Annual Bulletin on the Climate in WMO Region VI - Europe and Middle East - 1999

The bulletin is a summary of contributions
of the following national meteorological services
and was co-ordinated by Deutscher Wetterdienst, Germany,

Armenia
Austria
Belarus
Belgium
Bulgaria
Croatia
Cyprus
Czech Republic
Denmark
Estonia
Finland
France
Germany
Greece
Hungary
Iceland
Ireland
Israel
Jordan
Kazakhstan
Latvia
Lithuania
Netherlands
Norway
Portugal
Russian Federation
Slovenia
Spain
Sweden
Switzerland
The Former Yugoslav Republic of Macedonia
Turkey
Ukraine
United Kingdom
Yugoslavia

Furthermore, contributions to the WMO Bulletin article on consequences of abnormal weather in 1999 were referred from the following countries:
Italy, Romania, Slovak Republic

List of Contents:

Foreword page 3

Outstanding Anomalies and Events in 1999 page 5

Annual and Seasonal Survey page 6

Seasonal Maps:
- Temperature anomalies page 14
- Precipitation anomalies page 18

Seasonal and Annual Tables page 20

Monthly Surveys:
- January page 26
- February page 27
- March page 29
- April page 29
- May page 30
- June page 32
- July page 35
- August page 37
- September page 38
- October page 41
- November page 42
- December page 44

Activities and Results of European Climate Centres:
- News from the European Climate Support Network page 48
- The Climate of the 20th Century in Sweden page 50
- The DWD Objective Weather Type Classification page 52
- The Solar Eclipse Effects in Bulgaria page 53
- The SAF on Climate Monitoring page 54

Foreword

In the year 2000 the Annual Bulletin on the Climate in WMO Region VI appears for the sixth time. Right after the start, dating back to 1995, it became obvious, that here a notable publication had been created, with great interest to a broad spectrum of users, ranging from scientists and National Services to economic and political decision makers.

On the other hand there is a growing number of contributing National Meteorological and Hydrological Services. About 80 % of the WMO member countries of the Region supported the latest editions and provided input. It is worth mentioning in this context that this time nearly all contributions were sent in on electronic media which considerably facilitated the further preparation of the publication and smoothes the way for the development of an Internet version.

With respect to conspicuous climatic events the year 1999 is noteworthy by all means. Catastrophic snow conditions and avalanches in the Alps in winter, severe inundation in Hungary, France and other parts in Central Europe caused heavy damage and losses. This is especially true for two disastrous storms in December, partly known as 'Anatol' and Lothar', one of which affected northern France, the North Sea and Denmark, whereas the other swept eastward over France, Switzerland and southern Germany. Information on these events and lots of other interesting analyses, tables, graphics and comments concerned with climate monitoring are contained in this edition of the Bulletin.

A special feature of the Bulletin is the chapter related to research activities in the region. The topics of the actual edition comprise the Climate of the 20th century in Sweden, the DWD Objective Weather Type Classification (OWTC), the solar eclipse effect on the surface temperature and humidity and the Satellite Application Facility (SAF) on Climate Monitoring.

When in January 2000 the ECSN (European Climate Support Network) - project "Generate Climate Monitoring Products" was launched it was decided to incorporate the Bulletin into this framework as a special sub-project thus broadening the basis for enhancing the fruitful European co-operation in the field of climatology.

I would like to thank all those who have contributed to the success of this remarkable publication. Above all, the participation of Sweden in the editorial review process and the co-ordination, publishing and distribution of the document by Germany were greatly appreciated.

Dr Iván Mersich
President of WMO RA VI

Outstanding Events and Anomalies in 1999

- Warmest year on record in many places with extremely high mean night-time temperatures.
- Wettest year of the century in southern Scandinavia.
- 1998/99 rainfall season driest on record in the Middle East.
- Heavy snowfalls bring deadly avalanches in the Alps in February.
- Sudden snow melt and heavy rains cause severe floods in Central Europe in spring.
- Very dry from December 1998 to August 1999 in Spain.
- Heat and drought cause high economic losses and engender numerous forest fires in European Russia and the Middle East in summer.
- Heavy rains cause several severe floods, esp. in and around Hungary in June/July.
- Warmest September on record in parts of Central Europe and Scandinavia.
- Catastrophic flooding in south-western France in November.
- Again very bad start of the rainy season in the Middle East in late 1999.
- Early winter in central Europe and the East in November.
- Series of fierce storms with high losses in Western and Central Europe at the end of the year.

Annual and seasonal survey:

1999 was another warm year, in many places warmer than 1998, which so far has been the globally warmest year on instrumental record (1860 – 1999).

The series of consecutive warmer years continued at many stations (e.g. in Macedonia with records since 1926, it was the 15th warm year in a row). Annual temperature anomalies (with respect to 1961 - 1990 normal) surpassed + 1 °C in most parts of the Region and up to + 2 °C in the Russian Federation. However, near the Barents Sea, slightly cooler temperatures than usual were recorded. The annual surface temperature anomaly percentiles exceeded 90 %. For many countries, it was the warmest or at least one of the warmest years on record (see figures 1 and 2). In Central England, 1999 became the warmest and equal with 1990 and 1949 in the 341-year record. For The Netherlands, 1999 equalled 1990, the warmest year since the start of regular measurements in 1706. A number of records illustrate, that the high annual means are caused by high night-time temperatures. e.g. the mean minimum Central England temperatures in 1999 were the warmest in the 122-year record (see figure 3). In Amman, a clear rise of the annual mean was due to the high daily minimum temperatures. Most months of the year showed positive night-time temperature anomalies (see figure 4), while maximum temperatures not were increased as much.

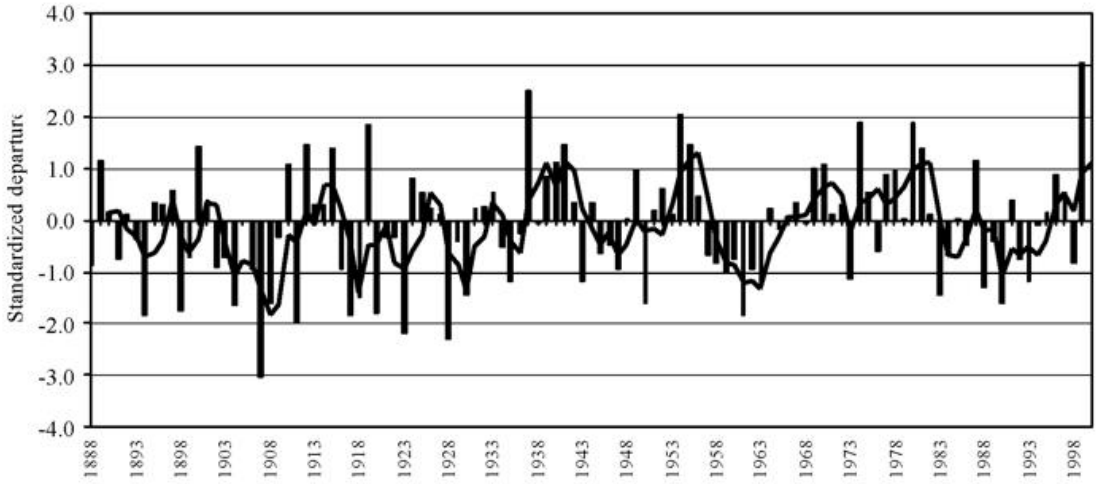

Fig. 6: *Standardised departures of annual precipitation totals from the 1961 - 1990 normal in Belgrade, FR Yugoslavia*
From: Federal Hydrometeorological Institute, Yugoslavia

The distribution of precipitation varied throughout the Region. Western Europe, southern Scandinavia, the Alps and most countries on the Balkans experienced a wet year. For Denmark and parts of the Federal Republic in Yugoslavia, it was the wettest calendar year in the history of registrations since 1874 respectively 1888 (see figures 5 and 6). However in Denmark, it was at the same time the 4th sunniest year since 1920, a rare combination which was also reported from other countries (e.g. The Netherlands). Heavy snowfall, downpours of rain, thunderstorms and hail inflicted massive economic and human distress in large parts of the Region. It was extremely wet in Hungary. There was almost continuous flooding and annual precipitation totals exceeded 200 % of normal.

Dry conditions prevailed in the southern parts of the Region. In Spain, precipitation was rare in the first half of the year with a considerable deficit in the southern half of the mainland. The situation was critical towards the end of August. However, intense rainfalls in autumn, improved the situation. In the Southeast of Spain and on the Balearic Islands, the year ended with less than 50 % of normal rainfall. Cyprus experienced the 5th consecutive year with below normal precipitation. An annual total of 321,6 mm (64 % of normal) had serious effects on the economy and the natural environment (see figure 6.3, page 34). The long-lasting dryness in the Middle East intensified during the year with very low water levels reported from Syria, Israel and Jordan (see figure 1.1, page 27). Crop development in the growing season was seriously affected by an intensive and prolonged drought in Finland, Belarus, Ukraine and in large parts of the Russian Federation.

Fierce storms battered Europe at the end of the year, avalanche catastrophes hit in February and a high number of floods occurred making 1999, a year of severe weather related disasters. In Switzerland, the total amount of damage is estimated at 4 billion CHF, thus considerably higher than the previous record of 1,2 billion CHF for the year 1987 (inflation taken into account). The monthly means of the Atlantic-European zonal index for the latitude belt 35 - 65°N for the 20 - 40°E region, as a measure of the intensity of the circulation, illustrate very well the outstanding zonality in December (see figure 7).

The Venetian lagoon was affected in 1999 by 15 days of water levels of more than 100 cm above mean sea level triggering inundation in vast parts of Venice.

The annul mean of total stratospheric ozone at Hohenpeissenberg, Germany, was slightly decreased (321 DU compared to a 32-year mean of 329 DU), (see figure 8). Individual periods of the year, however, show large variations. Thus, at the end of November/beginning of December, new all-time minimum values were recorded over wide parts of western and central Europe.

Though the 1998/99 **winter** season was mostly mild all in all (see figures page 14), out-standing wintry periods occurred. A cold wave in late January brought some of the coldest temperatures experienced since the late 1800s in northern Fennoscandia and the western parts of the Russian Federation. In February, colder than normal temperatures in much of Europe were accompanied by extremely heavy snowfalls. In the Alps, more than 60 people were killed in avalanches. Heavy snowfall disrupted communications, power supply and transportation in central Europe.

It was very warm in the Southeast (see figure 9) where temperature anomalies surpassed the 98 % percentile of the 1961 - 1990 normal. Dry conditions prevailed in the South (see figure page 18, above, figures 1.1 and 1.2, page 27). In the whole country of Israel, the 1998/99 rainfall season was, together with 1950/51, the driest recorded in the last 60 years.

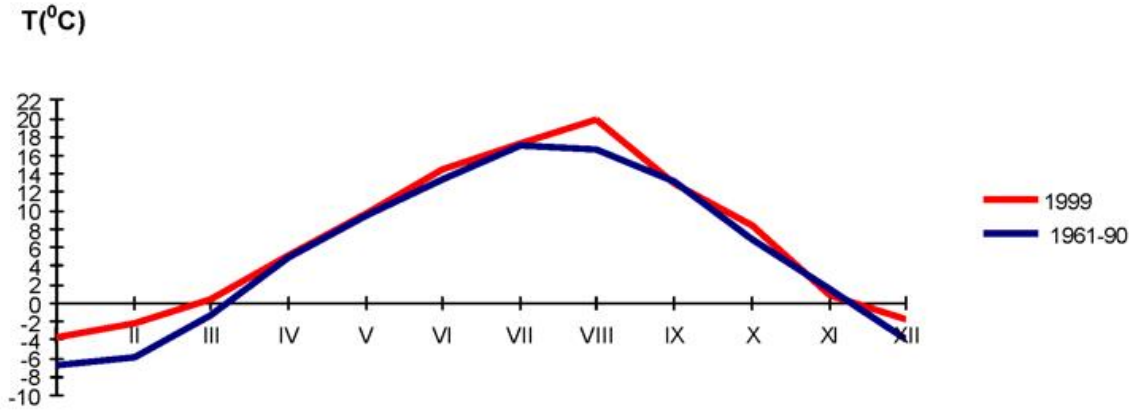

Fig. 9: *Mean monthly temperatures in Armenia*
Administration of Hydrometeorology, Armenia

Spring was wet and very mild in most areas (see figures page 15 and page 18, below). An early warm spring was followed by an extremely frosty period in May. In the East, this caused high losses to crops and plants. Spain experienced a very warm spring and early summer with an outstanding warm May (see figure 10).

Dry weather conditions continued to prevail in the South and East. The mild weather caused sudden ice and snow melt building up ice jams and with heavy rains this led to a number of severe floods. Latvia and Hungary reported high water levels in March and Lake Constance reached its highest level since 1858 in May. For Tyrol, Austria, it was the wettest spring in the last 50 years.

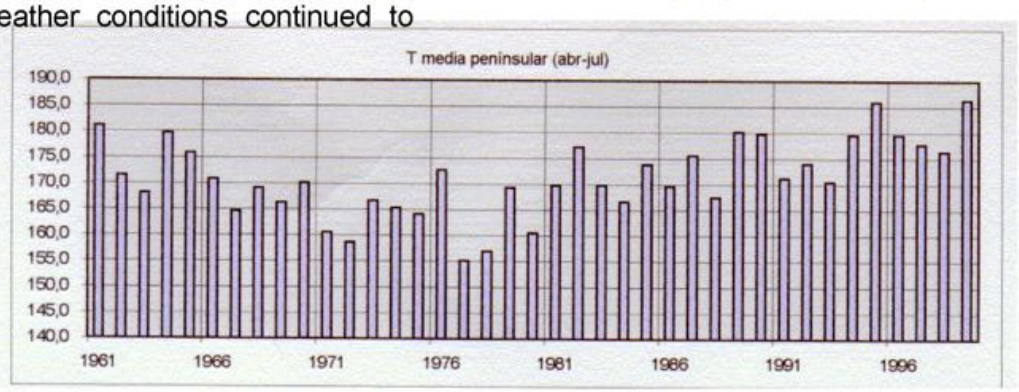

Fig. 10: *Mean temperatures (in 1/10 °C) for the April - July period on the mainland of Spain between 1961 and 1999*
From: Instituto National de Meteorología, Spain

Dry weather that had already prevailed in May in eastern Europe and the Middle East intensified from June to August making the **summer** season of 1999 one of the driest ever in those regions. It was at the same time extremely hot (see figure 7.1, page 35, and figures 9 and 11 - 13). Anomaly percentiles of the temperatures exceeded 98 % in many countries (see figures page 16). In some places in Latvia, it was the warmest summer on record. Heat and drought caused high agricultural losses and engendered numerous forest fires. Israel reported one of the hottest summers, although it was not as hot as in 1998 (see figure 13).

Frequent thunderstorms, gusts and hail caused flooding and much damage in the Region. Heavy rains and severe floods affected Hungary, Romania and the Slovak Republic in June and July (see figure 14, page 13). Large land areas were flooded, buildings collapsed and thousands of people had to be evacuated. In Hrubarnov, south Slovakia, June - July 1999 was warmest on record (since 1881). On Zugspitze, Germany, at nearly 3000 m altitude, the heavy snow falls during winter and spring led to a permanent snow cover at this station all year around for the first time since 1984.

From: Israel Meteorological Service

Autumn was extremely mild from the British Isles to Northern Scandinavia as well as in the Mediterranean region (see figures page 17). For Norway, it was one of the warmest autumns of the century. Record warm temperatures prevailed also in Germany. In some parts of this country, September was the warmest month of the year. An early cold snap extended from Spain to Russia in November. Dry weather predominated in the East and Southeast of the Region. Summer drought in eastern Ukraine turned into autumn drought and still increased until the middle of October. Regionally, there was hardly any precipitation at all for 20 to 45 days, which is extremely rare. Plenty of rains brought relief after the long-lasting drought in most parts of the Iberian Peninsula. There was a number of severe floods, among those, an outstanding flood in southern France in November. The rainfall season in the Middle East started dry (see figure 15). North and Central Israel received only 20 - 40 % of the long-term average and the southern parts of the country less than 10 %. This made it one of the worst starts of the rainy season and similar to the same period of the previous year.

Monthly Surveys

January 1999:

- **Extremely warm in Central Europe, bitterly cold in the North**
- **Mostly very dry, especially in the Middle East**
- **Destructive winter storm on the Canary Isles**

The year started warm in most parts of the Region with temperature anomalies surpassing +4 °C over Western Russia and Turkey. The mild conditions peaked towards the 6th when several places in Western and Central Europe noted all-time record January temperatures (e.g. London and Paris +16 °C, Jungfraujoch, Switzerland, 3580 m a.s.l., +3,3 °C). For Lithuania, it was the warmest month of the winter. For 13 days, the mean air temperature was positive and anomalies often exceeded +4 - 6 °C, up to +10 - 12 °C in the warmest period. In Estonia, the wet snow seriously wrecked power lines and damaged forests.

The wet and mild weather supported the generation of fog. Airports had to be closed in Central Europe on several occasions. Ljubljana, Slovenia, had 17 days with fog. At least 11 people were killed and 20 were injured in road accidents caused by foggy weather in Syria.

The warm conditions were on contrast to the cold weather in north-western Russia and northern Fennoscandia. On January 27, temperature dropped to –49 °C in Karesuando, Swedish Lappland, establishing a new record in a series from 1879. It is the lowest temperature at an official station in Sweden since February 1966 when Vuoggatjålme in south-western Lapland touched the national record (-53 °C). In Kittilä, northern Finland, a new absolute minimum temperature record of -51,5 °C, was recorded on January 28. On the same day, the second lowest ever recorded temperature in Norway occurred: -51,2 °C in Karasjok. The exceptional cold weather caused substantial problems to traffic, electric power supply and to the heating of houses. Shipping at Arkhangelsk port, Russia, was temporarily disrupted.

A wet belt stretched eastward from the UK over southern Sweden and the Baltic states. Heavy rain affected parts of Cumbria and North Wales, UK, on the 4th and 5th, and Cape Curig received 106 mm of rain in 24 hours. On the 11th and 12th, the Middle Volga region, was affected by heavy snow, with blizzards and gusts of up to 80 km/h. The city of Ulianovsk proclaimed a state of emergency. Heavy snowfall and icy winds caused havoc on the roads in parts of France and northern Spain around the 10th. Rain and flooding brought severe damage near Antalya, Turkey, on the 31st.

Elsewhere, dry conditions prevailed. In Hungary, the driest stations measured monthly sums around 10 mm and the country wide average of 16,3 mm was less than half of the climatological mean. Extremely dry conditions were also reported from Portugal and the Southeast of the Region (see figure 1.1 and 1.2). In Israel, rainfall amounts reached 60 - 80 % of normal in the northern and central parts and less than 50 % in the South. Dryness was even worse in Jordan where monthly precipitation amounted to less than 96 % of normal.

Strong winds occurred. In the town of Selsey in West Sussex, UK, a combination of high tides and gale force winds caused localized flooding in the town when the sea walls were breached. Malin Head, Ireland recorded the highest gust of the year on January 4 (154 km/h). In Galicia, Spain, a strong storm forced the fishing fleet to remain in port for two weeks.

Gusts exceeding 120 km/h haunted the Canary Islands on January 9 and 10. Storm and waves high up to 6 m caused losses above 400 Million US$ to port installations, fish farms and infra-structure.

From: Meteorological Department, Jordan

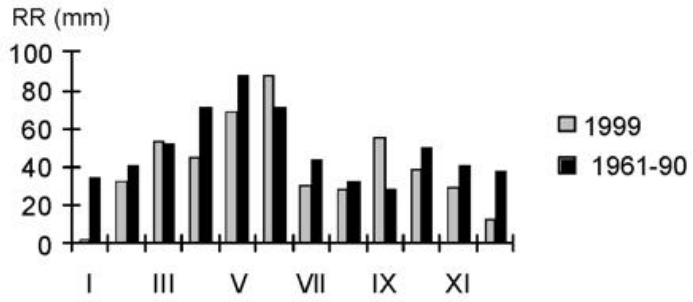

Fig. 1.2: *Monthly rainfall totals and long-term means at Yerevan*
From: Administration of Hydrometeorology, Armenia

February 1999:

- **Abundant snow and deadly avalanches in the Alps**
- **Very dry from the Iberian Peninsula to Greece**
- **Extremely warm in the Southeast**

From January 26 - February 24, enormous amounts of snow fell during several days in the Northern and Inner Alps (see figure 2.1) and snow depths in the mountains exceeded 5 - 7 meters in some regions (Switzerland: Braunwald (1330 m) recorded 723 cm, Säntis (2500 m) 735 cm). In the provinces of Tyrol and Vorarlberg, Austria, the monthly precipitation sums reached 300 - 400 % of normal. Kufstein, Tyrol, received 233 mm which is the highest monthly total in the last 50 years.

The snowfalls caused numerous avalanches, also in regions which had been considered as safe. A deadly avalanche hit Chamonix, France, on February 9. In Galtür, Tyrol, 38 people died on February 23. An avalanche swept away a holiday village near Evolène, Switzerland. All in all, there were at least 60 avalanche victims in the Alps. Many valleys were isolated and some of them during several weeks. More than 100 000 tourists were trapped in their ski resorts.

Around the middle of the month, snow related problems dominated from Spain to The Netherlands and from Germany to Ukraine and the Balkans. In Slovenia, the snow cover in the lowlands was between 30 and 90 cm. In eastern Slovakia, the maximum depth of snow came up to more than 50 cm in the lowlands and 120 – 140 cm in the mountain valleys. These are amongst the highest values since the beginning of snow registrations in 1921. Sicily had its first snow since 1981. Abundant snowfalls and blizzards were also reported from Lithuania and Estonia. The latter reported the greatest amount of snow in the 17 years' record. Two periods with severe blizzards occurred in the Middle Volga region. Wind speeds reached 97 km/h.

In the lowlands north of the Alps, snow, rainfalls and snowmelt caused landslides and flooding. Floods were also reported from north-eastern France and Germany. In the south-western parts of Turkey, heavy rain and strong winds caused considerable damage.

The precipitation was distributed unevenly. Excessive precipitation fell over wide parts of northern Europe, it was extremely dry in Portugal and in Middle East. The northern and central parts of Israel received only 40 - 60 % of average, while rainfall amounts in the southern parts were above normal.

Winds with gusts of 159 km/h were recorded at Kirkwall, UK, on February 4. Strong gusts in Yorkshire caused the closure of the A 1 road where 20 lorries were overturned. At the same time in North and West Scotland around 8 000 homes were left without power as a result of the winds. On February 16/17, a severe winter storm caused wide-spread damage across northern Germany. On the island of Norderney, a tornado destroyed several buildings. Hurricane-like winds devastated towns and villages in northern Bulgaria on February 22/23.

While warm conditions prevailed from Ireland across southern Scandinavia to Western Russia (where anomalies were most extreme with values above +8 °C) subnormal temperatures dominated in the North, over the Alps and in the south-western parts of the Region.

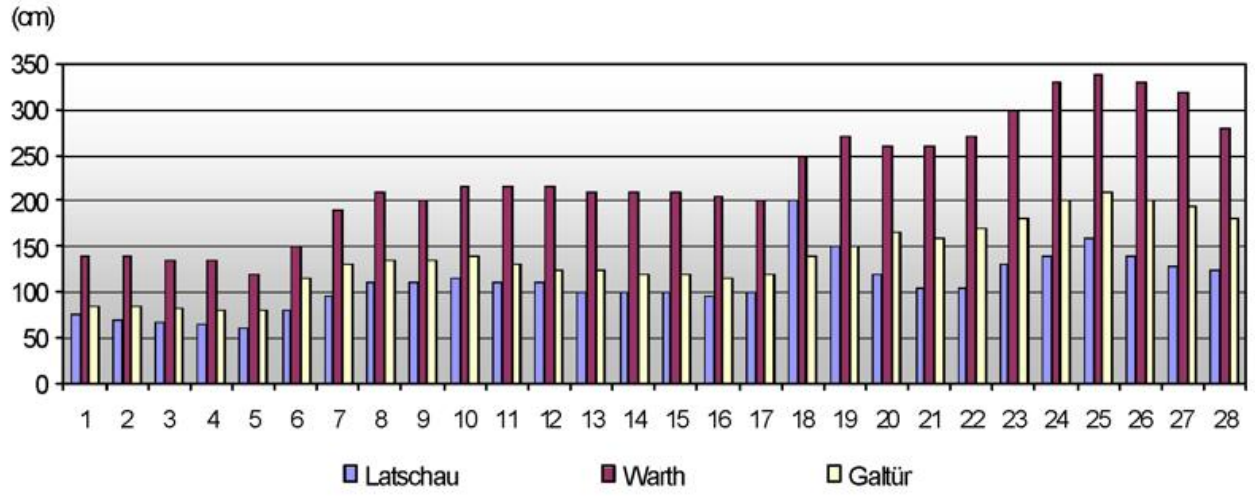

Fig. 2.1: *Daily records of depth of snow (cm) at Lantschau and Warth, Vorarlberg, and Galtür, Tyrol, in February 1999*
From: Central Institute of Meteorology and Geodynamics – ZAMG, Austria

March 1999:

- **Mostly very mild**
- **Heavy flooding over northern Hungary and in the Carpathian mountains**

In Iceland, March became the coldest month of the year and in most parts of the country this was the coldest March in 20 years. Except for the utmost East, unusually warm conditions prevailed in the Region. In the UK, it was the eleventh March out of the past twelve which were warmer than average.

The warm weather caused sudden snowmelt leading to severe flooding regionally. The situation was especially bad in north-eastern Hungary, Slovakia, Ukraine and Romania and Latvia: Many ice barriers developed, water from rainfall and melting snow could not penetrate into the already saturated soils. Therefore by mid-March about 370 000 hectares of land were flooded in Hungary and the resulting damage was among the biggest in this century, only comparable to the losses in the early 1940's or those in 1966. Thousands of homes were endangered or damaged. Rivers Tisza and Bodrog exceeded their highest water-levels, recorded during the past 150 years. In south-eastern Slovakia, the highest water levels since 1921 were registered in the Streda nad Bodrogom profile.

In Portugal, it was extremely rainy. Also northern Spain saw heavy rainfalls: La Coruña (246 mm) and much of the Galician coast, registered record high monthly totals. A new record of daily precipitation (up to 133 mm) was established in Galicia on March 8. In the UK, there were large regional variations in the rainfall amounts. South-east England was particularly dry with only 41 % of the average rainfall, the north-east, however, was very wet with 78 % more than normal. Heavy rain at the start of the month caused river Derwent to flood its banks, and the towns of Malton and Norton had their worst floods since 1931.

Israel and Jordan had another very dry month (see figure 1.1, page 27). South-west Iceland experienced the driest and sunniest March for 20 years. The month started extremely dull in The Netherlands with only 6,5 hours of sunshine in the first ten days of the month.

April 1999:

- **Unusually warm**
- **Regionally heavy snowfalls**

For all parts of Europe, except for Iceland, it was another warm month. The positive temperature anomalies were highest (more than +4 °C) in Belarus, the Baltic states and western Russia.

The rainfall distribution was uneven: Wet conditions prevailed in the UK, France and a belt, stretching from Scandinavia to Romania (more than +200 % of normal in north-eastern France and from southern Sweden to Poland).

Several villages in south-eastern Belgium were without electricity or telephone services after unusually heavy snow on April 15. In Switzerland, on the southern slopes of the Alps and in the central Alps new fallen snow piled up to more than 100 cm on April 16. On the Säntis, there was a record snow depth of 816 cm from April 21 - 23 (records started in 1959). On April 18, 30 - 50 mm of wet snow fell on higher terrain in south-western Sweden where about 12 000 households lost the electricity during the night 18/19. Rainfalls and the warm weather in April after a snowy winter led to severe ice jam and flooding in the Baltic states. River Emajogi in Estonia reached its highest water level in 43 years. On April 28, an ice jam near Arkhangelsk, Russia, caused the river Kholmogory to leave its banks, affecting 136 houses and 9 industrial enterprises.

In Hungary, the wet weather continued and hindered the decreasing of inland water.

An hailstorm caused heavy damage to vineyards in Pyrénées-Orientales on April 21. From April 22 - 25, severe showers with thunderstorms and hail crossed eastern Germany. Locally, hailstones with diameters up to 3 cm fell and hail covered the ground. Orchards and gardens were badly damaged.

There were also high losses by extreme winds: Kocaeli, Turkey, experienced a destructive storm on April 13. The city of St. Petersburg suffered from wind squalls with peaks of 101 km/h on April 18. Trees and advertising boards were broken and blown over, roofs blown off houses and power lines blown down. A tornado occurred in Povoa do Varzim, north-western Portugal, on April 21 leaving a trail of destruction.

May 1999:

- **Extremely cold in the Northeast and warm in the Southwest**
- **Severe flooding in the northern Lower Alps**

The north-eastern parts of the Region experienced extremely cold weather: Low temperatures, reaching 1 - 7 °C below zero, damaged the spring plantings, cherry and apple trees on large territories in European Russia. Such cold weather in May after an early spring had been registered only once before in this century (1918). New fallen snow on May 10 brought down power lines in many areas in Estonia. Lithuania saw as much as 20 nights with frosts, which damaged even cold-sensitive vegetables in greenhouses. After a sharp temperature drop, Armenia received 8 - 12 cm snow in the mountains on May 17 - 21.

While chilly weather prevailed in the Northeast, it was very warm in the South and West of the Region (see figure 6.3, page 34 and figure 9.2, page 39). In Greece, the month started extremely hot with maximum temperatures between 32 and 36 °C (long-term means 23 - 26 °C). In southern Spain, in the past 40 years only May 1964 was warmer. A significant Sharav event occurred in Israel on May 22/23: Temperatures reached 44 - 46 °C in the Jordan Valley and 42 - 43 °C in the coastal areas (the highest temperatures along the coast since May 1988). For England, the warm temperatures ensured that May 1999 was the sixth month in succession to be warmer than normal.

Heavy precipitation coupled with snow melting (see figure 5.1) in European alpine regions of more than 2 000 m altitude triggered heavy flooding in the catchment areas of the Danube River and Lakes Constance and Thune in Germany, Switzerland and Austria. Some regions received from May 20th until 22nd in 3 days precipitation amounts to be expected in a „normal" month of May. Large regions in the Danube catchment area received during May 1999 more than double up to threefold the normal May precipitation (see figure 5.2). Reutte, Tyrol, recorded a daily amount of 213 mm on May 21 and a monthly total of 445 mm. Precipitation totals of May 1999 as well as river levels exceeded record values. Lake Constance reached its highest level since 1858. 13 people died. Damage estimates due to flooding were calculated to more than 750 million US$.

Snowmelt floods caused inundation of hundreds of homes in the Sverdlovsk district, Russia, between May 9 and 15 and on May 29. A tornado with hail stones big as eggs caused damage of property in Jaltusha village, Bulgaria, valued above 250 000 US$ on 15 May. The wind blew off house roofs, rooted out trees and urned over trucks. Hail and rain damaged agricultural areas in parts, of Turkey on May 6 and 26. Edirne, Thrakya experienced heavy rain inundating settlements on May 14.

Towards the end of the month, there was a sequence of very warm days in southern England which triggered off several severe thunderstorms causing local flooding. The 30th of the month brought a series of devastating storms: 20 000 cars were damaged in a severe hailstorm which hit the port of Gent, Belgium.

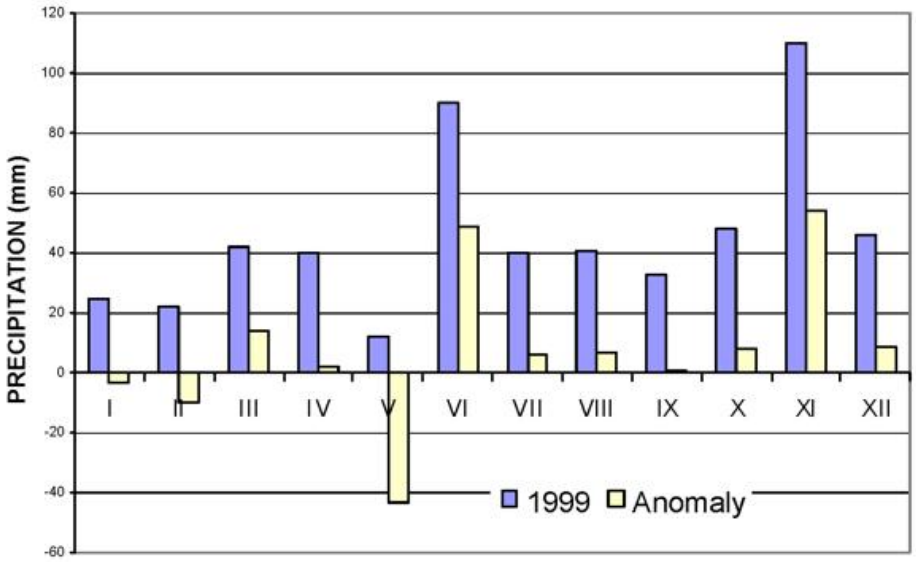

Fig. 5.3: *Monthly precipitation totals and anomalies in Skopje, in 1999*
Reference period: 1961 - 1990
From: Republic Hydrometeorological Institute, Macedonia

An exceptional thunderstorm, in the morning of the 30th of May, stroke Central France. Hail and strong winds were reported with gusts reaching 112 km/h. A cold front crossed with severe thunderstorms, squalls and hailstorms with stones having diameters of 20 - 30 mm in Lithuania.

Most parts of south-eastern Europe and the Middle East were affected by drought (see figure 5.3).

June 1999:

- **Exceptionally warm and dry in the East**
- **Very wet and cool from Scandinavia to the UK**
- **Devastating flooding in Hungary and Romania**
- **Extreme number of heavy thunderstorms**

After the very cold May, a heat wave swept eastern Europe in June (temperature anomalies surpassed + 5 °C, see figure 6.1). In spite of it, isolated frosts (down to - 8 °C) badly damaged 30 % of maize and buckwheat crops in the Perm district.

But also on the Balkans and in the south-western parts of the Region, hot and dry weather prevailed. For the Baltic states, it was one of the warmest Junes of the century. In many parts of Belarus, there was almost no rain from beginning of May - mid-June. As a result, the rainfall deficit increased to critical 50 - 80 % causing considerable agricultural damage. Spain recorded its lowest rainfall in 50 years devastating arable land, sugar beet and livestock farming.

In contrast, it was unusually cold and wet in the north-western parts of the Region. Despite of a temperature rise in the second half of the month, for the UK it was the coolest June since 1991, and the only month in 1999 to have below-average temperatures.

Denmark experienced its second wettest June since records started in 1874 (see figure 6.2). Very large amounts of rain fell also in south-western Sweden. 200 – 350 % of normal precipitation was observed along the west coast of southern Sweden. Varberg established with a monthly sum of 185 mm a new record for June (24 mm more than in 1912).

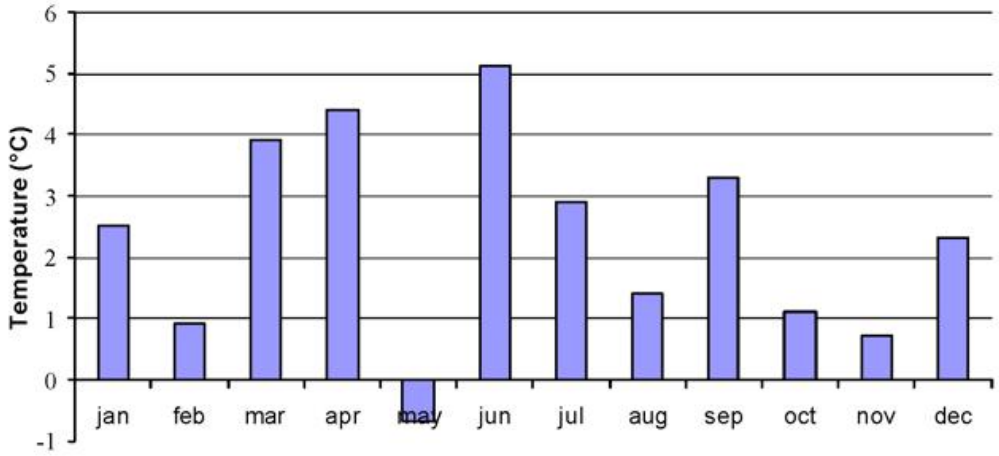

Fig. 6.1: *Monthly temperature anomalies in Riga in 1999, reference period: 1961 - 1990*
From: Latvian Hydrometeorological Agency

In the northern alpine region, the flood situation which had started in May eased slowly and in some areas further rainfall made it extremely long lasting. Lake Constance kept its record level for several weeks and large areas around the lakes of southern Germany remained inundated until July.

Macedonia, after extreme drought in May, received lots of rainfall this month (see figure 5.3). Inundation after heavy rain was reported from Elazig, Sakarya and Kocaeli, Turkey. Hungary and Romania, which had been hit by a severe flood in March, had another devastating flooding. In Hungary, precipitation fell evenly, rains returning every 3 - 4 days. In the northern areas 200 - 400 % of average was recorded. On the pre-saturated soil, on 21 June, 23 mm precipitation fell on the average. Many areas experienced more than 50 mm of rain causing short, but devastating floods. Situation was worst north of Budapest, in the Börzsöny hills, where 100 mm rainfall triggered a never before seen local flood on the small river Kemence. The water demolished houses, bridges and dams in two villages. Other local floods occurred around Budapest and the Balaton region. Losses amounted to about 145 million US$.

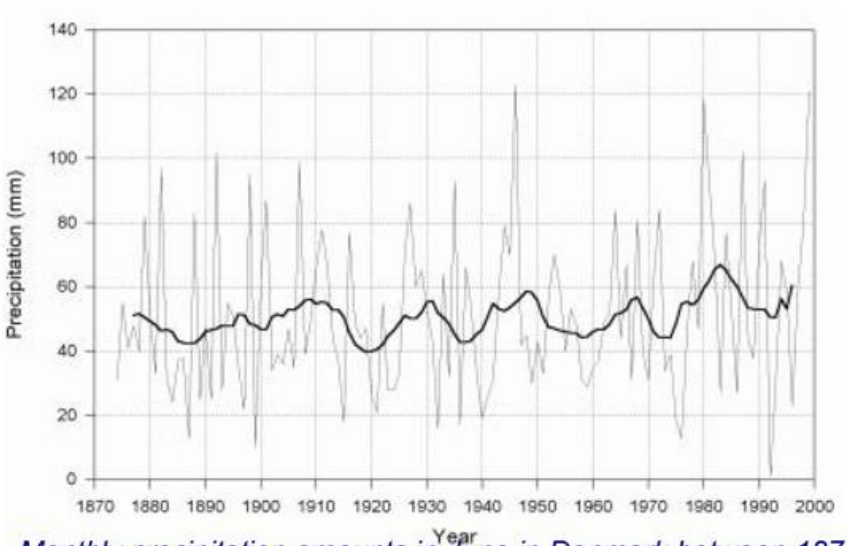

Fig. 6.2: *Monthly precipitation amounts in June in Denmark between 1874 and 1999*
bold curve : 10 year running mean
From: Danish Meteorological Institute

Also in Romania, floods destroyed numerous houses and bridges and inundated vast agricultural fields. In Slovakia, it was the 4th most rainy June in the 20th century, following June 1926, 1958, and 1965. The average precipitation total for the country was 140 mm, which is 163 % of normal.

The Region had a very high number of thunderstorms, hail and showers, especially in the hot countries in the East. In Lithuania, thunderstorms roared on 22 days of the month and there were a number of extreme showers: On June 18, Alytus meteorological station recorded 50 mm of rainfall in 12 hours. In the afternoon of June 20 in some areas of Eastern Lithuania hailstones 20 - 30 mm in diameter were falling. About 16 kilometres north-east of Vilnius, a very strong squall ravaged in the vicinity of the lake Balzio where many people were spending theweekend. A very heavy shower occurred in Trakai, Lithuania, on June 21 resulting in 54 mm of precipitation. A catastrophic shower was recorded by Birzai meteorological station on June 23 with 98 mm of rainfall in 6 h 49 min. More heavy showers occurred on June 29 resulting in 59 mm in 1 h 10 min.

In Latvia, thunders roared 15 - 16 times within the month as against 3 - 7 times normal for June. In Bulgaria, hailstorms occurred on 19 days. A shower with gusty wind and hail caused considerable damage in Plovdiv on June 12. Three persons were killed.

Although temperatures were near the 30 years-normal only 3 days without thunderstorm were recorded over Austria. Violent hail storms raged northern Switzerland on June 2. Flash floods caused by a severe summer storm trapped people in cars and flooded houses and roads in Cyprus (see figure 6.3).

