours more than normal occurring over Italy and the Mediterranean Sea, corresponding to a surplus of radiation in the range of 20 to 40 W m^{-2}. The northwest and east of Europe, on the contrary, experienced sunshine anomalies of 20 hours less than normal.

In March, it was sunnier than normal almost everywhere in the RA VI Region, corresponding to a positive anomaly of incoming radiation. Largest surpluses in sunshine hours were recorded over southern parts of European Russia and over eastern Ukraine with more than 100 hours. Parts of Spain experienced less sunshine than normal, locally up to 100 hours less, corresponding to a deficit in radiation of 30 to 40 W m^{-2}.

Western, central and eastern parts of the RA VI Region were not only very dry in April, but they also received much more sunshine than normal. Largest surpluses of sunshine duration occurred over a wide band stretching from the British Isles in the west to southern parts of European Russia in the east. These areas received more than 50 hours more sunshine than normal, partly even 100 hours more. This corresponds with surpluses of 40 W m^{-2} and more. Only Iberia received much less sunshine and radiation with deficits of 50 to 100 hours of sunshine or 30 W m^{-2} respectively. Several countries reported their sunniest April on record, among them the United Kingdom, the Netherlands (since 1901) and Germany, for Austria April 2020 ranked second sunniest on record.

May 2020 was sunnier than normal over the western and northern part of Europe as well as over the southeast with largest anomalies occurring over parts of France, the United Kingdom and Belgium. The latter experienced more than 100 hours more sunshine than normal and radiation

[6] This subregion is not fully covered, therefore the values are not representing the entire region (see maps)

surpluses of more than 50 W m^{-2}. In the United Kingdom, it was the sunniest May in a series from 1929, with 143% of average sunshine. Sunshine was relatively close to average in the north of both, Scotland and Northern Ireland, but it was the sunniest May on record by a wide margin for England and Wales, with numerous sites recording over 300 hours. In Belgium, more than 300 hours of sunshine were recorded in Uccle (normal: 191 h 03 min). Only in 1989 (327 h 41 min) and 1990 (308 h 31 min) did the sun shine even more. This high sunshine duration is also reflected in the very low number of heavily cloudy days: 4 days, as in 2011 (normal: 10.7 days). For the ninth time, there were no days with completely cloudy skies (normal: 2.7 days). The previous time this was the case was in 2015. Also, the Netherlands reported a very sunny month with a national average of 324 sunshine hours, compared to the normal of 213 sunshine hours. The east of the RA VI Region, on the contrary, experienced up to 100 hours less sunshine than normal.

The sunshine duration in Norway, Finland and Sweden was over 100 hours above normal in June. As a result, the radiation was 40–50 W m^{-2} above normal in Scandinavia and 30–40 W m^{-2} in parts of Eastern Europe. The Swedish east coast experienced the highest anomaly of radiation with +50 W m^{-2}.

In July 2020, the sunshine duration was above normal (w.r.t. 1986–2015) over most parts of the RA VI Region with large positive anomalies over Central Europe. Especially France and Germany had a surplus up to 50 hours more than normal, corresponding to a surplus of radiation in the range of 10 W m^{-2} to 30 W m^{-2}. Northern Europe (Scandinavia, the United Kingdom and Ireland), on the contrary, experienced anomalies from −20 to −50 hours.

Over Scandinavia and eastern parts of Europe, August was sunnier than normal with a radiation surplus of 30 W m^{-2} and more. The western part of Europe, on the contrary, experienced mostly less than normal radiation, especially the British Isles.

Over central and eastern parts of Europe, September was sunnier than normal with a radiation surplus of 20 W m^{-2} and more. Largest surpluses occurred over Germany, the Ukraine and southern parts of European Russia. The southwestern part of Europe and Scandinavia, on the contrary, experienced mostly normal or slightly less than normal radiation.

October: Western, central and eastern parts of the RA VI Region received mostly less than normal sunshine hours and radiation, with deficits up to 100 sunshine hours or 30 W m^{-2} respectively. Large parts of Iberia and the southeast, on the contrary, experienced more than normal sunshine hours and radiation with largest anomalies occurring over Türkiye and the South Caucasus region.

Due to the prevailing anticyclonic conditions in November, the sun shone generously over many regions for much of the month. As a result, it was sunnier than normal over Western Europe, Italy and Southeastern Europe (Southwestern Balkans, Greece) and Türkiye with up to 50–100 sunshine hours more than normal and radiation surpluses of up to 20–30 W m^{-2}. For the rest, the number of sunshine hours were closer to normal in absolute terms, but partly also outstanding. In Germany, the area average of sunshine duration was 85.7 hours. This is 32.1 hours or 59.9% more than in the reference period 1981–2010. This makes the month the third sunniest month since 1951 among the very sunny months of November. In France, sunshine was more than 25% above average across most of the country. Numerous monthly sunshine records over the 1991–2020 period have been recorded from the southwest to the northeast with a surplus reaching 1.5 to 2 times of normal, and even locally more than twice from Burgundy to the Great East with 132 hours in Langres (Haute-

Marne) and 144 hours in Nevers (Nièvre). In Switzerland, sunshine duration in November in the Alps and on the southern side of the Alps was between 150% and 180% of the 1981–2010 norm. North of the Alps, the values mostly rose to 120 to 150%, in northwestern Switzerland locally between 170% and 180% of the norm. Austria received 40% more sunshine than the average and had thus one of the five sunniest November in the history of measurements.

December: Most of the RA VI Region experienced normal or less sunshine hours and radiation than normal. Largest deficits occurred over the region experiencing largest precipitation surpluses, for example northern Iberia, northern Italy and parts of the Balkan Peninsula with up to 100 sunshine hours or 20 W m^{-2} less than normal. The east, on the contrary, saw more sunshine than normal with surpluses of up to 100 sunshine hours and 30 W m^{-2} occurring for example over Türkiye.

4.5. Monthly maps of selected significant climate anomalies and events

The following maps are based on different data (as noted in the legends in parentheses), and are meant to summarize weather conditions in each month of the year 2020. The monthly maps contain information about the extreme anomalies of temperature, precipitation and wind gusts. Points are calculated from station data and represent the number of very warm or cold days, the locations of strong wind gusts (≥ 32 m s^{-1}) and days with precipitation. If more than one extreme anomaly occurs at the same location, the point is subdivided into several different colours. Coloured areas are based on interpolated gridded data for temperature (land and ocean) and precipitation (only land areas). If more than one extreme anomaly occurs at the same grid, the area is shaded.