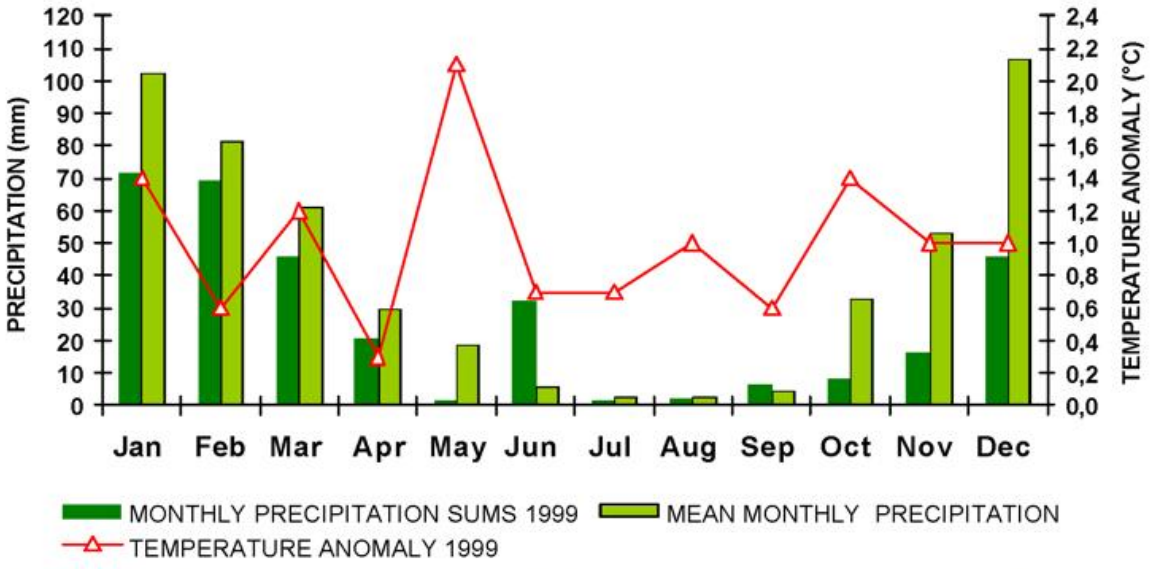

Fig. 6.3: *Monthly area average precipitation and temperature anomalies in Cyprus*
Reference period: 1961 - 1990
From: Meteorological Service of Cyprus

July 1999:

- **Hot and dry from Russia to England**
- **Heavy rains and devastating floods, especially in south-eastern Europe**

The heat over eastern Europe, that had started in June continued in July and for European Russia, it became the biggest heat wave of the century. The record temperatures were equalled last in 1895. Heat and drought sparked off some of the worst forest fires in the recent history. For the whole month, vast areas especially in the Northwest but also around Moscow, suffered from exceptional fire hazard. Also in Ukraine, the hot and dry weather (see figure 7.1), that had started in May, went on, becoming the most severe drought for the last 50 years.

Central and Western Europe experienced an extremely sunny and warm summer month. Across the southern parts of the UK, it was the driest July since 1911 and the sunniest since 1990. The first 10 days of the month were extraordinarily hot in Portugal, and July 8 - 10 set in many places new temperature maximum records (see figure 7.2). In Israel, too, the average daily temperature in July–August 1999 was one of the highest ever recorded, yet not as high as the year before (see figure 13, page 12).

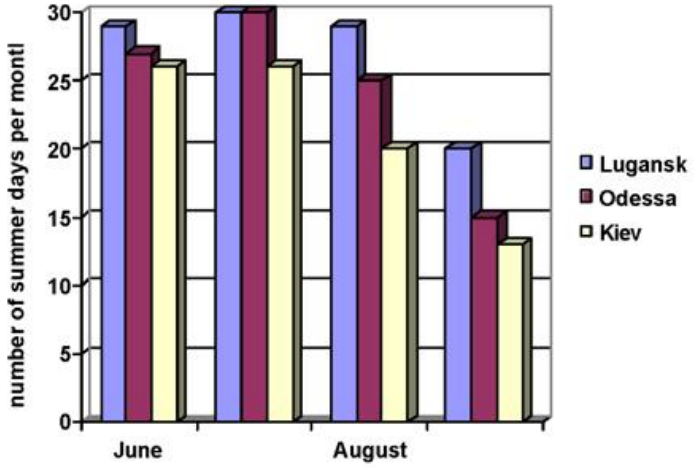

Fig. 7.1: *Number of days with maximum temperatures above 25 °C in Ukraine in 1999*
From: Ukrainian Hydrometeorological Center

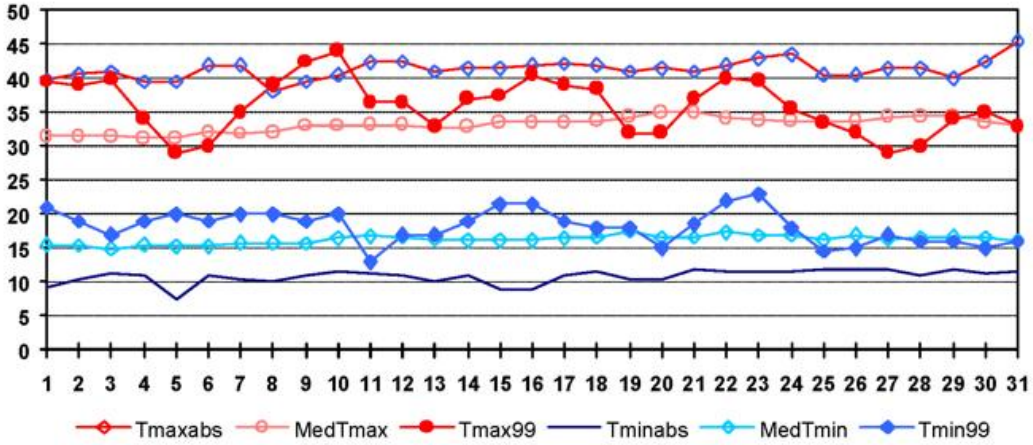

Fig. 7.2: *Daily temperatures in Elvas, Portugal, in July, reference period: 1961 - 1990*

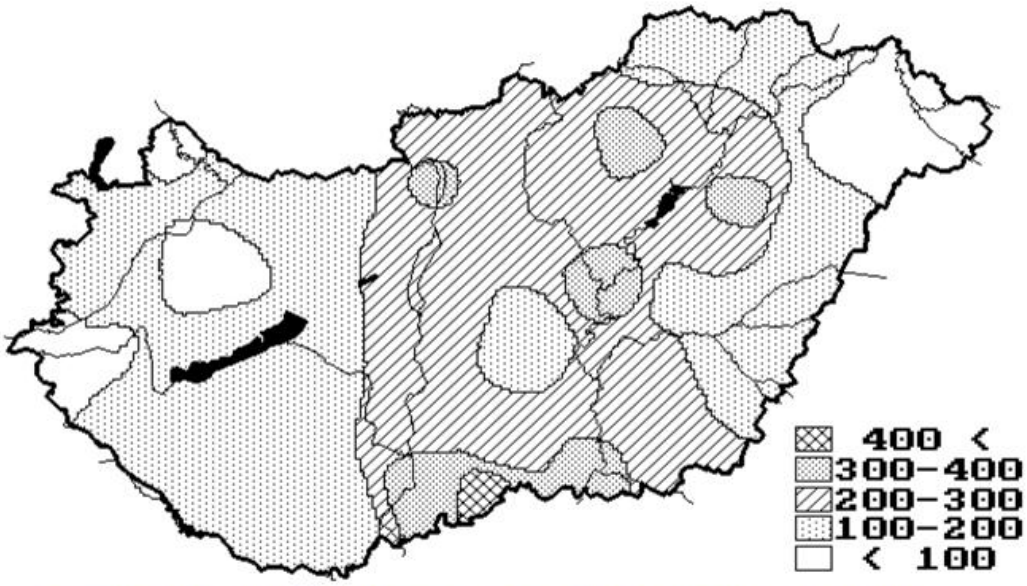

***Fig. 7.3**: Precipitation amounts in percent of normal in Hungary in July 1999*
Reference period: 1961 – 1990
From: Meteorological Service of the Republic of Hungary

July was also a month of heavy rainstorms:

- Floods causing substantial damage followed severe thunderstorms in eastern Belgium and southern Netherlands on July 4/5.
- In the UK, widespread thunderstorms (83 mm of rain at Charing, Kent), mini tornadoes and local flash floods occurred on July 5/6.
- Between July 4 - 8 and 12 - 20, again and again thunderstorms and downpours occurred in the Rhine-Main-area and in parts of south and south-eastern Germany. Intense rainfall (up to 160 mm within 3 hours) and hail (diameters up to 4 cm) caused damage amounting to more than 10 million Euro.
- A cold front, that had crossed Latvia on July 6, fostered showers, hail, thunderstorms and a squall line which raged Sigulda, near Riga.
- Considerable damage by hail occurred in western and north-western Switzerland on July 5.
- Rain and hail caused high, mostly agricultural losses in Turkey in mid-July. 4 people died and 200 houses were flooded in Ki?ikkale.
- Heavy rains caused severe mudflows in the Zaragoza province, Spain.
- On July 18, 21 members of a canoeing group lost their lives when the water level of a small river near Interlaken, Switzerland, rose abruptly after a violent thunderstorm.
- Widespread deluges occurred in south-eastern Europe causing extreme losses, estimated to more than 600 million US$. Vast fields were flooded, industry and infrastructure badly damaged. In Slovakia, the month belongs to the top ten rainy Julys of the century. The heavy rains caused isolated floods. The most extreme situation was in the Krupinica river basin, south-central Slovakia, where the culminating discharge had an estimated return period of about once per 1 000 years. Total losses in Slovakia were estimated to 56 million Euro.
- In Hungary, the monthly precipitation sums exceeded 100 mm at most places, this is for some locations 200 - 400 % of the average (see figure 7.3). Frequent thunderstorms occurred, some of these poured down more than 100 mm of rain in one day. In Heves county, unprecedented losses occurred as a result of floods and high waters, which affected about 40 000 hectares of agricultural lands, one third of the total in the county. In many settlements, water rose to surround houses, many buildings suffered damage or collapsed, several thousands people had to be evacuated. By the end of July, losses due to extreme weather in Hungary were estimated slightly less than 300 million US$.

- Severe damage was caused by rains in Romania on July 11/12: The heaviest losses (33 % of the total annual damage) occurred in the south-western parts of the country. 130 mm of rain in 12 hours made river Fenes to exceed its flooding level by 160 cm. The exceptional amount of 136 mm in 2 hours recorded on July 12 in the mountain area of the Raul Mare river basin caused very water levels flow which triggered flooding and destruction of two blocks of flats. 13 people died and many were injured by mud flows, driven rocks, logs and other wood debris. 217 mm of rain in 48 hours entailed flooding of river Husnita river on July 13.
- In Bulgaria, stormy winds and heavy rain caused disastrous flooding on July 10/11. On July 27, downpours with hail like "apple" (20 cm layer depth) (48 mm in four hours in Montana) led to floods and high damage in the north-west of the country.
- Belgrade, Yugoslavia, recorded a precipitation amount of 262 mm. This is a new record since instrumental measurements started in 1888 (see figure 7.4). The previous maximum precipitation amount was reported in July 1890, amounting to 191mm.

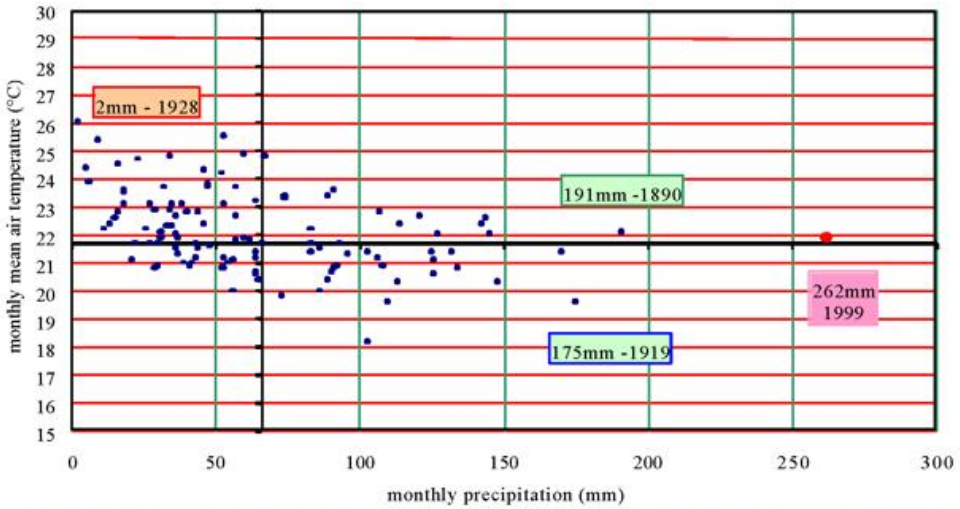

Fig. 7.4: *Monthly mean air temperatures and precipitation totals between 1888 and 1999 in Belgrade in July opposed to the 1961 - 1990 normal (temperature of 21,7°C, precipitation of 66 mm)*
From: Federal Hydrometeorological Institute, Belgrade

August 1999:

- **Relief from the heat wave in the East**
- **Warm and dry in the South**
- **Local heavy thunderstorms, abundant rain in Turkey and Portugal**

August started hot, dry and sunny in most parts, thus the bush fire risk in the Baltic States and European Russia still increased. From August 5 onward, normal temperatures and precipitation conditions brought relief from the long lasting drought. Southern Italy, Greece and Israel were affected by scorching heat waves: Temperatures climbed up to more than 40 °C setting new temperature records at some places (e.g. Catania Signonella 45 °C on August 10). Hot and dry weather affected also Armenia which recorded daily average temperature of 6 - 8 °C above normal. The dry weather in the South engendered a number of bush fires. In Bulgaria, losses due to wild fires reached 5 million US$ (see also figure 11, page 11).

Rainfall conditions varied a great deal across the Region. Precipitation totals of less than 50 % of normal were recorded in

Finland, regionally in Central Europe and in most parts of the Mediterranean. Cardiff and Birmingham, England, however, had their wettest August on record, with 176 and 154 mm of rain respectively. Abundant rain (more than 300 % of normal) fell in Portugal, in parts of Turkey and north of the Caspian Sea. Rainy weather persisted in Hungary. The northern part of the country suffered again receiving as much as 200 - 300 % of the long-term average. In a sub-basin of river Leitha, a tributary of river Danube, in Austria, an extreme flood with a return period of more than 100 years was observed.

Lithuania was hit twice by rain storms: On August 9th, a heavy shower in the city of Kaunas, resulted in 54 mm of rainfall in 1 h 25 min, with hailstones 22 - 30 mm in diameter. On August 16, in the town of Klaipëda 55 mm of rain fell in less than 12 hours and turned streets into streams. The lower parts of the town were inundated. Bulgaria, recorded 15 days with thunderstorms and 12 with hail. Most severe hailstorms (with stormy gusts > 90 km/h) crossed the South and Northeast of the country. Losses were estimated at about one million US$.

In Denmark, an unusual high number of water spouts caused locally considerable damage.

On August 28, a severe storm hit the Azores Islands.

September 1999:

- **Extraordinarily warm in most parts**
- **Very dry in the East**
- **Wet in the West and on the Balkans**

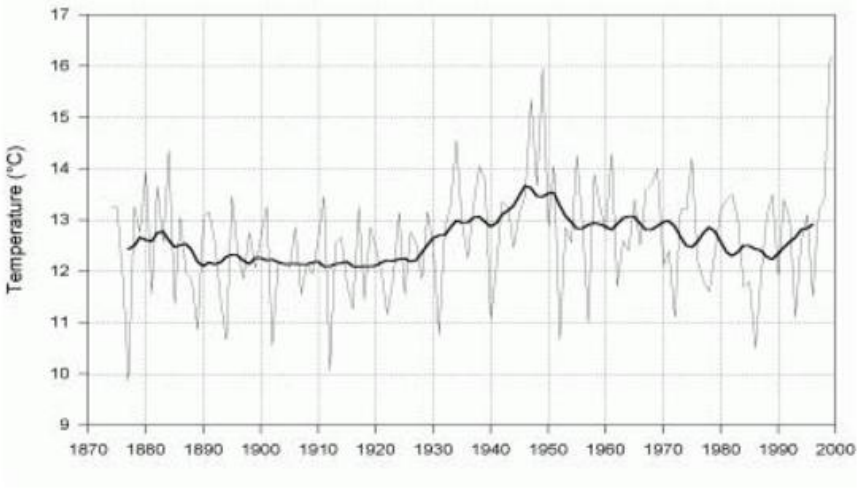

Fig. 9.1: *Mean temperatures in Denmark in September between 1874 and 1999*
Bold line: 10 year running mean
From: Danish Meteorological Institute

September 1999 was extremely warm and mostly very sunny. For Denmark (see figure 9.1), Norway and the Netherlands it was the warmest September since records started in 1874, respectively 1860 and 1706. Over all of Germany, it was the warmest September of the century and at several stations, it was the warmest month of the whole year. For Belgium, the mean temperature and the mean minimum temperatures equalled those of September 1949, which was the warmest since 1833 (see figure 9.2). Gravesend, Kent, reached 30,4 °C on September 11 - the highest September temperature in the UK since 1973. In spite of unsettled weather in the second half of the month, the high temperatures in the earlier part made it the warmest September since 1949, and

continued the trend for warm months during 1999. Also In Austria, it was one of the warmest September of the last 50 years.
Only in the utmost East of the Region and on the Iberian Peninsula, slightly sub-normal monthly mean temperatures were recorded.

In north-eastern Europe, the warm weather went along with extreme dryness. In south-western and southern Finland, an exceptional drought had developed during the summer (see figure 9.3). The deficit was considerable for more than two months from mid-July to the second half of September and caused a very poor harvest in these regions.

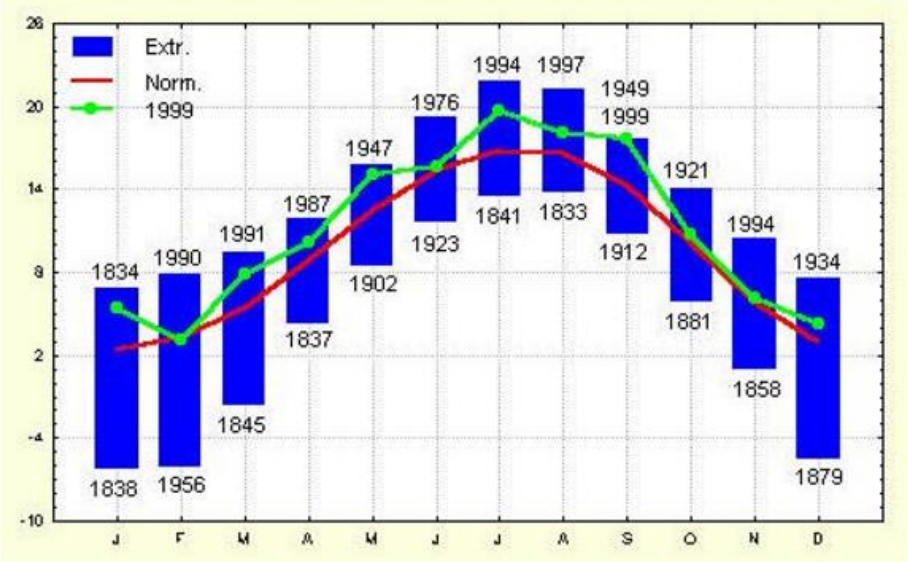

Fig. 9.2: *Mean monthly temperatures at Uccle, Belgium:*
1999 means, 1833 - 1985 normal and absolute extremes since 1833
From: Royal Meteorological Institute of Belgium

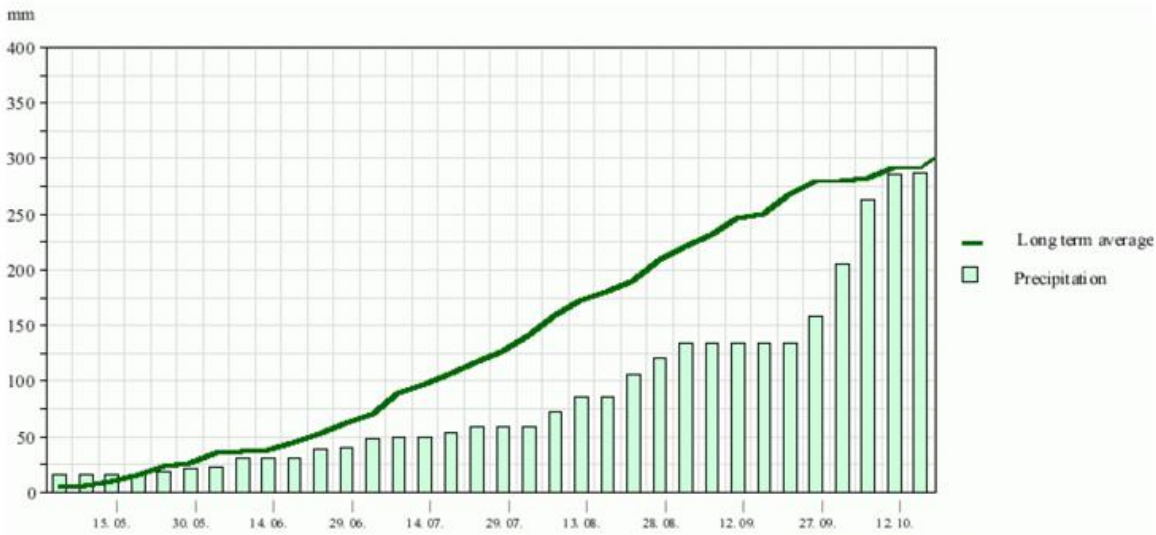

Fig. 9.3: *Accumulative precipitation (mm) of the growing season 1999 at Turku, Finland*
From: Finish Meteorological Institute

In the eastern parts of Ukraine, the summer drought continued and still increased severity in September. This period was one of the warmest and driest of the last 100 years. In many regions, there was hardly any precipitation at all for 20 - 45 days. In Estonia, there was no precipitation during the first 20 days of the month. The rains at the end of the month were the first in almost 3 ½ months.

After a series of extremely wet months, Hungary was more lucky in September when calm, sunny, warm and dry weather prevailed.

The weather was extremely unsettled, especially in the West of the Region and on parts of the Balkans:

- In Ireland, it was the wettest September on record at many stations;
- Heavy rains, local flooding and storms occurred in the second half of the month in central and southern England;
- In Portugal, the rainfall amounts were much above normal all over the country causing great damage due to flooding;
- Valladolid, north-western Spain, received 106,8 mm of rain, the highest monthly total in more than 130 years of measurements. In Segovia, there were up to 17 days with more than 1 mm of rain, this was the highest number of rainy days in September for any year in the last century. Three severe tornadoes occurred in the south-eastern provinces of Alicante, Murcia and Granada;
- The north-eastern parts of Italy were affected by severe rainfall on September 20/21 (up to 230 mm per day with estimated return periods exceeding 50 years);
- Towards the end of the month, a flood situation at some tributaries of the river Inn in Austria appeared with a return period of about 100 years;
- In Slovenia, especially the coastal region suffered from drought. However, precipitation in the central parts were copious. The surrounding of Kocevje and Bela Krajina got about twice their long-term precipitation amount. There were several episodes with intense precipitation, causing local landslides and flooding;
- In north-eastern Bulgaria and along the southern parts of the Black Sea coast, rainfalls from September 2 - 5 caused disastrous floods. The total precipitation for the 4 days period reached 270 mm in Preslav (see figure 9.4) and 289 mm in Staro Oryahovo. Rivers left their banks, dams broke. There were bridges and vehicles carried away, arable fields were flooded with mud, houses, camping and hotels were inundated. Losses surpassed 25 million US$. Thirteen persons died;
- On September 22, torrents in the mountains of the Republic of Dagestan destroyed roads and houses.

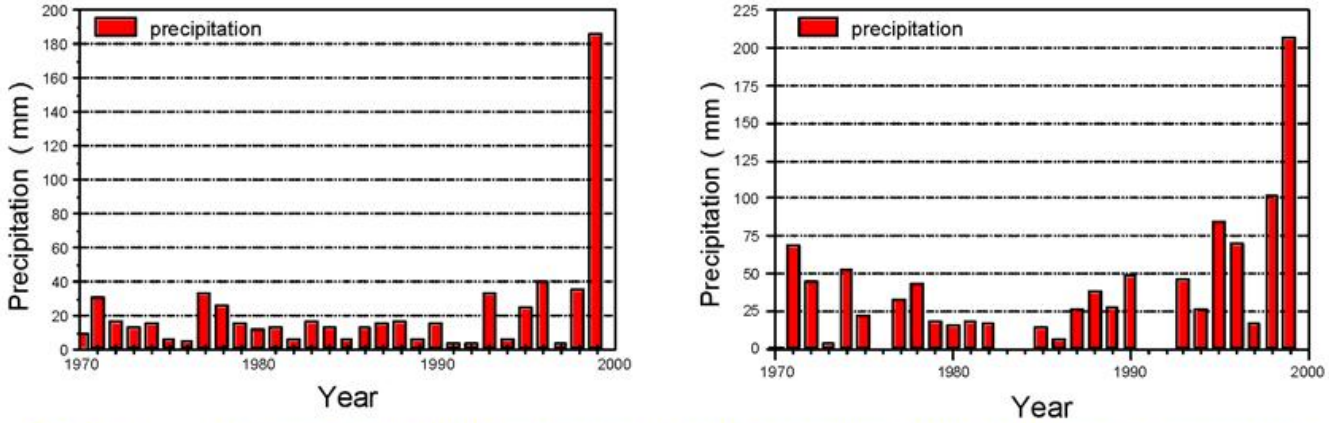

Fig. 9.4: *Maximum daily (left) and monthly (right) precipitation totals at Preslav, northeastern Bulgaria, in September between 1970 – 1999*
From: Bulgarian National Institute for Meteorology and Hydrology

October 1999:

- **Very warm in the South and Northeast of the Region**
- **Early frost in the East**
- **Abundant rains on the Iberian Peninsula**

October temperatures were near normal in most countries. Temperature anomalies of more than + 2 °C were restricted to the Mediterranean and the far Northeast of the Region. Warm weather in southern Europe led to temperatures of 37,4 °C in Palermo and 38,6 °C in Catania, Sicily, towards the end of the month. On contrast, early cold snaps with temperatures as low as –8 °C and snow affected eastern Europe in the second part of the month. In the north of the Astrakhan district, snow and sleet caused havoc on October 22/23: Roads were blocked by snowdrifts, power and telecommunication lines demolished and schools closed.

In the UK and in Central Europe, rainfall was mostly sub-normal and there was an above-average number of sunny days. In England, it was even the sunniest October since 1959, and the second sunniest on record.

Copious rains caused floods and damage in wide parts of Portugal and Spain and the monthly totals reached more than 400 % of normal in the Southeast of Spain.

Moreover, there were a number of regional severe rainfall events:

- The second highest daily precipitation amount in October of the period 1863 – 1999 was recorded in Zagreb-Gric, Croatia, at the beginning of the month (see figures 10.1 and 10.2).
- During the night between October 3 and 4, heavy showers brought 60 - 80 millimetres of precipitation in the western area of The Netherlands, causing a lot of troubles in this rather low lying area of the country.
- On October 6, heavy rain and lightning in the centre of the town of Rujiena. Latvia, were accompanied by falling of 29 – 40 mm large hailstones that covered the ground with a 10 cm deep layer. The hail destroyed greenhouses, damaged crops and cars. This hail event was the fifth during the last 40 years.
- Torrential rains with floods occurred in the mountain watersheds near the Venetian Plain and along the northern Apennines, Italy, between October 23 and 26.
- On October 24, heavy rain and gales hit the British Isles. Many places in North Wales had more than 60 mm of rain in 24 hours while Portland reported a gust of 113 km/h.

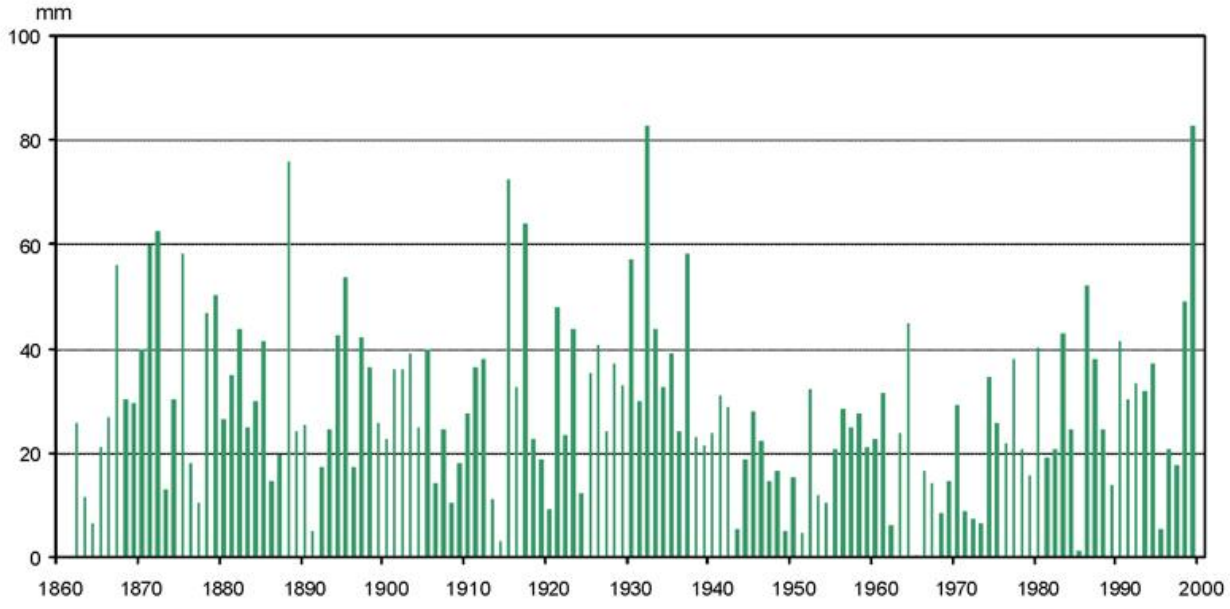

Fig. 10.1: *Maximum daily precipitation totals in October in Zagreb-Gric from 1863 - 1999*
From: Meteorological and Hydrological Service of Croatia

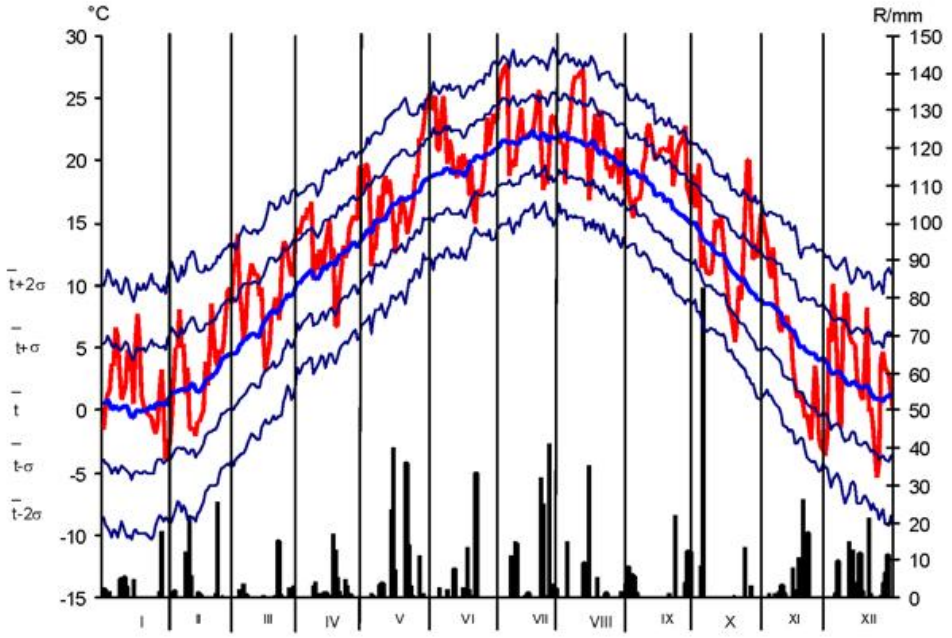

Fig. 10.2: *Mean daily temperatures in Zagreb-Gric in 1999 (thick line), compared to long-term means (central line) and standard deviations (thin lines), reference period:1862 -1995. Daily precipitation sums (columns) in 1999 From: Meteorological and Hydrological Service of Croatia*

November 1999:

- **Very mild in the North**
- **Cold, especially in the East**
- **Mostly dry, but severe floods in southern France, Italy and Greece**

This month, northern Europe was on the warmer side. New monthly maximum temperature records were set in Sweden. In Iceland, two short but extremely warm periods occurred: During the first, there was a new absolute November temperature record for the country as a whole when in the evening of the 10th the temperature rose to 22,7 °C at Dalatangi in the east (prior record 19,7 °C, set in 1971). On the 19th, the temperature in Reykjavík reached 12,6 °C which is the highest temperature ever at that location in November.

For 8 consecutive days (November 17 - 24), temperatures in the coastal area and in the Negev in Israel exceeded 28 °C (5 °C above normal) and even reached 32 - 33 °C.

To the contrary, in a broad belt from Spain across Central Europe to Russia, it was extremely cold. In Russia, monthly temperature undercut the long-term means by more than minus 5 °C and dozens of people died from the early cold snap. For Spain, it was one of the coldest November of the reference period. Only 4 years since 1961 had registered lower November values, and all those were before 1974. For Bulgaria, it was the only month of the year with a negative anomaly of the monthly mean.

The cold and heavy snowfall caused traffic chaos in Central Europe in the second half of the month. In Tyrol and Vorarlberg, Austria, up to 70 cm of snowfall in only 48 hours were recorded on November 22 - 23. On the 24th, Innsbruck reported a new record snow depth for November with 55 cm, the former being only 29 cm in 1977. In eastern Switzerland, too, snow depth records were established (e.g. St. Gallen and Bad Ragaz 62 cm). An unusual high number of days with snow cover occurred in Croatia (see figure 11.1). In Hungary, 20 - 40 cm snow fell and

stormy winds built snowdrifts blocking roads and villages.

It was dry in most parts of the Region. Precipitation totals reached less than 50 % of normal in the Middle East, in southern Scandinavia and in the Southwest of the Iberian Peninsula. In Denmark, November – the statistical wettest month of the year of that country - became the driest month in 1999 (33 mm). In Israel, rainfall amounts were just 15 - 30 % of normal. The dry and warm weather engendered immense forest fires in some areas causing severe damage.

Unsettled weather prevailed in northern Scandinavia and in some parts of South Europe (see also figure 5.3, page 32):

- In Greece, heavy rains and thunder-storms occurred between the 7th and 9th. The heavy storms led to floods and landslides which caused high losses to infrastructure and crops. Four people died.
- From November 12 – 14, an exceptionally rainy episode caused catastrophic floods in Aude, Tarn, Hérault and Pyrénées-Orientales departments, south-western France. Remarkable rainfall amounts were reported, reaching 620,2 mm in 48 hours at Lézignan-Corbières (Aude) (see figure 11.3). The losses were estimated to more than 500 million US$.
- Seven speleologists were captured in a flooded cave for 11 days.
- In Italy, on November 13, an exceptional flooding occurred in the Cagliari district, Sardinina (the Decimomannu weather station recorded 196 mm of rain in 24 hours). A state of emergency had to be declared.
- On November 18/19, rainstorms (100 mm in 10 hours), snow and gale-force winds caused serious problems in Tuscany, Italy. Industrial areas and settlements were inundated, trees uprooted and roads blocked .
- In the lowlands of Slovenia, fog and low cloudiness was very frequent. Thus it was the least sunny month of the year (see figure 11.2).

The month ended stormy in the Baltic area: On November 29, in western part of Estonia storm with gusts over 116 km/h damaged forests and power lines. The same storm felled huge amounts of wood in the provinces Närke and Södermanland in south central Sweden. In St. Petersburg, Russia, wind speeds up to 83 – 94 km/h entailed a severe tidal wave, and badly damaged the municipal infrastructure.

A wild storm caused several casualties and large material damage in the Rize area, Turkey.

Reference period: 1961 - 1990
From: Hydrometeorological Institute of Slovenia

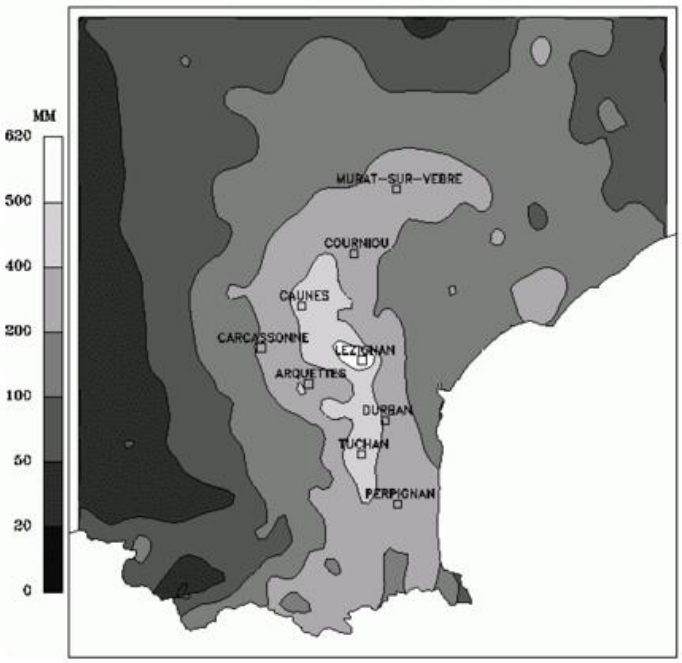

Fig. 11.3*: Precipitation totals in south-western France from 12/11/1999 to 13/11/1999*
From: METEO FRANCE

December 1999:

- **Devastating storms**
- **Wettest December on record in places, but dry in the South-east**
- **Very mild in the East, but cold in the North-west**

It was a very windy and rainy month in most parts of the Region. A series of severe storms brought the highest wind speeds ever recorded in parts of Europe. Two periods of strong winds stand out.

The first major storm, *Anatol,* struck northern Europe on December 3-4 (see figure 12.1, above). New records of maximum wind speed (up to 185 km/h) were set on the islands of Rømø, Denmark, and Sylt, Germany (see figure 12.2). Denmark was hit hardest, but also southern Sweden, Poland and the Baltic states suffered high losses: The winds downed trees, blew off roofs, knocked over trucks and raised hazard tidal waves. Storm-related deaths totaled 20.

Two more fierce storms, *Lothar* (Dec. 25-26, see figure 12.1, below)) and *Martin* (Dec. 27-28), struck wide parts in the West and South of the Region after Christmas, causing even higher losses. In France, these events combined led to wind gusts of more than 200 km/h (see figure 12.3) (Mandelieu-la-Napoule: 205,2 km/h. The corresponding

return period of such an event is estimated to 150 years, or even more.) In the mountains, wind squalls of more than 250 km/h (Wendelstein, Germany: 259 km/h, Jungfraujoch, Switzerland, 249 km/h) were recorded. Freak storms and avalanches claimed over 130 lives in France, Spain, Switzerland and southern Germany. Material losses were estimated at about 11 000 million US$.

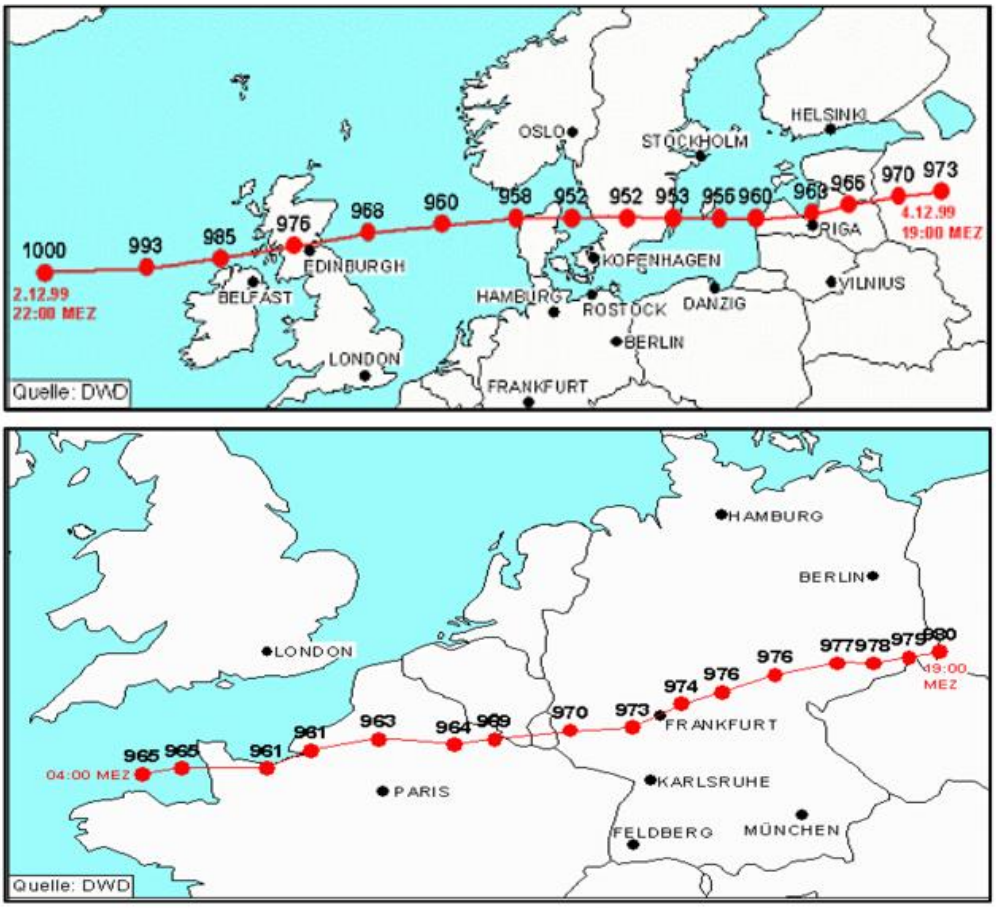

Fig. 12.1: *3-hourly positions and core pressure values in hPa of "Anatol" on Dec. 2/4 (above) 1-hourly positions and core pressure values in hPa of "Lothar" on Dec. 25 (below) From: Deutscher Wetterdienst, Germany*

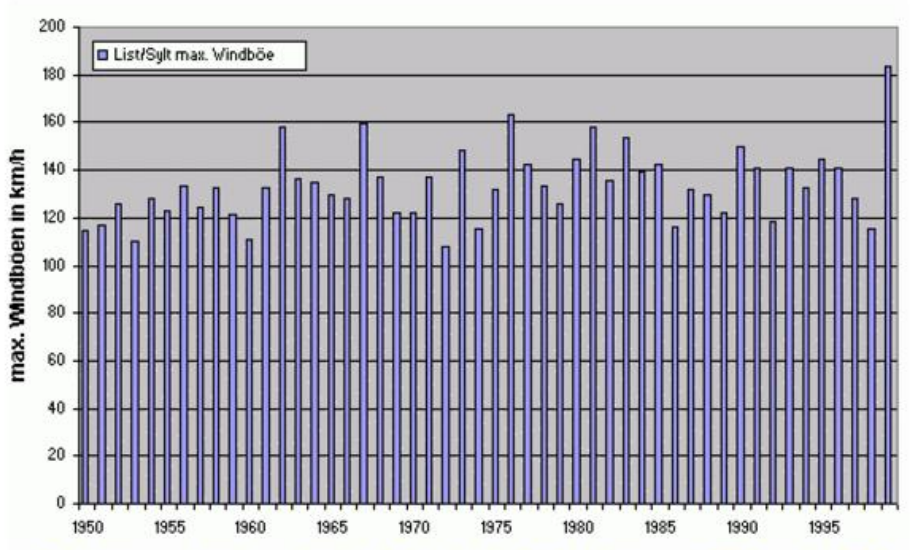

Fig. 12.2: *Maximum wind gusts (km/h) in List, Sylt, between 1950 and 1999 From: Deutscher Wetterdienst, Germany*

The stormy days went along with considerable pressure changes, even at sites far from the pressure centres (see figure 12.4).

The westerly winds brought mild and unsettled weather. And there were frequent rains and thunderstorms. For Belgium (see figure 12.5) and Ireland it was the wettest, for Denmark, the second wettest December on record. From south-western Sweden, several new records and maximum monthly precipitation amounts of around 300 mm were reported. Again, there was plenty of rain in Hungary, increasing the still existing risk of floods in parts of the country.

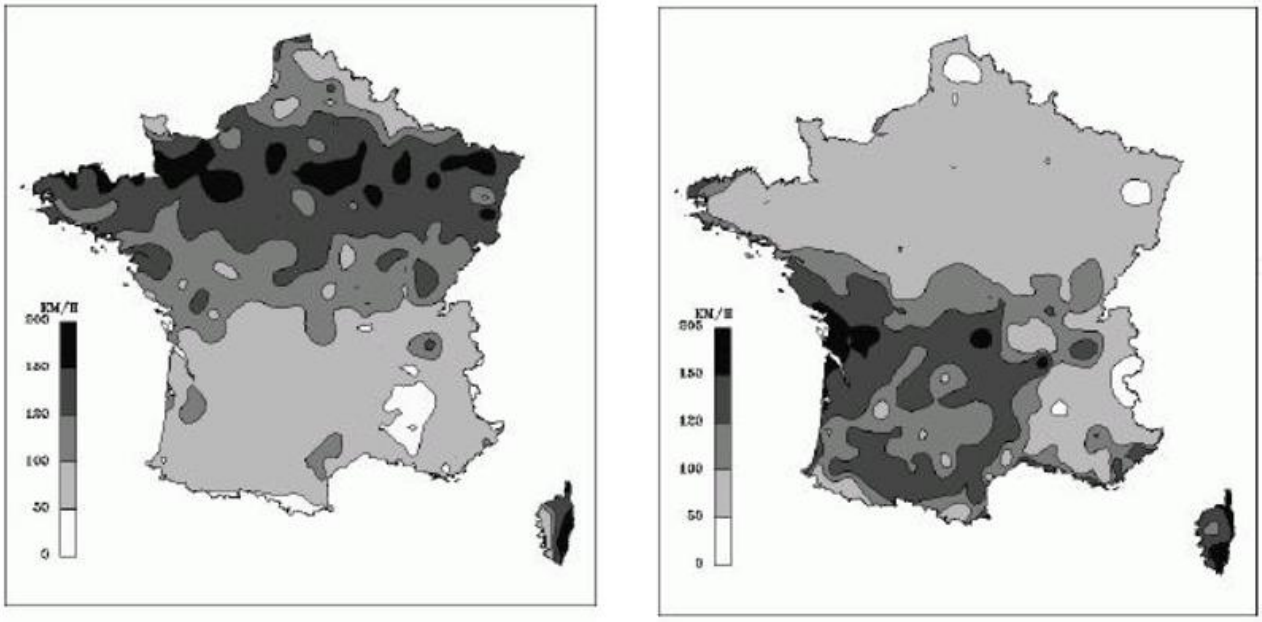

Fig. 12.3: *Maximum gusts in France on December 25 - 26, 1999 (left) and December 27 - 28,1999 (right), using stations with elevation <= 500 m*
From: METEO FRANCE

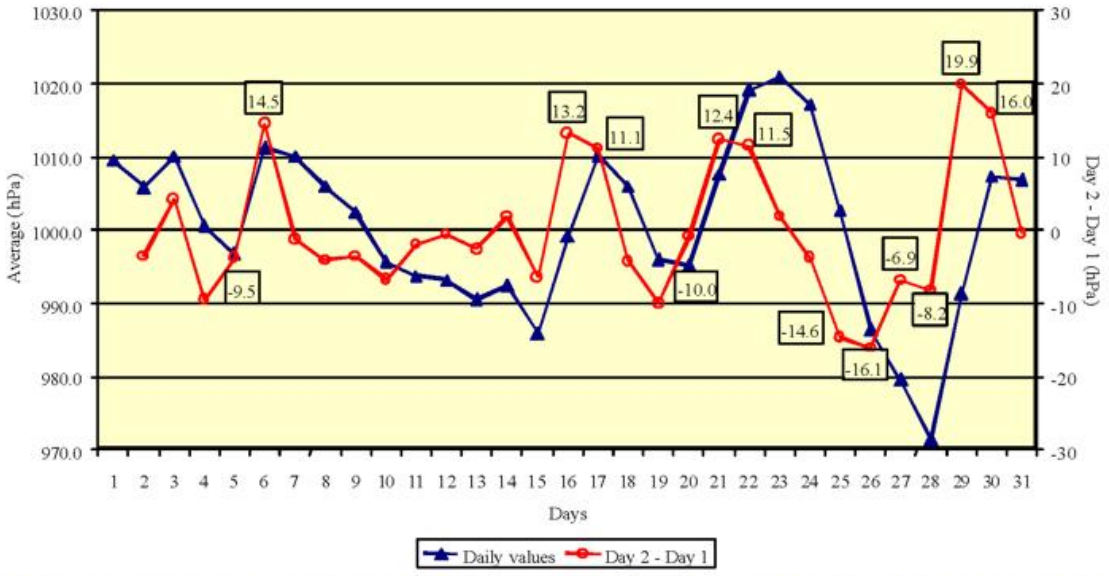

Fig 12.4: *Station pressure and pressure change from day to day in Belgrade in December 1999*
From: Federal Hydrometeorological Institute of Yugoslavia

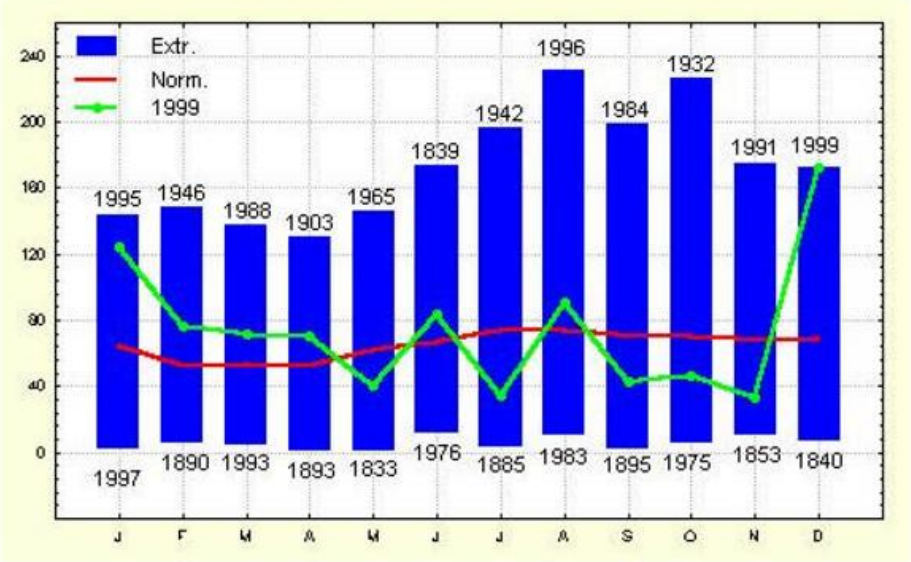

Fig. 12.5: *Mean monthly precipitation totals in mm at Uccle, Belgium: 1999 means, 1833 - 1985 normal and absolute extremes since 1833 From: Royal Meteorological Institute of Belgium*

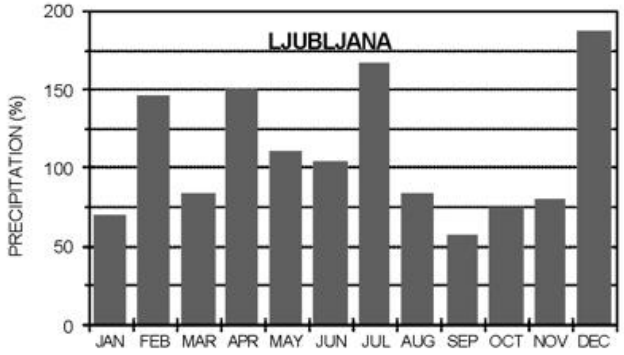

Fig. 12.6: *Monthly precipitation totals in percent of normal (1961 - 1990) in Ljubljana in 1999. From: Hydrometeorological Institute of Slovenia*

On December 14 - 17, a severe rainstorm affected central and southern Italy as well as parts of the former Yugoslavian Republic, triggering regional floods and mudflows with 6 casualties. In the Campania area, east of Naples, 324 mm of rain were recorded within 2 days (return period 80 years).

In Slovenia rainfall was abundant. Some areas in the western mountains received more than twice the monthly average (see figure 12.6). Nevertheless, the bright sunshine duration considerably exceeded the long-term average (see figure 11.2., page 44). This was also true for the UK where the month was mostly wet but, at the same time, one of the sunniest since records started.

However in the Southeast of the Region it was again extremely dry. With only 20 - 40 % of normal precipitation, dry conditions caused severe water shortage in parts of Armenia (see figure 1.2, page 27). Jordan received not even 10 % of normal (see figure 1.1, page 27). In Israel, December rainfall amounts were just 30 – 50 % of the long-term averages. Thus, altogether the accumulated rainfall amounts from the beginning of the rainy season in September till the end of December were much lower than normal – North and central Israel received only 20 - 40 % of normal, and the southern areas less than 10 %. This makes it one of the worst starts of the rainy season, and very similar to the beginning of the 1998/99 rainfall season.

While mild weather prevailed in the East with monthly anomalies surpassing plus 5 °C, it was very cold in the North. Reykjavík, Iceland, recorded 25 days with snow cover, which is highly unusual.

Activities and Results of European Climate Centres

News from the European Climate Support Network

ECA2000

The European Climate Assessment 2000 has as its main goal the description of the climatological variability through observed records of temperature and precipitation. Since the latter are essential in order to fulfil the objective, during the last year the project has continued to put a lot of effort in building its long series dataset. This dataset now comprises over 150 daily and 200 monthly time series form 28 European countries, but the aim is to cover all RA VI territory. Such valuable dataset will form the basis for another ECSN project that will soon be started with the objective of producing a historical daily dataset with no restrictions of use.

Besides making headway in the necessary groundwork of data gathering, the series have also been analysed. A list of climatic variability indicators has been drawn up and applied to the series (these can be found at: http://www.knmi.nl/samenw/eca/index.html). This has allowed the intercomparison of the behaviour of the indicators between nearby stations and so detect possible breaks of homogeneity or anomalies in the spatial coherency that may have escaped the earlier controls at the NMSs. On the other hand the trends in the different indicators have been computed and drawn on maps that give an overall view of the climatic variability for the period analysed. In some regions the lack of complete series casts some doubt on the significance of the trends found, although the precise formulation of those limits is a difficult task that is being tackled now.

Database management

The first workshop of this project took place in Oslo in October 1999. The participants, 27 from 14 countries, gave an overview of the different climate databases in their respective countries. In addition to this different topics were discussed, among them the problems in using commercial database products, the opportunities offered by the relational databases, questions about design and optimisation, storing techniques and retrieval possibilities. Special attention was devoted to the use of web-tools in presenting the information stored in climate databases, which was recognised as having a great potential. A report on this workshop has been issued by DNMI (DNMI Klima 05/2000).

In order to continue this exchange of views and experiences on a regular basis the possibility is being studied of setting up an Internet-based news group. The next workshop is scheduled for next year, and workshops addressing special topics could also be arranged. One of this could deal with quality control issues, a subject that has been already discussed inside the NORDKLIM group and could clearly benefit from a collation and standardisation of methods among the NMSs.

GIS in climatological applications

The Oslo meeting of the Databases project also offered an opportunity for discussing the work plan of this GIS project and exchanging ideas about how to proceed. An enquiry on the use of GIS in the different NMSs has been compiled. The project has produced a report about the different spatial interpolation methods, schematically describing their relative advantages and disadvantages and listing some of their characteristics. It is planned to distribute a package of interpolation methods to be compiled by each receiver.

The relation of this ECSN project with the similar COST719 action, was clarified in a meeting in March this year in Vienna. Both activities should interact constructively, and the broader scope and scientific depth of the COST action will permit the better development of GIS applications in the frame of the ECSN project. Two possibilities are being considered in this respect at the moment, GIS-based information tools and analytic applications.

Climate monitoring products

A kick-off meeting was held in Hamburg (January 2000). A first point in the agenda was to review the activities related to climate monitoring matters that are presently done at the NMSs, as well as the products available from other international institutions like WMO, especially those published by Internet. It was recognised that there is a great variety of weekly, monthly, seasonal and yearly monitoring reports and products available on national levels. However, in order to provide European monitoring products on a monthly and event related basis in a timely manner it is necessary to smooth differences at the border and to standardise formats. The project envisages giving access to such products through a special homepage. The work was divided in five areas according to the type of data, with co-ordinators appointed for each of them: in situ data, satellite data, model output data, special climatological events and RA VI Bulletin.

European Climate Atlas

After a feasibility study showed that the initial objective of making a European Atlas of extremes and climate applications related parameters lacked sufficient agreement on technical questions and was likely to have difficulties in gathering the necessary data, the idea now is to concentrate on producing a climate description for Europe based on monthly values for the 1971 - 2000 "normal" period. Tables with climate statistics and maps will be put in a CD-ROM, extending to Europe the CD-ROM that Meteo-France has commercialised for the 1961 - 1990 normal period. If the proposal of the project co-ordinator is found acceptable to all Members work could begin next year.

Drought project

The activities of this project with few participants (Hungary, Spain and Portugal) have consisted mainly in the comparison of drought indices. At the last ECSN Advisory Committee meeting (Oslo, June 2000) the idea was suggested of including in the ECA2000 some indicator for drought, probably the SPI index. More countries like Austria and Norway have shown their interest in collaborating with this project.

ECSN Climate Dataset (ECD) project

Last year ECSN undertook the creation of a dataset of historical instrumental long series of daily data in order to meet the demand that the scientific community has expressed in this sense (for instance EUROCLIVAR). The EUMETNET Council (June 1999) considered positively a proposal presented by the ECSN Responsible Member INM consisting in building such a dataset with basically no constraint on use and distribution and a network density at a minimum that of the GCOS-GSN. A small working group worked out the details in the summer of 1999. The density of stations envisaged now for this daily dataset is 2 per 100 000 km^2 (plus some mountainous stations and a correction for coast line) and the basic parameters to be included are temperature (both maximum and minimum), precipitation and pressure, starting from as long in the past as possible (recommended at least since 1951). A call for proposals in order to carry out this plan was distributed and only one joint proposal from KNMI-DNMI has been received. If everything goes all right, the project should get its official start with the approval by the EUMETNET Council in November this year.

Results of the ECSN Council Review

Since this is the last year of the present 3-year EUMETNET-ECSN Programme contract, the Council reviewed in April the ECSN activities. Summarising the conclusions, the objectives for ECSN remain valid and the continuation of ECSN was agreed. For the climate Atlas, the drought and climate monitoring projects a decision will be taken as to their further continuation in a year. The Council also gave some general guidelines for the future work of ECSN, for instance to foster the common development of tools and exchange them, to focus the research actions in exploiting the wealth of data stored by the Members and provide a structure allowing to merge European climate data, and to improve the access to the Members' climate data bases.

The climate of the 20th century in Sweden

By: Swedish Meteorological and Hydrological Institute

In an effort to summarise the climate of the 20th century 10 homogenised series of temperature and 20 series of homogenised precipitation have been used to produce graphs of winter and summer temperature and annual precipitation. It should be emphasised that especially precipitation is loosely or even negatively correlated between some parts of the country so it is a bit artificial to construct nation-wide averages.

The warmest decades of the 20th century were the 1930-ies and the 1990-ies, especially in winter. In both temperature plots there is also a maximum in between around 1970 - 1975. Two very contrasting pairs of summers (very warm and then very chilly) occurred close to the ends of the interval, 1901 - 1902 and 1997 - 1998.

The most obvious trend is the increase of the annual precipitation and it is thought that this, in spite of the efforts to homogenise data, to some extent depends on better instruments and better shelter from winds. But it has also been shown in various studies that the increase is, at least qualitatively, supported by an increase of wet, cyclonic (often westerly or southerly) weather types and/or a decrease of dry, anticyclonic (often easterly) types. The increase from the 1970-ies to the high levels 1980 - 1999 is quite large and undoubtedly real.

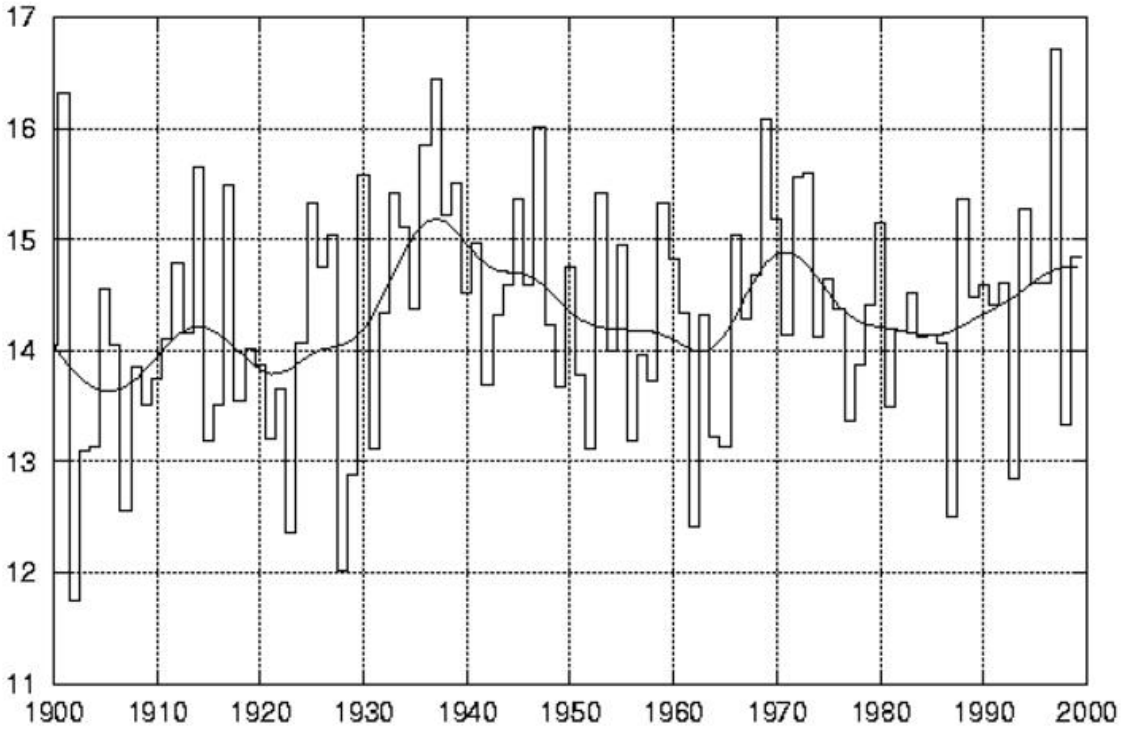

Fig. 1: *Summer (June - August) temperatures in Sweden 1900 - 1999, average from 10 homogenised series. The smooth line represents a low-pass filtered curve of Gaussian type emphasising variations on time scales of ten years and longer.*

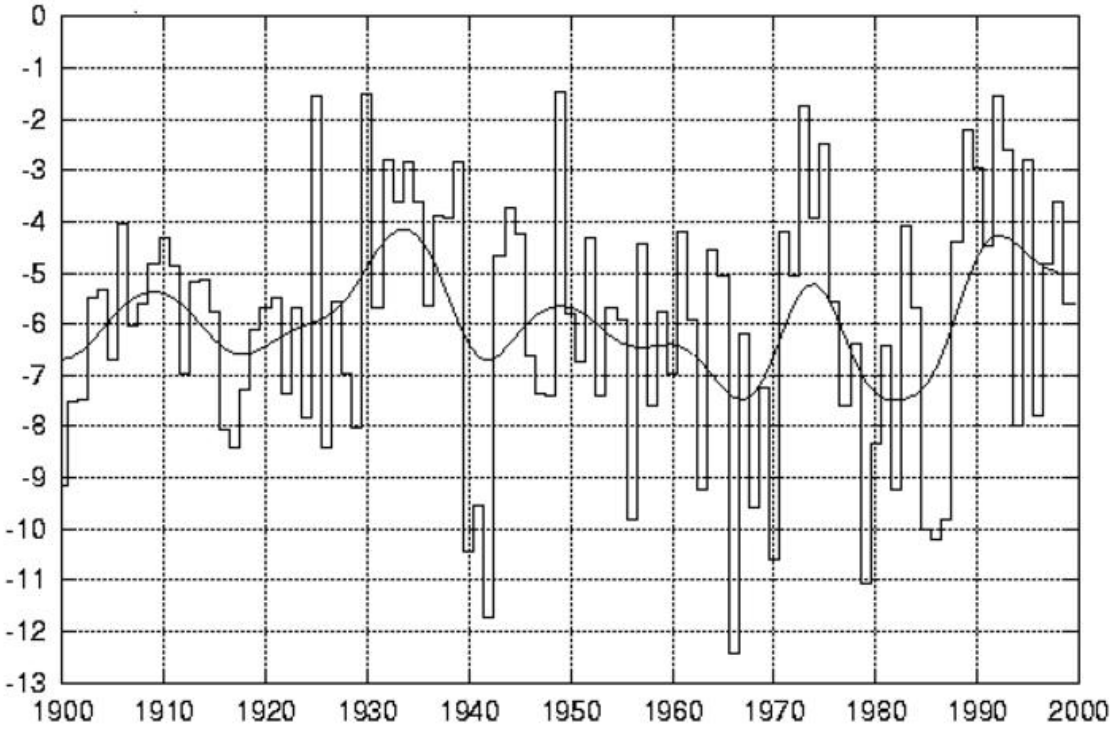

Fig. 2: *Winter (December previous year to February actual year) temperatures in Sweden 1900 - 1999, average from 10 homogenised series. The smooth line represents a low-pass filtered curve of Gaussian type emphasising variations on time scales of ten years and longer.*

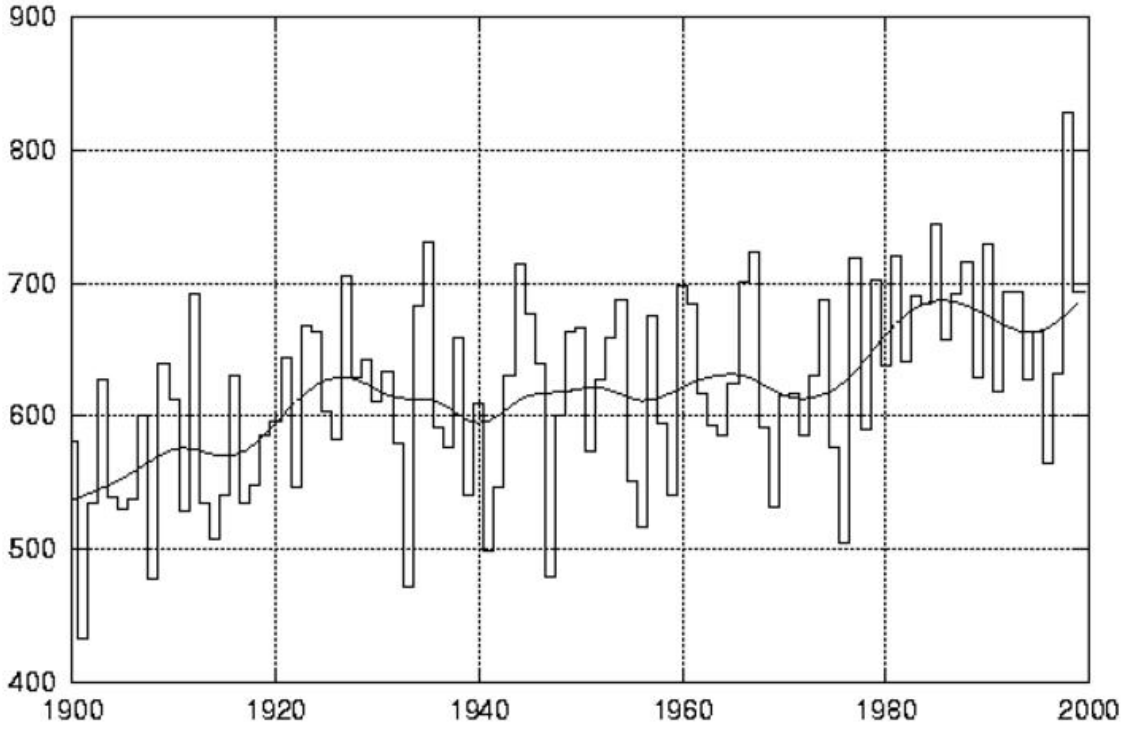

Fig.3: *Annual precipitation in Sweden 1900 - 1999, average of 20 homogenised series. The smooth line represents a low-pass filtered curve of Gaussian type emphasising variations on time scales of ten years and longer.*

The DWD objective weather type classification (OWTC)

By: Dr. Peter Bissolli and Dr. Ernst Dittmann, Deutscher Wetterdienst

The OWTC is based on daily numerical 12 UTC-analyses of the operational weather forecast models of the German Weather Service (Deutscher Wetterdienst = DWD). The focus is on an area covering Germany and adjacent regions. Principally, the OWTC could be applied to other European regions as well.

The classification consists of 40 different weather types, based on the following criteria:

- the advection of air masses (prevailing wind direction in 700 hPa),
  5 classes: NE = Northeast,
  SE = Southeast, SW = Southwest,
  NW = Northwest,
  XX = no prevailing direction;
- the circulation pattern (cyclonality) in 950 hPa and in 500 hPa, 2 classes each (anticyclonic or cyclonic);
- the humidity integrated over the whole troposphere, 2 classes (dry or wet, referring to deviations of the precipitable water from climatic monthly means 1979 - 1996).

In 1999, the most frequent weather type was a north-westerly one with anticyclonic conditions near the surface, but cyclonic conditions in 500 hPa and a mainly dry atmosphere (see figure 1). Such a situation happens quite often in summer and is frequently accompanied by convective precipitation. This year, however, this weather type has occurred in February and December too for several days. During these months the precipitation sums in Germany were considerably higher than normal.

Other weather types which were quite frequent in 1999 are those south-westerly and north-westerly ones with anticyclonic conditions in both height levels and a humid atmosphere. But this is not unusual.

The Christmas storm over Central Europe (December 26, named "Lothar" in Germany) has been taken place during a south-westerly type with cyclonic conditions in both levels and a humid atmosphere. Some other storms have occurred in Germany in December during south-westerly weather types too.

It is remarkable that there is a tendency to an increasing number of wet weather types during the last 20 years (see figure 2). In 1999 this number was in fact the highest since the beginning of the time series 20 years ago.

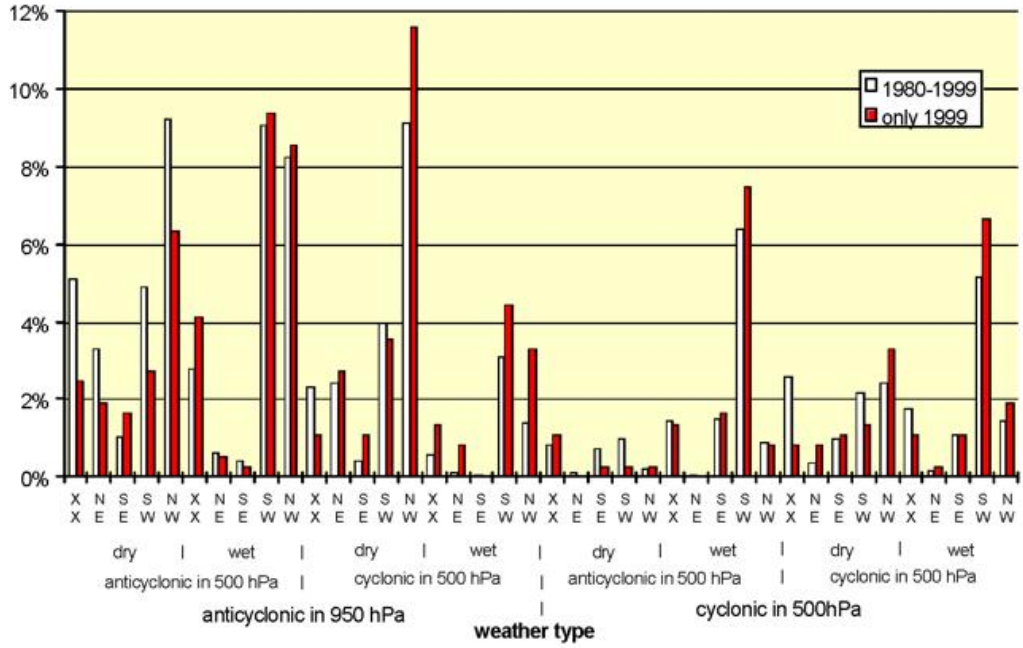

Fig. 1: *Relative frequency distribution of the 40 DWD objective weather types 1999 in comparison to 1980 - 1999.*

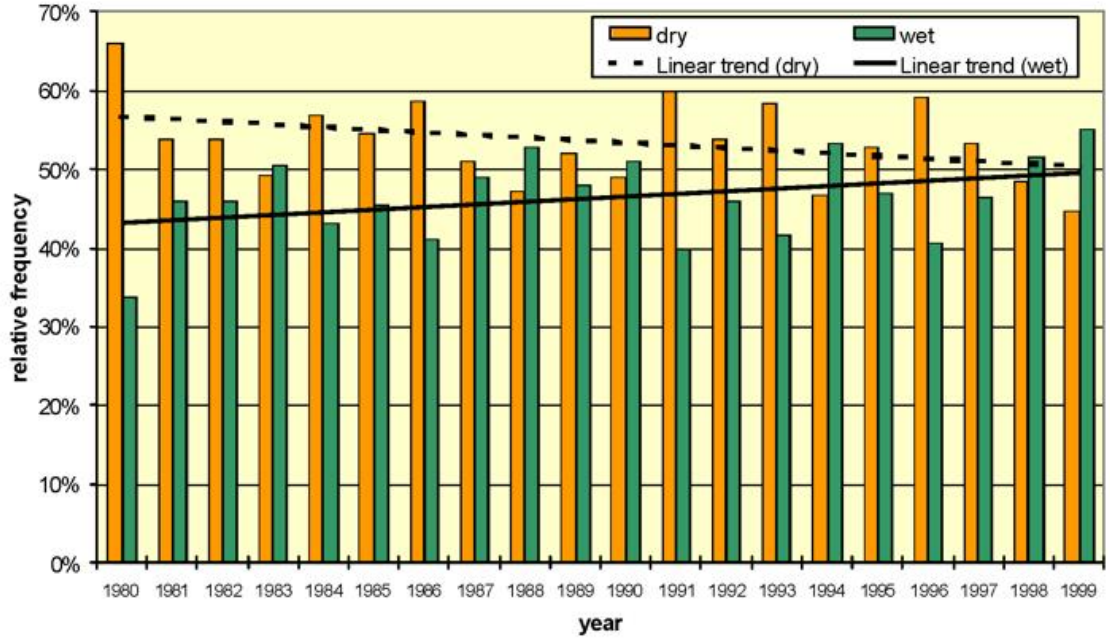

Fig. 2: *Annual relative frequencies of the humidity types of the DWD objective weather type classification 1980 - 1999. Lines are linear trends of these frequencies.*

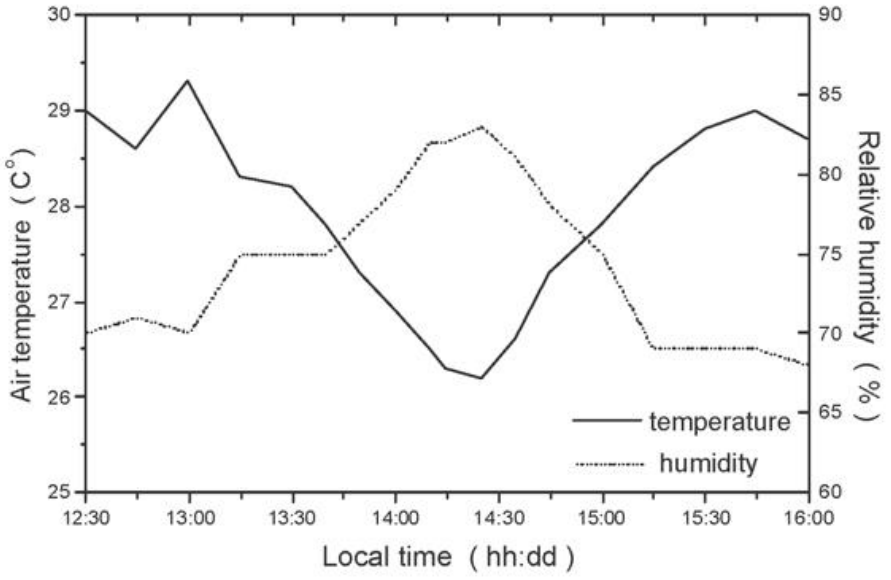
The Solar Eclipse effects in Bulgaria

By: Bulgarian National Institute for Meteorology and Hydrology

Surface temperature and relative humidity variation during the Solar eclipse on 11.08.1999 recorded by the Bulgarian NIMH team in Shabla (on the North Black Sea cost).

The partial eclipse began at 12h 46min LT and closed at 15h 33min LT. The full eclipse began at 14h 11min LT and lasted 2min and 27sec.



The SAF on Climate Monitoring

A European Initiative to Support the Use of Satellite Data for Climatological Applications

EUMETSAT, the European Organisation for the Exploitation of Meteorological Satellites, developed the idea of decentralised Satellite Application Facilities (SAFs) for the use of satellite data, especially those from EUMETSAT's MSG (METEOSAT Second Generation) and EPS (European Polar System).

Climatological applications are one of the areas, that will make profit from the use of satellite data. Therefore, a SAF on Climate Monitoring was established as an element of the distributed EUMETSAT ground segment. The SAF is hosted by Deutscher Wetterdienst (DWD) and comprises a common project effort, based on the know-how of several partner institutes.

Partners are:

- Finnish Meteorological Institute
- Royal Netherlands Meteorological Institute
- Royal Meteorological Institute of Belgium with Free University of Brussels and Royal Military Academy
- Swedish Meteorological and Hydrological Institute
- Federal Maritime and Hydographic Agency of Germany with German Climate Computing Centre
- Deutscher Wetterdienst with GKSS Research Centre

The project started in 1999 and is designed for 5 years ending with a quasi-operational phase. The outcome of the SAF will be meteorological products, that may be used for climatological applications especially climate monitoring.

Core products are:

- cloud parameters like
  - cloud fractional cover
  - cloud top height
  - cloud type
  - cloud top temperature
- components of the surface radiation budget like
  - surface incoming short wave radiation
  - surface albedo
- components of the radiation budget at the top of the atmosphere like
  - incoming solar radiative flux
  - reflected solar radiative flux
  - emitted thermal radiative flux
- atmospheric humidity parameters...like
  - vertical profiles
  - precipitable water
- and others.

These products will be provided in an area covering Europe and parts of adjacent seas. The horizontal resolution will vary from 15 - 50 km on a time scale between 1 hour up to monthly means, depending on the specific parameter. The products will be distributed to any interested party, be it scientific, administrative, commercial, or else.

DWD itself will be a user of SAF products. A coupled project, financed exclusively by DWD, started simultaneously to generate climate monitoring products using satellite data, together with data from other sources, like the traditional synoptic and climatological networks as well as output from NWP (numerical weather prediction)-models. The outcome of these activities will be maps, diagrams, tables, and interpretations, monitoring climate on a monthly and yearly basis of an area to be defined, starting with central Europe.

Annual Bulletin
on the Climate
in WMO Region VI
- Europe and Middle East -
2000

The bulletin is a summary of contributions
of the following national meteorological services
and was co-ordinated by Deutscher Wetterdienst, Germany,

Albania
Armenia
Austria
Belarus
Bulgaria
Croatia
Cyprus
Czech Republic
Denmark
Estonia
Finland
France
Germany
Hungary
Iceland
Ireland
Israel
Jordan
Latvia
Lithuania
Moldova
Netherlands
Norway
Poland
Portugal
Romania
Slovakia
Slovenia
Spain
Sweden
Switzerland
The Former Yugoslav Republic of Macedonia
Turkey
Ukraine
United Kingdom
Yugoslavia

Furthermore, contributions to the WMO Bulletin article on consequences of abnormal weather in 2000 were referred from the following countries:
Bosnia and Herzegowina, Greece, Italy, Russian Federation, Syrian Arab Republic

Dr Iván Mersich
President of WMO RA VI

Outstanding Events and Anomalies in 2000

Temperature

- Warmest year on record in many places
- Warmest spring and autumn on record in parts of Central Europe
- Fierce cold spell in eastern Central Europe in May
- Extraordinary hot and dry summer on the Balkans and in Middle East

Precipitation

- Wettest year on record in south-eastern Norway
- Driest year of the century in south-eastern Hungary
- Drought in eastern Spain aggravates until October
- Abundant snow in northern Fennoscandia in late winter
- Severe flooding in north-eastern Hungary, Romania and Serbia in April
- Extreme drought in parts of south-eastern Europe from mid-April to July
- Extremely wet in Scandinavia in June and July
- Wettest autumn on record in England, Wales and Ireland with repeated floods
- Devastating floods in northern Italy, southern Switzerland and eastern Spain in October

Annual Survey:

Warmer than average **temperatures** prevailed in all seasons and except for Turkey, the annual temperature anomaly was positive all over Europe and in the Middle East. For wide parts of the Region, it was one of the warmest year on record and for parts of Central and North Europe, it was even the warmest of the century (see figures 0.1, 0.2, 0.3 and fig. xc (Croatia, Germany, Poland, Slovakia, UK)). For the Netherlands, it was together with 1999 and 1990, not only the warmest year of the century but also since the start of regular measurements of the temperature in 1706. For Vienna, Austria, and Prague, Czech Republic, the annual temperature means of 11,8 °C and 11,93 °C were the highest since the beginning of measurements in 1775.

Heavy **precipitation** resulting in flooding, loss of life and extensive property damage occurred at several places in the Region. The most notable events were the flooding in north-eastern Hungary, Romania and Serbia in April, in northern Italy and southern Switzerland in October and in the United Kingdom and France from September to December. April was the wettest April, and the autumn the wettest autumn on record in the 235-year monthly England and Wales precipitation series (see fig. 0.10, page xx). South-eastern Norway experienced the wettest year since measurements began in 1895.
On the other hand, major droughts affected the south-eastern part of the Region engendering numerous wildfires and causing water shortages and high agricultural losses. Between mid-April and July, some parts of south-eastern Europe received hardly any precipitation. The Balkans and the Middle East had an extraordinarily hot, dry and sunny summer (see fig. 0.4, fig.xc (Croatia) p. xx,). For parts of south-eastern Hungary, it was the driest year of the century (see fig. xc, p.xx). During the year, the precipitation deficit in the large water-collection basins of Levante and the south-eastern mainland of Spain aggravated the drought from which the area was suffering: The precipitation total in the September 1998 to September 2000 period amounted to 614 mm, only. Such a low 2-year precipitation sum occurs on average once every 118 years. The deficit ended in October 2000 with an intense storm affecting most of the Mediterranean side of Spain (see fig. 0.5).

In Iceland, it was warm and very sunny. In Akureyri, the total number of bright sunshine hours was 1276. This is the highest number of sunshine hours there since the beginning of sunshine duration measurements in 1928 and 230 hours above the 1961-1990 average.

There was in general less **storminess** as in the preceding years. No fierce winter storms affecting larger regions occurred and the number of intense Atlantic winter cyclones was about normal (see fig. 0.6).

Most parts of the Russian Federation recorded normal to slightly reduced values of **total ozone.** For a few days around November 20, there was a deficit of 25 - 25 % over central European Russia and an absolute minimum of total ozone (196 Dobson units) was registered on November 18 over Moscow. At the meteorological observatory Hohenpeißenberg, southern Germany, subnormal ozone values prevailed almost over the year, resulting in the fifth lowest annual mean in the record of the station going back to 1968 (see article page xx).