4.5.1. January

In Russia, many stations reported new maximum air temperature records, some of these were also broken for several days running. During a warm spell from 31 January to 4 February in Serbia highest numbers of bright days were registered on Sombor and Zlatibor as well as new records of insolation hours in Kursumlija. January 2020 belongs to one of the 10 driest Januaries in Greece. The stations Kerkyra (sixth driest since 1901) in the northern Ionian Sea, Kakmata (fifth driest since 1901) in southern Peloponnese, Andravida in western Peloponnese (second driest since 1959) and Larisa in Thessaly (second driest since 1949) reported new drought records for January. In Thessaly only 1 mm precipitation occurred, which is 31 mm less than normal.

Exceptional above-normal precipitation of 470 mm was recorded for Israel in January, making it the second rainiest January on record. In Mikve Yisrael, it was a record-breaking wet January. In Tel Aviv highest rain intensities of 79 mm within two hours occurred and caused flooding. Heavy precipitation events of intensities returning only every 10 to 20 years were observed over the Azores (Portugal) causing landslides and flooding. In Spain, extreme rainfall was reported due to the storm *Gloria* along the Mediterranean coast between Catalonia and Alicante, as well as the coast of Málaga and the Balearic Islands from 18 to 25 January.

4.5.2. February

Several new heat records occurred in February. In Türkiye, 201 stations set new maximum temperature records as well as many cities in Russia, for example Petrozavodsk and Kotlas. The capital city, Moscow, even measured the second warmest February since start of the timeseries. Record-breaking daily air temperatures were also observed in Kopaonik (Serbia). Vilsandi and Kuusiku in Estonia measured its second (3.4 °C) and third to fourth (9 °C) warmest monthly mean temperature, respectively. More records were set in Italy, where in Emilia Romagna and Piedmont due to a heat wave the warmest February since 1961 and 1958 was recorded. Piedmont broke the daily temperature record of the month on 3 February. A heatwave from 14 to 25 February occurred in the Inner Centre Region of Portugal.

Sweden reported low temperatures of −36.4 °C at Nikkaluokta on 20 February which was the lowest for the winter 2019/2020.

In February, a few precipitation records were set. Monthly total for Virtsu station in Estonia was 110 mm (307% of normal) – first rank since 1911. The monthly total for Tallinn station was 105 mm (293% of normal) – the first rank since 1883. Exceptionally high rain amounts occurred as well in Luxembourg. At some stations for example Grevenmacher and Koerich new precipitation records

were set. In Russia, after heavy rainfall a flood occurred on the Pshish river on 4 February. The town of Khadyzhensk in the Krasnodar Territory was inundated leading to infrastructural damage.

February 2020 was an extraordinarily stormy month in some places. The month started with cyclone Petra, followed by cyclone Sabine on 10 February and finishing the month with the cyclones Yulia and Bianca. These storms affected main parts of Austria. The wind gusts reached up to 140 km h^{-1} causing damages on infrastructure, cancelled flights as well as power breakdowns in many households. Damages occurred mainly north of the Alps (Vorarlberg, Tyrol, Salzburg, Upper and Lower Austria as well as in Vienna and Burgenland). Poland also was hit by the heavy storm called Sabine on 10 and 11 February. Three casualties where caused through the extratropical cyclone. Storm Yulia also affected Poland at the end of February with wind gusts of 110 km h^{-1}. In Lens (Belgium), a tornado was reported on 10 February. A heavy storm (named Uta in Central Europe) hit the country of Iceland on 14 February, the worst storm for many years. There was considerable damage in the south, southeast and west.

4.5.3. March

In March, a cold wave over Central Europe held on up to 8 days. At the end of March, the cold period started for Austria continuing until April and causing frosty nights and late frost. This cold wave was also the reason for agricultural damage especially in Vorarlberg, Styria and Burgenland, where fruit cultivations were damaged. Hungary too, was affected by the cold wave between 22 and 26 March and between 30 March and 3 April reaching new regional daily minimum temperatures. In Russia, three warm spells were reported. Regional temperature anomalies of +5 °C were observed setting new temperature records.

Intensive rainfall occurred over the Mediterranean and the Balkans, Spain and the Middle East. In Dimitrovgrad (Serbia), record-breaking daily and monthly sums were measured. The storms Karine, Myriam and Noberto hit especially the north of the Iberian Peninsula between 1 and 6 March. Spain recorded new precipitation records on 31 March when heavy rainfall was observed. Castellón-Almassora set a new record of 150 mm as the highest rainfall at this station since 1976. In Russia, an Atlantic cyclone caused warm conditions.

Sweden reached its annual maximum sea ice extent during the first week of March. However, it was the lowest maximum extent for at least 120 years.

4.5.4. April

Cold waves extending from France over the Alps and the Mediterranean and Balkan countries to Türkiye were dominating in April. In Austria, the cold period from March continued to the beginning of April. Cold conditions prevailed up to 26 days over Bulgaria and Rumania starting on 1–5 April with minimum temperatures of −6.7 °C and affecting fruit cultivations in Bulgaria. Cold conditions at the beginning of April were also observed in parts of Serbia like Kikinda and Belgrade as well. Hungary recorded new daily minimum records up to −11.9 °C at Zabar station due to this cold wave. A second frost period occurred from 6 to 10 April in Bulgaria. Slovenia observed a cold period from 30 March to 3 April and between 14 and 16 April over the whole country leading to snow fall and damage of fruit cultivations. Another period with frost was registered between 21 and 25 April, where minimum air temperatures of −3.9 °C were measured in Bulgaria (e.g. Vidin and Dobrich). This cold wave caused damages to orchards as well.