Seasonal Surveys

Winter 1999/2000 was mostly mild. In European Russia, it was one of the warmest of the last decades (see fig. xx, page xx). Temperature anomalies in north-eastern Europe exceeded 2 °C and locally the 98th percentile. Precipitation was distributed unevenly: Surpluses in the northern and south-eastern parts of the Region contrasted with extreme deficits in the Southwest (see fig. xx page xx). For Portugal it was the driest winter of the century. In France, it was the driest winter since 1949 in Provence and along the Mediterranean coast. Dryness affected adversely the agriculture and hydropower production in Italy. Across England and Wales, it was the sunniest winter since 1909. Wet and mild weather brought a lot of snow to northern Fennoscandia.

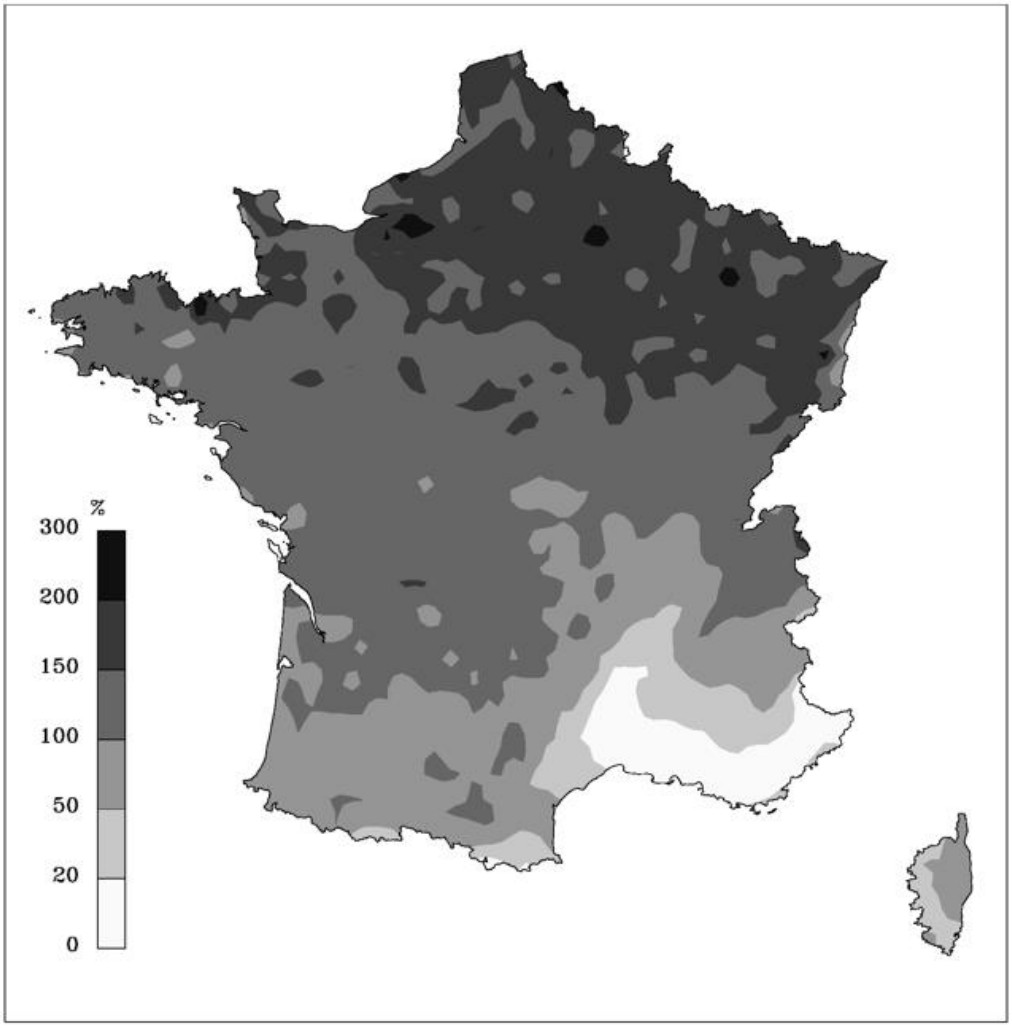

Fig. xx: *Winter precipitation in percentage of 1961-1990 normal in France from December 1999 to February 2000*
From: Meteo France

Spring 2000 was exceptionally warm in northern central Europe, parts of the Mediterranean area and the Middle East (see figures page xx). The spring was early and in general very mild. In Central Europe, the mild winter was followed by a warm spring (see fig. xx). For the whole of Germany, Slowakia and parts of Switzerland, spring 2000 was the warmest spring of the century (see fig. xx). However, in the eastern parts of Europe, a fierce cold spell caused considerable damage to the crops.

In south-eastern Europe, dry weather prevailed from mid-April to July. Some areas received hardly any rain. In contrast, April was the wettest April in the 235-year England and Wales Precipitation series and heavy rains and melting snow caused severe floods in norht-eastern Hungary, Romania and Serbia. In Israel, the 1999/2000 rainfall season ended in general drier than normal, in spite of a very wet January. Snow loads were extremely heavy in northern and eastern Finland, as the water content of the snow was high. However, the snow in Lapland melted away evenly and bare ground appeared in mid May.

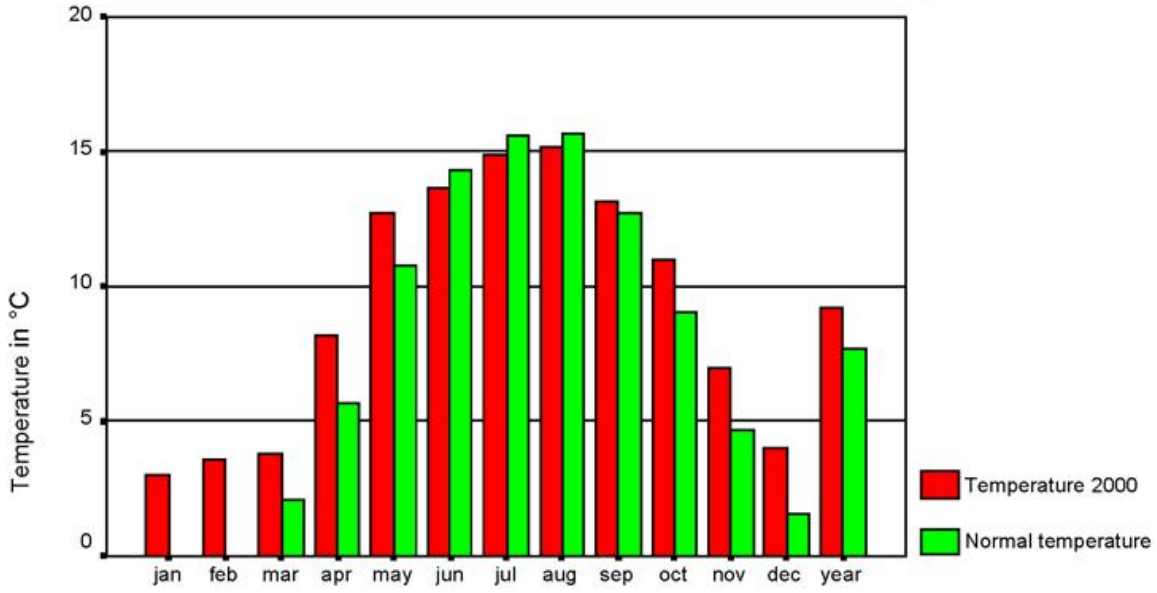

Fig. xx: *Monthly and annual temperature means in 2000 and 1961-1990 normal in Denmark*
From: Danish Meteorological Institute

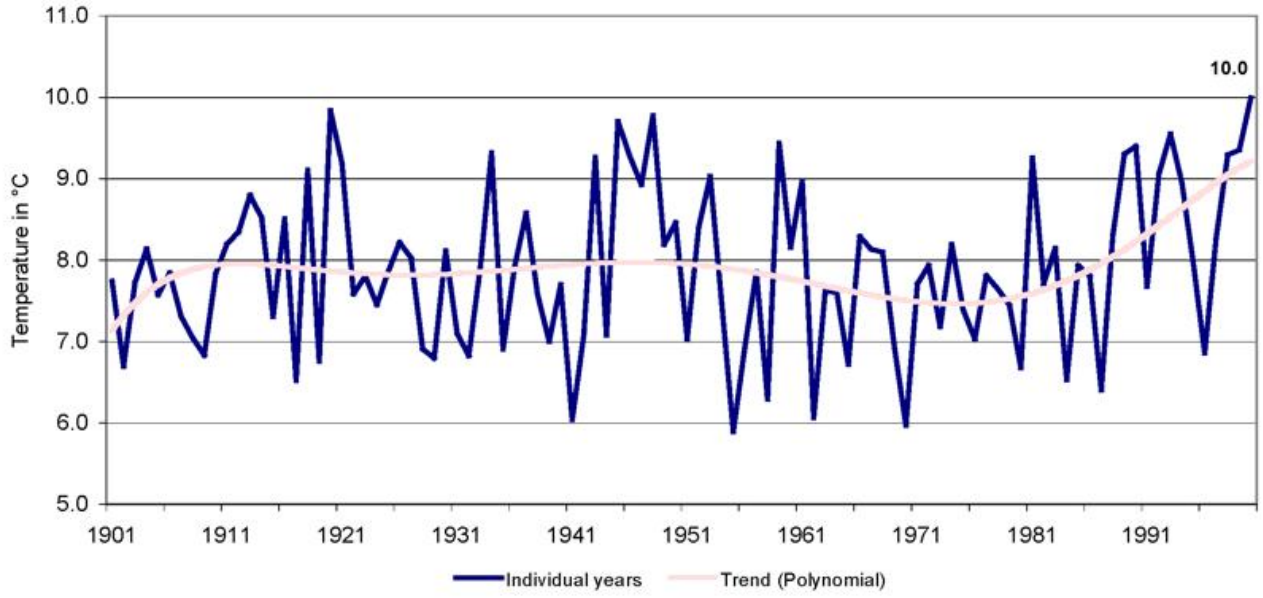

Fig. xx: *Areal mean of the spring temperature for Germany in 2000*
From Deutscher Wetterdienst, Germany

Temperatures in **summer 2000** were below normal in Scandinavia but elsewhere mainly above normal. It was extraordinarily hot and dry in south-eastern Europe and in the Middle East where the temperature anomalies surpassed the 98th percentile (see figures page xx). For Armenia, it was the hottest summer of the century. Major droughts affected much of south-eastern Europe and the Middle East. In Armenia, shortage of precipitation (the rainfall total for the whole summer was only 28 % of normal) caused losses estimated to 110 million US$. In Bulgaria, the warm and dry conditions led to about 1150 wildfires that damaged 127,000 hectares forest and crop areas. Greece suffered from hundreds of fires during the height of the heat wave, particularly on Samos, where fire consumed one-fifth of the island. In Croatia, drought covered about 70% of the country by the end of August. In Hungary, May to August 2000 was drier than in any other year of the century (e.g. Szeged received 64 mm, that is 30 % less than the earlier record). Jordan reported the longest heat on record (since 1923) with temperatures up to 43 °C (see fig. 7.5 page xx).

Although the summer 2000 was not especially dry in the United Kingdom, rainfall total in England and Wales was consistent with the tendency for drier conditions in July and August since the mid-20thcentury.

Autumn 2000 and the early winter were exceptionally warm from Scandinavia to Central Europe (see figures page xx) and the first frost appeared as late as December 17 at many places in the low-lands of Central Europe, which was the latest occurrence on record. For Slovakia, it was the warmest autumn on record. (since 1871).

Except for the south-eastern and south-western parts of the Region , wet conditions prevailed. In wide parts from the UK to northern Italy and in southern Scandinavia it was extremely wet. In much of England, Wales and Ireland, persistent wet weather began around mid-September and lasted beyond the end of the year. In all, the 503 mm of rain recorded was nearly twice the 1961 to 1990 average and there has been no wetter autumn in the 235-year England and Wales Precipitation series (EWP). (see figure xx). As a result there was widespread flooding in many parts of Britain. The worst affected areas were southern England, the headwaters and valley of River Severn in western England and east Wales, and Yorkshire. New precipitation records for autumn were also set in Ireland, which experienced over 60 consecutive days of rain in parts of the West and Southwest.

Two-months rainfall records for October-November were broken across many areas of France, leading to floods (especially in the North in November and in Britanny in December) and to saturated soils nearly everywhere at the end of October.

Torrential rains caused deadly flooding and mudslides in north-eastern Italy and southern Switzerland in October. The 10-day lasting river Po watershed flood was caused by severe rainfall with values never recorded before and recurrence periods exceeding in some sites 1000 years.

Extremely wet weather prevailed in southern Norway and Sweden from October to mid-December resulting in unprecedented high levels in lakes and streams. The biggest lake in Sweden, Vänern, rose to its highest level since regulations commenced in the middle of the 1930-ies.

January 2000:

- **Very wet in the Middle East**
- **Cold in the South, but warm in the North**

Abundant rain poured down in the Southeast. In Israel, in many areas rainfall amounts were more than twice of normal. Near the coast, January 2000 was the second rainiest since the beginning of measurements in the late 1930s, and in some stations even the rainiest (fig. 1.1). Tel Aviv received 150-200 mm on January 4-5 causing severe flooding especially in the southern parts of the city. The same areas were flooded again on January 27-28 when 110-120 mm of rain fell on Tel Aviv within 24 hours. During this extreme event, heavy snow fell over the mountain areas. Snowfall occurred also in areas with an altitude of only 200-300 m above sea level – a rare event in Israel. Jordan received half of the year's rainfall (see fig. 1.2). Turkey recorded the maximum areal average precipitation value of the year 102.8 mm (see fig. 1.3) and snow caused again and again problems across the country. Heavy rains and local floods affected Crete on January 14-15.

Wide parts of south-eastern Europe suffered from cold and wet weather with plenty of snow and local blizzards. In Bulgaria, the snow cover reached a depth of 50 cm almost throughout the country in the beginning of the month. During the third decade, new snowfall and high wind speeds plagued the Northeast of Bulgaria. Abundant precipitation triggered local floods in northern Yugoslavia. In Croatia, drifting snow and a strong Bora with gusts up to 150 km/h afflicted the coastal regions. Some harbours in the middle Adriatic were partly frozen. In Armenia and the adjacent Russian districts, in the period from January 18 to 23 heavy snowfall and blizzards occurred and the avalanche risk was severe. Together with strong winds (up to 28-30 m/s), they caused the river Gavaraget to flood the coastal grounds, 50 houses in the village of Krasnoe were damaged.

The year started extremely cold in the South: New temperature records were set in Spain, e.g. Salamanca registered an average temperature of - 4.6 °C which has been 0.2 °C lower than the previous record of January 1976. It produced the lowest January minimum temperatures in 55 years of registration. On Cyprus, frost caused substantial losses to the agricultural crops. The cold weather mostly went along with dry conditions. Wide parts of Slovenia and Albania got less than 30 % of the 1961-1990 normal precipitation (see fig. 8.2 page xx and 11.4 page xx). In the central parts of Slovenia, the number of sunshine hours were twice as high as usual (see fig. 1.4).

From Iceland across Scandinavia to western Russia, it was unusually warm. While the far North received plenty of snow, long spells of mild weather reduced the snow depth in the southern and western parts of Finland and the Baltic states. The wet snow wrecked power lines and damaged forests.

An unusual high number of thunderstorms appeared in Central Europe: In Slovakia, where only during 10 January months since 1881 there had been one day with thunderstorm, altogether 5 days with thunderstorms were recorded between December 28, 1999 and January 29, 2000.
A severe winterstorm hit northern Germany, Denmark and Sweden on January 29-30. Four people died. Vast amounts of sand were eroded along the coasts.

February 2000

- **Mostly extraordinarily warm, especially in Eastern Europe**
- **Very dry in the South**

In nearly all parts of Europe, it was a warm month. The mild conditions peaked from Poland to Western Russia with anomalies surpassing +4-5 °C (see fig. 2.1 and 2.2). In Spain, some 30 % of the mainland stations registered new average maximum temperatures. Also new records of the monthly average temperature were recorded for 100-year reference periods, including Madrid, with 16.0 °C, which is 0.6 °C higher than the previous record. An abrupt temperature rise of 20-25 °C in the course of a day and snow, blizzards and gusty wind of up to 13 - 17 m/s occurred in St. Petersburg Oblast and Karelia, north-western Russia, on February 27-28. Ice floes broke away with over 1200 amateur fishermen; rescue operations were carried out, but six people died.

The month was stormy and cold on Iceland with an unusually persistent snow cover in the south and west. Cold conditions prevailed also in the south-eastern parts of the Region (see fig. 11.xx (Cyprus) and 7.5 page xx)).

Whereas wet weather prevailed in the North, dryness predominated in the South. Drought was most extreme on the Iberian Peninsular where large parts received less than 25 % of normal. For the North of Spain as a whole, the average monthly atmospheric pressure levels were the highest registered for 40 years. Bilbao registered a level 1.5 hPa higher than the previous record (1961) and in the north-east, the 1962 record was exceeded by 2.4 hPa (see fig. 2.3). In Israel and Jordan, which had received excessive rainfall in the January, February was cool and dry (see fig. 1.2, page xx) with rainfall amounts of 40 % - 80 % of normal in the northern and central parts. The southern parts received almost no rain at all.

Dry and very sunny weather prevailed also on the Balkans. Primorska and Julian Alps, Slovenia got less than 30 % of the normal precipitation. Wild fires damaged 216 ha in Slovenia. In Ljubljana, more sunshine hours than this year were only recorded in February 1998.

There were plenty of rain and snow on the northern slopes of the Alps. A catastrophic flood caused 3 deads and high damage in northern Poland on February 2-3, where the dam of a water reservoir was broken. Heavy snowfalls, partly with storms caused problems in northern Norway and Sweden. Tromsö region got more than 0.5 m snow depth during a 24-hour period.

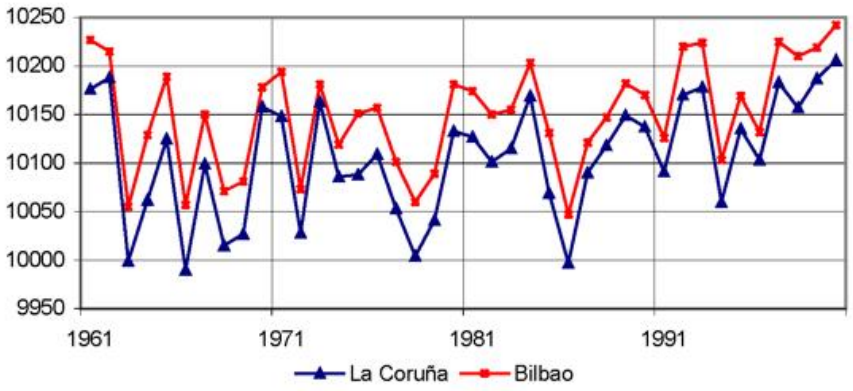

Fig. 2.3: *Mean sea level pressure (in 1/10 hPa) in La Coruña and Bilbao in February from 1961 to 2000.*
From: Instituto Nacional de Meteorologia, Spain

March 2000:

- **Heavy snowfalls in the North**
- **Very wet in wide parts of Central Europe**
- **Cool in the Southeast, elsewhere mostly mild**

Heavy snowfall continued in northern Fennoscandia. In Troms, Norway, roofs broke because of the heavy snow burden. Several settlements in Troms and Finnmark had to be evacuated for longer periods because of avalanche risk. Precipitation records were established at several stations in Troms, one of them with five times the normal precipitation amount of the month. In Sweden, one person was killed on March 6, when an avalanche crushed a house in the north-western mountains. Eastern and northern Finland had between 50 and 100 cm of snow, which was 20 cm above normal. The greatest snow depth of the winter (151 cm) was recorded in Haapovaara in Suomussalmi in early March.
Iceland experienced unusually adverse weather. A fierce storm hit the north-east coast on March 5. The precipitation total in Reykjavik was the highest since 1953. Heavy precipitation and snow melt caused landslides and local flooding in the western part of the country in late March.

Apart from the Southeast of the Region, mild weather prevailed also in March. Record high temperatures (up to 26.4 °C) were reported from southern Switzerland. Cold weather gripped Turkey. On March 7, several hundred people stranded in freezing temperatures on buses and trucks on a snow-blocked road in the north-eastern parts of the country. Fierce frosts caused considerable damage to the vineyards in Edirne region.

Whereas dry conditions prevailed in the western and southern parts of the Region, it was extremely rainy in Central Europe. The areal average rainfall of the Czech Republic amounted to 289 % of the 1961-90 normal and in Poland to 212 % (see fig. 3.1). In Slovakia, new daily precipitation records were set on March 9, some much higher than the monthly normal. The water equivalent of the snow cover reached extreme 53-years' extremes in the second half of the month (401 mm at Oravská Lesná (780 m above m.s.l.) on March 20, 528 mm at Štrbské Pleso (1354 m above m.s.l.) on March 27). Heavy rains and melting snow caused severe flooding in eastern Germany around March 15. A severe flood with a return period of 100 years occurred in the upper Labe river basin in north-eastern Bohemia. Precipitation totals during March 7 to 9 exceeded 100 mm and the additional contribution of melting snow was about 40-50 mm. For Tartu, Estonia, it was the 5th wettest March of the 1870 - 2000 period. The wet and mild weather resulted in a deep snow cover in the high mountains of the Alps. It led to a permanent snow cover for the whole year at Zugspitze, Germany, 2960 m above m.s.l.. A number of avalanches hit the upland regions of the northern Caucasian republics.

Cyprus experienced severe hailstorms on March 22 and 23.

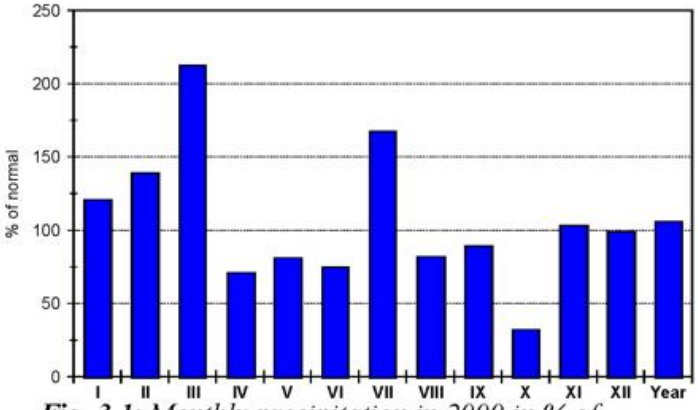

Fig. 3.1: *Monthly precipitation in 2000 in % of normal in Poland in 2000 (reference period: 1961-1990), averages of 8 stations. From: Institute of Meteorology and Water Management, Kraków, Poland*

APRIL 2000:

- **Mostly extremely warm**
- **Abundant rain from Spain across the British Isles to northern Scandinavia**
- **Severe floods in Hungary and Romania**
- **Very dry in south-eastern Europe and on Iceland**

It was another very warm month in the Region. Temperature anomalies surpassed +4 °C, locally +5 °C in the East (see fig. 2.1 and 2.2, page xx). A series of extremely warm days occurred at the end of the month. For Vilnius, Lithuania, it was the hottest ten-day period in April since 1881. Temperatures above 30 °C set a number of new records in Germany. In Tartu, Estonia, it was the warmest April in the 1866 to 2000 period. Norway had the warmest April since 1937. Several stations in southern Norway established new maximum records for April, with the warmest at Høland on April 19 with 26.2 °C. As a consequence of the unusually warm weather, the crop development was more than 14 days ahead of normalin many areas.

Israel experienced a large number of sharav events (hot and dry spells). The highest temperatures were recorded on April 12: 37 °C -38 °C in the coastal areas. The sharav event of April 18-19 ended with severe haze (the visibility throughout the country was less than 2 km) which lasted for three days. Also Cyprus reported extreme hazy conditions on April 19 with a visibility restricted to less than 300 m.
Only in the West of the Region temperatures were subnormal. In Iceland, it was cold, dry and unusually sunny, an unfavourable combination for some types of vegetation at that time of the year. The April records of bright sunshine hours were broken both in Reykjavik and Akureyri.

Dry weather prevailed and initiated in south-eastern Europe a drought that lasted for three months (see fig. 3.1 page xx). Some regions, e.g. western Slovakia, received hardly any rain at all. Whereas a cloud burst on April 25, caused high damage north of Cracow, Poland, most other parts of the country recieved monthly precipitation totals of less than 50 % of normal (e.g. Wroclav 11 mm or 29 % of normal).#

In the western part of the Region it was wet:

- On the Iberian Peninsula, westerly winds brought abundant rain to the river basins on the Atlantic side and to parts of the Ebro Basin. Several new rainfall records for April were set (e.g. Vigo 477 mm, Navacerrada NW of Madrid 375 mm, Spain and Beja and Oporto, Portugal).
- For the UK it was the wettest April in the 235-years' England and Wales precipitation series. The areal average was 143 mm against 139 mm in 1782 (the previous April record).
- In northern Norway, April brought the highest amount of precipitation in 100 years.

Rapidly melting snow in the Carpaths caused the highest water levels ever recorded in a more than 100 km section of river Tisza, Hungary, at the beginning oft the month. The flood also afflicted neighbouring Romania and northern Serbia. All in all 10 people died, 10.000 houses and 2.000 km^2 were flooded. On April 26, heavy precipitation engendered flooding in Bulgaria (daily totals up to 115 mm in Botev).

Southern Switzerland experienced heavy rain balancing the winter deficit (e.g. Locarno-Monti) received more precipitation than the January-April normal.

Frequent storms and hail caused considerable losses in Turkey (see fig. 1.3 page xx). Trees were broken, roofs and power lines destroyed. The maximum gust of the year for France, was recorded on April 4 at Cap-Béar (187 km/h). Storm winds brought sandy grains from the Sahara to Bulgaria on April 4-5.

May 2000:

- **Dry, sunny and warm in most parts**
- **Fierce cold spell in eastern Central Europe**

The dry weather that had started in April continued into May in many parts (see fig. 5.1 and 3.1 page xx). As a consequence, severe drought afflicted western Slovakia (e.g. Maldacky received only 5 mm of rain between April 6 and May 17 (7 % of normal), Kráľová pri Senci only 3 mm from April 6 to May 21, 2000 (5 % of normal)). In Belarus (see fig. 5.2), there was no rain from about April 20 to mid-May and together with very dry air the soil was extremely dry, causing high losses to the agriculture. In Poland, drought was worse in the Northeast: Suwalki received 13 mm of rain which is 22 % of normal. Eastern Austria experienced an unusually dry period from April 16 to May 17 (Vienna 4 mm) causing crop losses of up to 100 %. Also in Hungary, which had suffered from devastating floods in April, weather was hot, dry and sunny in May.

Temperatures were significantly above normal in most parts of the Region (except for the far East). New maximum temperature records were set. Kongsberg, SE Norway, recorded 30.0 °C on May 14, a temperature that had never been exceeded at any station in Norway so early in the year before. Ibiza, Spain, recorded a new absolute maximum for May with 30.4 °C in 50 years of observation. The first half of the month was warmest ever in the low lands of Switzerland. With a mean temperature of 15-18 °C, it was nearly as warm as in July. New records of maximum daily temperature means were reported from Germany. The Netherlands recorded a remarkable sequence of 12 consecutive "summer days", equalling the record set in 1992. It may be noted that this had not even happened in June before, where the present record is 10 such days in a row.

There was a number of severe cloudbursts and thunderstorms.

- Bracknell, southern England, experienced more than 50 mm of rain on May 7 and hail with diameters of 1.5 cm.
- Thunderstorms with heavy rain and hail hit Germany at the beginning of the month.
- Heavy rain and hail caused severe damage in north-western France and Belgium.
- On May 9, a heavy cloudburst hit western Poland.
- On May 27, some cornfields were completely damaged by severe thunderstorms with hail (diameters up to 4 cm) in Lower Silesia, Poland. Afterwards, the strong winds with hail crossed Poland from Cracow to Warsaw.
- Storms with local floods occurred in Croatia at the end of the month.
- Some stations in the Julian Alps, Slovenia, registered monthly totals of more than 250 mm.
- Turkey reported a number of hail events and local floods

In the eastern parts of the Region, the month started with a spell of fierce frost:

- Temperatures dropped to - 4 °C in Suwalki, Poland, on May 3.
- Soil temperatures fell to minus 5 - 10 °C in south-eastern Lithuania and Belarus.

The frost was especially disastrous, as it followed a period of very warm weather in April.

The Arkhangelsk Oblast experienced heavy snow with blizzards and gusty wind of up to 20 m/s on May 12-14. Wide-spread snow cover of 5-28 cm deepness (up to 77 cm in Mezen) destroyed power and telephone lines. On May 2, north-eastern Norway was hit by heavy snowfall and strong winds. Several roads were closed even in southern Norway.

On May 28, unusually strong winds for the season caused considerable damage in the forests and destroyed power lines in Germany. In the western parts of the Netherlands, the gusts reached 35 m/s. Some stations reported a maximum hourly wind speed of 25 m/s. Six people died, buildings were damaged, trees uprooted.

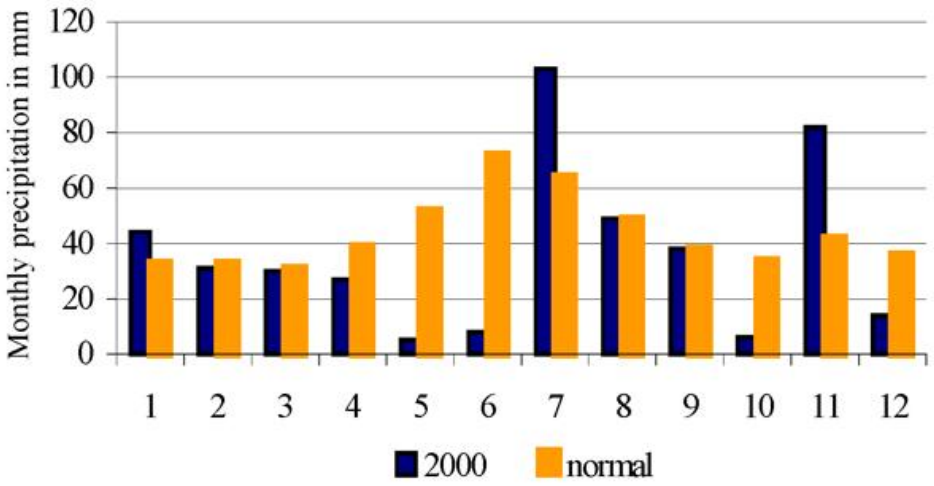

Fig 5.1: *Monthly precipitation totals in mm in 2000 and long-term means in Chisinau*
From: Hydrometeorological Service of the Republic of Moldova

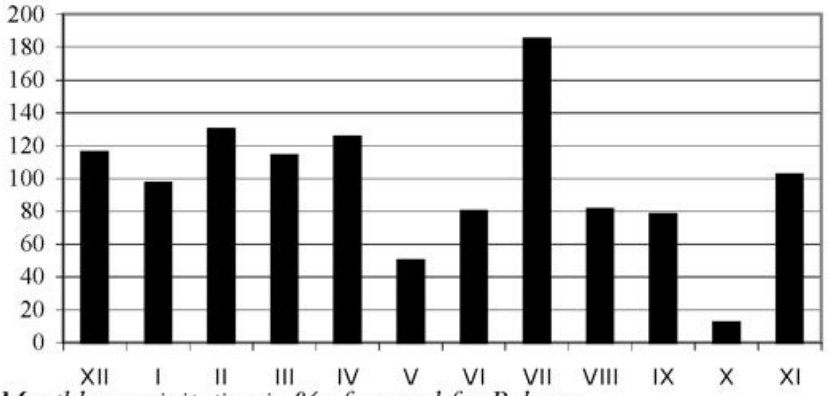

Fig. 5.2: *Monthly precipitation in % of normal for Belarus*
between December 1999 and November 2000,
reference period: 1891-1990.
From: Commitee for Hydrometeorology of the Republic of Belarus

June 2000:

- **Mostly extremely dry, very warm and sunny**
- **Wet and cool from Scandinavia to the Caspian Sea.**

For large parts of Central Europe it was the third dry month in a row (see fig. 6.2, 5.1 page xx) Together with extreme high temperatures the drought situation intensified. Hurbanova, Slovakia, received only 66 mm of rain during the April to June period which corresponds to a 93 mm deficit and mean temperature anomalies exceeded + 3 °C. In Warsaw, Poland, the monthly total precipitation was only 13 mm (18 % of normal). In Slovenia, water deficits varied from 100 mm to more than 200 mm causing the most severe drought since 1964. In northern Germany, the dryness engendered forest fires.

With prevailing high pressure influence, it was prevailingly sunny and warm. There was a new June record of bright sunshine hours in Akureyri, Iceland. For Slovenia it was the warmest June on record. At the mountain observatory Kredarica, there were only 7 days with snow cover, which is the lowest number ever recorded up to now.

An extreme hot spell occurred between June 20 and 23. On Poznan, Poland, temperatures climbed to 36.5 °C, Berlin's 36.1 °C were a new June record as well. 10 % of Spain's mainland stations registered record-high June average temperatures, notably La Coruña with 18.7 °C, exceeding by 0.3 °C the record for 130 years of observation (see fig; 6.1). Yugoslavia reported an exceptional number of "tropical days" (see fig. 6.3)

From Scandinavia across the Baltic States to the Caspian Sea it was wet and cool. In north-western Norway, several stations established new precipitation records. An outstanding cold spell occurred in mid-June, just after a torturing hot spell. Belarus recorded frosts and temperatures down to minus 5°C. Lithuania had morning frosts and Nagykaizsa, south-western Hungary, had a night minimum of 2.6 °C on June 17-18. such cool night's frequency is less than 1 % at this time of the year.

There was a high number of severe thunderstorms, local floods, hail events and storms:

- Heavy showers brought 50-80 mm of rain to the Southeast of the Netherlands on June 3-4.
- On June 5, a bursting thunderstorm and heavy rains caused a severe landslide in Carinthia, Austria. The small village Ingolsthal was badly devastated.
- Heavy thunderstorms , hail and flash floods haunted Switzerland on June 5, 11 and 13.
- Exceptional rains poured down in the Queyras region and Hérault, south-western France, causing severe flooding.
- Heavy rain and floods affected northern Spain.
- A new record-building regional rainfall of 28 mm on June 3, following several wet days led to flooding in north-eastern England.
- Heavy thunderstorms occurred in southern Germany on June 5 and 11. On June 14, hail covered the ground to a depth of 0.5 m in the eastern Allgäu area at the Alpine foothills.
- Poland reported severe thunderstorms some went along which with strong winds. A tornado destroyed several hectares of forest north of Bydgoszczon June 8. On June 15-17, heavy precipiation caused high water level of river Wisłoka.
- On June 16, the Mid-Wolga region experienced squalls of 24 - 31 m/s.
- North-western Tartastan was severely affected by hail with diameters up to 22 mm.
- An unusual deep depression (minimum core pressure < 970 hPa) passed by north-western Scotland in the middle of the month. Gusts up to 35 m/s set new records for June in Lerwick.
- A vast area with heavy thunderstorms caused considerable damage in parts of south-western Sweden on June 21. Several football players and camping youth were severely injured by lightning strokes. Intense thunderstorms caused several fires in late June.
- Several severe storms with hail occurred in Slovenia and Turkey.
- Thunderstorms damaged power-lines and forests in Estonia.

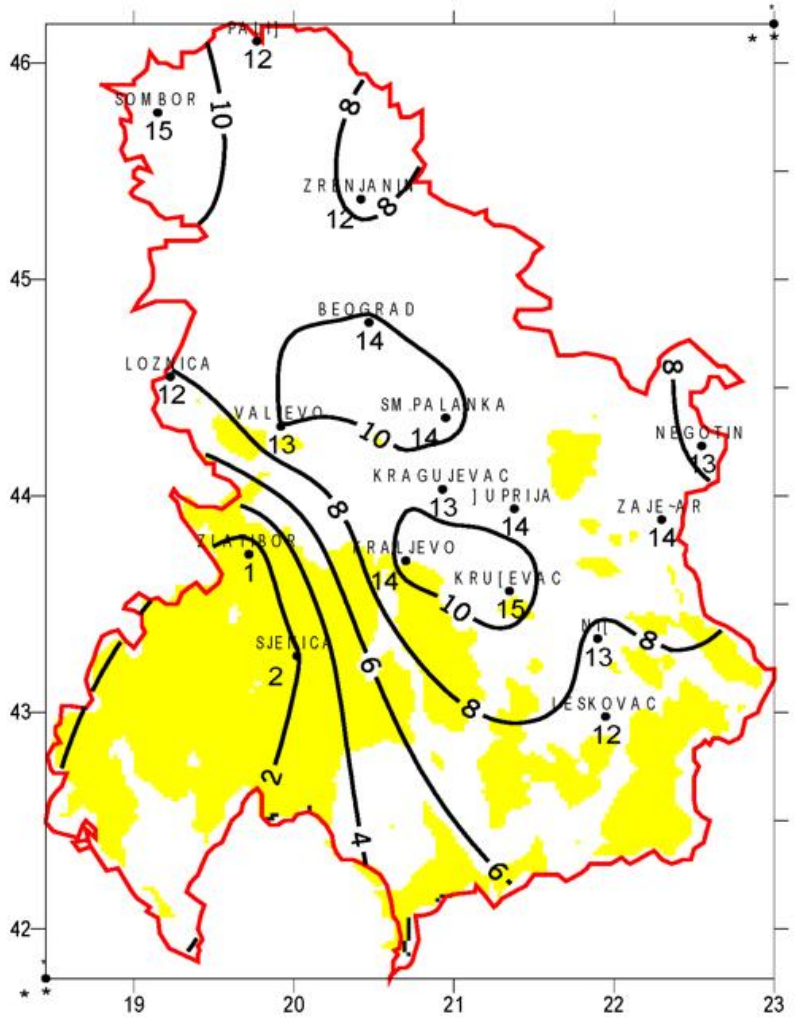

Fig. 6.3:
Number of days with maximum temperatures > 30 °C in Yugoslavia in June 2000
(values below the station names)
and deviations from 1961-1990-normal (isolines).
From: Federal Hydrometeorological Institute of Yugoslavia

July 2000:

- **Abundant rains and flooding in Scandinavia**
- **Cool and rainy from France to Russia**
- **Severe hail storms in the Alps**
- **Hot and dry in the Southeast**

July was even wetter than June in most parts of Scandinavia. During the period July 12-25, more than 200 mm was recorded at several stations in southern Norrland, Sweden. The heaviest rains occurred July 18-19, when many streams and rivers rapidly rose to near record levels and hundreds of roads, bridges and railway embankments were severely damaged. Several houses were washed away, but no people lost their lives. In Norway, July was very dry in the west (Takle 18 mm), but extremely wet in the Southeast. Oksoy fyr received 84.3 mm which is a new July record for that station with measurements since 1875. Finland reported an extreme number of thunderstorms: Except for the last week in July, there was thunder almost every day in many regions and the Häme region had 28 rainy days.

After the outstanding warm early summer, wide parts of the Region from France to Russia experienced an unusual cool and rainy July (see fig. 5.1, 5.2 page xx and 3.1 page xx). Negative anomalies surpassed 2 °C in wide parts of Central Europe. A number of stations in France set new records of precipitation totals, minimum sunshine duration and lowest maximum temperatures (see fig. 7.1 to 7.3). In the Netherlands, only in July 1919, the sun shone less than this year. Heavy showers poured down 30-50 mm within a few hours on July 29. In north-western Lithuania, the monthly precipitation totals amounted up to 240 % of normal. Heavy rainfall and local floods occurred on July 17-18 in Vilnius (75 mm) and on July 27 in Rokiškis, where 53 mm were registered in 12 hours. In Latvia, it was the rainiest month of the year. Precipitation was most extreme between July 24 and 27. Near Jekabpils, a two-days' total of 89 mm was recorded, which is 10 mm more than the monthly normal. Severe thunderstorms with heavy rain and strong wind caused considerable damage in western Germany. Switzerland experienced one of the most severe storms ever on the southern slopes of the Alps on July 4 (gusts up to 38 m/s).

Three extreme hail events occurred in Austria:

- On July 3, heavy damage was caused by hailstones with diameters up to 5 cm along the line Kirchberg in Tirol – Saalfelden, Salzburg – Hartberg, Styria (more then 200 kilometers). Around the area of Saalfelden, 4000 roofs were damaged and many people wounded by hailstones.
- On July 4, the second extreme hail event followed along the line between the towns Salzburg and Enns, Austria: The hailstones with the size of tennis balls wounded a group of 12 girls and caused enormous damage to houses and crops. At the same time, gusts destroyed power lines and trees and blocked roads. There were wind speeds up to 39 m/s. One man was killed.
- On July 7, heavy hail damage was recorded in Styria, near the capital town Graz, with great crop losses of fruits and corn, and finally in Upper Austria there were in Hallstatt heavy damage due to hailstones with diameters up to 5 cm.

A cold front over Latvia in the morning of July 12 caused thunder, precipitation, hail and an abrupt temperature decrease from 28°C to 13°C within one hour. Local whirlwinds reached hurricane-strength. Power lines were destroyed, trees uprooted and hundreds of roofs were blown away or damaged. The risk for forest fires continued to be high in a number of other Russian regions (e.g. in the Arkhangelsk oblast and the Republic of Komi).

An unusual hot spell occurred in north-eastern Norway on July 20: Kirkenes had the highest maximum temperature for the country in 2000 with 30.2 °C. A number of stations in Finnmark had so called "tropical nights", with temperatures not below 20 °C. The minimum temperature on the night of July 20 at the

lighthouse Makkaur fyr (70º 42`N, 30º 04`E) was 22.7 °C.

The Mediterranean region suffered from extreme hot and dry weather. In Greece, temperatures climbed up to more than 40 °C between July 4 -9 and 25-29. At places in the mainland, maximum temperatures of up to 43-45 °C and mean daily temperatures of up to 34 °C were recorded. The hot and dry weather engendered a number of severe wild fires. In Cyprus, the monthly mean temperature was 2.4 °C above normal and severe heat prevailed from July 6 to 14. About 80 % of the Bulgrian stations recorded new maximum temperature records (many surpassing 44 °C) on July 5.

Turkey reported the lowest monthly average precipitation mean of the year with 5.1 mm (see fig. 3.1 page xx). Armenia received only 7-16 % of the normal rainfall. Drought conditions prevailed also on the Balkans. In Slovenia, the dry weather caused high agricultural losses and the discharge of the rivers was on July 8 nearly the lowest one in 30 years. In Yugoslavia, monthly rainfall totals were only 20-50 % of normal.

In Israel, July was much warmer than usual. Temperatures were 3-4 °C above normal, and in many areas it was the hottest July since the beginning of measurements 40-50 years ago (see fig. 7.42), even in comparison with August (normally the hottest month) and only in August 1998 the monthly average temperature was higher. The month was characterised by a long period of hot weather – daily maximum temperatures exceeded 31 °C in the Coastal Plain and in the Foothills for 22 consecutive days and for 13-16 consecutive days in the Mountain Areas. The hot weather reached its peak towards the end of July – temperature in Jerusalem reached 40.8 °C, which is the highest temperature recorded in Jerusalem since 1942.

August 2000:

- **Mostly warm, especially in the Southeast**
- **Very dry in the South**

A severe hot spell scorched the Balkans. Temperatures climbed up to 41.7 °C in Békéscaba on August 21, setting a new record for Hungary. Also Croatia (see fig. 8.1) reported new maximum temperature records (e.g. 41.4 °C in Knin on August 22, surpassing the old record, set in 1950, by 1.0 °C). In Slovenia, with unusually dry and warm weather (see fig. 8.2) the amounts of available soil water for most crops diminished seriously and resulted in severe water stress. Yugoslavia reported precipitation deficits of 10-50 %. The water levels in the rivers were very low, e.g. river Savahad had on August 31 the lowest level of 80 years' observation. The dry conditions in July continued as precipitation totals reached only 20-40 % of normal and it was unusually warm again, in Armenia (see fig. 8.3). Losses due to the drought were estimated to 100 million $. In Cyprus, it was extremely hot between August 14-16 and 21-22. In Israel, August was not as extreme as July, yet it was still warmer than normal.

Nice, stable weather prevailed from Iceland across the UK to Germany. In the Netherlands, it was the sunniest month of the year with 223 h of bright sunshine (normal 192 h). Summer storms were comparatively rare. However, a high number of local thunderstorms and hail events with strong winds occurred in Poland. Heavy rain, hail and gusts ravaged near Moscow, Russian Federation, at the beginning of the month. On August 25, a mountain torrent and rains washed away river banks and roads in the Republic of North Ossetia-Alania. Heavy hailstorms caused severe damage in wide parts of Bulgaria, on August 28.

In the Gulf of Finland, a number of powerful waterspouts occurred in early August. A whirlwind downed hundreds of trees on its 150 m wide track in the Trakai district, Lithuania, on August 19. A tornado north of Lublin, Poland, destroyed about 100 buildings in the village of Ciotcza on August 20. Gusts up to 34 m/s raged in northern Switzerland on August 21.

September 2000:

- **Cold in eastern Europe**
- **Dry in northern and south-eastern Europe**
- **Regionally heavy rainstorms**

September was cool in eastern Europe (see fig. 2.1, 2.2 Page xx). Lithuania reported 19 nights with morning frosts, which from September 16 to 19 occurred everywhere in the country with soil surface temperatures down to minus 5 - 8°C.

Greece experienced unusual dry and warm weather. From September 18 - 23, temperatures climbed up to 34 - 38 °C. 37 °C was also recorded in south-western Bulgaria.Under high pressure influence, it was extremely sunny and dry in Scandinavia and the Baltic States. In Finland sunshine reached record levels and even exceeded the July figures. In Estonia, it was the driest September in 50 years (24 % of normal).

In mid-September persistent wet weather begun in much of England and Wales (see fig. 9.1). It should last beyond the beginning of the next year. Torrential rains poured down in places on the 15th and it was the wettest September in England and Wales

since 1981. On September 7-8, the city of Stavropol, Russian Federation, experienced heavy rain, gave wind gusts of up to 20 m/s and hail of 20-25 mm diameter. On September 13, a severe thunderstorm with hail completely destroyed about 1500 ha of cereals within 20 minutes near Strzelin in Lower Silesia, Poland. By September 18, thunderstorms with hail and heavy rain caused significant damage in wide parts of Bulgaria. On September 19 south-eastern France saw in some places more rain in a few days than the annual normal. Heavy rains were reported from southern Switzerland and northern Italy on September 19-20 and 29-30. On September 22, once again there was flooding caused by rain in the area south of the Danube, Germany. In Yugoslavia, it was the only month of the year with abundant rain. Heavy rains caused flooding in parts of Turkey and Cyprus between September 24 and 28.

The most severe storm, however, occurred in Italy's southern region of Calabria. Torrential rain triggered flooding and mudslides between September 8 and 10 (see fig. 9.2). Several villages were fully or partially isolated, a state of emergency was declared. Worst affected was the town of Soverato, where 13 people died.

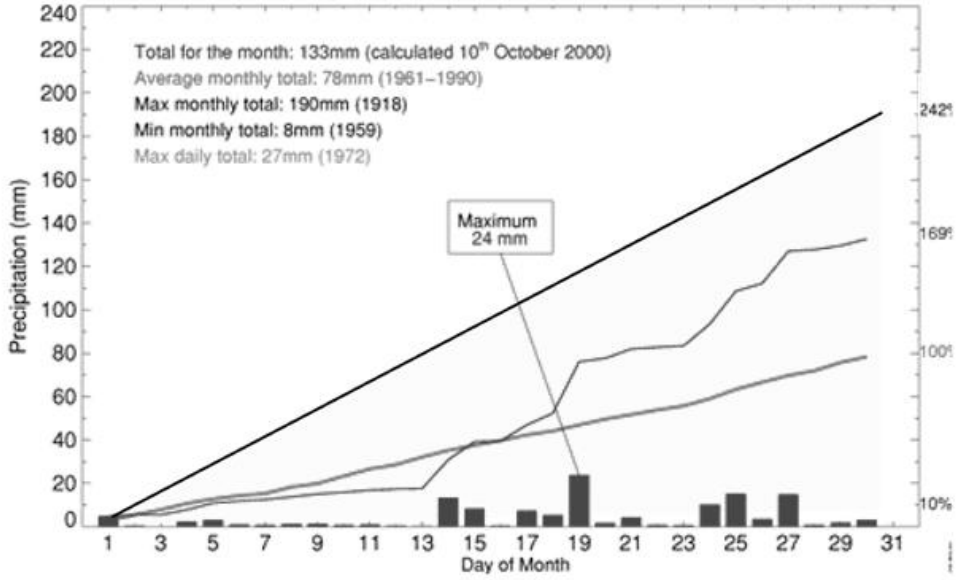

Fig. 9.1: *England and Wales daily precipitation totals in September 2000*

October 2000:

- **Very warm in northern and Central Europe**
- **Rainiest October on record in the UK, South Scandinavia and Israel**
- **Devastating floods in north-eastern Italy, southern Switzerland and eastern Spain**
- **Severe first winter storm**

It was exceptionally warm in Northern and Central Europe. For Norway, it was the second warmest October since 1866 (the warmest was in 1961). The station Tafjord in western Norway recorded a maximum temperature of 25.4 °C on October 1; this is the highest official October temperature ever measured in Norway. In parts of Poland, monthly temperature means equalled those of September and anomalies were above 4.8 °C (see fig. 2.2 page xx).

From Poland across the Baltic states to western Russia, precipitation was subnormal (see fig. 5.1 and 5.2 page xx). Poland as a whole received only 32 % of normal (see fig. 3.1 page xx) and in Suwalki, the monthly precipitation total was only 3 mm (6 % of normal). In Lithuania, too, a number of stations received only 1 - 4 mm.

In the UK, the wet weather that had started in September continued (see fig. 10.1 and 12.2 page xx) and in the England and Wales precipitation series (EWP), it was the wettest October since 1903 with 188 mm. Several coastal areas in southern English were inundated at the beginning of the month. On October 9-10, 103 mm of rain poured down in East Sussex and the 122 mm recorded in West Freugh, SW Scotland, have an estimated return period of once in 311 years. Potent wave depressions brought widespread floods and gales to much of England and Wales at the end of the month. The EWP figure of 40 mm on the 29th was the largest daily total in October in the 70-year daily series. Also in southern Scandinavia, the month was unusually wet. Lillehammer, Norway, recorded a monthly total of 227 mm, which is 324 % of normal.

In Israel, the 2000/2001 rainfall season started with very heavy rain. In some areas, it was one of the rainiest Octobers ever recorded (see fig. 10.2). On October 15, 44 mm of rain fell over Sede Boqer in the Negev Desert within less than one hour (almost 50 % of the average annual rainfall). This caused river flooding and 100 travellers had to be rescued by helicopters. The heaviest rains occurred on October 23-25, mostly in the Coastal Area with rainfall amounts above 100 mm. In the southern parts of Tel Aviv 150-160 mm of rain fell in 24 hours and 190-200 mm in 48 hours. Such an event is rare - in Miqwe Yisrael, a station located a few kilometre south of Tel Aviv, with rainfall measurements since 1925. Greater amounts of rain in 24-48 hours were recorded only 3 times for the whole rainy season. The heavy rains caused severe damage. The southern parts of Tel Aviv were flooded for the third time this year (twice in January). Jordan reported cool and wet weather (see fig. 1.2 page xx and 7.5 page xx). Rains and thunderstorms raged all over Greece between October 6 and 10. Heavy rain caused flooding in Cyprus on October 9 and in northern Turkey on October 11 (Giresun) and 22 (Kocaeli).
Very rainy and cloudy weather was reported from western Slovenia. Station Lod pod Mangartom in the Julian Alps (650 m above m.s.l.) received 638 mm of rain (286 %of 1961-1990 normal) and Bilje in the Vipava valley, recorded only 88 sunshine hours, which is 56 % of the 1961-1990 normal.

For all parts of France, it was extremely wet and at the end of the month, the soil was saturated nearly everywhere.

The most outstanding event of the month, however, was a flood that lasted ten days in the Po river shed. From October 11 to 16, southern Switzerland, the north-western sector of Piedmont and the Valle d'Aosta were affected by heavy rain (up to 335 mm/day, and in 6 consecutive rainy days up to 800 mm (see fig. 10.3), with values never recorded before and recurrence periods exceeding 1000 years at some sites). Many Po tributaries were inundated in alpine valleys. Downstream the Dora Baltea and the Po partly flooded the town of Turin. The Maggiore lake reached the highest level since 1868 with 4.66 m and the water level rose 3.87 m in a week. Thanks to

artificial control of inundation of the floodplain losses, similar to those during the 1951 flooding of the Polesine, when about 70 people died, were avoided. However, the death toll amounted to 38, and the material losses were estimated to 8,500 million US $.

October brought intense rain to the Mediterranean side of Spain, from the Pyrenees to Almería, causing river overflow and flooding, especially on the western side of the Sistema Ibérico and in Levante. Between October 21 and 24, new records were established for 24-hour precipitation values in many locations in the mid and lower Ebro basin, some setting 50-years' records. Castellon registered 120 mm of rain on October 24.

Between October 7 and 9, a wind wave in the Taganrog Bay, Russian Federation, stranded 98 vessels on river Don. The month ended stormy and wet: An intense storm hit the southern parts of Britain, northern France, the Netherlands and Germany on October 29-30. 50 mm of rain poured down over already saturated river catchments. Winds exceeding 43 m/s were recorded on exposed southern coasts of England and Wales. North of the storm centre 15 cm of snowcover was reported in Durham, north-east England. Gusts of up to 35 m/s and 80 - 90 mm of rain were recorded on the Frisian Islands in the Netherlands causing local flooding.

November 2000:

- **Another warm month**
- **Abundant rain in South Scandinavia and West Europe**

It was very warm in most parts of the Region. Temperature anomalies above 3 °C were recorded from Scandinavia across the Baltic states, Poland and Belarus to the Balkans (see fig. 2.1 page xx, fig. 8.1 page xx, fig. 11.1). In large parts of Norway and Sweden, it was the warmest November ever, with 6-7° C above normal at many places in south-eastern Norway. The monthly mean temperature in Svinoy (9.1 °C), western Norway, was the highest November temperature since the Norwegian Meteorological Institute was established in 1866. The unusual November weather enabled farmers in certain areas in Western Norway to harvest for a third time during the year, which never had happened before. The bears started their hibernation much later than normal this year! With an average temperature anomaly of 3.2 °C, it was the another extremely warm month for Poland (see fig. 2.2 page xx). The highest deviation from normal was recorded in south-eastern Poland (+ 5.6 °C in Lesko). Central and southern Greece experienced a very warm first fortnight with maximum temperatures of 28-29 °C.

Southern Scandinavia experienced another rainy month causing unprecedented high water levels in lakes and streams, especially in Värmland, Dalsland and Bohuslän, Sweden, near the border to Norway. The largest precipitation amount of 545 mm during the two months October and November was recorded in Östmark, western Värmland. This can be compared with 181 mm, which is the normal value for these two months together. In the city of Arvika large areas close to the bay Glafsfjorden were inundated. The water levels rose to more than three metres above normal. The biggest lake in Sweden, Vänern, rose to its highest level since regulations commenced in the middle of the 1930-ies. Southern and south–eastern Norway had the wettest November ever. One of the stations near Oslo received precipitation every day during 87 days from 24 September to 19 December. Certain areas received more than 5 times the normal amount of precipitation for November. The heavy precipitation amounts caused floods and damage to roads, railway lines etc.

n the British Isles, wet weather that had brought widespread flooding in the preceding weeks continued and more heavy rain fell early in November (see fig. 11.2). On November 2, Leeming in New Yorkshire recorded its wettest November day, a total of 48.4 mm fell. The England and Wales Precipitation (EWP) series showed 32 mm on November 5, setting a new daily record for November. Until November 6, many areas had more than their normal monthly rainfall, particularly in the east and at the end of the month, the EWP had its highest November figure since 1970. In parts of south-eastern Ireland, more than 100 mm of rain poured down within 24 hours on November 5-6. Dublin (Phoenix Park) measured 76.2 mm, its highest daily rainfall for November in over 150 years of record.

In the Netherlands, excessive rainfall caused local flooding in the Westland area.100 mm of precipitation was recorded locally during November 7-11 in the western parts (see fig. 11.3).

There was also abundant rain in wide areas of France: Daily totals exceeded 100 mm in the Southeast on November 6, leading to flooding and landslides. Floods and landslides occurred also in Carinthia and Eastern Tyrol, Austria, where monthly precipitation totals up to 300 - 400 % of normal were recorded (see fig. 11.4). In the Julian Alps, Slovenia, some stations registered more than 1000 mm (station Soča 1493 mm, resp. 494 % of 1961-1990 normal). The most catastrophic landslide, occurred in Log pod Mangartom. Half of the village was destroyed and there were a number of casualties. Water levels of many rivers and of the lakes reached record heights.

Heavy rainfall affected the north-eastern sector of Italy. Large areas were inundated. New maximum records of monthly totals were recorded (Reisa 1482.4 mm, Stolvizza 1352.4 mm). In the Adige River, during November 13-18 two flow peaks

triggered widespread flooding near Trento. Recurrent flash floods affected the Ligurian District between November 5 and 24. Towns and villages along the "Riviera di Ponente" were inundated.

Torrential rains caused flooding in north-western Corfu. Ioannina received 206.0 mm within 12 hours (maximum so far 126.9 mm). A severe storm caused flooding on Corfu and the southern Peleponnissos. Torrential rain and strong winds wreaked havoc on Cyprus on November 27. The monthly rainfall totals surpassed the long-term mean by more than 100 % (see fig. 11.5).

It was extremely rainy in the north-eastern parts of the Iberian Pensinsula. Record monthly totals were registered at almost all stations in Galicia, with monthly values of 590.6 mm in Vigo, 493.4 mm in Pontevedra and more than 300 mm in adjacent areas.

The excessive rainfalls were in contrast to drought conditions in other parts of the Region. In Reykjavik, Iceland, it was the driest November since the beginning of continuous registration in 1920. In Norway, it was very dry in the western, middle and northern parts, with record low amounts of precipitation at many places (Vaernes near Trondheim had the driest November since 1952) which resulted in water restrictions in certain area. Substantial precipitation deficits occurred in the south-eastern parts of the Region (see fig. 1.3 page xx). For Macedonia, it was the 6th dry month in a row (see page 11.6). In most parts of Israel and Jordan, rainfall totals were just 10-40 % of normal (see fig 1.2 page xx).

A fierce winter storm on November 26-27 caused severe damage in Moldavia and Ukraine with widespread power failures.
Sao Miguel Island, Azores, was hit by a severe flash flood. Many streets in Ponta Delgada were flooded and trees uprooted.

Around November 20, deficits of totals of ozone of 25-30 % were recorded over Central European Russia and on November 17, an absolute minimum of total ozone (196 Dobson units) was registered in Moscow (previous minimum 214 Dobson units on December 7, 1996).

December 2000:

- **Record warm**
- **Abundant rain in the far South-west and South-east**

A belt of monthly temperature anomalies above 4 °C stretched from southern Scandinavia across Finland to the Baltic states. In France, December was warmer than November. The high monthly values were due to an extremely warm start which grasped nearly all Europe (see fig. 12.1, fig. 8.1 page xx, fig. 11.3 page xx). For many stations, from the Canary Islands across Spain, France and the Netherlands to Germany and from Scandinavia across eastern Europe to the Balkan, it was the warmest first decade on record. The very warm start was slightly balanced by cold conditions later in the month. The Netherlands and the low-lands in Germany recorded the first frost of the winter season only between December 17 and 19. Never before had this event occurred so late in the

year. Only 4 days with snow cover were recorded at Štrbské Pleso, Slovakia, up to December 15 which had been the absolute minimum since the beginning of observation in 1921.

A cold spell with snow and blizzards occurred in wide parts of Europe around Christmas. This led to a breakdown of the electricity supply for some 40,000 households just before New Years Eve in southern Sweden. Snow fell quite widely on December 27-28 in West and Central Europe. North-west England, Wales, Ireland and the northern parts of the Netherlands got a snow cover of over 20 cm.

Dry weather prevailed from the Aegean Sea to the Ukraine (see fig. 1.3 page xx, fig. 5.1 page xx). For Iceland, it was another dry month threatening the water supply in some rural areas. From the Iberian Peninsula across northern France to Scandinavia, it was wet again. Record high monthly precipitation totals were recorded in Portugal. Bragança (with registrations since 1941) totalled 352 mm. Oporto received 481 mm, the second highest value of the century. New records of daily precipitation totals were set in Castelo Branco and in Beja (registrations since 1941 resp. 1899). The number of days with precipitation (≥1 mm) was more than twice the mean of the 1961-1990 reference period. The heavy precipitation caused flooding and landslides, that resulted in some cases in loss of lives and destruction of homes. Strong winds contributed to the uprooting of trees, breakdown of power supply, telephone lines and road obstruction. There were still abundant rains and floods in Brittany, France. Monthly precipitation totals were more than 200 % of normal at some places in Norway. In Finland, there was hardly any sunshine in November and December. In Jyväskylä, there was only one hour of sunshine recorded for both months. Southern Greece reported heavy rain and thunderstorm on December 6-7.

Fogs were frequent this month. Slippery roads due to freezing rain caused many traffic accidents in Germany on Christmas Eve. In wide parts of Lithuania, traffic obstruction after freezing rain on December 28-29 lasted for almost three days.

Activities and Results of European Climate Centres

Report on ECSN activities

by: José Antonio Lopez Diaz, INM

The year 2000 was the last of the three-year period during which the INM was the Responsible Member of the EUMETNET ECSN project. This job has been taken over by MeteoSwiss, with Dr Walter Kirchhofer as new Manager. An outline of the activities in the different projects is as follows:

- European Climate Assessment 2000 (KNMI)

  This project is now in its final stage. It has amassed daily precipitation and temperature data from more than 170 stations in Europe and the Middle East. Almost all daily series cover the standard normal period 1961-1990, and about 50 % extend back to 1925 or earlier. A draft version of the publication was presented at the Pisa ECAC 2000 Conference. It begins with sections dealing with the data availability and the homogeneity analyses carried out on them. Temperature trends for mean, maximum and minimum values in each season of the year and through the two periods 1910-1945 and 1946-1999 are visualised and discussed. They are also compared when possible with the corresponding trends in the Jones temperature dataset. The precipitation amounts and a few related indices receive a similar treatment, using for comparison the Hulme dataset.

  This analysis is extended to a number of indicators for temperature and precipitation extremes (11 for temperature and 6 for precipitation), with the NCEP/NCAR data used for comparison. Most of these indices are based on the counts of days exceeding certain thresholds that can be either fixed for the whole region (for instance number of frost days) or site dependent (based on fractiles of the series analysed.

- European Atlas (Meteo France)

- Climate Databases (DNMI)

  After successfully holding its first workshop in 1999 in Oslo, the project this year started focussing on establishing some kind of forum for discussion among participants through the Web. However for technical reasons this has not been possible. The collaboration of DNMI inside the NORDKLIM project has been a source of ideas for the ECSN project in this period, but the person in charge at DNMI got a new job so that at the moment this project has to find a new leader. The second workshop will be held by DWD in November 2001, with a point in the agenda dealing with recommendations for the EUMETNET project UNIDART.

- Generate Climate Monitoring Products (DWD)

  This project's objective is to fill the gap in comprehensive and coherent climate monitoring products, including significant events, at the European scale. Its raw input is mostly already being done at the national level, but to integrate it technical problems related to different practices, choice of variables, smoothing across frontiers, language, etc have to be overcome.

  The project showed some provisional web-pages (still restricted to internal use) developed at DWD in the EAC meeting in Tenerife (December 2000). The structure envisioned contains the following headings: European Climate Monitoring products, National Climate Monitoring

products, RAVI Bulletin issues and Significant Climate Events. The next step starting after the summer will be a pilot phase, using mainly existing products so as to assess the possibilities and needs.

- GIS in climatological applications (ZAMG)

  This new technology is gaining rapidly importance in the field of climatological applications, and with this the need to share expertise is becoming evident. This ECSN project is a first step in this direction. It has produced a questionnaire on the use of GIS in the NMS's and guidelines for the use of interpolation methods. For the future it is important that more NMS's get actively involved and to clarify the relation with the similar COST 719 action that has started this year. At the Tenerife EAC meeting it was agreed that the continuation of this ECSN project will be reconsidered at the end of this year, though it looks likely that its activities will be integrated in the COST action.

- Drought project (OMSZ)

  The participant countries (Hungary, Spain and Portugal) have made some progress towards achieving the initial objectives, namely in the study of long series of drought indices (Hungary, Portugal), the intercomparison of indices (Hungary) or the introduction of a daily operational water balance using the SPI index (Spain). The project will produce a final report in 2001.

- ECSN Climate Dataset (KNMI, DNMI)

  This project's aim to build a daily dataset of temperature, precipitation and a few more parameters with a density of around 2 stations per 100,000 km^2 . Its first phase will comprise the data already collected by the ECA2000 project. In a meeting in April this year between both leading partners the working plan for next year was discussed. According to it, in a year's time the project expects to produce a CD-ROM and provide access through Internet to the data.

The Third European Conference on Applied Climatology - ECAC-2000 16-20 October 2000, Pisa, Italy

by: Walter Kirchhofer, Meteo Swiss

ECAC-2000 was the third European Conference on Applied Climatology and it gave clear evidence that the field of applied climatology is still growing. At the first conference that was held in Norrköping, Sweden, there were 130 papers, at the second conference in Vienna, Austria, there were about 200, and in Pisa there were about 300 contributions on the programme. Over 300 participants, most of them from European countries, attended the conference. With Prof. Giampiero Maracchi as Chairman, the conference was excellently organised by the National Research Council - Institute of Agrometeorology and Environmental Analysis for Agriculture, Florence, Italy.

The high number of about 140 oral papers had to be given in parallel sessions most of the time. Additionally, there were 7 poster sessions, with about 160 presented posters.

ECAC-2000 was structured around seven themes:

- Climate Prediction and Climate Variation for Climate Applications
- Climate, Agriculture and Forestry
- Development and Integration of Climate Data Sets

- Remote Sensing and GIS
- Urban Health and Tourism
- Air Pollution and Renewable Energy Sources
- Extreme Events and Risk Assessment

The proceedings of the conference are available in printed form (short abstracts) and on CD-ROM (extended abstracts) by CNR-IATA, Via Caproni n.8, 50145 Florence, Italy.

The 4th European Conference on Applied Climatology, ECAC-2002, will be held in Brussels, Belgium.

CM-SAF Training Workshop in Dresden

by: Peer Hechler, Deutscher Wetterdienst

Officially started in 1999, a five year's international project is currently being in execution in order to develop methods to exploit data of new EUMETSAT satellite generations MSG (Meteosat Second Generation) and EPS-METOP (European Polar System- Meteorological Operational Satellites) for climatological purposes (for reference see Klimastatusberichte 1997, page 74ff and 1999, page 128f and http://www.dwd.de/research/event.htm).

DWD -kindly sponsored by EUMETSAT and WMO and supported by the project partner institutes- organised a first CM-SAF Training Workshop in Dresden from 20 – 22 November 2000. Nearly 100 scientists –mainly climatologists and satellite experts- from 30 countries convened, amongst them well-known scientists as Prof. Hartmut Grassl, EUMETSAT's Director-General Dr. Tillmann Mohr, WMO Director Dr. Michael J. Coughlan, Prof. Ehrhard Raschke and DWD's President Udo Gärtner.

The aim of the Workshop was threefold:
- make potential users aware of the CM-SAF, its plans and future products
- consolidate the definition of user requirements for the forthcoming Operational Phase
- initiate training activities in the use of CM-SAF products.

The Workshop was accompanied by a public exhibition and a press conference. On the occasion of the latter Dr. Mohr announced that all Member States finally approved EUMETSAT's amended Convention which now widens the Organisation's objectives to include the operational monitoring of the climate and detection of climate change.

CM-SAF plans to derive cloud-, radiation- and water vapour products as well as parameters of the ocean's surface and interior (see background information) were presented and discussed during the Workshop sessions. It can be summarised that DWD together with its partner institutions gained common consent for the strategic direction chosen with the CM-SAF effort.

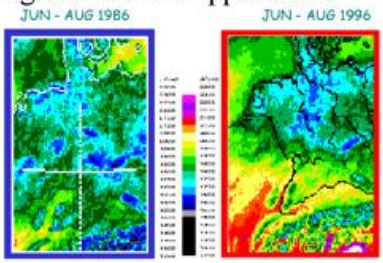
In this context major results and recommendations have been:

- to strengthen the CM-SAF involvement in international projects and activities
- to discuss the feasibility of common data formats and processing algorithms for the whole SAF network
- to explore the definition of homogeneous products covering both MSG and METOP processing areas.

Background: The CM-SAF Products

Cloud and Radiation: Determination of consistent parameters suitable for regional climate applications

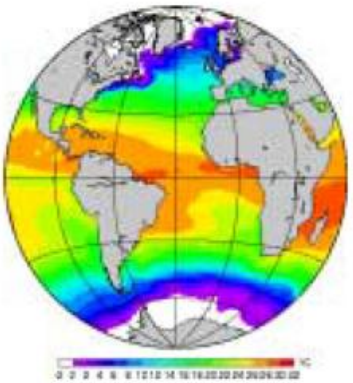
The SAF on Climate Monitoring fills a gap in providing consistent data sets of cloud and radiation budget parameters for an area which covers Europe (including parts of the North Atlantic Ocean). The spatial resolution will be 15 km (except of components of the radiation budget at the top of the atmosphere where a spatial resolution of 50 – 70 km is envisaged). Besides surface- and top of the atmosphere radiation budget components (including albedo), several cloud parameters, such as fractional cloud cover, cloud classification, cloud top temperature and height and others will be derived.



Downward Surface Short-wave Radiation over Germany

Global Ocean State Estimate: Dynamical extrapolation of sea surface observations into the global ocean interior

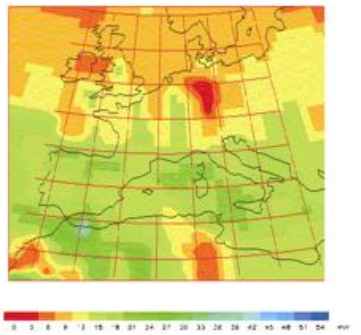
The ocean assumes the central role in the planet's climate system on behalf of its immense capacity to store and redistribute water, heat and radiatively active trace substances. Climate monitoring and predictions therefore require the continued assessment of the state of the interior ocean. By merging data from remote sensing facilities with numerical models of the global ocean circulation the SAF on Climate Monitoring will generate an estimate of the state of the global ocean circulation at monthly time intervals. The estimate includes sea-ice extent, temperatures and salinities of the ocean interior as well as circulation velocities.



Global SST, January 1996

Water Vapour in the Atmosphere: Validation and merging of satellite derived water vapour information

Water vapour in the atmosphere is for several reasons of special interest in climatology: as a greenhouse gas, as a component in the water cycle and because of the latent heat and its role in atmospheric dynamics. The SAF on Climate Monitoring will contribute merged and gridded daily data sets of total precipitable water as well as layer precipitable water (3 layers) based on operational level-2.0 satellite products and validated with in-situ observations as well as ground-based remote sensing data. With an initial spatial resolution of 100 km x 100 km the products cover Europe and parts of the North Atlantic.



Total precipitable water over Europe, 26.12.99

European Ozone Centre at the Meteorological Observatory Hohenpeissenberg

by: Ulf Köhler, Hans Claude, Wolfgang Steinbrecht, Deuscher Wetterdienst

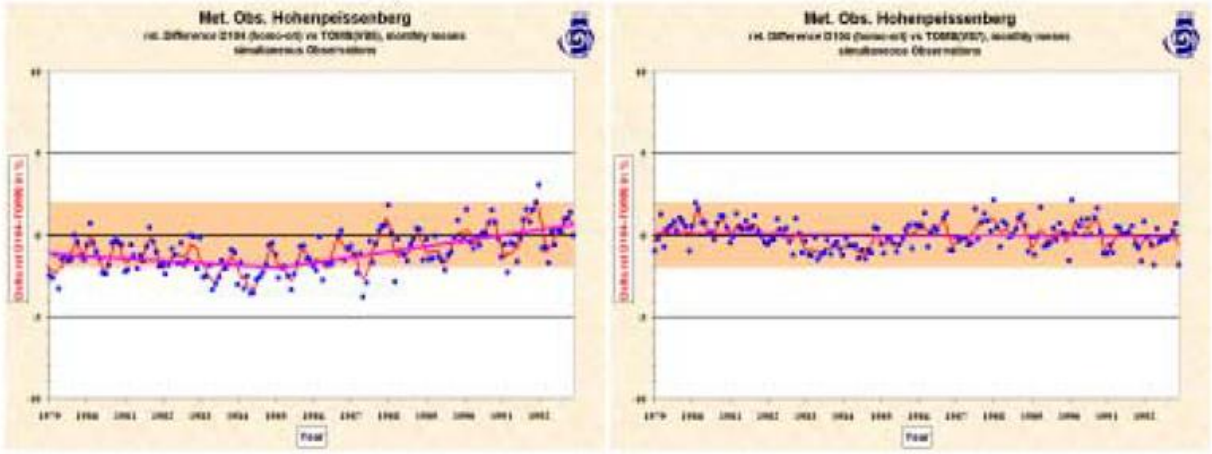
An important part of the global ozone monitoring network GO_3OS within the WMO GAW programme are Dobson spectrometers measuring the total ozone amount. To ensure data quality of these intruments a system of 1 World (NOAA, Boulder, USA) and several Regional Dobson Calibration Centers (RDCC) has been installed. For WMO Regional Association VI (Europe and Middle East) the Meterological Observatory Potsdam had been in charge of this task until the beginning of the 1990s. When the task of European Ozone Centre was assigned to the Meteorological Observatory Hohenpeissenberg (MOHp) in 1994, the function of the RDCC in RA VI (and the Regional Standard Dobson No. 064) were transferred to MOHp as well. After setting up the necessary facilities the RDCC at MOHp (in close co-operation with the Solar and Ozone Observatory in Hradec Králové, Czech Republic) began regular work with two International Dobson calibration campaigns in 2000. In total 7 of the approx. 30 operational European instruments were examined and calibrated during these first campaigns. The main tasks of an RDCC are:

- Service, maintenance and calibration of Dobson spectrometers at least once every 4 years
- Technical and scientific support to Dobson stations incl. training of Dobson operators
- Improvement of technical equipment (Dobson instrument, calibration and repair tools etc.)
- Dissemenination of Standard Operation Procedures (SOP's)
- Providision of software for data processing

The goal is to keep the data quality of Dobson total ozone records on the high level obtained over the last decades. This high quality level is absolutely necessary for:

- Reliable trend analyses
- For validation and verification of satellite data (ground truthing)

***Fig. 1a and b**: Monthly averages of the relative difference (in %) between simultaneous total ozone measurements by MOHp-Dobson No. 104 and by TOMS on NIMBUS 7. Left panel shows the comparison for TOMS Version 6 data, right panel for TOMS Version 7 data.*



The two graphs in Figure 1a and 1b are an example for ground truthing of satellite data with data from a well maintained and calibrated Dobson instrument. The left panel shows a clear indication of a gradual change of the calibration level of one instrument, in this case of the satellite instrument TOMS. After implementation of corrections the TOMS Version 7 data fit much better to Dobson 104.

Only long term ozone records (> 30 years) acquired by reliable instruments like the D104 allow meaningful comparisons of one year's ozone levels with a climatic baseline.

Figure 2, for example, shows, that 2000 was a year with subnormal ozone values almost over the entire year, resulting in the fifth lowest annual mean in the MOHp-record since 1968. From April to June (absolute record minimum) the ozone layer was unusually thin, which led to very high UV-doses compared to years with normal ozone. Although the ozone deficit in February and March 2000 is higher (up to –20 %) the low ozone values later in the year are much more relevant for the amount of UV-radiation penetrating to the earth's surface due to higher sun elevation.

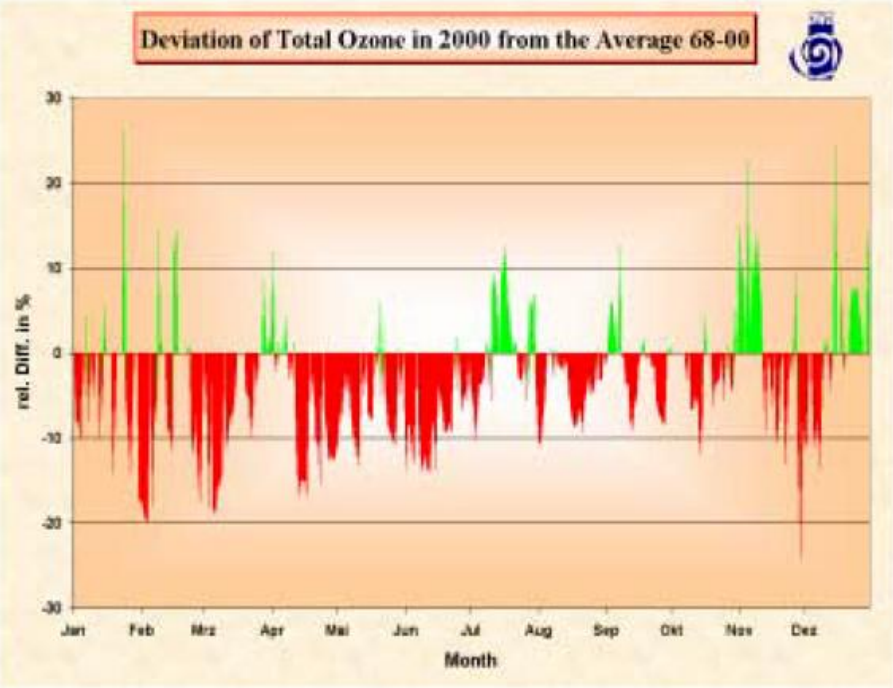


Fig.2: *Relative difference (in %) of the daily total ozone amount over the year 2000 compared to the baseline defined by period 1968 – 2000, for Hohenpeissenberg (Southern Bavaria).*

Figure 3 shows the complete record of June averages of total ozone (solid line) and UV-B radiation at 305 nm (columns) since 1968. It is obvious, that the strongly depleted ozone layer after the eruption of the Philippinian volcano Mt. Pinatubo in the early nineties has not recovered until today, although the volcanic aerosol load has been back to normal values since 1995. At the same time the UV-B-radiation has increased, culminating in a record maximum in 2000. While the strongest negative trends for the entire period 1968–2000 are found for January to April, the last 10 years are characterized by consistently low values in May/June. Recent investigations revealed, that the observed ozone depletion cannot be explained only by chemical reasons (CFC's). Approx. one third of the trend, particularly in spring, is caused by climatic changes (tropospheric warming, stratospheric cooling,

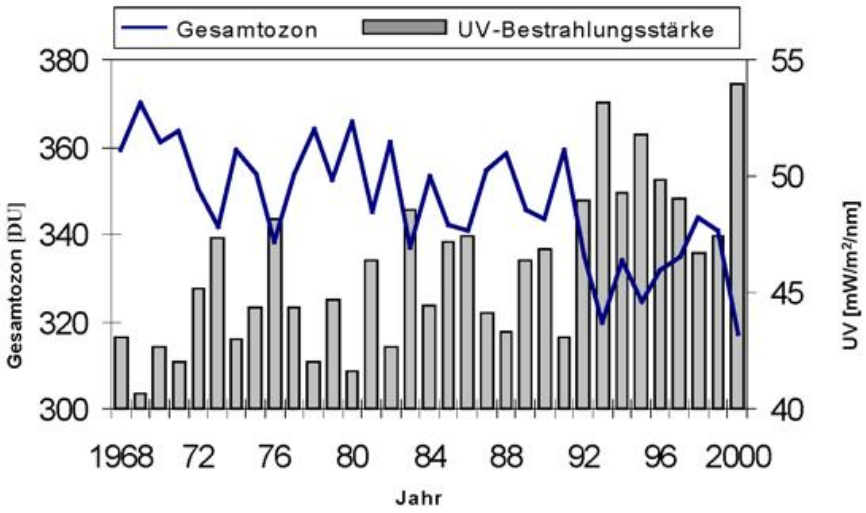

Figure 3: *Trend of total ozone (solid line) and UV-B at 305 nm (columns).*

change of atmospheric circulation) which appear to be related to the increase of greenhouse gases. This might substantially reduce the positive effect on the chemical ozone depletion expected from the stop of CFC-production after the Montreal and following Protocols.

Long-term meteorological changes and UV-Irradiance

by: Sebastian Trepte and Peter Winkler, Deutscher Wetterdienst

The long-term decrease of total ozone observed at Hohenpeissenberg (48°N, 11°E) led to a very low monthly average value in June 2000. At the same time, erythemal UV-irradiance for high solar elevation and clear sky conditions peaked at very high values, which are usually seen over Southern Europe only. Under clear sky conditions (and an otherwise unchanged atmosphere) the long-term ozone decrease clearly plays the key-role for UV-irradiance. However, matters become much more complicated when other factors, like cloud cover or visible irradiance, are considered. In contrast to the increase of UV-irradiance under clear sky conditions, global (total) irradiance shows a significant decrease since 1953 (Fig. 1, left).

This decrease is related to the observed increase in the frequency of high cirrus clouds (Fig.1, right). Since cirrus clouds attenuate visible radiation but also UV-B-irradiance, it is quite possible that the average UV-dose has remained unchanged or even gone down, whereas peak values have increased.

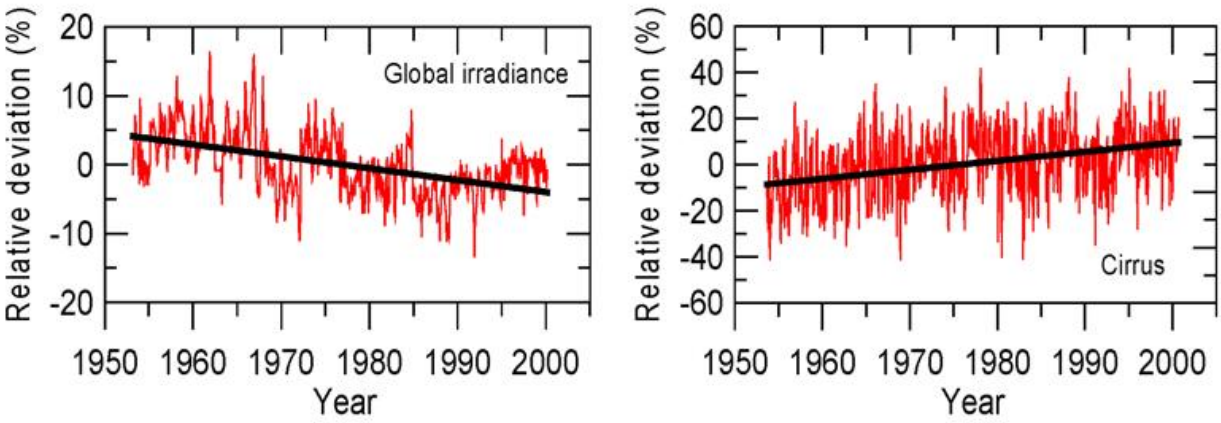

Figure 1: *Left: Monthly deviations of global irradiance from long-term means at Hohenpeissenberg. Data are for sunshine and for solar elevations greater than 10 deg in the period 1953-2000. To eliminate diurnal and annual* variations *the measured global irradiance is normalized with the calculated irradiance of a turbidity-free atmosphere. The fitted trend line shows a long-term decrease of 1.8 % per decade. Right: Monthly deviations of the relative frequency of cirrus clouds, same data sampling as in the left panel. Here the trend line shows an increase of 3.9 % per decade.*

For sunshine situations, cirrus clouds have changed in frequency by 3.9 % per decade. This explains about 20 % of the global irradiance decrease. Cirrus might have also changed in spatial coverage and/or in optical depth. For spatial coverage we found no significant long-term change.