In Belgium, contrary conditions were observed. In Uccle, the daily maximum temperature was at least 20 °C from 5 to 12 April, which was the earliest year series of consecutive spring days in April. In general, April was extremely dry and sunny in Belgium (new record for sunshine duration in Uccle for April and May of 578.9 hours since 1887). Between 9 to 13 April a warm spell was recorded in Banatski Karlovac (Serbia). Beside a record-breaking warm April at Kap Morris Jesup and station Nord in Greenland, another record was set in Denmarkshavn for the second warmest April and May. Poland reported a dry spell over the whole country with total precipitation of 8.3 mm.

Heavy precipitation occurred over Greece, causing floods and infrastructural damage on 4–8 April. Thessaloniki station recorded its wettest April, measuring 111 mm rainfall which is almost 3 times above the normal value.

4.5.5. May

Cold and wet conditions occurred in Eastern Europe, especially in Poland and Russia, during May. In Russia, mainly western and southwestern regions were affected by cold air masses and night frost. Moreover, many records of minimum air temperatures and maximum precipitation were observed between 29 and 31 May.

Especially warm conditions were registered over the Iberian Peninsula and southern France. Several heat waves appeared in the Mediterranean, the Balkan states and the Middle East. In the first half of May drought caused wildfires in Austria which had to be extinguished by large scale operation of firefighters and helicopters. In Portugal, new heat records were set due to a heat wave with particularly high intensities and duration (13–31 May) over the whole territory. Another warm spell was registered in Dimitrovgrad (Serbia) from 13 to 17 May. An especially extreme heat wave was reported in Greece from 15 to 20 May. It was the hottest heat wave in May in the past 50 years. During the same period, an intense heatwave overcame Israel starting one day earlier on 14 May. In several regions of Israel, temperatures of 35–42 °C lasted for a week. In May, many monthly and daily maximum temperature records were observed for example in Armenia, Cyprus and Estonia.

On 20 and 21 May, extreme storms with hail and rainfall including thunderstorms induced damage and fires in Bulgaria. Especially northwestern Bulgaria was affected. Regional egg-sized hailstones fell during the storm destroying houses, agriculture and cars. Heavy rainfall and thunderstorms occurred as well in Austria causing floods in the last third of May. Especially on 23 May, thundery rain showers showed extreme intensities and damaged infrastructure of regions in Austria.

In Lithuania, an impressive temperature drop and a snow cover over the whole country was observed from 12 to 15 May. Big damage to active plant vegetation was caused due to the temperature drop from 16–25 ºC to 9–11 ºC. Arctic airmass let to a sleet and snow cover of 16 cm in the entire country.

4.5.6. June

In June, warm conditions were observed in Eastern Europe, Scandinavia, parts of Spain, France and United Kingdom. This weather situation came along with heat waves, which occurred with high intensities in parts of Eastern Europe. The second half of June recorded a heat wave in Estonia causing temperatures over 30 °C. Russia recorded several new monthly heat records as well as Sweden, where at Skellefteå Airport with 34 °C the highest temperature for June was observed since 1970 .

In the Mediterranean, the Balkan States and Central Europe especially wet conditions and flooding were recorded. June was a very wet month in Austria with precipitation anomalies of +25% of normal. Heavy precipitation events and thunderstorms, especially at the end of June, caused fires, mudflows, flooding and damages of more than eight million euros. In the states Salzburg, Upper Austria, Styria and Lower Carinthia the events were intensive. An amount of 90 mm of rain during two hours was measured in Gleisdorf.

Large parts of Europe observed more precipitation than normal. New records were set in Russia on 3 and 4 June, when the Uzlovaya station recorded a daily precipitation record of 144 mm. Similar records for the month of June were registered in Serbia (in Kragujevac and Nis). Heavy precipitation events caused floods. Between 14 and 15 June, thunderstorms, rain and hail desolated parts of Bulgaria. Even landslides were observed. In Bursa (Türkiye), on 21 June extreme rainfall triggered flooding and damaged agriculture and cars, five people died as well as many farm animals.

In Poland, a tornado destroyed 23 buildings, infrastructure and power grids near Kaniów on 7 June.

4.5.7. July

In July, a few prolonged heat waves occurred. Over parts of the Iberian Peninsula, the Middle East, Eastern Europe, the Mediterranean and Balkans heat waves continued the whole month. The warmest July since 1931 was recorded in Portugal due to the occurrence of a heat period. The station Uccle in Belgium registered the third highest temperature (36.5 °C) on record. Abnormally hot conditions and new heat records were also observed in many regions of Russia. In Rostov-on-Don 40.2 °C were measured, which is the highest absolute temperature for the summer period.

Hot weather conditions were observed, followed by thunderstorms and heavy rainfall. On 6 July, large parts of Sofia (Bulgaria) were flooded as the Perlovska river burst its banks after extreme rainfall. Some stations in the capital measured up to 50 mm. The Vladayska River also inundated the districts of Orlandovtsi and Benkovski. In Lithuania, five heat waves were recorded followed by powerful convection including a tornado on 7–9 June. In Austria, a heavy storm with wind gusts up to 90 km h^{-1} caused infrastructural damages at the end of July. Floods and mudflows occurred. Krusevac in Serbia even measured its third wettest July with a value of 187.5 mm precipitation. Seven million euros of damage were caused by heavy rainfall, hail and storm in Slovenia on 29 July. In Luxembourg, on the other hand, July ranked among the 10 driest July months since 1851 at all stations. In Fouhren and Hosingen it was even the driest July since 1951.

4.5.8. August

August 2020 was dominated by heat waves and stormy extreme events. Many parts of the RA VI Region showed extremely warm conditions, causing wildfires due to drought or flooding due to thunderstorms. Heat periods of July continued during August in most subregions (Mediterranean, Balkan states, the Middle East, the Iberian Peninsula). High temperatures were reported in Central Europe, especially in Poland, Belgium and Luxembourg. In Poland and Belgium, heat waves with temperatures about 30 °C occurred setting new heat records during the first half of August. At Findel Airport in Luxembourg, the second warmest August (monthly mean value 21.2 °C) since 1947 was measured. At the end of August, an intense heat spell prevailed in Israel reaching temperatures up to 46 °C in the eastern valleys. The only country that registered a cold wave was Armenia from 21 to 28 August. During this time period temperatures around 0 °C were measured which were the lowest in August on record.

Heat spells ended in thunderstorms including heavy rain, hail and wind causing floods and mudflows. For example, in some regions in Austria (Dornbirn, Kötschach-Mauthen, Brenner) it rained up to 150 mm accompanied by hailstorms and lightning strikes from 28 to 31 August. Due to heavy precipitation events, Matrei/Brühl was close to reach its 100-year flood mark with 449 cm. The neighbouring country Switzerland measured heavy rainfall up to 224.5 mm on 29 August. Exceptionally wet conditions were also observed over the Balkan Peninsula, the Iberian Peninsula and the United Kingdom. On 8 August, Greece reported on storms causing heavy floods, erosion phenomena and destruction on the island of Evia. The state of emergency was declared, eight people even died. In Demir Kapija (North Macedonia) extremely heavy precipitation with more than 700% of normal were measured. For North Macedonia as a whole, August 2020 was the wettest on record. Several million euros damage on infrastructure was caused by a fast-moving supercell storm in eastern Slovenia on 30 August. Especially wine yards were damaged by a heavy hailstorm.

4.5.9. September

Exceptionally dry conditions during September were observed in the east and southeast due to the occurrence of heat waves. Bulgaria recorded a prolonged heat spell in the entire country during the first half of September. Dry conditions and wind gusts triggered a higher risk of fire. Cyprus measured the highest maximum temperature of 46.2 °C (Athalassa Park) on record. In Israel, an exceptionally strong heat wave between 3 and 20 September occurred. Highest temperatures were measured between 3 and 5 September, setting monthly and annual records for September. However, warmer than normal conditions occurred in barely every subregion. Belgium set a new maximum temperature record in Uccle with 34.3 °C and in Steinsel in Luxembourg the highest monthly temperature on record of 35.2 °C was observed. Luxembourg registered even more new records on 15 and 16 September. This heatwave affected even Poland between 14 and 16 September with temperatures about 30 °C.

Several floods were recorded in the southern part of the RA VI Region, especially in the Mediterranean and the Balkan states. Extremely high precipitation amounts occurred in Hungary during 25 September and 13 October causing river floods. In Austria, heavy precipitation was accompanied with a temperature drop between 24 and 26 September. These weather conditions led to heavy snowfall and flooding in September.

On 18 and 19 September a subtropical storm including thunderstorms and strong gusts up to 90 km h^{-1} occurred in Portugal. In Beja and Palmela, even two tornados were reported. A dust storm affected life in Ankara (Türkiye) on 12 September. Six people were injured.

4.5.10. October

In October, extremely wet conditions occurred in Western Europe, Scandinavia and on the Iberian Peninsula. Flooding occurred in many RA VI subregions. Heat periods continued in Eastern Europe and the Middle East. In Israel high temperatures occurred again due to a Sharav on 8 and 9 October. Temperatures reached up to 42 °C in the Jordan Valley and the Arava. An unusual warm period was also registered in Estonia during October. Several monthly heat records were set. The monthly mean anomaly was +2.8 °C in Tallin – the highest anomaly since 1883.

Stormy weather and thunderstorms were reported in Austria at the beginning of October. In Feuerkogel wind gusts reached up to 160 km h^{-1}. Heavy rain events were especially observed in East Tyrol and Upper Carinthia followed by flooding and mudslides. Historic Mediterranean rainfall

with dramatic floods and more than 20 victims occurred on 3 October (associated to Alex storm): a rainfall record was set with 513 mm in 24 hours (Saint-Martin-Vésubie, Alpes-Maritimes, France)." The Iberian Peninsula was affected by the storm *Barbara* on 19–22 October leading to heavy rainfall especially in the Central System Mountains of Spain. Crete (Greece) also experienced an extremely wet October. Thunderstorms and heavy rainfall caused floods and landslides on the island. October 2020 was the wettest since 1931 at the Heraklio station where 304 mm precipitation was measured which is 6.5 times above normal (1971–2000).