Another aspect is that increased absorption by increasing atmospheric water vapor may have contributed to the reduction of global irradiance as well. Positive long-term trends of the air temperature at Hohenpeissenberg suggest an increasing water vapor content.

Figure 2 shows how increasing cirrus coverage affects UV-irradiance: Compared to clear sky conditions, the erythemal UV-irradiance is attenuated by about 20 % when 7/8 of the sky are covered by cirrus clouds. Note, however, that for short time periods and moderate sky-coverage UV-irradiance can be increased by increased scattering from clouds. In these situations, clouds and total ozone contribute to UV-irradiance peaks.

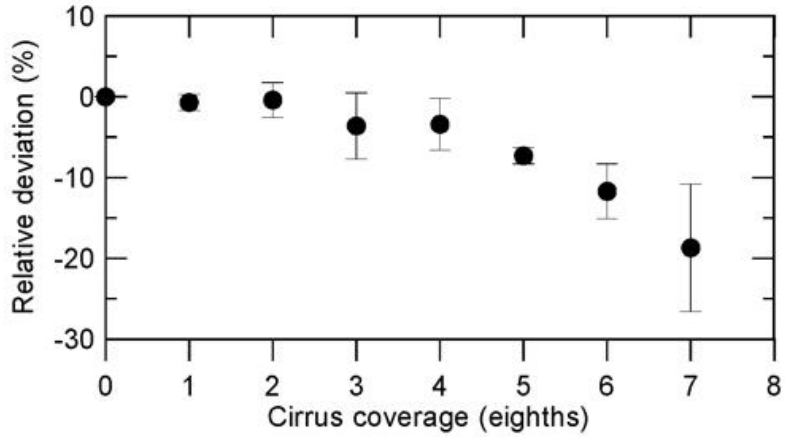

Figure 2: *Averaged attenuation of UV-irradiance (308 nm) for different fractions of sky-coverage by cirrus. Values are given relative to clear sky conditions. Data are for the period 1990-1998. Seven classes of solar elevations between 30° and 45° have been used. Error bars show the standard deviation of these classes.*

Other important meteorological processes relevant for long-term changes in UV irradiance are:

- Global warming leads to an upwards shift of the tropopause and to a cooling of the lower stratosphere. It should also result in an intensification of the water circulation. All these factors would increase the probability of cirrus formation.
-
- A high tropopause is usually coupled with low total ozone. The resulting increase of UV-irradiance may be partially compensated by increased frequency and optical depth of cirrus clouds. However, this compensation would not occur for UV peak values under clear or slightly cloudy sky conditions.

Surface Temperatures of the North Sea in 2000

by: Peter Löwe, Bundesamt für Seeschifffahrt und Hydrographie, Germany

An annual mean sea surface temperature (SST) of 10.4°C made 2000 the 6th warmest year on the record dating to 1971.

Exempting June and July, North Sea SSTs exceeded climatological monthly means at all times and all over the place. Spatio-temporal monthly means assumed ranks between 2 and 6 within the 30-year observational record.
The seasonal warming in June averaged only 1.4K which is 50 % short of the usual heating rate. This caused the jump-like change from anomalously warm conditions in May to a widespread cold anomaly that grew even more intense in July making it the 4th coldest July since 1971. The mean SST of 13.4 °C remained 2.1K behind the 2nd warmest July of 1999.

While usually seasonal cooling sets in around mid-August, August 2000 was special in that a belated extreme increase in SST of 2K occurred which exceeded the average heating rate by 200 %. This again was associated with a rapid return to anomalously warm conditions. The warm anomaly strengthened during fall which underlines the significance of too warm SSTs in fall during the past decade of the 1990s.

Additional information is available at http://www.bsh.de/Oceanography/Climate/Climate.htm

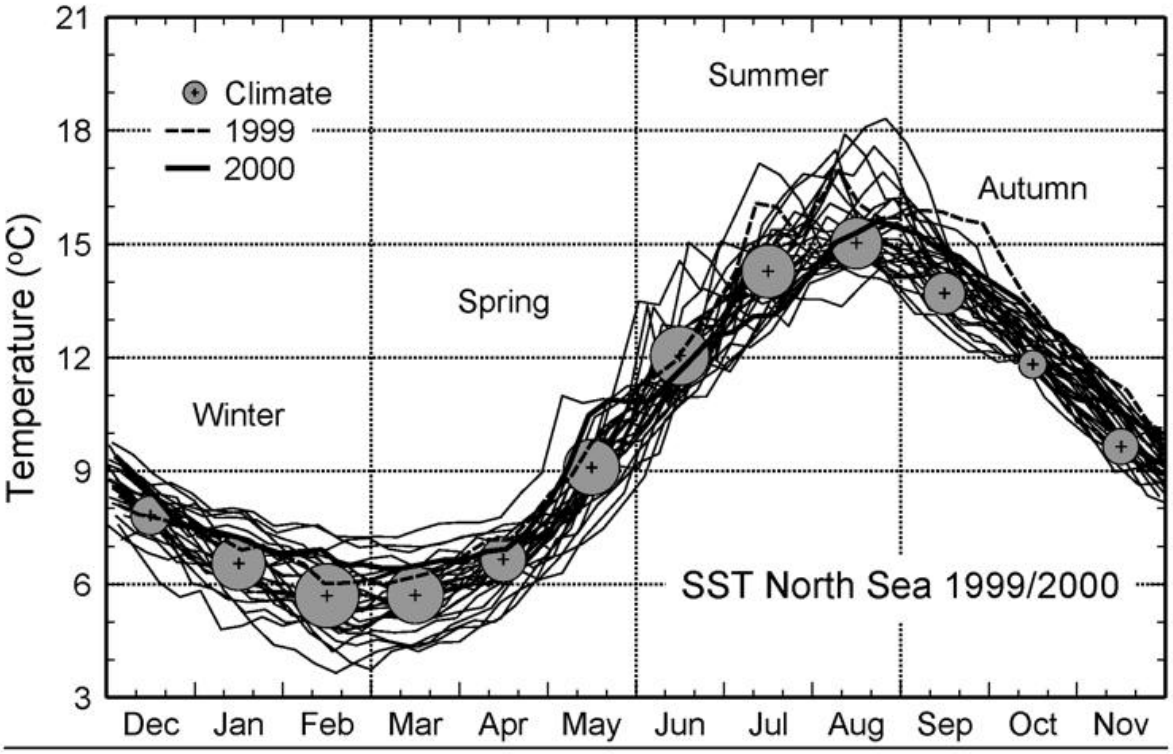

***Figure**: Seasonal cycle of the areal mean SST of the North Sea from December 1999 through November 2000 and ensemble of corresponding cycles since 1971. "Climate Bullets" are for the base period 1971-1993, their size (radius) is equivalent to 1 standard deviation.*

Climate of the Region in the 20th Century

This chapter contains a variety of articles and graphs with long-term perspective concerning the climate of the 20th century mostly out of national scope. Contributions of the national meteorological services of following countries are presented:

Belarus	Latvia
Bulgaria	Moldova
Croatia	Poland
Denmark	Portugal
Germany	Slovakia
Hungary	Sweden
Ireland	United Kingdom

German Bight storminess between 1879 and 2000

H. Schmidt, Deutscher Wetterdienst

A time series of geostrophic winds has been calculated as a first order approximation from the pressure readings of three stations forming a nearly equilateral triangle with a side length of about 250 km covering the German Bight. Data base were the three climatological pressure readings per day from meteorological annuals. From 1970 on the pressure data were taken from synoptic observations. Basically, the triangle was formed by the stations List/Sylt, Borkum and Hamburg. For several reasons, however, all of these stations had to be replaced temporarily by neighbouring stations.

The data correction was rather difficult, especially for the first decades. Here, error detection could only be performed by plausibility checks. Later on, more neighbouring stations existed, allowing also for cross checks. Most of the errors found were misprints, erroneous pressure readings, or scanning errors. Some errors, especially those of minor magnitude, may still be present in the data.

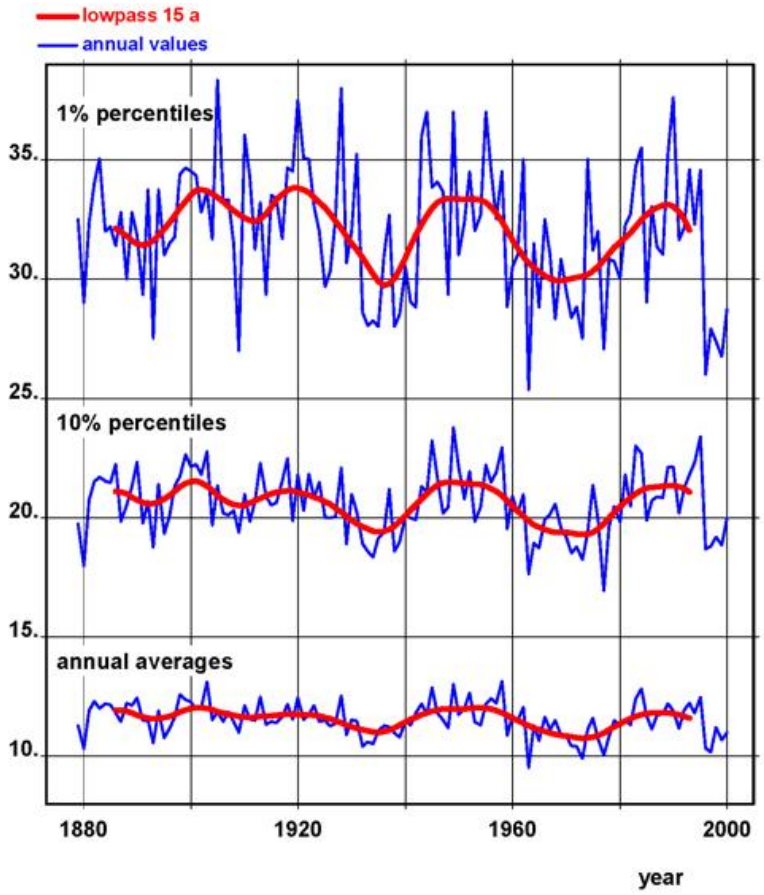

Fig. 9: *Statistical parameters of the annual frequency distributions of geostrophic wind speed. The original annual values are plotted in blue. Smoothed values, calculated with a 15 years low pass filter, are plotted in red. The lower curve are the annual averages. The curves above are those geostrophic wind speeds, which are exceeded by 10 % and 1 % of all of the wind speeds per year, respectively*

The time series of the three distributional parameters are rather similar, only their variance increases with wind speed. There are strong irregular interannual variations. The dominant feature, however, is a low frequency variation with a period of about 35 years, for which no explanation can be given. It also seems to be an irregular variation. The spectral energies of all other periodicities are much lower. All three time series exhibit a slight negative trend, which is -0.4 ms^{-1} per century in the annual averages. Due to the strong

variability of the annual wind values this trend cannot be regarded as statistically significant. Similar results were found by SCHMIDT and VON STORCH (1993) for the German Bight, and by ALEXANDERSSON et al. (1998) for triangles covering the whole northwestern Europe.

The much discussed positive "trend" of the last three decades now appears as part of a low frequency variation. The last five years had very low wind values, which are among the lowest of the century. The smoothed curves already clearly begin to drop since 1990. This was also found by ALEXANDERSSON et al. (2000). But they point out, that "it is, however, dangerous to trust too much in the tails of these smoothed curves, as they will change, when new data points are added".

Ireland: Weather of the 20th Century in Ireland

Met Eireann, Ireland

Trends from long-term stations show a sharp rise in mean air temperatures during the 1990s, the warmest decade of the century. Four of the warmest ten years of the century were recorded since 1995; these include 1997, which was the warmest year at almost every station. This trend follows the global pattern, as figures from the World Meteorological Organisation show that the 1990s was the warmest decade of the century globally, which itself was the warmest century of the millennium. In Ireland, the warmest month of the century was August 1995, when mean temperatures were around 18 °C, up to four degrees above normal. The highest temperature on record in Ireland, 33.3 °C at Kilkenny Castle in June 1887, was not exceeded during this century, but values of over 32 °C were recorded during June 1976 and in July of 1921, 1934 and 1983. The coldest months of the century were February 1947 and January 1963, when mean monthly air temperatures were below freezing in places and there were also significant snowfalls during both months. The lowest air temperature of the century, -18.8 °C, was recorded at Lullymore, Co. Kildare, on January 2nd 1979, very close to the lowest temperature measured in Ireland, -19.1 °C at Markree Castle, Co. Sligo, in January 1881.

At the long-term stations of Valentia Observatory and Malin Head, the last two decades were the wettest of the century, but elsewhere there was little variation in decadal means of rainfall. The highest monthly total of the century, 790mm, was recorded at one of the mountain gauges in the Cummeragh Mountains of Kerry during October 1996. In contrast, there were a number of months during the century when no measureable rainfall was recorded in places, particularly April 1938, February and September of 1986 and during May 1991. Daily rainfalls of around 200mm were recorded in the east of the country during the 'Hurricane Charley' storm of August 25th 1986, but the highest daily total of the century, 243.5mm, was recorded at Cloone Lake, Co. Kerry, on September 18th, 1993. Over a shorter time span, just over 75mm of rain was recorded in an hour in the Mount Merrion area of Dublin during an intense thunderstorm on June 11th, 1963.

Annual sunshine totals show a downward trend during the century at all stations, but the 1990s were a little sunnier than the 1980s, which was the dullest decade everywhere. The sunniest years of the century were recorded during the first 20 years and also during the 1950s, particularly 1955. July of that year was the sunniest month of the century, when Valentia Observatory measured a total of 308 hours, or almost 10 hours sunshine per day. Winds gusting to around 100 knots have been measured on a few occasions during the century: 98 knots (113 m.p.h.) was recorded in a gust at Malin Head during the 'Hurricane Debbie' storm of September 16th 1961, while a gust of at least this value was recorded at Foynes, Co. Limerick, on January 18th 1945. Mean windspeeds of violent storm force 11 (over 55 knots, or 63 m.p.h.) are extremely rare events at inland stations, but these were recorded in the Dublin area in February 1903 and at both Cork and Shannon Airports during the Christmas Eve storm of 1997.

Monthly extremes recorded at the majority of stations:

Warmest Month: ***August 1995***
Mean temperatures over four degrees above normal in places

Coldest Months: ***February 1947, January 1963***
Mean temperatures below freezing at some inland stations

Wettest Month: ***Variable***

December 1978 in much of east & southeast

Driest Months: ***April 1938, February & September 1986, May 1991***
No measureable rainfall at a number of stations

Sunniest Months: ***July 1955, June 1957, August 1995***
Totals over 250 hours in many places

Dullest Months: ***December 1977, November 1983***
Less than 20 hours sunshine at some stations

Moldova: Climate Change Tendencies in the Republic of Moldova

Hydrometeorological Service, Republic of Moldova

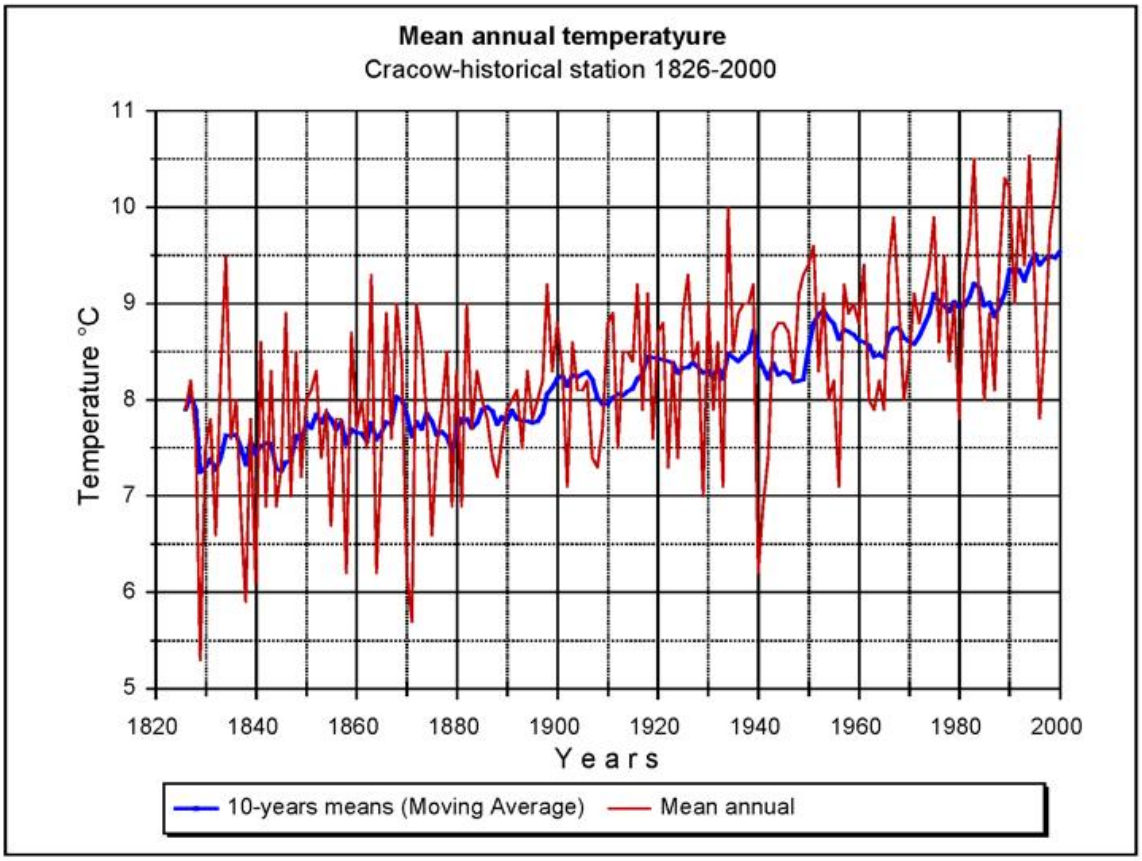
The last ten years, 1991 – 2000, were characterised by a high temperature regime in comparison with many years' period. The yearly average air temperature on the territory during this period was 8.4 – 10.1 °C, exceeding the norm with about 0.5 °C. It is important to be mentioned that especially in these ten years the yearly average air temperature reached twice the highest amounts 9.5 – 11.5 °C, 1994 and 2000, in the observation period of 100 years. The lowest yearly average temperatures were observed in 1996 and 1997 with 7.1-9.3 °C.

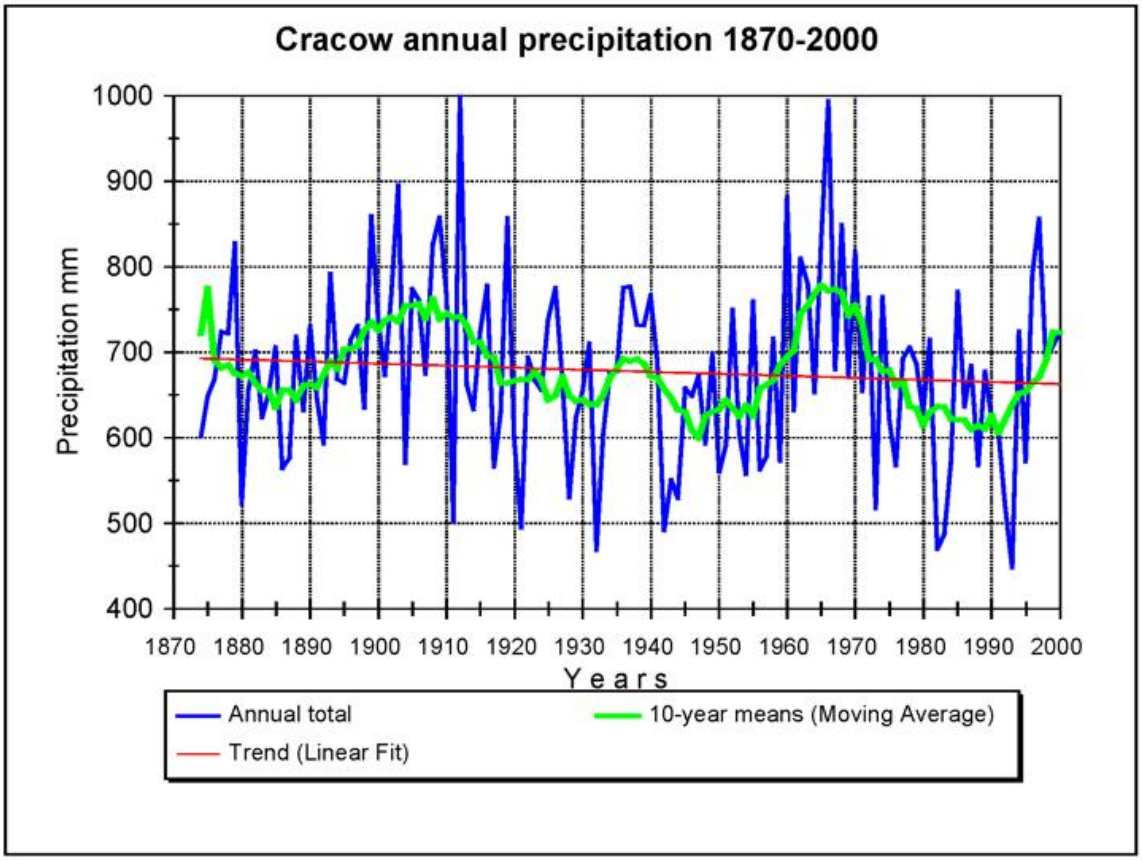
The yearly precipitation quantity average of the territory between 1991 and 2000 was close to the norms of 520 – 620 mm. The precipitation totals of some years oscillated between 400 mm (1994) and 890 mm (1998).

A special characteristic of the last decade was that of a higher temperature regime in **winter**, spring and summer. The average air temperature in winter was -0.9 – -2.3 °C, which is 0.2 – 1.4 °C warmer than usual. Out of 10 seasons, the average temperature exceeded the norm in 9 winters and only the 1995/1996 winter was anomalous cold. Its seasonal average temperature was lower than norm with 3 °C. The warmest winter was in 1993/1994, the average air temperature in Chisinau was 0.9 °C, as for some days in February the temperature reached 17.6 °C. In **spring** the seasonal average air temperature was 8.6 –10.1 °C, exceeding the norms with 0.5 °C. The warmest spring (exceeding the norms with 2 °C) was in 1994 and 2000; the coldest in 1991. The summer in this decade exceeded many years norms' with 0.5 – 0.9 °C and was 19.1 – 21.4 °C. The warmest **summer** was in 1999, the average of the seasonal temperature for the territory oscillated from 20.8 to 23.0 °C. The coldest summer of this decade was in 1993, the temperature was 17.5 – 20.3 °C. The **autumn** temperature regime (8.1 – 10.2 °C) was closer to many years norms. The autumn of 1994 was warmer, the air average temperature was between 9.7 and 11.7 °C. The coldest autumn was 1993 (6.4-8.7 °C).

Poland: Mean annual Temperature and Precipitation

Institute of Meteorology and Water Management, Kraków





Portugal: Climate in the 20th Century

Instituto de Meteorologia, Portugal

1. Introduction

One of the most relevant features of the climate in Portugal during the 20th century was the generalised increase in air temperature. The air temperature increase rate was larger in the growing towns, where there was a larger increase in time of the "urban island effect". When the mean trend related to the urban effect is removed, it is found that the mean air temperature has increased at a rate similar to the global warming rate for similar periods.

When the mean trends of air temperature increase are computed over the whole century, it is found that the maximum air temperature raise was larger than the increase rate in the minimum temperature. This implies an increase in the mean diurnal temperature range *DTR* over the century. Fig. 1 shows, as an example, the time series of the annual averages of minimum, maximum and mean air temperatures in Lisbon Geofisico from 1901 to 2000; the other secular time series show similar behaviour.

However, it is well known that, in recent years, the increase in minimum air temperature has been larger than the increase in maximum air temperature, that is, in the recent years the diurnal temperature range has decreased. This behaviour is generally interpreted as being associated with the increase of the greenhouse effect.

Several questions seem pertinent:

- When did the change in the sign of the trends in *DTR* occur?
- Did the change occur simultaneously in different places and regions?
- Did this change occur just in urban areas or is it a larger scale phenomenon?

2. Analysis of Portuguese Diurnal Temperature Range Time Series

The air temperature series from Lisbon - Geofisico and Coimbra – Geofisico, the best long series of air temperature in Portugal, were analysed to try to find at least preliminary answers to these questions. In Lisbon, the urban island effect is significant and has a considerable effect in the temperature rise; this has been found to be relatively small in Coimbra, a much smaller town.

The time series of *DTR* at Lisbon – Geofisico and Coimbra – Geofisico are represented in Fig. 2; the graph also shows the 5 years moving averages.

It is clearly visible that the series show opposite trends in the beginning and at the end parts. Also there is an acceleration in DTR increase near 1939 and a change of sign in the trends in the vicinity of 1945.

To locate the years of change in the signal of *DTR* two methods where used:

i) Locate the local maxima of moving averages (5 years).

ii) Identify trough Singular Spectral Analysis trends and slow variation principal components and use the time series reconstructed by using only these components to find the local maxima.

With the first method the inversion in the trends is estimated to occur in both series in 1945. With the second one the change is located between 1946 and 1947 for Lisbon and between 1947 and 1948 for Coimbra.

The metadata with the history of the two stations were checked.

For Coimbra there is no registered change in those years. In Lisbon, in 1941, there is a change in the thermometer height from 23.8 m to 1.6 m. This change should have produced a jump in *DTR* of about +0.08 ºC (small compared with the amplitudes of the *DTR* variation of the order of some ºC); however, it can not explain the change from an increasing trend to a decreasing trend in the *DTRs*.

In Fig. 3 the time series of diurnal temperature range in Lisbon – Geofisico and Coimbra – Geofisico are shown, together with the trend lines fitted from 1901 to 1945 and from 1946 to 2000. The trends, of +0.04ºC/year and –0.03ºC/year for Lisbon and of +0.06ºC/year and –0.03ºC/year for Coimbra, are statistically significant (level lower than 0.01).

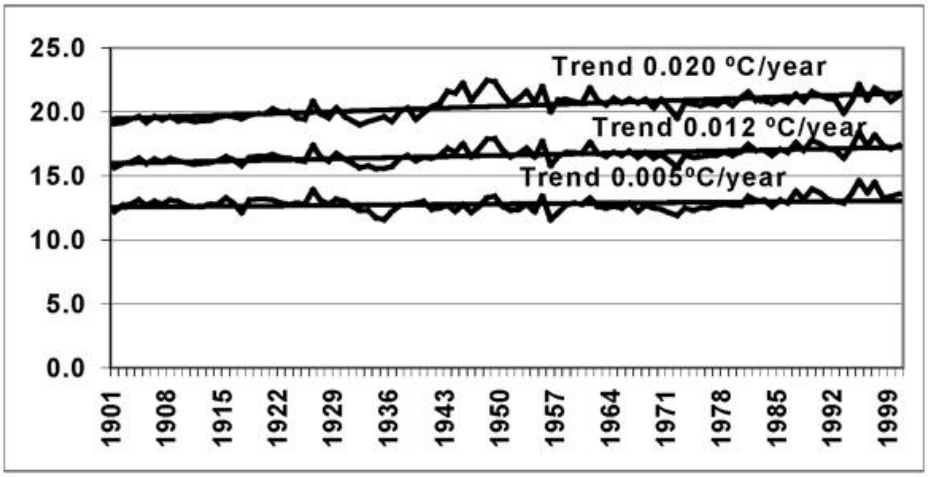


Fig. 1 *- Annual averages of minimum, maximum and mean air temperature at Lisbon and respective trendlines.*

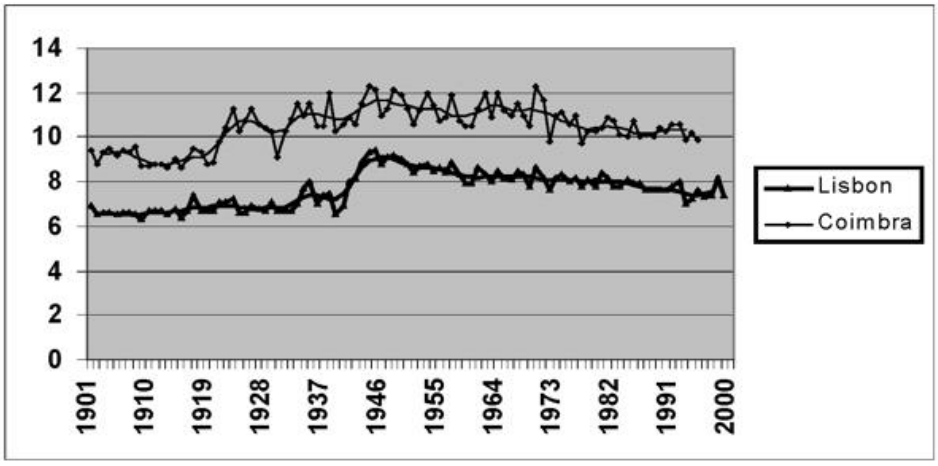

Fig. 2*: Annual averages of Diurnal Temperature Range at Lisbon and Coimbra and 5 years moving averages.*

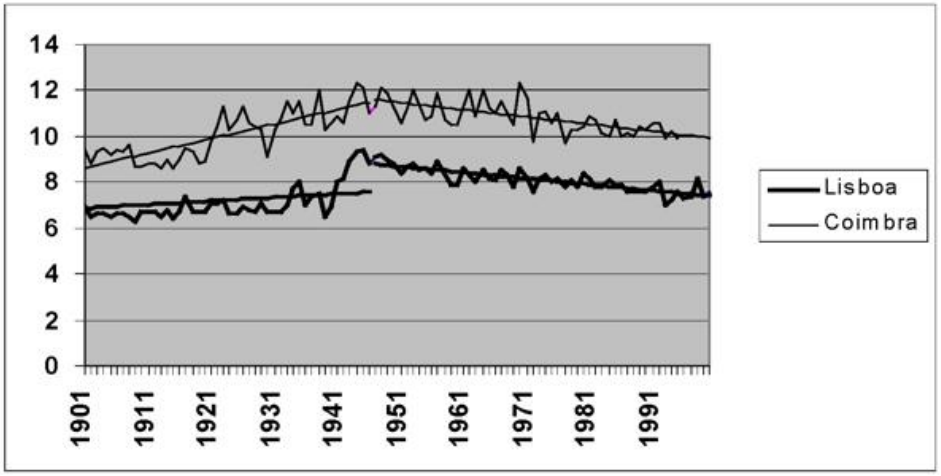

Fig. 3*: Annual averages of Diurnal Temperature Range at Lisbon and Coimbra. Trend from 1901 to 1945 and from 1946 to the end of the series.*

3. Comparison with other European Series of Diurnal Temperature Range

A reversal of trends in *DTR* about the year of 1945, or in the just following years, similar to that observed in Portugal, can be found looking at the graphs of several other European climatological series of *DTR* that are available trough the European Climate Assessment (ECA). Some of those where this behaviour is most obvious are:
Basel Binningen (Switzerland), Stensele (Sweden), Praga Klementinum (Czech Republic) and Uccle (Belgium) – see Fig. 4.

SLOVAKIA: The Climate in Slovakia in the 20th Century

Climate Service Division of Slovakia

Significant increase in mean annual temperature by about 1.1 °C was observed in whole Slovakia in the 20th century. This increase can be illustrated also as the deviation of decade mean temperatures from the 1901-2000 average. In January 1991-2000 it was +1.5 °C and in August 1991-2000 it was +1.6 °C, but in December 1991-2000 the decrease by -0.1 °C and in September, October and November 1991-2000 the increase only by 0.4 °C was observed. Figure 1 shows the temporal development of annual temperature means. There can be seen exceptional high values between 1988 and 2000. Only the year 1996 can be considered as slightly below normal, the years 2000 and 1994 were in Slovakia probably the warmest since 1775. Frequent cold summers were observed in Slovakia in the 1901-1920 period and frequent cold winters occurred in the 1928-1947 period. The year 1940 was the coldest in the 20th century, but February 11, 1929 with -41 °C temperature measured at Viglas Pstrusa (central Slovakia) was the day with the lowest minimum temperature in Slovakia. Development and trends of annual precipitation totals show Figure 2. In southern Slovakia decreasing trends up to 15 % was observed in the 20th century. Some stations at the northern border of Slovakia have slightly increasing trends up to 5 %. The areal average annual precipitation totals calculated from 203 precipitation stations have decreasing trends by 5.8 % (Figure 2). The 1986-1993 period had the lowest precipitation totals in Slovakia in the 20th century. The Figure 3 illustrates an occurrence of the highest daily precipitation totals in Slovakia (Hurbanovo observatory). No significant trend in the maximum daily totals can be seen, some increase was observed in the 90ies. The absolute maximum daily total observed in Slovakia in the 20th century was 231.9 mm at Salka (lowland in southern Slovakia) on July 12, 1957. June 29, 1958 can be considered as the most rainy day in the 20th century with daily totals above 100 mm at 36 stations in Slovakia.

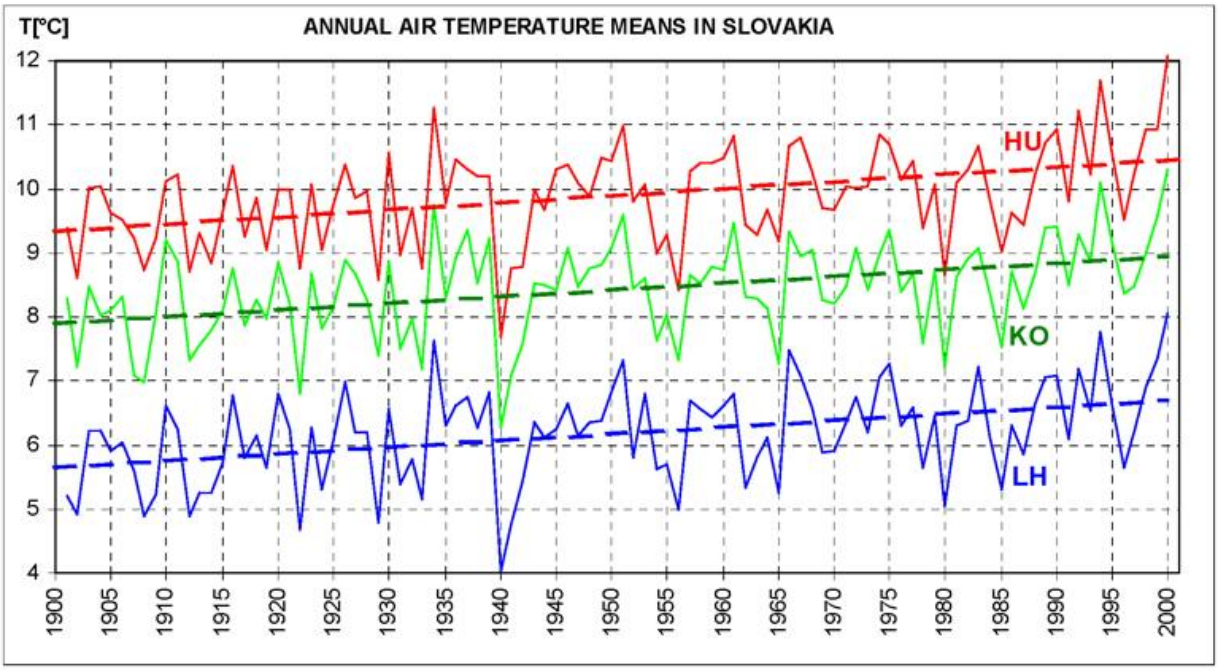

Fig. 1 *Annual air temperature means at the main climatological stations in Slovakia in 1901-2000 and linear trends (HU - Hurbanovo, SW Slovakia, 115 m a.s.l., 47°50'N, 18°12'E, KO - Košice, SE Slovakia, 230 m a.s.l., 48°40'N, 21°13'E, LH - Liptovský Hrádok, N Slovakia, 640 m a.s.l., 49°02'N, 19°44'E)*

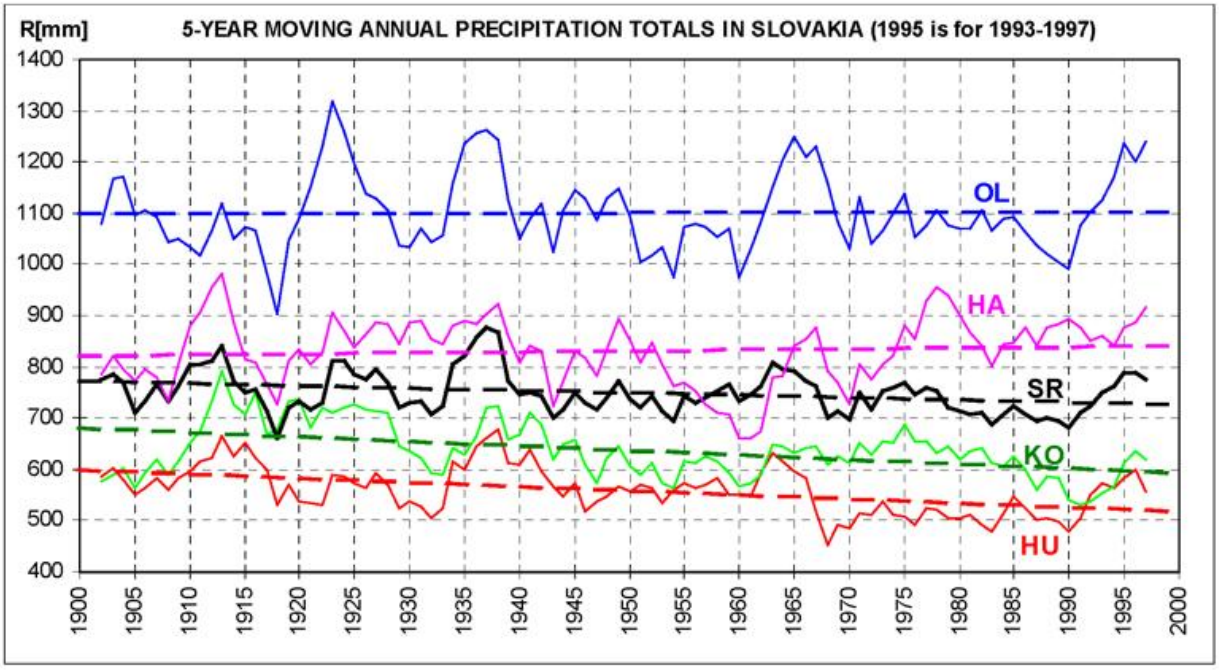

Fig. 2 *Five-year moving annual precipitation totals at the main precipitation stations in Slovakia in 1901-2000 and linear trends (HU - Hurbanovo, SW Slovakia, 115 m a.s.l., 47°50'N, 18°12'E, KO - Košice, SE Slovakia, 230 m a.s.l., 48°40'N, 21°13'E, SR - areal average from 203 stations in Slovakia calculated by double weighted averages method, HA - Habura, NE Slovakia, 372 m a.s.l., 49°19'N, 21°52'E, OL - Oravská Lesná, 780 m a.s.l., 49°22'N, 19°11'E)*

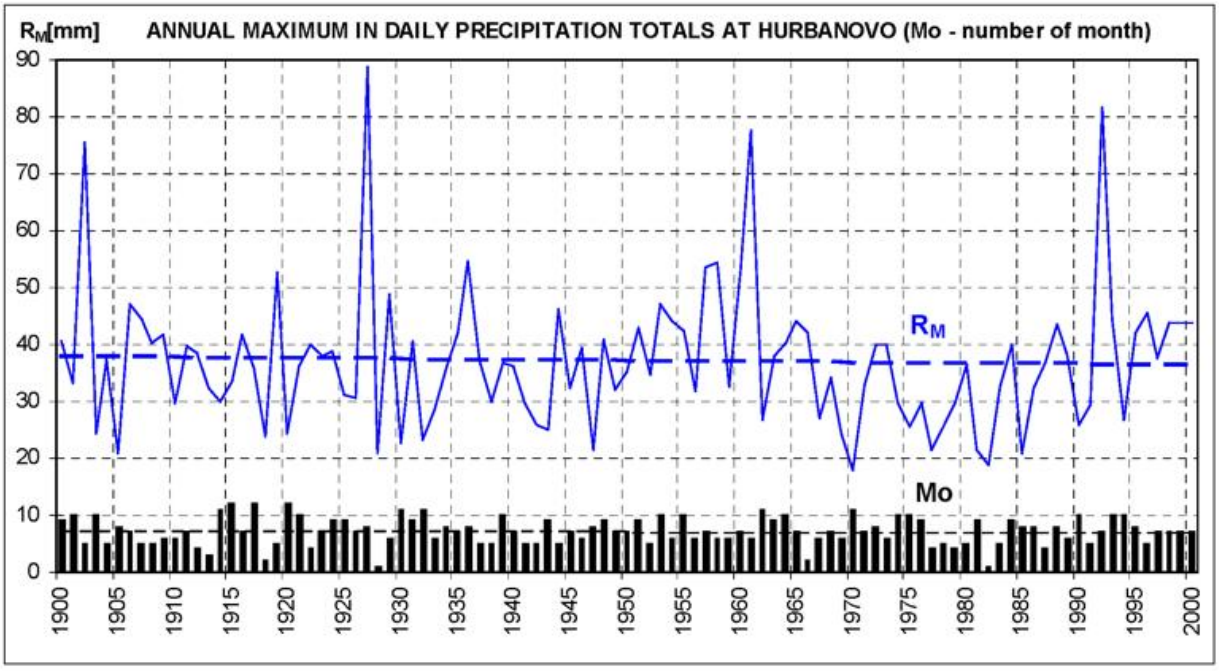

Fig. 3 *Annual maximum in daily precipitation totals at Hurbanovo 1901-2000 (R_M) and linear trend, number of month with maximum daily total (Mo); Hurbanovo, SW Slovakia, 115 m a.s.l., 47°50'N, 18°12'E, Mo = 12 (December), Mo = 7 (July); no significant trends in R_M and Mo values was observed*

United Kingdom: Temperature Anomalies in Central England between 1878 and 2000

UK Meteorological Office

A century time-scale perspective on Central England Temperature is given in the following figure. Analyses indicate that about a quarter of the warming in recent decades has arisen because of changes in atmospheric circulation. The series has been designed to avoid urban warming, and the absence of this is confirmed by the equality of warming trends on calm days (when any urban warming would be most evident) and windy days (when any urban warming would be dissipated).