4.5.11. November

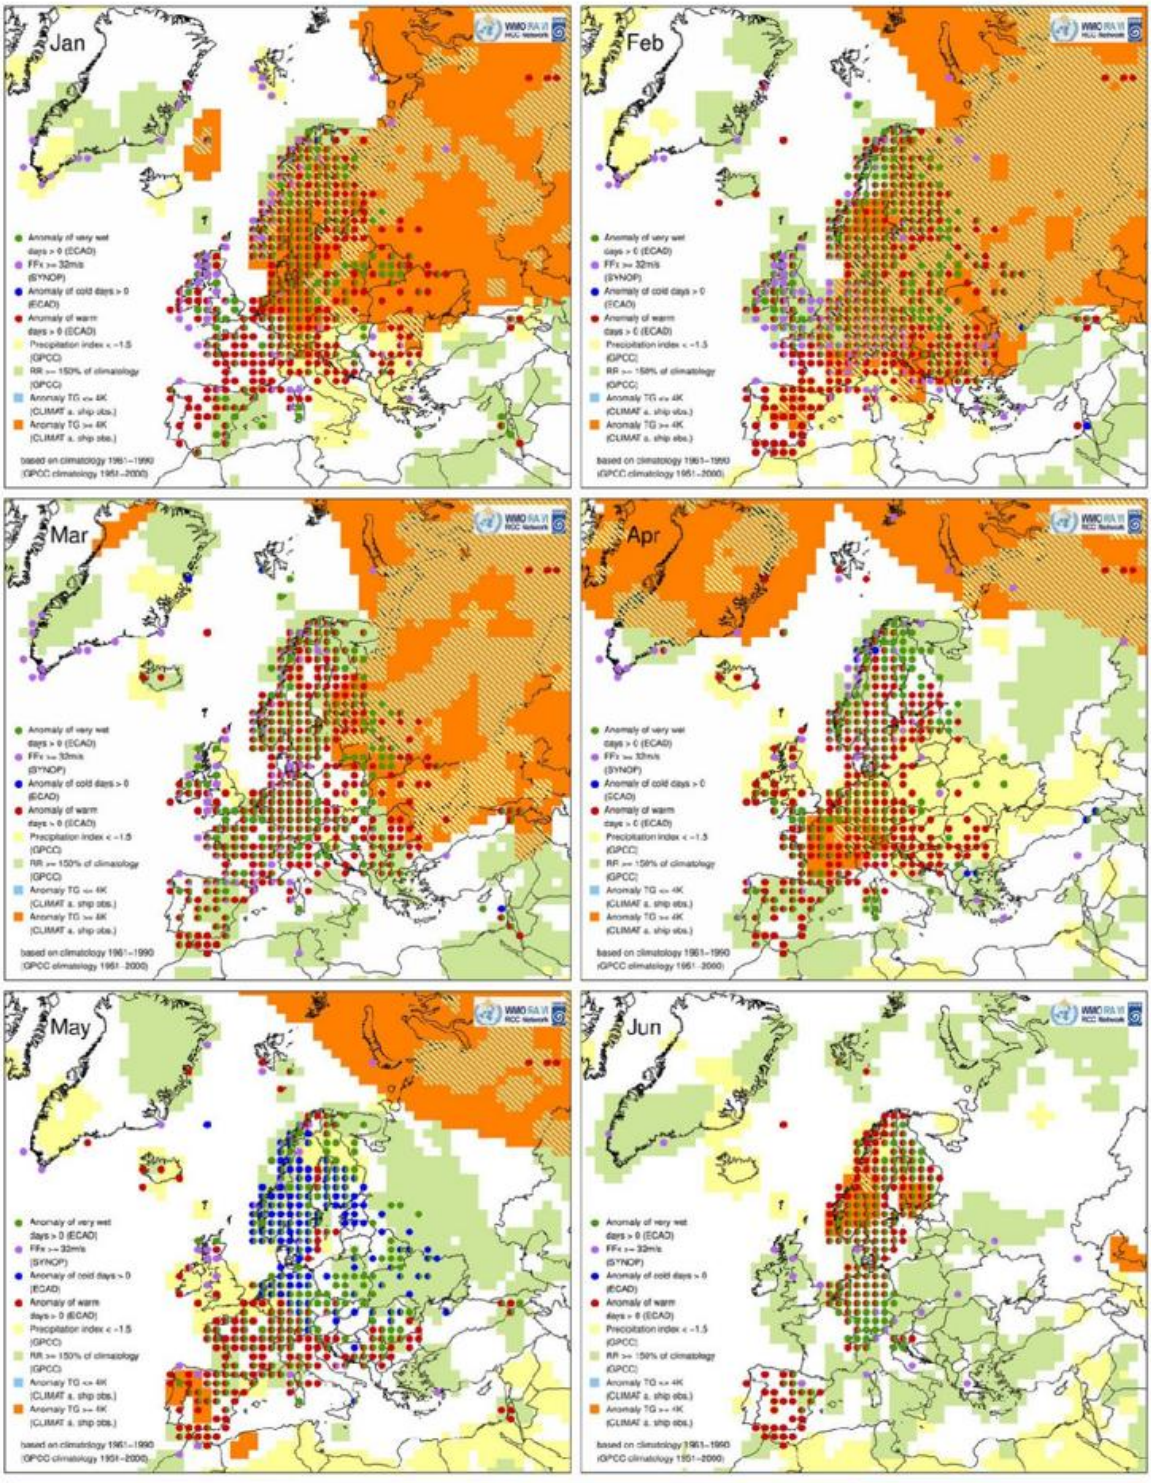
November was especially warm in Scandinavia with a temperature anomaly of +3 °C. In Estonia, the warm spell of the previous month continued. Several new records were set for November. Tallinn experienced an anomaly of +4 °C (monthly mean temperature of 5.3 °C) making it the warmest November since 1883. New maximum air temperature records were also measured in Luxembourg. In Greece dry conditions were observed. The station Aktio only received 5.3% of the normal precipitation (1971–2000). Another dry spell was also registered in Poland: Several stations reported monthly precipitation values only up to 10 mm. Drought and heat waves also occurred across most of Serbia.

In November, several extreme precipitation events occurred in countries bordering the Mediterranean Sea. On 4 and 5 November, the first heavy rainfall occurred in Spain. From 7 to 10 November Greece was hit by a storm causing floods, mudflows and destructions. With a surplus of 471% precipitation it was the wettest November for Kastelli station in Crete. The Azores (Portugal) were affected by heavy rainfall on 9 and10 November. During 24 hours 152 mm rain fell in São Miguel. Precipitation amounts of these intensities are only received every 40 to 50 years. Exceptional precipitation amounts were registered in Israel as well. From 19 to 21 November the Middle East countries received precipitation amounts up to 200 mm. Bet Dagan station measured highest precipitation intensities during 30 minutes since 1962.

4.5.12. December

Floods and storms occurred in many parts of the RA VI Region during December. In Austria, heavy precipitation came down as snow. New records of snow in East Tyrol and Upper Carinthia caused widespread traffic and infrastructural problems. The unstable snow cover triggered a higher risk for avalanches. In lower altitudes like Lenz, rain led to damage due to flooding and mudflows. Exceptional rainfall was measured in Iceland as well. Seyðisfjörður received highest precipitation amounts with 577.5 mm from 14 to 18 December causing landslides. New precipitation records since start of time series were reported in New Yaar and Ramat David (Israel) on 15 December.

Storms *Dora* and *Ernest* caused heavy rainfall in Spain from 4 to 10 December. Foehn wind occurred in Poland. In Kasprowy Wierch wind gusts up to 170 km h^{-1} were measured.



- Anomaly of very wet days > 0 (ECAD)
- Wind gusts (≥ 32 ms^{-1}) (SYNOP)
- Anomaly of warm days > 0 (ECAD)
- Anomaly of cold days > 0 (ECAD)
- Anomaly of TG ≤ −4 K (CLIMAT and ship obs.)
- Anomaly of TG ≥ 4 K (CLIMAT and ship obs.)
- Precipitation index < −1.5 (GPCC)
- RR ≥ 150% of climatology (GPCC)

Based on climatology 1961-1990 (GPCC climatology: 1951-2000)

4.6. Selected contributions by NMHSs

4.6.1. Temperature September: Prolonged heat wave in Israel from 3 to 21 September

(Contribution from the Israel Meteorological Service)

A prolonged heat wave prevailed for the first three weeks of the month. The peak of the heat wave was at its beginning, between 3 and 5 September, when extreme values were measured, some of them set new records not only for September, but also for the entire year. The highest temperature with 48.9 °C was measured on 4 September in Eilat (southern Arava). This was an all-time record at this station, where measurements began more than 70 years ago. All-time records were also set in Kefar Blum −47.0 °C, Ayyelet HaShahar −46.6 °C (both in the Hula Valley, northeastern Israel) and in Zefat (Upper Galilee), with 40.6 °C. At some of the stations, new maximum temperature records were set for September. In Jerusalem, the old record from 89 years ago was replaced by a new one on 3 September with 42.3 °C, much higher than the previous 39.4 °C in 1931. It was broken once again on the next day (4 September) with 42.7 °C (**Figure 4-11**).

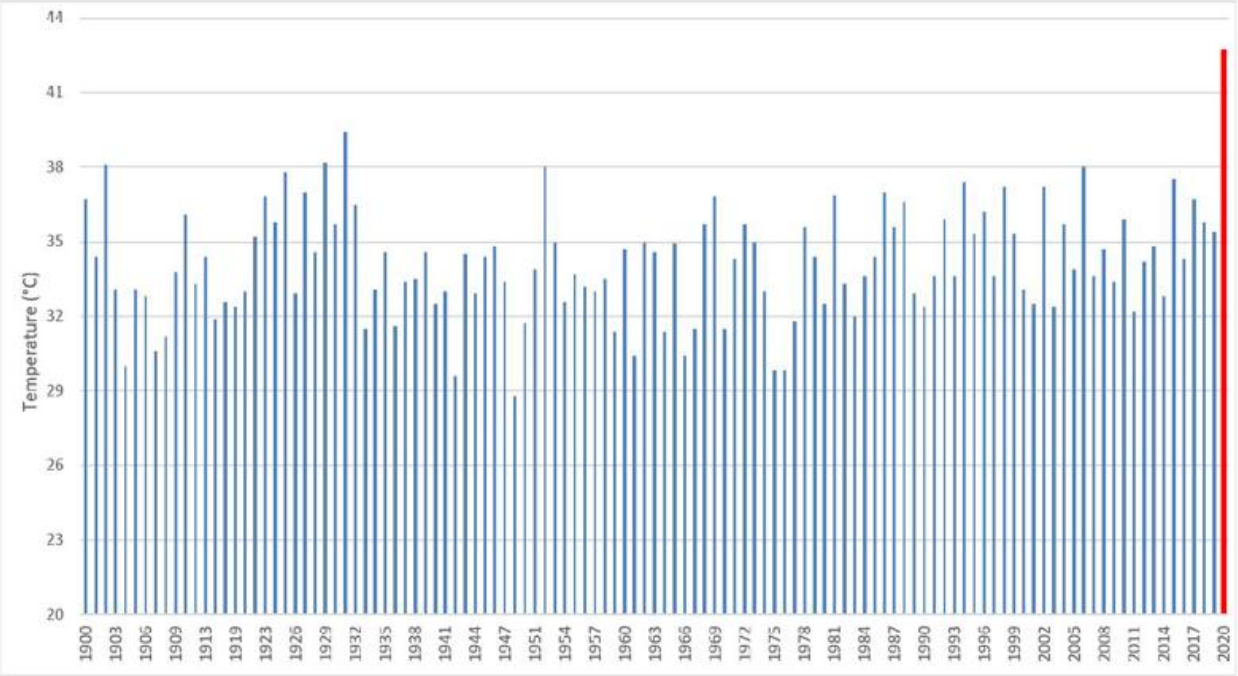

Figure 4-11: *Absolute Maximum temperature in Jerusalem in September 1900-2020. Source: Israel Meteorological Service.*

New historical records were also set with the minimum temperature, most of which occurred during the night of 3–4 September. In Jerusalem, a minimum temperature of 31.6 °C was measured and thereby replaced the previous record of 30.5 °C from June 1942. In Bet Dagan (28.9 °C) as well as in Zefat (30.3 °C), a new record was set for the entire year.

- Jerusalem (Judean Mountains): 24 days with temperatures above 31 °C (28 August to 20 September). No comparable sequences (concentrated in September) have ever been recorded since the beginning of measurements in 1867. In July–August, there were only two similar cases, in 1922 and 1887.
- Beer Sheva (northern Negev): 12 days with more than 36 °C. In the past, similar cases occurred only in September 1931 and August 1922.
- Kefar Blum (Hula Valley, northeastern

Israel): 8 days with more than 40 °C. There were no comparable sequences since the beginning of measurements at this station for more than 65 years, for all months of the year.

- Bet Dagan (central Coastal Plain): 16 days with more than 33 °C. Such a sequence did not occur at this station since the beginning of measurements in 1962.

4.6.2. Extreme events May: Intensive Saharan outbreak in Bulgaria

(Contribution from the National Institute of Meteorology and Hydrology, Bulgaria)

An intensive Saharan Dust outbreak occurred in the period 12–22 May 2020 over the southeast parts of the continent and the Balkans. It took place under a cyclone over the southern part of the Iberian Peninsula and an upper ridge over the central Mediterranean. A very deep and strong low at 500 hPa formed over the Atlantic, extending from the Pyrenees towards Northwest Africa, taking in its circulation an anomalous amount of dust from the Sahara Desert. In the front part of this cyclone, in a strong southwest flow, the dust was transported through the Central Mediterranean over the Balkans.

Figure 4-12: *MSLP (contours 5 hPa) and 200 hPa wind (vectors and shading: speeds > 30 m s^{-1}) on 15.05.2020 at 00 UTC, ECMWF-HRES model, https://www.ecmwf.int.*