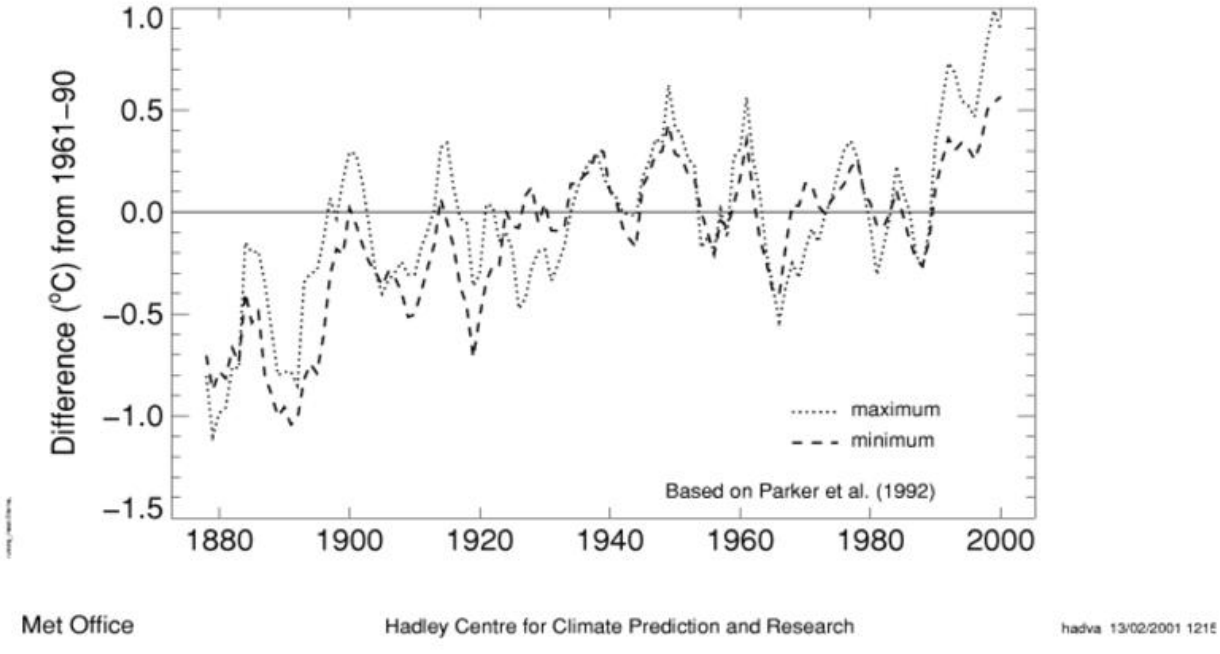

Fig. xx: *Central England maximum and minimum air temperature annual anomalies between 1878 and 2000*

The Bulletin is a summary of contributions provided by the National Meteorological Services.

REPORT ON ECSN ACTIVITIES 53

Foreword

The Annual Bulletin on the Climate in WMO Region VI – Europe and Middle East – for 2001 is now presented as the 8th edition in a sequence since the series started in 1994. All of the 49 national Meteorological and Hydro-Meteorological Services in WMO Region VI have been asked for input to this edition. There were direct responses from 40 member states of the Region. Additionally, WMO Secretariat supported the compilation of the report by providing the contributions to the WMO Bulletin article on consequences of abnormal weather in 2001.

The report from the ECSN manager is also highly appreciated and incorporated to this edition of the Bulletin. The Project 'Generate Climate Monitoring Products' (GCMP) of the ECSN Application Area is closely connected to the objectives of the Bulletin. As for the first time last year, this edition of the Bulletin will be presented again also via Internet.

In 2001, numerous climatic highlights occurred in WMO Region VI on different scales in space and time. Prominent features on the monthly time scale were the record breaking high temperatures in October exceeding those of September in many places, while September had extremely high precipitation rates in large parts of the Region. Devastating floods and long lasting drought affected different and in some cases the same areas at different times.

There were also many reports of extreme short time events on a more local scale. While reports on local whirlwinds and tornadoes have increased compared to earlier years, this may be due in part to enhanced reporting procedures that have been introduced in recent years. A new feature of this edition of the Bulletin is the photographic illustration of some extreme events, that occurred within in the Region.

I would like to thank all those who contributed to this publication. The reader of the Bulletin will find a compilation of selected parts from all national reports with the intention of presenting the characteristic climatic features of the WMO Region VI in 2001.

Last not least I want to thank Germany for the co-ordination, the editorial review, publishing and distribution of the document.

Petras Korkutis
Acting President of WMO RA VI

Outstanding Events and Anomalies in 2001

Temperature

- Overall warmer than normal with highest positive deviations in SE-Europe and the Middle East
- October extremely warm with highest temperatures on record and higher mean values compared to September in many places
- December very cold in nearly all parts of Europe except for the Northwest, with extreme deviations from normal in the Southwest and in eastern Europe
- In contrast to other parts of Europe, absolute records of maximum temperatures were set up on islands in the Norwegian Sea in December
- March extremely warm in the Mediterranean and Middle East
- Extremely mild January in the Volga region

Precipitation

- Overall rainfall slightly above or near normal except some parts of southern Europe and the Middle East
- Intense drought with high temperatures in summer months from central-south to south-eastern Europe, in the Caucasus region and Uzbekistan
- September very wet in Central Europe with extreme rainfall amounts in the Alpine and Balkan regions
- Extreme wintry rainfall in Brittany and the northern part of Portugal, succeeded by abundant flooding at the beginning of the year
- Abundant snowfall in Western Altai leading to frequent avalanches in January and flooding in spring-time

Wind

- Violent storms in November in the mid Baltic area

Annual Survey

Temperature deviations from normal all over the year within the Region were generally positive with maxima above +1°C in south-eastern Europe and the Middle East (e.g. see fig. 0.1), but still below the level of the preceding year.

October temperatures were extremely high in many parts of the region (e.g. fig. 0.2) and exceeded previous all time records at many stations. Monthly mean values lay above September means in many places in Europe (see fig. 0.3).

The Mediterranean and the Middle East were hit by an extraordinary heat wave in March (see fig. 0.4).

On Iceland and Jan Mayen absolute maximum temperature records were broken in December, whereas from the Iberian Peninsula over central to eastern Europe December was very cold with temperatures significantly below normal (see figs. 0.5, 0.6).

Precipitation was generally near to normal or slightly above over the Region (e.g. see fig. 0.7) except for some parts of southern Europe and the Middle East.

September was extremely wet in Central Europe with deviations in some areas up to 300% of the normal precipitation and even more (e.g. see fig 0.8).

In summertime, some parts of southern Europe and the Caucasian region suffered from severe drought, especially at the beginning and the end of the season (see fig. 0.9).

Starting from the second half of November, a growing snow cover affected Latvia and Poland, reaching more than 40 cm in some parts of the area at the end of December (see fig. 0.10).

Sunshine duration was reported to be near normal or slightly above with the exception of central France, where a deficit of sunshine occurred. At the beginning and at the end of the year, the U.K. enjoyed record-breaking sunshine. Ireland gained significantly more sunshine than normal all over the year at nearly all stations (see fig. 0.11).

Extreme **Wind** events occurred all over the Region throughout the year in many localities. In France, the highest gust was recorded on April 8 by 187 km/h at Cap Béar in the eastern Pyrenees near the Mediterranean Sea. A thunderstorm, that developed into a tornado on September 30 hit the county Westmeath in Ireland with impacts illustrated by fig 0.12.

In mid-November, violent storms uprooted millions of trees when crossing Scandinavia to the Baltic States, and caused exceptional sea level rise in the Gulf of Riga.

Seasonal Survey

Winter 2000/2001 was generally mild except in Ireland with a country-wide slightly negative deviation of 1°C from normal. Positive temperature anomalies occurred elsewhere and increased from the European coastal regions in the West and Southwest into the continental area, where they reached maximum values up to +5°C in eastern Europe. Switzerland had a remarkable relative maximum of positive temperature deviations (see figure page 14 above). The wintry precipitation was distributed in a more complex way over the Region. While some coastal parts of western Europe received enormous amounts of precipitation, other parts like south-central France, the Levante, and areas around the Black Sea had significant deficits (see figure page 18 above). Continuous rainfall over several days around New Year caused large floods on saturated soil in Brittany (France) and in the northern part of Portugal (see fig. 0.13).

Spring 2001 was generally warm with positive temperature anomalies except for northern Scandinavia. Positive deviations from normal occurred up to +3°C, rising from western to eastern Europe and the Middle East (see figure page 15 above). In Tartu, Estonia, the April mean temperature exceeded the normal value by far; the long term linear trend of this parameter shows an increase of +1.9°C since the beginning of observations in 1866 (see fig. 0.14). The spatial distribution of precipitation in springtime has a patchy pattern over the Region. There are areas of up to 200% of the normal precipitation in the north-western part of the Iberian Peninsula, in France, Poland, and north-east of the Black Sea. Significant precipitation deficits occurred in eastern parts of Spain, in several coastal areas of the Mediterranean and the Norwegian Sea, around the central part of the Caspian Sea, and in eastern Europe with centres in Belarus and Moldova (see figure page 18 below). High spring temperatures in western Altai, Kazakhstan, melted large snow reserves and together with abundant rainfall led to extraordinarily high floods in the mountain rivers with destruction of villages, bridges and motorways.

Temperatures in **Summer 2001** were above normal except for the coastal area of middle Norway. The positive deviations from normal increased from the European coastal areas to the centre of the continent up to +2°C and had an even higher maximum around the eastern Black Sea and north of it (see figure page 16 above). The most prominent feature of the precipitation regime in summer was a large deficit of rainfall around the Mediterranean coastline and in the Middle East leading to severe drought in many areas. Central and northern Scandinavia and other, more or less isolated areas in France, eastern Europe, Greece and eastern Turkey had remarkable precipitation amounts exceeding 150% of the normal values (see figure page 19 above).

Autumn 2001 was generally mild with centres of positive temperature deviations from normal in the British Isles, in Scandinavia, and south-eastern Europe (see figure page 17 above). The spatial distribution of precipitation had a more complex structure over the Region (see figure page 19 below). Precipitation amounts up to more than 200% of normal occurred in southern Russia (Volga region) and in some parts of Turkey, especially in the North-East and in the south-western coastal area. Central Europe received precipitation above normal up to 150% as well as the northern Balkans and the Ukraine. The Pyrenees, the Alps, Italy, the southern Balkans, and the eastern Caucasus suffered from precipitation deficits causing severe drought. The special climatic characteristic of autumn 2001 in many European countries was a very wet and cool September followed by a warm October with precipitation significantly below normal. This feature is exemplarily illustrated by fig. 0.15.

Monthly Surveys

January 2001

- **Extremely mild in the East, additionally dry in the Southeast**
- **Catastrophic floods in Brittany and northern Portugal**
- **Sunny and cold in the British Isles**

Temperature anomalies were positive in northern and central Europe by +1...+3°C and increasing significantly eastwards. As an example, the monthly mean temperature anomalies at the station Ljubljana, Slovenia, show, that January was the month with the highest positive deviation from normal by +4.5°C throughout the year (see fig. 1.1). In the Volga region, Russian Federation, the monthly mean temperature exceeded the normal value extraordinarily by +8.6° C.

During the second pentade of the month, a south westerly airflow transported warm and dry air from Africa to south-eastern Europe. As a consequence, record-breaking maximum temperatures were observed in several places: in Greece, on January 6-7 by 18-19°C; at the station Kiskunmajca, Hungary, by 17.6°C on January 7; one day later at Loznica, Yugoslavia, by 21.6°C.

In the Southeast, the relatively high temperatures were combined with deficits of precipitation, especially in Turkey, Cyprus, parts of Israel, and the Caucasus region, where the percentages of normal precipitation ranged from 60% down to 30%.

In contrast to this, some western parts of Europe received unusually high amounts of precipitation. In north-western France, continuous heavy rainfall during the first 5 days of the year (especially 50-90 mm on January 3-4) on already saturated soil caused flooding with catastrophic damage in the southern basins of Brittany.

In the northern part of Portugal rainfall rates near to 300% of normal occurred (see fig. 1.2). In Coimbra, Viana do Castelo and Vila Real, the actual monthly precipitation sums exceeded the previous maxima of cumulated amounts for the 5-month period of September to January, which were 1040 mm, 1511 mm and 1163 mm respectively. Due to these extraordinary precipitation amounts, the dams reached their maximum storage capacities. Their discharges led to floods in north and central areas, causing submerged roads, insulated villages and evacuation of people, landslides and closure of some railways.

Ireland and the U.K. had sunny and cold weather. In England and Wales, it was the sunniest January since 1959; but despite of the sun, January was also the coldest in four years.

In southern Sweden, heavy snowfall on January 2 caused problems to power lines. As a consequence, 80,000 families stayed up to one week without electricity supply. Also in Estonia, wet snow wrecked power lines and caused damage to forests. Although Germany had a small deficit of precipitation and a temperature anomaly of slightly above +1°C, there were a lot of events with heavy snowfall and freezing rain during the month and located all over the country, leading to mass accidents on motorways.

From January 14-16 heavy rains and thunderstorms affected the central and southern parts of Greece, leading to floods in Attiki and the north eastern Peloponnisos with significant destruction. Due to bad weather conditions, a first aid helicopter crashed over the South Agean with the loss of 5 people.

In Kazakhstan, snow depths in the western Altai mountains exceeded normal by 2-3 times, giving cause to frequent avalanches and consequently to the blocking of railways and a 1500 km stretch of the main road.

In Tajikistan, temperatures fell below -50°C in some places, at Bulunkul station down to –56°C.

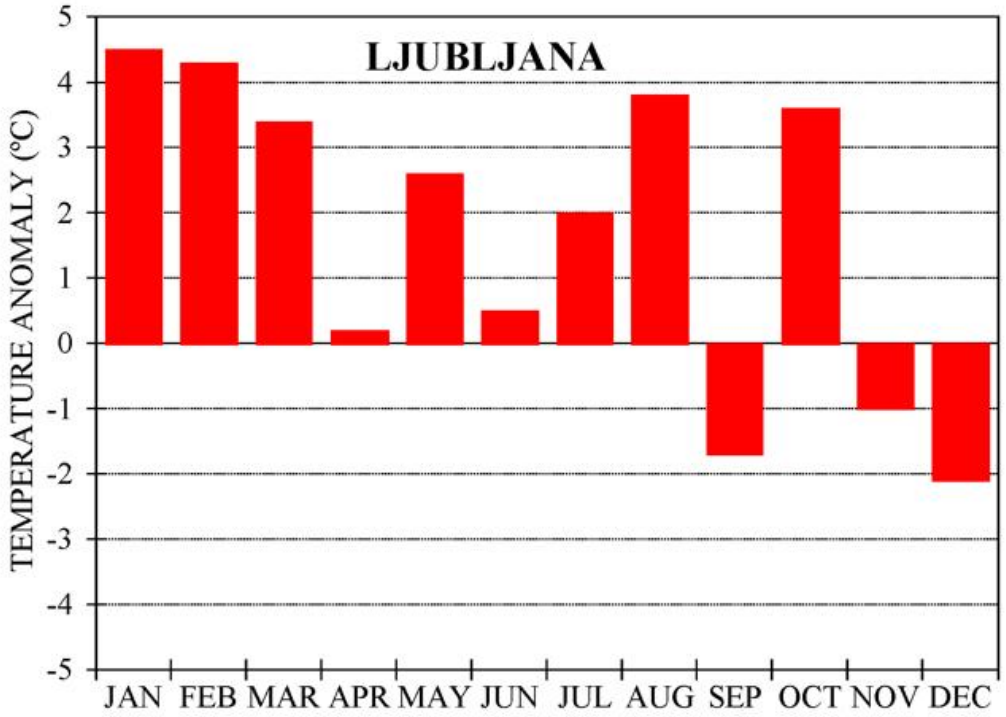

Fig. 1.1: *Monthly temperature deviations from normal 1961 – 1990 at station Ljubljana in 2001*
From: Environmental Agency of the Republic of Slovenia

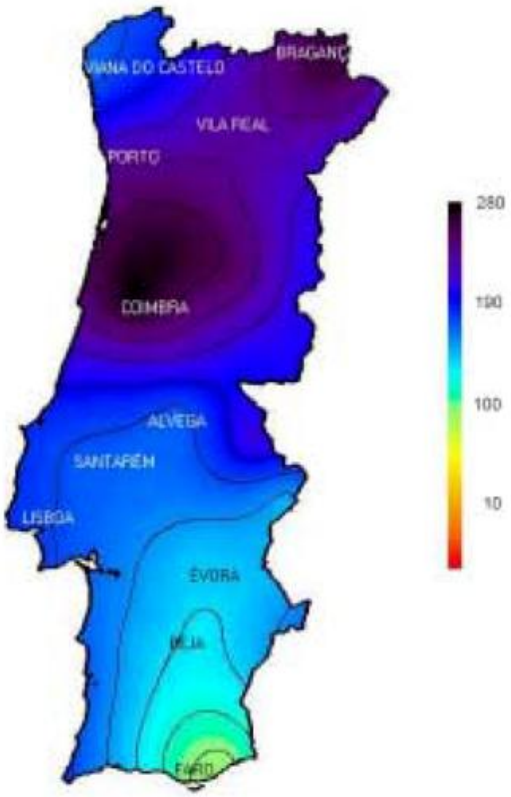

Fig. 1.2:

Precipitation rate for January in % referred to 1961 – 1990 in Portugal
From: Instituto de Meteorologia, Portugal

February 2001

- **Warmer than normal in central, eastern, and south-eastern Europe**
- **Very wet in some parts of western Europe**
- **Very dry on the Balkans and in the Caucasus**

Temperature anomalies in central Europe were above +1°C and up to more than +2°C in the northern Balkan region. In the Caucasus area, positive temperature deviations from normal were up to +4°C.

Precipitation amounts in central Europe were near to normal except for Belgium, where the station Uccle received 158% of the average in 1961-1990.

Heavy snow and widespread floods affected the U.K. in the first week of the month. Snow and ice closed areas of north-eastern England and Scotland, while at the same time parts of southern England were under water. In Kent, more rain fell in one day than normally would fall in a month.

In Portugal some daily maximum records of precipitation were broken (with 71 mm in Porto, 70 mm in Évora and 50 mm in Beja).

On February 21, heavy snowfall, thunderstorms, and icing led to severe calamities on roads in many districts of the Czech Rebublic. On the same day in Austria, gusts up to 100 km/h caused damage of greenhouses, roofs, and trees in the area of Vienna; additionally, traffic was blocked on highways by a lot of accidents.

At station Freiburg, a maximum temperature of +19.5°C was measured on February 6, the highest temperature in Germany for the first decade of the month since more than 100 years.

In France, heavy snowfall in the Southeast led to the closing of roads and motorways. Damage to power lines and trees occurred due to the weight of the snow.

A spell of warm air occurred in Hungary in the second pentade of the month. The country-wide average temperature was +15.5°C on February 9. On the same day, the maximum temperature at the station Baja was +18.6°C.

In the Netherlands, the month was very wet by 168% of the normal rainfall. The first decade of the month was the second wettest on row since 1901 with 70 mm. On February 1, heavy snowfall and icing disrupted public life in the northern half of the country.

At station Svenningdal, Norway, the largest precipitation amount of the country for 24h was observed by 144.5 mm.

In the Russian Federation avalanches blocked transport on the main Transcaucasian routes and broke power lines.

A cold episode early in the month brought a new February record to the province Dalarne, Sweden, with –44°C.

In Switzerland, the weather was very mild in the lowlands during an episode of several days at the beginning of the month; Vaduz/Liechtenstein had an extraordinarily high mean daily temperature of +16.4°C on February 7.

In Turkey, whirlwinds, frosts, and storms caused damage to agricultural areas; telephone and power lines. In Izmir, the seaport was closed on February 26 because of bad weather conditions.

March 2001

- **Extremely warm in the Alps, around the Mediterranean, and in the Middle East**
- **Cold in Scandinavia**
- **Very wet from the South-West over central to eastern Europe**

In Cyprus, it was the warmest and driest March in the last 100 years. The temperature anomaly was +4.4°C combined with a precipitation rate of 14% from normal.

Exceptionally heavy rainfall in France engendered flooding in Franche-Comté, Paris, Lyon, and the whole centre of the country.

In Luxembourg, the highest monthly precipitation amount since 1947 was recorded with 138 mm.

At the end of the month, very cold air came into Germany, producing a snow cover of 25 cm in the North. In Berlin, the coldest March 25 since 1919 was observed by a maximum temperature of –0.1°C.

In Greece, unusually high temperatures were recorded, exceeding normal by +6°C up to +15°C. Daily maximum temperatures varied from 28°C to 35°C within the period March 22-27.

Extreme floods were triggered by intensive precipitation in north-east Hungary from March 3-5. The highest amount of a 3-day accumulation was recorded at the station Tiszabes with 80.2 mm, which has a 20 years' return period.

In Ireland, the highest gust of the year was observed with 122 km/h at station Malin Head on March 6.

Israel experienced the hottest March since the beginning of measurements 40-50 years ago (see fig. 3.1). Several hot and dry spells (called sharav) throughout the month led to temperatures above 30°C. A significant sharav event occurred in the end of the month with temperatures up to 38°C in the Coastal Plain and the northern Negev.

Also in Jordan very warm air invaded the country at the end of the month and caused maximum temperatures exceeding the normal of the daily maximum by +6.3...+13.8°C.

In the first half of the month, frequent fog obstructed aviation in Lithuania. The station at airport Vilnius recorded visibility below 100 m for 15 hours on March 11, delaying all flights. Temperature in Lithuania had an abnormal course during the month. Up to March 20 it was rather mild. In the last decade of the month, temperatures fell to -1.5...-5.5°C below normal and were lower than in the first half of January.

In Belgium (see fig. 5.1) and in the Netherlands, March was rather dull. The station De Bilt received only 55% of the normal sunshine, which is the 4th lowest record since 1901.

At station Sihcajavri in Norway, the lowest monthly mean temperature (except for mountain stations) was measured with -17.0°C, which is –5.7°C below normal.

Heavy snowfall in northern Poland caused much trouble to transport. In the Russian Federation, heavy snowfall on March 16 interrupted transport and damaged power lines in the Moscow area.

In the high mountains of Slovenia, an abundant snow cover had accumulated at the end of the month, combined with country-wide relatively high temperatures and a sunshine deficit. On Kredarica (2514 m), a snow cover of nearly 6 m was observed, the highest ever recorded in March.

South-westerly winds prevailed during the month over the Iberian Peninsula. The result was an extremely warm month in most parts of continental Spain, especially in the East. Historical records for mean monthly values were beaten at many observatories.The greatest anomalies are to be found in the Levante with values around +3ºC. The prevailing winds of Atlantic origin were responsible not only for high temperatures but also for intense precipitation. In almost all Galicia and the Duero Basin new records were registered of monthly precipitation sums. In La Coruña, the monthly total of 262 mm exceeded the previous record over a 124-year long series. In sharp contrast to this, the month was very dry in the Southeast and the Balearic Islands.

In Portugal, daily maximum precipitation amounts were exceeded in some places in the North, e.g. in Porto with 108 mm. Monthly maximum precipitation records were exceeded in places distributed all over the country, e.g. with 629 mm in Viano do Castelo, 327 mm in Bragança, 432 mm in Vila Real, 570 mm in Porto, 177 mm in Alvega and

110 mm in Faro. The fall of a bridge crossing the Douro River, due to the increase of river flow and eventually to the local extraction of sand, caused 59 deaths. The material losses to the whole country were estimated to € 500 million.

In Switzerland, March was extremely mild, wet and dull. Temperature anomalies were up to +4°C. Highest rainfall rates reached 400% of normal and there were up to 26 days with precipitation of at least 1 mm, the maximum number recorded since the beginning of observations in 1864. The snow depth on Bernina pass (2256 m asl) was highest with 641 cm on March 14. It was the most alarming avalanche situation since winter 1950/51. Water levels in rivers and lakes were extremely high, but no major flooding occurred. Sunshine duration was unusually low with 40% to 60% of the average. At the mountain station Säntis, it was the March with the lowest rate of sunshine since records started in 1901.

Hail and heavy rainfall caused large damage to agriculture, roads, and houses on March 8 in the Sanliurfa district, Turkey; 3 people died.

A drought situation affected The Former Yugoslav Republic of Macedonia, caused by decreasing precipitation rates since the beginning of the year (see fig. 3.2) and accompanied by extraordinarily positive temperature anomalies (see fig. 3.3).

During March 3-5, intense rainfall in western Ukraine led to catastrophic floods on the rivers of Zakarpattya in the Carpathian Mountains.

In the U.K., March was rather cold and accompanied by blizzards, high winds and a snow cover of up to 25 cm in Scotland, England and Wales.

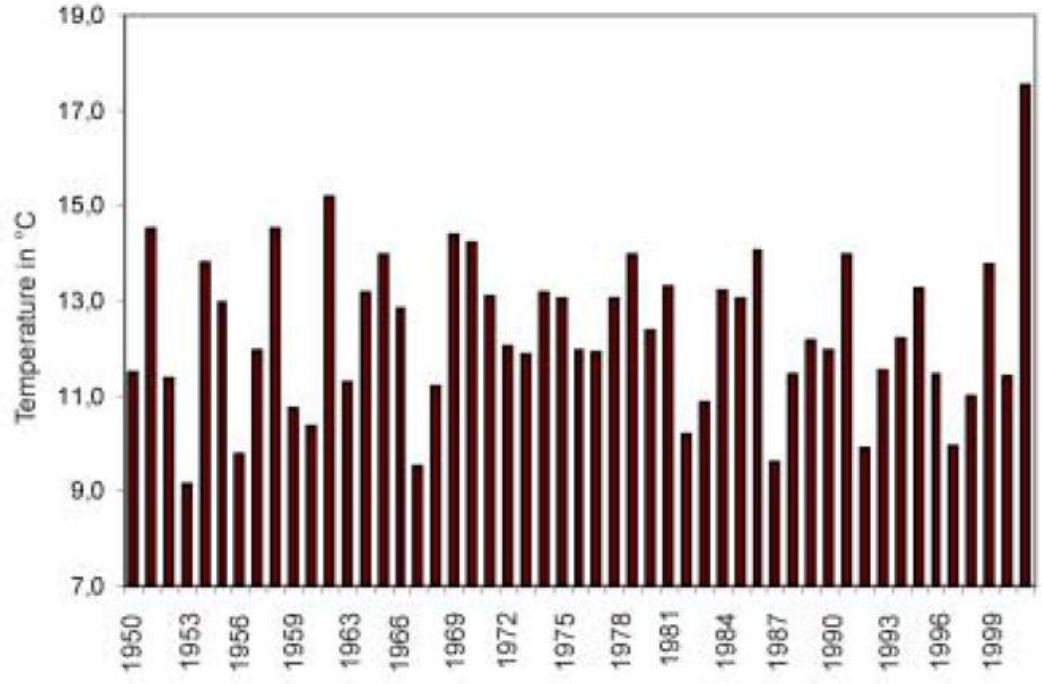

Fig. 3.1: *Mean daily temperature in March, Jerusalem 1950 – 2000*
From: Israel Meteorological Service

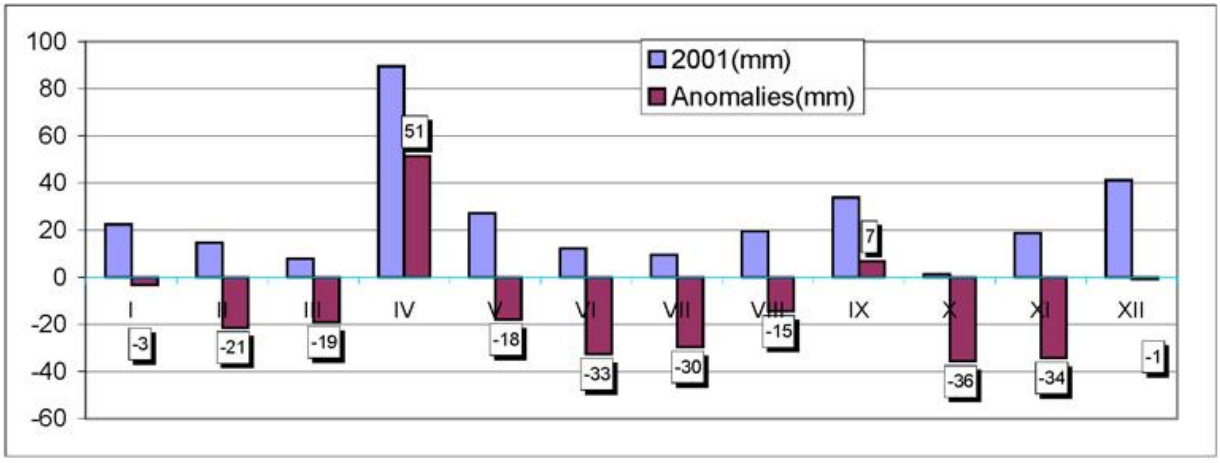

Fig. 3.2: *Monthly precipitation totals and anomalies in SkopjeZajev Rid, in 2001, reference period: 1961 – 1990*

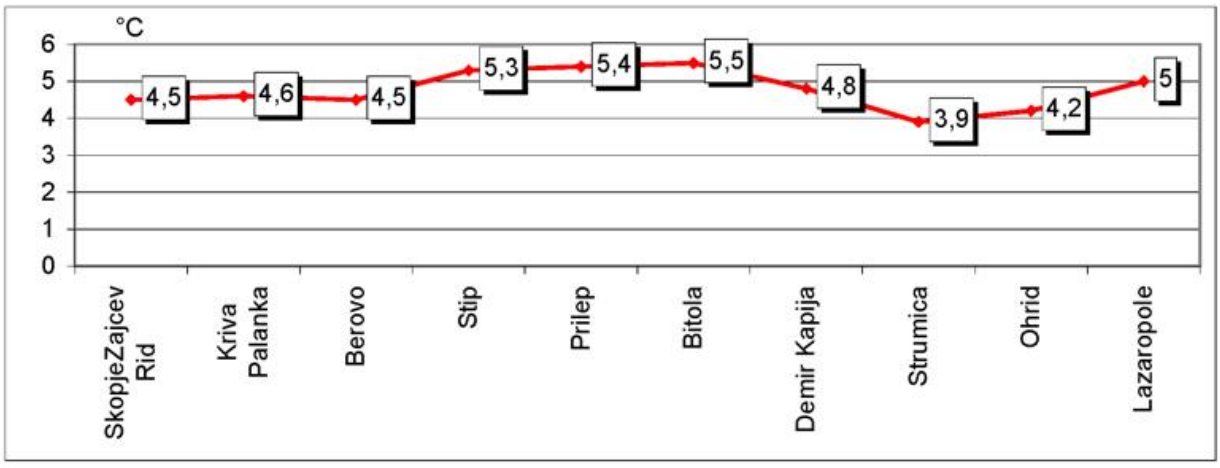

Fig. 3.3: *Monthly temperature anomalies in March 2001, Macedonia, reference period is March 1961 – 1990*
From: Hydrometeorological Institute of Republic Macedonia

April 2001

- **Very wet in a broad strip from the British Isles and northern France over central Europe to the Baltic States, Belarus and parts of the Ukraine as well as on the Balkans**
- **Return of wintry weather in the second decade of the month in central and eastern Europe**
- **Dry on the Iberian Peninsula and in the Caucasus**
- **Very warm in eastern Europe and the Middle East**

At station Uccle, Belgium, a precipitation amount of 134.2 mm was measured, which is 253% of normal and thus as absolute record since observations started in 1833.

A long lasting rainy period in northern France, starting from October 2000 (see fig. 4.1) led to disastrous floods in Brittany and the Somme area. In Lille, the monthly precipitation amount was 112.2 mm and thereby the highest ever recorded in April.

From April 13 to 15, snow and ice lead to chaos on motorways all over Germany. It was the coldest Easter time since more than 20 years. On April 20-21, fresh fallen snow covered S-Germany up to more than 50 cm and increased the avalanche danger in the Alps.

In Hungary, the month started with temperatures around normal. From April 13 on, a very cold period brought enormous damage to flowering fruits and trees.

After a start with warm weather, Latvia was hit by snowstorms from the middle of the month on. After a 24h lasting snowfall, Riga had a fresh snow cover of 20-24 cm accompanied by frost down to –6°C; such an increment of fresh fallen snow has never been observed before in Riga in April. Traffic was paralysed by long lasting snowfalls, -storms and –drifts.

In Lithuania, temperatures in the first decade of the month were above normal up to +5°C. In the second decade, it became cool with temperatures below the average by –1...-2°C. Snowfall led to a snow cover up to 16 cm. During the third decade, mean daily temperatures rose significantly above normal by +3...+5.5°C.

The characteristic climatic feature of the month in Poland was an overall abundant precipitation rate of nearly 150%, compared to normal. Station Kielce received even 400%.

In Portugal, maximum temperatures at the end of the month were +12°C above the normal maximum temperatures. The return period of this event is estimated to more than 500 years.

Cyprus was hit by tornadoes, partly connected with hailstorms, before and at the end of a hazy period in the second half of the month.

In Israel, several sharav events occurred in the second half of the month, leading to sandstorms with severe haze in a warm and dry atmosphere. In the coastal area and northern Negev, maximum temperatures up to 39°C were observed at the end of the month.

A heat wave affected Georgia in the second decade of the month. Daily maximum temperatures up to 40°C were measured.

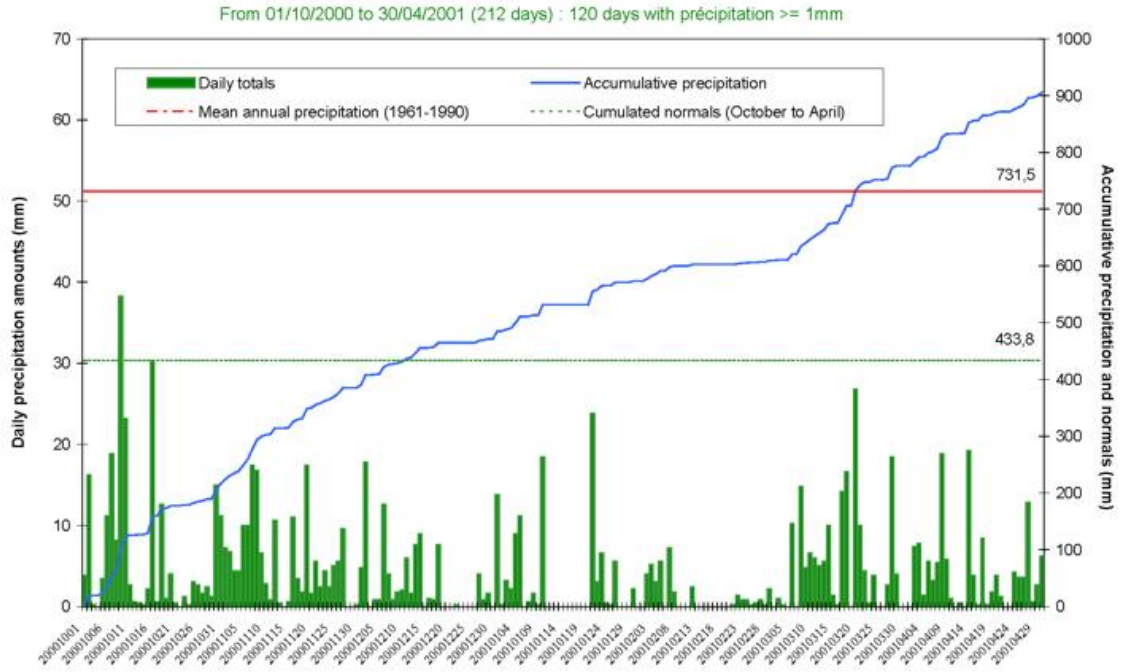

Fig. 4.1: *Daily and accumulated precipitation from October 2000 to April 2001 in Abberville, northern France*
From: Metéo France

May 2001

- **Much warmer than normal except in eastern Europe and the Middle East**
- **Very dry except in France and some parts of the Middle East**

Switzerland experienced the warmest May since 1868. The monthly mean temperature was above normal by +2.5...+4°C.

In the U.K., the month had a very warm start in Southampton (27.3°C).

In the Netherlands, the month was very sunny. Station De Bilt received 277 hours of sunshine, which is 136% of the normal value. This corresponds to the measurements at station Uccle in the neighbour country Belgium, where 130% of the average sunshine duration was observed (see fig. 5.1).

In Lithuania, the month started warm and dry. On May 1, maximum temperatures were up to 27°C. In the second half of the month, daily maxima of temperature fell below 10°C locally, and there were 17 nights with morning frost and minimum temperatures down to −6°C.

New records of the month were set in northern and southern Portugal for daily maximum temperatures by 35.6°C in Viana do Castelo and 37,0°C in Beja.

At the end of the month in Greece, maximum temperatures were up to 37°C and thus +5..+6°C above the long term average maxima of May.

In Slovakia, only 10 mm of precipitation fell during the month. So, it was the third driest May since 1901.

In Italy, especially in the northern and central parts, a long lasting period of very dry weather started in May.

France again suffered from continuous rainfall over several days causing floods in the Paris area and in the Atlantic Pyrenees.

On May 2-3, thunderstorms with hailstones of diameters up to 2 cm affected northern and western Germany. Precipitation amounts up to 110 mm caused floods and the interruption of transportation lines. On May 31, a tornado over Saxony damaged 26 houses and some forest areas, causing the material losses of several million Euro.

On May 8, hailstorms and heavy rains caused local flooding of houses and the destruction of dams in the Czech Republic; 62 mm of rain were measured on that occasion. On the last day of the month, a tornado was observed during the passage of a cold front, damaging houses and woods.

On May 29, a tornado over southern Poland damaged about 140 buildings in Morawczyna.

In the first half of the month, Cyprus was affected by severe hailstorms and heavy rains, leading to floods.

On May 2 in Israel, an unusually heavy rainfall occurred at station Jerusalem. 70 mm of precipitation fell within 4 hours (see fig. 5.2) and caused the flooding of 200 homes. This rainfall intensity was the highest since the beginning of measurements in 1950.

In Turkey, several hail events affected crops in different parts of the country.

On May 28, strong winds with gusts up to 122 km/h broke communication and power lines in Armenia.

In the second half of the month, numerous frosts ruined a lot of agricultural crops in Belarus.

Throughout 24 days of the month, intense frosts in the air and at the soil surface damaged agricultural crops in the Russian Federation. On May 14, torrential rains and hailstones of diameters up to 4 cm caused the damage of about 4500 homes and the death of 34 people in Stavropolsky Kray on the northern slope of the Caucasus mountains.

On May 7-8, landslides and mudflow interrupted traffic on roads and motorways in Kazakhstan.