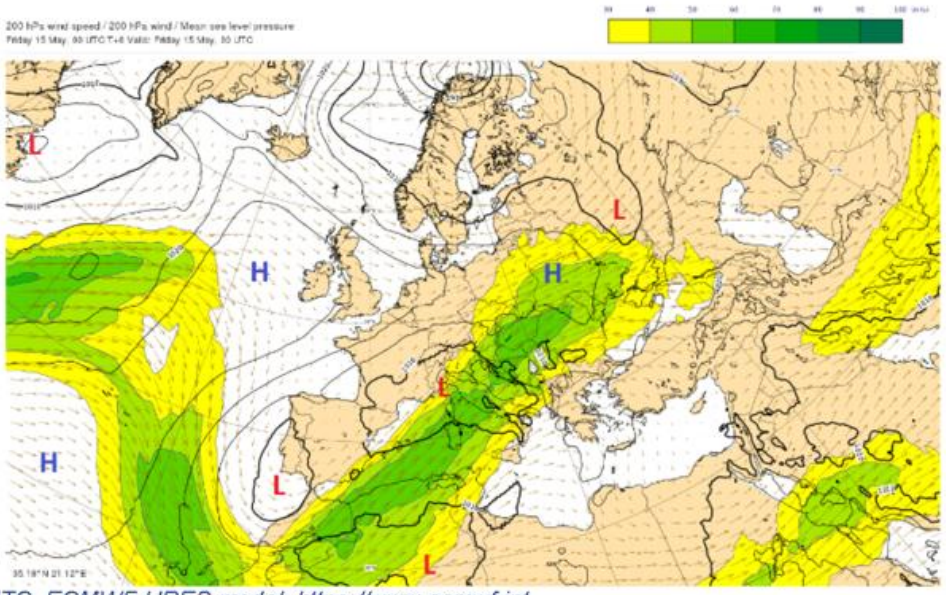

Figure 4-12 shows synoptic charts for this very specific situation in which the jet stream noticed easily on 200 hPa helped for transporting the dust far away from Northwest Africa as seen by satellite pictures. The cyclone remained stationary over the Western and Central Mediterranean and caused a heat wave with a temperature anomaly at 850 hPa of 12 °C–16 °C warmer air than the mean for the period (1979–2010), as estimated by the ECMWF ENS model. Over Bulgaria, the Saharan outbreak lasted for an exceptionally long period: from 12 to 22 May 2020. The peak was on 15 May 2020, when Foehn winds on the northern slopes of the mountains in Bulgaria were observed. In combination with the warm air mass advection, the temperatures in many regions of Bulgaria were above 30 °C, (in Sevlievo, north of the Balkan Mountain, 37.7 °C). An extremely dry situation with dusty atmosphere was observed in the next four days. The visibility at peak Musala (2925 m) was reduced from 40 km on 14 May 2020, 06:00 UTC to 15 km at 18:00 UTC. The particulate matter concentration PM10 at the mountain peak Kopitoto (1345 m) near Sofia increased to a daily mean value of 104.7 μg m^{-3} on 14 May 2020, higher by a factor of 15 compared to the mean of the previous 2 weeks. The chemical analysis of PM10 samples collected at NIMH on 15 May 2020 and

16 May 2020 showed high concentrations of the elements Ca, Mg, Al and Fe. The ratio of Ca to Al was 2.24, the ratio of Fe to Al was 0.52 and the ratio of Mg to Al was 2.42, confirming the origin of the aerosol particles in northwestern Africa (Algeria and Tunisia).

4.6.3. Extreme events September: Medicane over Greece on 17–20 September 2020

(Contribution from the Hellenic National Meteorological Service)

Greece was impacted by a so-called Medicane (MEDIterranean hurriCANE), a cyclonic low-pressure system with tropical characteristics that caused high winds, waves, torrential rain and extensive flooding between 18 and 20 September 2020.

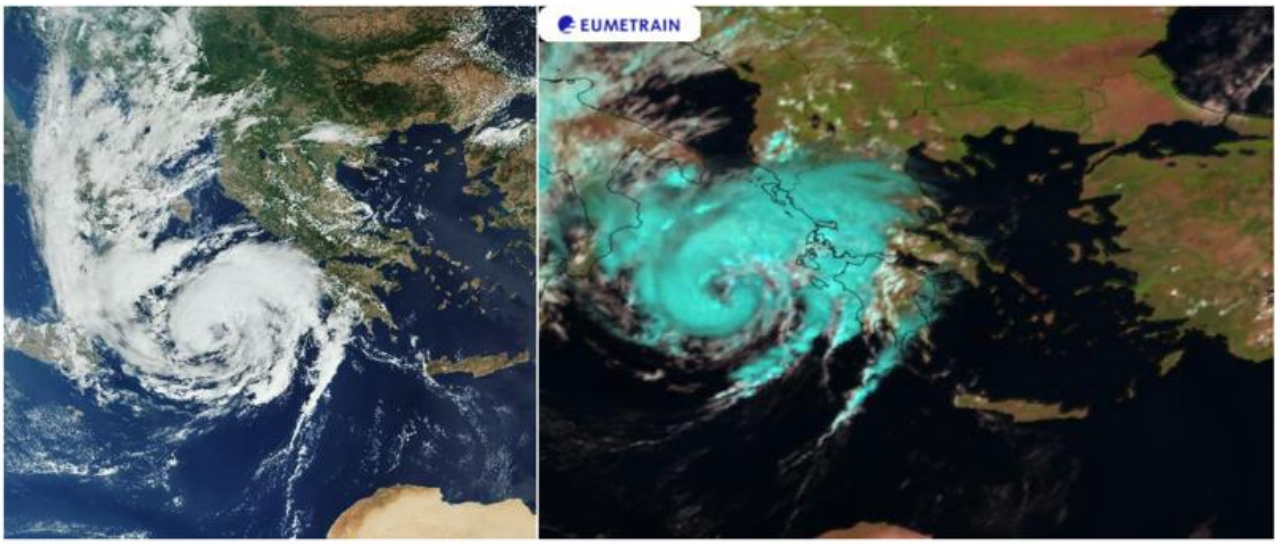

Figure 4-13: *The Copernicus Sentinel-3 mission captured this image of the Medicane, crossing the Ionian Sea and approaching west Greece on 17 September 2020 at 10:48 CEST (lefi); Day natural colors at 12:00 UTC (right).*

On 14 September 2020, a low-pressure system began to develop over the Gulf of Sidra, quickly developing in the coming hours while slowly moving north-northeastwards. The cyclone gradually intensified over the warm waters of the Mediterranean Sea, acquiring an eye-like feature, making landfall over the Greek island of Kefalonia on 17 September 2020 evening, with maximum wind gusts of 120 km h^{-1} (65 knots) and a surface pressure in the vicinity of 993 hPa (Figure 4-13, Figure 4-14). The Hellenic National Meteorological Service had issued top-level Red Alerts to warn people of hazards. Greece was last hit by a strong explosive cyclogenesis in 2018. Due to its long life, its tropical characteristics and its intensity, it can be classified as one of the most powerful Mediterranean Cyclones recorded since 1969, that is, from the beginning of satellite observations.

As the medicane shifted eastwards, strong convergence conditions were established in Thessalia and central Greece, resulted in heavy rains for a prolonged period, mainly in the areas around the cities of Karditsa and Farsala. Although the medicane didn't swept across east mainland since it moved south southeast to the area of Crete, the large-scale circulation brought warm moist air masses in the area of Thessaly. The eastward movement of an upper level trough enhanced the strength of the easterly to north-easterly winds. Also, the impact of orography caused convergence

zones leading to deep convection. By the evening of 19 September, the medicane had reached the island of Crete, bringing heavy rainfall that flooded streets and properties.

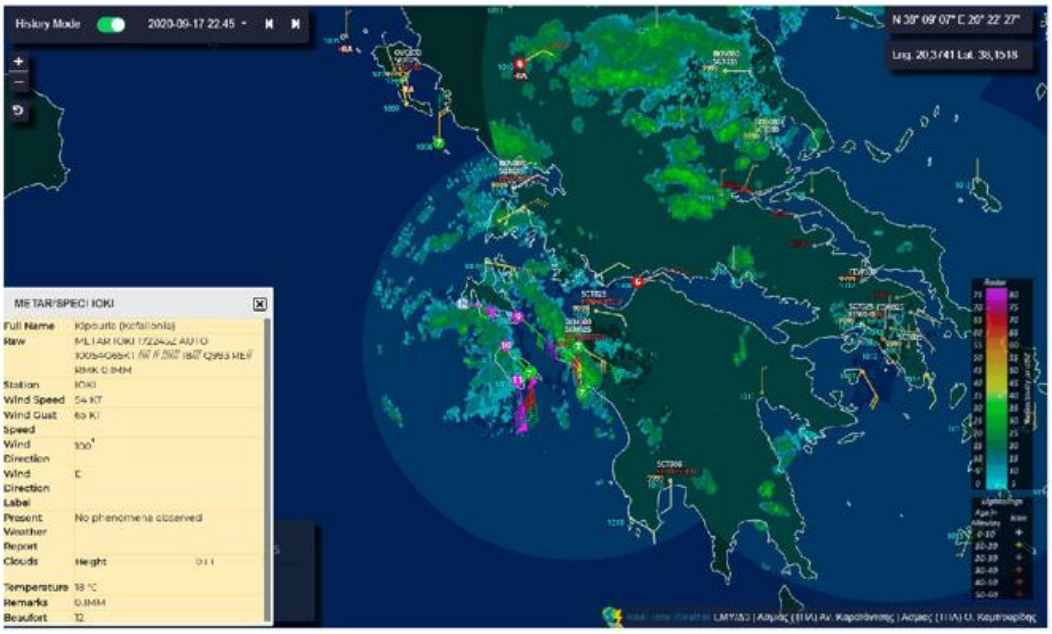

Figure 4-14: Radar image and station observations on 17 September 2020 22.45 UTC. A station located in the westernmost point of Paliki peninsula in Kefalonia island recorded a wind gust of 65 knots (12 Beaufort) and a pressure of 993 hPa.

Impacts

- The Ionian Sea islands of Zakynthos, Kefalonia and Ithaca were badly hit by the cyclone, as winds reaching 120 km h^{-1} damaged buildings, uprooted trees, sank sailboats and left thousands along Greece's western coast without power, while huge waves lashed the beaches.
- Flights and ferry services were cancelled and people were advised to stay indoors.
- The torrential rain caused flash flooding and landslides.
- The tourist village of Assos, in Kefalonia, was buried under mud and stones, while many houses were uninhabitable.
- The areas of Karditsa and Mouzaki in Thesallia were flooded and triggered significant landslides. A bridge collapsed and about 5 000 homes in the area were affected by flooding, while roads were also damaged. A river flooded its banks and damaged roads and a medical centre in the town of Mouzaki.
- Greece's cotton crop was at maturity with harvest set to begin soon, and the storm resulted in significant impacts and crop losses where rain was heaviest, most notably in Thessaly and central Greece.
- Throughout the country, over 1 000 people were rescued by the national firefighting service and four people lost their lives.

8. Abbreviations

Abbreviation	Meaning
AO	Arctic Oscillation (circulation indices)
BAMS	Bulletin of the American Meteorological Society
CLIMAT	Monthly climatological data provided by the NMHSs via GTS
DWD	Deutscher Wetterdienst (German Meteorological Service)
EA	East Atlantic Pattern (circulation indices)
EA/WR	East Atlantic/West Russia Pattern (circulation indices)
ECA&D or ECAD	European Climate Assessment & Dataset, located at Royal Netherlands Meteorological Institute (KNMI)
EMCC	Eastern Mediterranean Climate Centre
E-OBS	Dily gridded observational dataset for precipitation, temperature and sea level pressure in Europe based on ECA&D information
GCC	Global Collection Centre operated by the Deutscher Wetterdienst
GHCN	Global Historical Climate Network
GPCC	Global Precipitation Climatology Centre located at the Deutscher Wetterdienst
GTS	Global Telecommunication System
ISPRA	Istituto Superiore per la Protezione e la Ricerca Ambientale (Italian National Institute for Environmental Protection and Research)
JRC	Joint Research Centre of the European Commission
KNMI	Koninklijk Nederlands Meteorologisch Instituut (Royal Netherlands Meteorological Institute)
maxT	Maximum temperature
m a.s.l.	Metre above sea level
NAO	North Atlantic Oscillation (circulation indices)
NMHSs	National Meteorological and Hydrological Services
POL	Polar/Eurasia Pattern (circulation indices)
PDSI	Palmer Drought Severity Index
RCC	Regional Climate Centre
RCC-CM	Regional Climate Centre on Climate Monitoring
RR	daily total precipitation
RR1	count of days where RR ≥ 1 mm
SCA	Scandinavia Pattern (circulation indices)
SCE	Annual snow cover extent
SU	Number of summer days
SYNOP	Surface synoptic or weather observations provided by the NMHSs via GTS