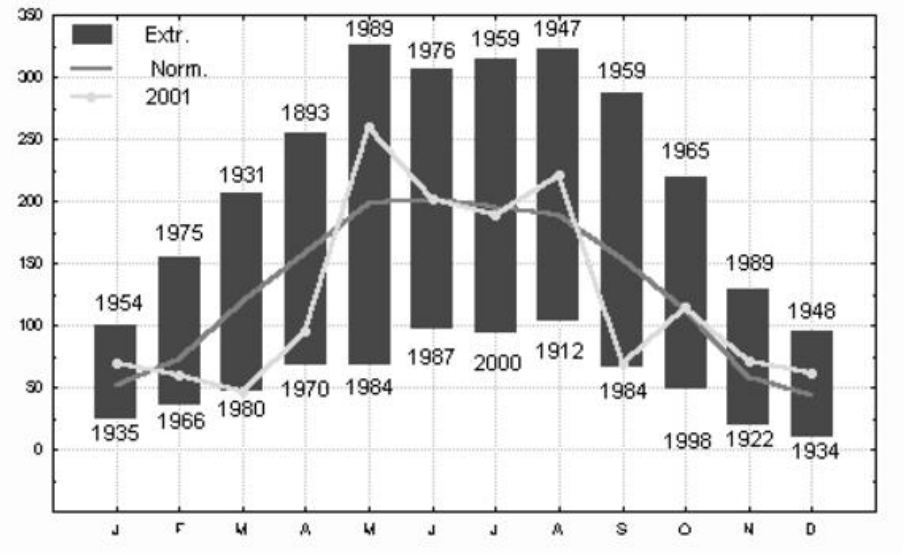

Fig. 5.1: *Monthly Sunshine duration at station Uccle (hours)*

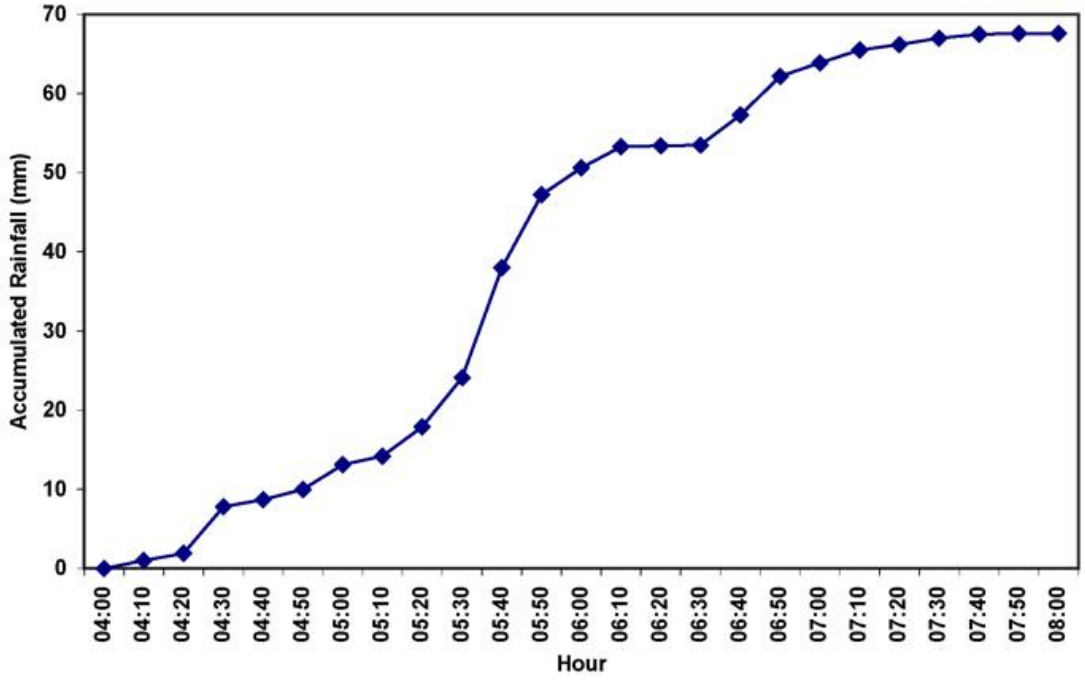

Fig. 5.2: *Accumulated rainfall in Jerusalem on May 2nd, 2001*
From: Israel Meteorological Service

June 2001

- **Cool in Central and East Europe**
- **Wet in some eastern European countries**
- **Very warm and extremely dry in southern Europe and the Middle East**

In Iceland, the month started with snowstorms over the northern lowlands. In the U.K. also, it was chilly during the first days of the month: on June 9, a minimum temperature of –1.8°C was recorded from Redhill station. Later on, it became very warm: the absolute maximum temperature of the year was observed on June 26 in Barbourne with 32.6°C.

The North of France suffered again from heavy rainstorms causing floods. In the north-eastern part of the Netherlands heavy showers accumulating to 60 mm of rainfall on June 15.

Gusts up to Beaufort 8 on Lake Constance (Austria, Switzerland, Germany) capsized several boats during a yacht race on June 15. Two ships were lost and 10 people injured.

On June 8-10, precipitation amounts of up to 230 mm were measured on the southern slopes of the Swiss Alps. This corresponds to a local percentage between 100 and 150 of the normal monthly precipitation.

A heat wave struck the Iberian Peninsula from June 22-24. Maximum temperatures were above 40°C (see fig. 6.1) and temperature anomalies up to +4°C in the central and south-eastern parts of Spain. The mainland of Greece was affected by a heat wave during the period of June 10-13: maximum temperatures reached values up to 39°C. Cyprus recorded a heat wave from June 12-15.

Germany experienced 2 major episodes of heavy rains, strong winds and thunderstorms: the first one from June 15-17 with flooding of houses, uprooting of trees, lightning damage to communication lines and traffic lights in the North. The second one from June 27-30 was even worse and affected areas all over the country; e.g. the airport of Stuttgart received 100 mm rainfall in 2 days leading to

flooding of buildings, streets and subways; in Castrop-Rauxel 42,8 mm precipitation fell within 1 hour including hailstones of a size up to tennis balls, which caused catastrophic damage to public and private property and injured a lot of people.

A violent thunderstorm with cloudbursts in Czerwinsk on June 28, was the most remarkable extreme weather event of the month in Poland. Hungary had a chilly June.

In Estonia, power lines and forests were damaged by thunderstorms and tornadoes. Latvia received abundant rainfall in the third decade of the month. On June 23, new daily precipitation records were set up in the East and the South of the country by rainfall amounts up to 72 mm. Wind induced surges and heavy rain made water levels of rivers rise up to 3 m and led to flooding of some localities for 10 days.

June was the coolest summer month in Lithuania with soil surface temperatures down to –5°C on the first two days and morning frost reaching –1°C in some places until the middle of the month. There were only 6 days without rain. On June 18, station Širvintos recorded 63 mm rainfall in 3 hours. On June 22-23, intense rainfall at stations Nida and Vėžaičiai amounted to more than the monthly normal precipitation. River levels rose enormously and caused the flooding of houses, streets and crop fields.

The month was also very rainy in the Ukraine, especially in the northern parts; up to 235 mm and 4 times the average precipitation were observed. On June 11-12, whirlwinds of destructive force caused catastrophic damage with the loss of human lives in the western and central parts of the country. On June 20-22, intense rainfall in Prykarrpattya caused landslides and the interruption of communication and power lines.

Moldova was affected by heavy rainstorms in the period from June 4-6. Precipitation amounts accumulated locally to 173 mm, which is twice the normal monthly precipitation. On June 5, an absolute record of 147 mm was measured; it exceeds the previously observed daily maximum by 30 mm in a 110 years' series. Agricultural lands were flooded and many buildings destroyed. The material losses are estimated to 1.5 Mill. Euro.

In the Russian Federation, torrential rains poured down on June 21-22 in Krasnodarsky Kray and in Karachevo-Cherkesiya. The rain was mixed with hail up to 30 mm in diameter, accompanied by strong squally winds and caused floods on the mountain rivers of the northern Caucasus with damage to economic facilities, homes, and more than 20,000 ha of agricultural crops.

In Tajikistan, the weather was hazy throughout the month. Maximum temperatures exceeded 40°C in Dushanbe and reached 47°C in the Isanbaya region. At Khumraga station, a maximum wind speed of 122 km/h was observed.

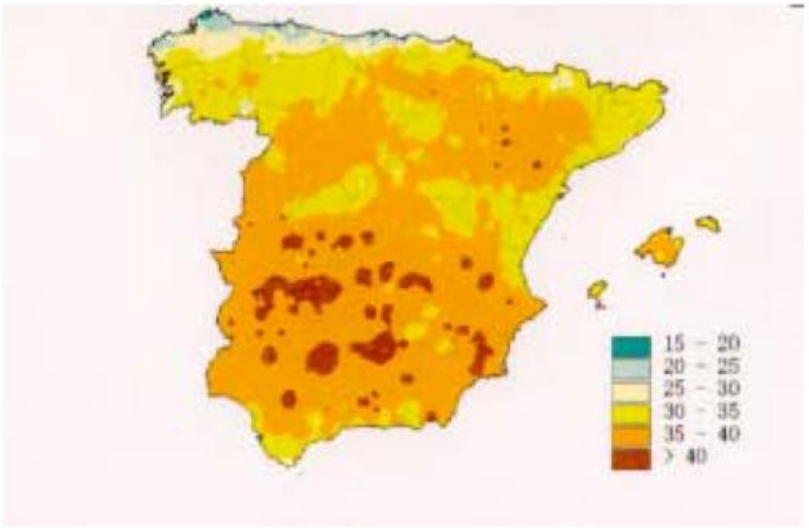

Fig. 6.1: *Maximum Temperatures (°C) in Spain from June 22-24, 2001*
From: Instituto Nacional de Meteorologia Spain

July 2001

- **Very warm in Central Europe and the Middle East, hot in eastern Europe**
- **Rainy in several eastern and some western European countries**
- **Extreme number of thunderstorms in Poland and the Baltic States**
- **Drought in the Mediterranean and in south-eastern Europe**

The month was very warm in southern Norway. The absolute maximum temperature of the year was 31.5°C, measured at Nesbyen station on July 5. The highest monthly mean temperature was observed at the Ferder Lighthouse by 17.8°C, which is +1.3°C above the long term average.

In Denmark, July was the sunniest month of the year; the spatial averaged sunshine duration was 309 hours. In Iceland, unlike in other parts of the Region, the month was rather cool with many afternoon showers.

Thunderstorms and Tornadoes in Estonia damaged houses and 7,000 ha of forests, 2 people were killed. Station Tartu recorded a mean monthly temperature of +4.1°C above normal, which is the third highest value since 1866.

In Latvia, it was the second warmest July since 1914. Subtropical air masses caused the rise of daily maximum temperatures above 30°C for 7 consecutive days. The sun duration was about 100 hours above normal. During the hot weather, the water temperature in rivers rose up to 27°C, exceeding the long term averages by up to +5°C. Thunderstorm events occurred more than twice as normal. On July 1, a thunderstorm accompanied by a spout caused the damage of hundreds of trees, a lot of cars, power lines and obstruction on roads in Riga; one woman was killed. On July 16, another thunderstorm combined with a whirlwind devastated forests in a 20 km long and 5 km wide zone.

In Lithuania, the mean monthly temperature was +4°C above the average. On July 16, the mean daily temperature was 28°C. This value was exceeded only twice in July during the last 50 years. The month was also very wet. There were 24 days with thunderstorms at various places and locally intensive downpour of rain, e.g. station Buivydžiai received 56 mm in 2 hours on July 9, and at Jovana hydrological station 55 mm were measured in 1 hour on July 26.

In Poland, the month was very warm and rainy. The country-wide monthly mean temperature was +2.5°C above normal. On July 9, a downpour of exceptional intensity combined with thunderstorms caused a local splash flood in Gdansk with disastrous consequences to the city. High rainfall rates were observed also in other places, e.g. a daily total of 127.7 mm at Rebiechowo airport. From July 15-17, severe thunderstorms with hail and intense downpours affected many areas all over the country. In Upper Silesia, a thunderstorm with rotor wall was observed on July 16; gusts exceeded 130 km/h and caused large damage to forests near Katowice. During this thunderstorm rapid and frequent pressure variations were measured. In the last decade, more extremely intense rainfall events were observed throughout the country; the most remarkable was on July 25, when station Makow Podhalanski received 190.8 mm within 4 hours.

At many stations in Ireland, the heaviest daily precipitation rates of the year were measured. Johnstown Castle in county Wexford recorded 84,5 mm rain on July 13-14, including a 2-hour fall of 65 mm. July 28 was the hottest day for most stations, e.g. Dublin airport recorded 26.9°C. In the U.K. localised flooding occurred in Nottingham as a consequence of 95 mm rainfall within 15 hours.

Exceptional rainstorms affected France in different areas. Frequent floods occurred in many watersheds, and again in the Somme area. Strong winds associated to a squall line caused 14 casualties to people attending a side-show in Strasbourg, due to tree fall.

In the Netherlands, severe thunderstorms with hail caused extensive damage in South Holland on July 5. On the Frisian island of Terschelling, a downpour of 70 mm rain in 2 hours caused local looding on July 19. Tilburg in the South of the country recorded 69 mm preciptation from heavy showers on July 23.

In southern Germany, heavy rains and storms with gusts up to 130 km/h hit the Black Forest on July 6; a lot of people were injured and 6 died from falling trees. Cars, railways and power lines were broken. Locally, 90 mm

rain fell within 4 hours leading to floods on roads and the interruption of transportation. On July 31, a tornado over Saxony cut thousands of trees, removed roofs from houses and hurt dozens of people.

On July 7, a cold front passage with gusts up to 120 km/h caused heavy damage to forest areas in Austria on a line from Salzburg to Vienna, 12 persons were injured from broken trees. On the lakes of the region, some sailing ships overturned, 1 man was killed.

Slovakia experienced the third rainiest July since 1871. Extreme precipitation totals were recorded from the Tatras region: 582 mm at station Zuberec, 521 mm in Javorina. The highest daily precipitation amount was 142 mm, measured at station Hronec on July 16, including a downpour of 40 mm in 45 minutes within the hour starting at 10 pm. Hundreds of villages were hit by floods, the total amount of material losses is estimated up to 50 Million Euro.

In Belarus, the monthly mean temperature was 22.1°C and thus +5°C above normal (see fig. 7.1). This is the highest value since the beginning of observations 120 years ago.

The Ukraine suffered from an intense drought. In Moldova also, the month was hot and dry. The monthly mean temperatures were up to +4°C above long term averages and the precipitation rate was only 20% of normal.

In the Russian Federation, torrential rain with hail and strong squally winds affected the city of St. Petersburg on July 16-17. On July 24, a thunderstorm with intense rainfall up to 50 mm in 2 hours, hail and strong winds damaged power lines and thousands of trees in Moscow. During a hot weather situation on July 21, photochemical smog formed in Moscow with extremely high values of surface ozone concentration in the afternoon. In the more southern areas like the Volga region and the northern Caucasus, it was not only hot but also very dry with the consequence of a high risk of fire.

In Turkey, the monthly mean temperature surpassed the averages by +3°C. The highest temperature was measured in Cizre by 46.7°C on July 25.

Cyprus experienced a heat wave.

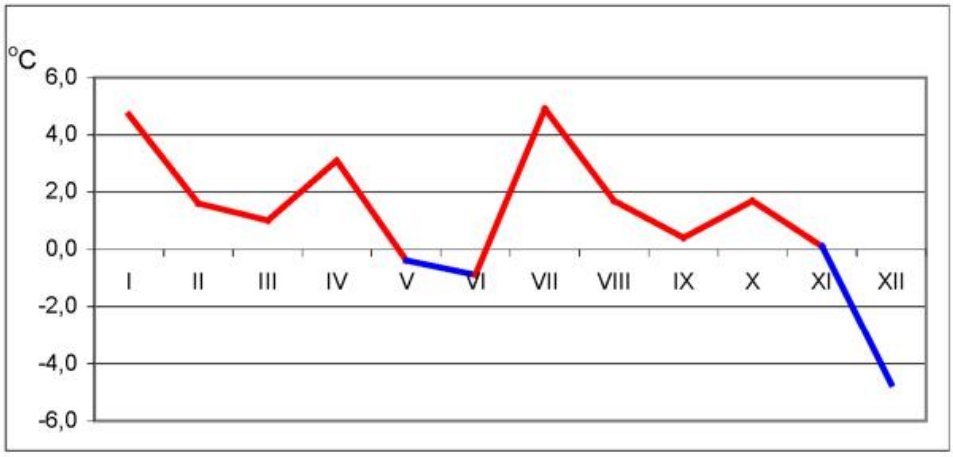

Fig. 7.1: *Deviation of monthly mean temperatures in Belarus from the norm 1961 – 1990*
From: Hydrometeorological Centre of the Republic of Belarus

August 2001

- **Warmer than normal nearly all over the Region, very warm in Central Europe and South East Europe**
- **Wet in the Netherlands, the British Isles, Scandinavia except the Northeast, and Turkey**
- **Dry in the Alpine region, extremely dry around the Mediterranean and north of the Black Sea**

In the Netherlands, the highest temperature of the year was recorded on August 26 in Maastricht with 34.2 °C. The period August 22-26 was marked by a heat wave with temperatures of 25°C or more and three days with maxima ≥30° C. The month was very wet:: Averaged over the country, 108 mm of precipitation was observed compared to 62 mm normally. Hoek van Holland recorded 216 mm. On 5 days at least 50 mm of rain was recorded at one of the Dutch stations. On August 5, 86 mm fell at Honselerdijk in the western part of the country. On August 2, severe gusts caused damage to trees in the province of Limburg. A tornado caused extensive damage to buildings, trees and crops on August 7 near the city of Nijmegen.

In contrast to the nothern neighbouring country, Belgium experienced a very dry August (see table on page 23).

A emarkable rain event in the U.K. was the fall of 56 mm within 12 hours in Northolt.

In Ireland, August was wetter than normal throughout the country. In Iceland, the weather during August was generally mild and fair.

In Austria, a lot of farm houses caught fire by lightning strokes throughout the month. An extreme hail event around Innsbruck caused heavy damage to buildings and agricultural areas on August 2. On August 20, a holiday camp and a reed area of 1 square km at Lake Neusiedl burnt down after lightning strokes. Station Graz airport registered a monthly precipitation of only 28 mm, which is only 24% of the normal and thus the lowest amount since 1951.

From August 3-4, heavy property damage caused by thunderstorms, hailstones and gales was reported from České Budějovice and Holešov, Czech Republic. The maximum wind velocities were up to 126 km/h.

In Bavaria, southern Germany, hurricane like winds with gusts up to 161 km/h devastated forests, homes and power lines on August 3; hailstones injured more than 50 people and accumulated to a layer of several cm on the ground, transportation was blocked on roads and railways. On August 6, a whirlwind near Osnabrück in northern Germany cut a 1 km long break into an inhabited area, causing severe damage to houses, cars and trees. On August 15, maximum temperatures of about 37°C were recorded from western Germany. On August 26, the country-wide mean of daily maximum temperatures was up to 35°C.

In Italy, the month was very dry with temperatures above normal by about two standard deviations.

Heat waves affected several areas of Greece, mostly mainland areas, during the period August 8-9. Maximum daily temperatures exceeded 40 °C.

In Slovenia, the monthly mean temperature all over the country was significantly above normal. Sunshine duration exceeded the long term averages everywhere in the country by at least 10 %, in some parts the normal was exceeded by more than 30 %. Precipitation was rare; in the South and Northeast of the country less than one fifth of the 1961–1990 normal fell with the consequence of a severe drought. On the coast and at station Kočevje, only 5 mm fell, which is 4 % of the norm.

In Poland, August was significantly warmer than the long term average with a precipitation rate near to normal. The highest temperature anomaly was recorded from Cracow by +2.9°C. On August 3, severe thunderstorms with strong winds were observed near Pila. Within the period of August 17-27, several thunderstorms and tornadoes caused a lot of damage to houses, forests and power lines in different parts of the country. On August 22, several fires were caused by lightning strokes in the vicinity of Cracow.

In Hungary, it was the warmest month of the year and the country-wide monthly

mean temperature was +2.3° above normal; in combination with a precipitation rate of only 60% from normal, there were nearly drought conditions.

On August 16, the Swedish capital of Stockholm was seriously hit by an extremely heavy thunderstorm: Three persons were killed and several more injured. On August 27, a powerful rainstorm first hit Uppsala and then even more seriously Sundsvall, two cities in the eastern part of Sweden. Around Sundsvall several roads and also the railway were disrupted due to erosion. Close to Sundsvall 134 mm of rainfall was registered within 24 hours, and a bit further to the north at station Rössjö, a new official Swedish record for daily rainfall in August was set by 160 mm.

An exceptional local rain event occurred in south-western Finland at Merimasku and Rymattyla on August 28: In a convergence zone, precipitation accumulated to 97 mm and 90 mm, respectively. The rain lasted for some six hours and the recurrence period of this event exceeds 100 years.

In Lithuania, the month was moderately warm and moist in the first half, but warmer and drier in the second half. It was raining frequently in the first and the second ten-day period. The heaviest rain occurred around the town of Ukmergė on August 18, amounting to 57 mm in 2 hours. Lowlands were flooded and mechanised harvesting was brought to a standstill, due to over-saturated soil. The third ten-day period was less wet; the monthly amount of precipitation was 69 mm and thus below those of June and July.

The hot weather in Moldova continued in August with an overall precipitation rate of less than 15% of normal. The number of days with a maximum temperature $\geq 30^{0}$C was twice of the normal value. Such an extreme drought event occurred for the first time during the last 50 years in this country.

Drought conditions in the Ukraine lasted throughout the month, especially in the steppe and forest- steppe zones. Dry wind events occurred up to twice the normal number. The heat wave was occasionally interrupted by showers from squall-lines, sometimes including hail.

In southern parts of the Russian Federation, especially the Lower Volga region, the month was very warm and dry. These drought conditions caused the loss of more than half of the crops. Additionally, an extremely high risk of forest fires continued throughout the month in the Volga region and the Northern Caucasus.

The drought in Georgia, which started in June, ended in the third decade of the month. Then, within 4 days the normal monthly precipitation amount was nearly reached or even exceeded at most stations.

In northern and western areas of Turkey, hailstorms damaged houses and agricultural areas, and caused the death of two children in the period from August 21-23.

In Armenia, 80 mm of rain poured down during 6 hours at the station Ashotsk on August 23. This amount of rain equals twice the normal monthly precipitation. The consecutive floods caused considerable material losses.

In Israel, August was very warm with temperatures up to +2.0°C above normal. Nights in the Coastal Plain were especially warm. On August 10-11 the daily minimum temperature in Tel Aviv was 27.5°C.

September 2001:

- **Extremely wet and rather cool in Central Europe and the northern Balkans**
- **Very warm in Greece and Turkey, drought in the Caucasus region**

In the northern Balkan states, the month was extremely wet (e.g. see fig. 9.1). Cloudy and rainy weather was prevailing in Slovenia and the month turned out to be very wet (see fig. 9.2). The Julian Alps were the rainiest region; more than 500 mm fell on some measuring sites. The 1961–1990 normal values were exceeded everywhere, in the south of Slovenia precipitation rates were between 250% and 300% of normal. In the Julian Alps, where abundant rain in autumn is frequent, there fell more than 150 % but less than 200 % of the normal precipitation. The mean air temperature was well below the 1961–1990 average, the largest anomaly was in the high mountains by around -3°C. Sunshine duration was well below normal everywhere in the country, only 55% to 80% of the average sunshine duration of the period 1961–1990 was observed.

Extraordinarily high precipitation rates were recorded from Yugoslavia with maxima in Zrenjanin and Novi Sad (see fig. 0.8).

In the Federation of Bosnia and Herzegovina the overall rainfall rate was more than 300% of normal and especially at station Tuzla the monthly precipitation amounted to 304 mm, which is 475% of the normal value.

Hungary experienced also a very wet September. The country-wide precipitation rate was about 250% of normal (see fig. 9.3). In several places rates up to 400% were observed. The maximum of the 24-hours precipitation total was measured at station Bakonyszücs in 704 m by 132 mm on September 5. The return period of such an extreme event is more than a hundred years.

In Poland, similar to some neighbouring countries, the weather was dominated by a cyclonic circulation pattern. As a consequence, the precipitation rate was country-wide near to double of the long term average. At stations Zielona Gora and Czestochowa the monthly totals of precipitation exceeded even 300% of normal. The monthly mean temperature was moderately below normal by –0.5°C. A severe storm was observed over the Baltic Sea on September 8; lots of trees were uprooted at the seashore near Slupsk and Koszalin.

Lithuania had a rainy, but not too cold month. There were 22–26 days with rain in the western parts of the country while only 14–18 in the eastern regions. Thus, the amount of precipitation was very uneven varying from 47 to 191 mm (70–170 percent of normal). By the end of the month the weather cooled down to morning frosts from 0 to –4°C, at some places to –8°C.

In Sweden, two major precipitation episodes occurred in the first decade of the month. First, the area around Sundsvall was flooded after heavy rains on September 6. Two days later, 108 mm rain was measured within 24 hours in the southern part of the generally dry island of Öland.

Within the last week of the month, tornadoes affected different parts of Ireland. On September 25, a funnel cloud was observed in County Galway accompanied by some localised heavy thundery showers. On September 30, a frontal trough moved eastwards across the country and brought a spell of heavy rain to most areas. Embedded within the front were a number of thunderstorms, at least two of which developed into tornadoes over the midlands. One of these followed a track through County Westmeath for approximately 5 miles. Winds associated with the tornado broke large branches from mature trees along its length (see fig. 0.12), while a 40 m² section of roof from a farm building was lifted over a road and fell almost intact in a field over 100 m away.

September was extremely wet in the Netherlands with a country-wide average of 177 mm rainfall (normal: 75 mm). The month ended in De Bilt as the second wettest on record since 1901 with 211 mm (213 mm was measured in 1953). Hoek van Holland again recorded the highest amount of precipitation: 289 mm, approximately 35% of the normal annual amount. 107 mm fell in 21 hours on September 19. On that day, more than 50 mm fell in a large part of the province Zuid-Holland resulting in flooding in the Westland area.

Precipitation all over Germany was more than twice the normal value, while temperatures were significantly below the long term averages. In northern Germany near Hamburg, heavy rains of more than 30 mm

together with hail caused flooding of streets, subways and houses on September 26. In Austria, a monthly rainfall amount of 159 mm was recorded from station Eisenstadt, which is 350% of the normal precipitation.

In Switzerland, September was wet and cool with very little sunshine in the Alps and north of the Alps. In higher mountain areas the month was 3.5 to 4.5°C colder than normal – the coldest since 1972. From September 9 to 17 occasional snowfalls occurred down to terrain of 1500 m–1200 m asl. On the northern slopes of the Alps and in the neighbouring regions of the Mittelland and the Jura this was the September with the least sunshine since records started in 1901. The rate of sunshine reached 30-60% of the normal monthly total.

Italy experienced an intense cold period throughout the month, characterized by temperatures lower than normal by more than a standard deviation at about 50% of the stations and with precipitation much above normal in the Po valley and over the Alps.

In central and southern parts of Ukraine, intense rains of 90-110 mm during 4-12 hours caused the flooding of a great number of homes on September 26.

In the Russian Federation, 1 man was killed and 37 people injured, when a tornado hit the north-eastern coast of the Black Sea near Sochi at the beginning of the month. Additionally, many houses and power lines were damaged and energy and water supplies were cut off.

In Greece, unusual high temperatures by +5...+10°C above normal were recorded from almost all over the country. The daily maximum temperature varied between 34°C and 37°C. In Turkey also, the overall average temperature was significantly above normal by +1.5°C.

The monthly precipitation amount in Armenia was much below normal (fig. 0.9) and caused, together with positive temperature anomalies, severe drought conditions throughout the country. In Georgia, the weather was also generally hot and dry. Nevertheless, a hailstone event on September 18 caused heavy damage to vineyards in the Gurjaani and Telavi regions on September 18.

October 2001

- **Record breaking warm in Central Europe**
- **Extremely dry in south-eastern Europe**

Nearly all over the Region, the monthly mean air temperatures were above normal (see figs. 0.1, 0.2, 0.3, 0.6, 0.15). In Central Europe, they were extremely high and exceeded September means at many places (see tables on page 23). For example, at the Dutch station De Bilt, this had happened never before since the beginning of observations in 1706. Additionally, the month was very dry in the middle of Europe and extremely dry in the Mediterranean and in a broad strip from Poland southwards over the Balkans to Turkey.

In Norway, the overall monthly mean temperature was +1.7°C above normal. The most southern coastal areas experienced the warmest October since the measurements started in 1874, and they are the northern border of the area with warmest October on

record in Denmark and further south in Europe.

In Denmark, October was record breaking warm and without any frost. With a mean temperature of 12.0°C, the month was 2,9°C above the normal of 1961-1990 and 0,6°C warmer than the earlier record from October 1995 and thus the warmest since the start of observations in 1873.

In the U.K., the rain of the preceding month continued. Cambridge had 90 mm of rain on October 21 causing severe flooding in the adjacent county. But October was also a record-breaking month, being the warmest on record since 1659, with a mean Central England temperature of 13.3°C, which is +2.7°C above the 1961-1990 average. The continuity of high temperatures during the month is shown by fig. 10.1.

October mean temperature was 13.4°C and had never been so warm since the start of regular temperature measurements in the Netherlands in 1706, and for the first time since then, October was warmer than September.

In Belgium at station Uccle, the monthly mean temperature was 14.4°C and thus +0.4°C higher than the preceding record from 1921 and the highest since the beginning of observations in 1833. On October 6, a tornado caused severe damage in areas around Brussels.

In Luxembourg, the monthly mean air temperature was the highest since 1947 with 12.7°C and thus +1.4°C higher than for the preceding September.

In France also, October was an exceptionally warm month with record breaking temperatures. For a large portion of the country, it was the warmest October since 1949, after October 1995, with temperatures as much as 3°C or 4°C above average (see fig. 10.2). On October 29-30, daily temperature maxima up to 30°C were measured at several stations, exceeding records of earlier years since the beginning of observations between 1947 and 1959. Some exceptional rainy and stormy events took place in the Southeast leading to floods in the periods of October 6-9 and 17-20. On these last days, two tornadoes caused much damage close to Montpellier and Perpignan.

The country-wide monthly mean temperature in Germany was 12.5°C and thereby the highest since more than 100 years. On October 2, a daily minimum temperature of 14.9°C was measured at station Potsdam, which is the mildest night since the start of records in 1893. On the same day, a maximum temperature of 29.5°C was observed in Altenstadt and of 27.8°C in Munich, which was the second warmest day of October since 1923 (28.2°C). On October 1, a whirlwind with gusts up to 100 km/h damaged the roofs of 50 houses in a row of 1.5 km in Lower Saxony. On October 31, a stormy depression affected the area north of Berlin with wind speeds up to 115 km/h, uprooting a lot of trees near the coast of the Baltic Sea; 1 man was missed from a capsized sailing boat.

In most places in Switzerland, it was the warmest October since records started in 1864. The month was +2.5°C...+5°C warmer than normal. In the highest regions of the mountains, October was 4°C to 5°C warmer than the preceding September. On October 2, station Chur registered 29.4°C and the mountain station Jungfraujoch +3.9°C in 3580 m above sea level.

In Italy, October was quite dry and warm, particularly on the coastal region in the central and southern part.

The general temperature anomaly in Poland was +3.1°C with a maximum of +3.8°C at station Cracow. The country-wide precipitation rate was 73 % of normal and in S-Poland below 50%.

The relatively warm October weather in Lithuania was predominantly determined by southern edges of Atlantic cyclones, except a steady cold spell of the fifth five-day period caused by a sudden southward move of a northern anticyclone. The monthly mean air temperature was 9.1ºC (+1.9ºC above normal). The monthly amount of precipitation (64 mm) was close to normal at most places, whereas the heaviest rainfalls occurred in the beginning and in the end of the month.

An intense cyclone caused large problems for transportation lines in southern Sweden on October 31, e.g. the bridge over Öresund had to be closed. Additionally, electricity supply was interrupted for about 15,000 families. The highest wind gusts reported were 133 km/h in the Stockholm archipelago.

At Hurbanovo observatory in Slovakia, the mean monthly temperature was + 3.3°C above the average of the normal period 1961-1990, which is the fourth highest record since 1871.

In Slovenia, the mean air temperature in October was well above the 1961–1990 norm, the anomaly was mostly between +2°C and +4°C and statistically significant. In some regions the monthly mean air temperature was even slightly higher than that of September. Sunshine duration exceeded the 1961–1990 average everywhere in the country. There was even more sunshine than in September this year. As mostly sunny weather was prevailing, October turned out to be quite dry. Precipitation was well below normal everywhere in the country.

In Hungary, the country-wide precipitation rate was only 15% (see fig. 9.3) and the overall monthly mean of the temperature +3°C above normal (see fig. 0.6).

In Greece, unusual high seasonal temperatures, significantly +5°C...+8^{0}C above normal, were reported from most parts of the country during the period October 4–24. The daily maximum temperatures varied between 29°C and 33°C.

In Iceland, the weather was generally mild and good. The eastern districts experienced a few days of heavy rain with landslides blocking roads for short periods. On October 18, the temperature in Reykjavik reached 15.6°C, which is the highest ever so late in the year.

In Ireland, mean temperatures for October were well above normal. A localised downpour in county Waterford produced 124 mm of rain in the 2-day period of October 19-20.

The mean monthly air temperature was near to normal in Georgia. The first half of October was warm and dry for the territory of East Georgia. On October 17-19, precipitation amounts of 25 mm-45 mm were very welcome to replenish the soil surface water content. From October 20 to the end of the month, there was not more than 5-10 mm of additional precipitation over most of the territory.

Rainfall amounts in Israel were not homogeneous. They were above normal in the Coastal Plain and below normal in the inner parts of the country.

November 2001

- **Violent Storms in many places of the Region**
- **Very wet in Greece and Turkey**

In Iceland, a very dry westerly storm caused some material damage and local disruption of electrical power because of unusually heavy sea-salt deposition on electrical transformers on November 10. The last week of the month brought unusually heavy snowfall to the south-western part of the country.

In Ireland, the highest gust of the year was measured at Malin Head by 122 km/h on November 8 (same record as on March 6).

On November 15, a severe storm affected the middle part of Sweden. Lots of trees were uprooted, constituting a volume of 2 million cubic metres of wood.

Finland was hit by two violent storms at the beginning and in the middle of the month. The first event, in western Finland, started with sleet and freezing rain. Considerable amounts of ice were accumulated on trees and caused, together with upcoming gale force winds, the fall of lots of trees. The second violent storm occurred in south-western Finland on November 15-16 and caused also severe damage to forests. The clearing of this devastation took more than half a year and the economic losses of the forest owners were large in both cases.

Latvia experienced two major storm events. The first one occurred on November 1:

Westerly winds drove enormous water masses from the Baltic Sea into the Gulf of Riga; then, even stronger winds up to 112 km/h from the Northwest caused the rise of the water level in the estuary of the Dauga River up to 1,60 m above normal. The second extreme wind event was a thunderstorm on November 15-16. This time, the water level of the Dauga River exceeded the critical mark of 1,70 m, which is observed only once in ten years. The wind caused damage to the electric power supply of many districts. Latvian ports were non-operational. Traffic on land was made difficult or paralysed because of fallen trees on roads and railways. The roofs of buildings in Riga, some of them of public interest, were damaged or blown away. About 20 people were injured, and one woman was killed. A stable snow cover was formed in the eastern part of the country since November 13 and in central Latvia one week later.

November was the windiest month of the decade in Lithuania. The strongest winds with gusts up to 115 km/h were observed at the Lithuanian seaside on November 1, 11 and 15. These strong winds caused significant damage to the infrastructure in western Lithuania and impeded marine operations. There were 20 days with bad fishing conditions in the Baltic Sea. In the north-eastern region a steady snow cover of 3–9 cm formed since November 13.

On November 1, very strong winds caused lot of damage in N- and NE-Poland. On November 29 the international airport of Warsaw was closed for half a day, due to exceptionally dense fog. A lasting snow cover appeared in Poland at the end of the month.

Although the monthly mean wind speed in Belgium was significantly below normal, the strongest storms of the year were recorded from the Belgian coastline with more than 100 km/h on November 8.

Strong winds crossed Germany under a westerly upper air stream on November 8. Gusts up to 137 km/h were recorded at station Feldberg in the Black Forest. In Frankfurt/Main scaffolding broke down and smashed parking cars. In a place near Osnabrück in Lower Saxony, a whirlwind uprooted trees and damaged cars and the roofs of 40 houses. Starting at the same day, snow fell in many parts of the country in several episodes until November 22. Five people were killed and many more injured by more than a hundred accidents on slippery roads, and numerous trees fell down under the weight of fresh fallen snow.

In the Czech Republic, local damage caused by strong winds was recorded on November 11.

In the middle of the month, snow and ice disrupted traffic on roads in south-eastern France. In Switzerland, a long lasting drought period started in this month.

In Hungary, Croatia, and Bosnia and Herzegovina, the national monthly mean temperature was significantly below normal.

In Slovenia, anomalies exceeded –2°C at several places. On November 9, snow fell over most of the country. The monthly mean sunshine duration exceeded normal everywhere in Slovenia, in most places by 40% up to 60%.

Although dry on a monthly time scale, Spain recorded torrential downpours on the occasion of some extreme local events. E.g., 125.7 mm of rain fell within 24 hours in an episode on the island of La Palma (Canary Islands), leading to several mortal casualties. On November 9, a tornado was observed in the town of Motril near Granada (see fig. 11.1); a nearby camping area suffered from material losses.

Heavy rains and thunderstorms affected central and southern parts of Greece on November 2-5. These extreme conditions led to floods in East Sterea and Attiki with destructive consequences to the infrastructure of the region and the loss of three people. Again, during the period November 28-30, heavy rains and thunderstorms occurred almost all over the country, mainly in the western part and in the East Aegean islands, where the island of Samos was extremely hit by devastating floods.The monthly precipitation amount in several areas of the country (Peloponnisos, East Sterea, Attiki, Cyclades, Crete, Dodecanisa, Islands of East Aegean) was twice to three times greater than normal and thus higher than ever recorded before.

Fig 11.1 : *Funnel cloud of a tornado near Granada on November 9 From: Instituto Nacional de Meteorologia Spain*

In Turkey, the national monthly mean precipitation rate was about 200% (see fig. 11.2). Several extreme rainfall events, some of them combined with storm, caused severe damage to buildings, bridges and agricultural areas, at least 6 people died. Such events were recorded from Rize on November 10, Izmir on November 14, Anamur on November 21 and 24, and Alanya on November 24.

In Cyprus, heavy rains, severe hailstorms with gale force winds and flooding occurred on November 29. Stormy weather was also recorded on November 17.

In Belarus, a positive temperature anomaly continued from the preceding month until November 20. Then, cold weather in the last decade lead to a balanced monthly mean of the country-wide temperature compared to the long term average.

In Israel, rainfall was distributed non homogeneously over the country. Rainfall amounts were above normal in the Coastal Plain and in the Judean Mountains (120%-140% of normal), but in the Galilee and in the Northern Negev they were below normal (60%-80% of normal).

In Jordan, the national monthly rainfall amount was above normal.

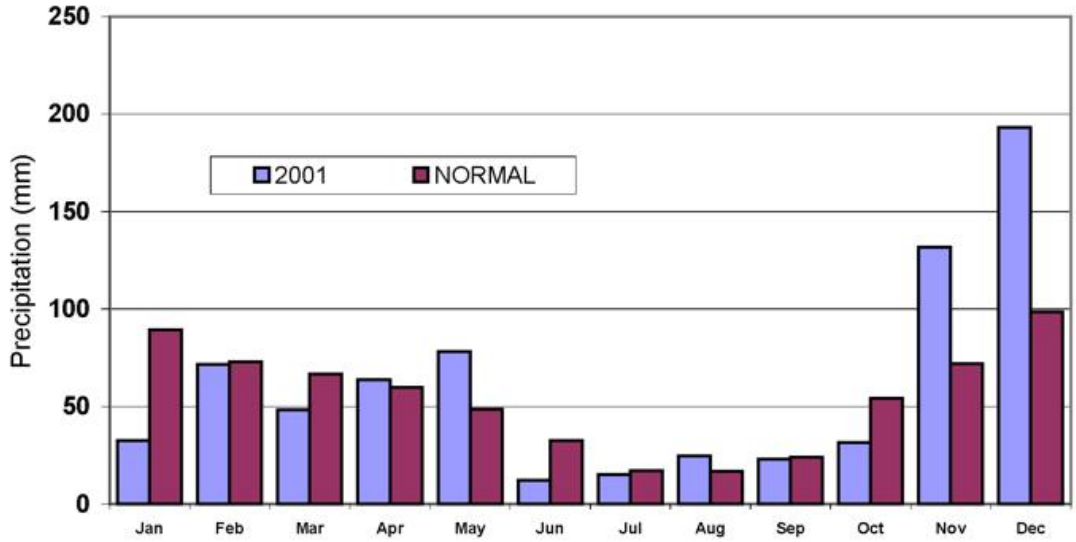

Fig. 11.2 : *Monthly precipitation in Turkey From: Turkish State Meteorological Service*

December 2001

- **Extremely cold in southern and eastern Europe**
- **Record breaking daily maximum temperatures on islands in the Norwegian Sea**
- **Very dry in the Alps, Italy, the northern Balkans and eastern Europe**
- **Wet and cold in the Middle East**

In France, December was very cold, especially in southern parts (see fig. 0.5.), where the temperature average during 14 days (December 14-27) was the coldest since 1949. Snowfall affected large areas of the country. Nevertheless, dry conditions prevailed in the Southeast.

December was very cold in most parts of the Iberian peninsular except for the southernmost areas. Monthly mean temperatures in the centre and the northern half of Spain were down to 4°C below normal. All-time records of low monthly mean temperatures were set in the observatories of Cataluña and Aragon for series, that started more than 60 years ago. Station Zamora in the Duero Basin recorded -10.6ºC, which is the lowest value of its 90-year long series. On December 13, an easterly circulation pattern initiated a very cold phase, that culminated on December 16 and 25.

December was extremely cold in Portugal. Rivers froze and water pipes broke down due to negative temperatures that are unusual in the north-eastern part of Portugal. The record of daily minimum temperature was exceeded in Viana do Castelo, where -5.0 °C was observed. Heavy rains and strong south-easterly winds in the southern mainland areas caused floods and road obstruction. The weather conditions in Terceira Island, Azores, caused damage to the breakwaters, located at the northern and eastern coast of the island. Heavy rains in S. Miguel Island caused floods and road obstructions.

In Greece, heavy rains and thunderstorms occurred during the period December 15–17, affecting the areas of western Greece, Peloponnisos, Aegean, Crete and Dodekanisa. Severe snowfalls occurred almost all over the country, mainly in the northern and central part. The snow depth reached 1.5 to 2 m in many areas. Due to these snowfalls, several aerodromes in the North of the country remained closed for 3 to 4 days. Also many roads in several areas were closed. Floods were recorded on December 16 in the north-western Peloponnisos, which resulted in catastrophic damage to the infrastructure and the loss of two lives. Unusual low daily temperatures and frost were recorded in most areas of the country on December 19-20. Particularly the minimum daily temperatures recorded were the absolute lowest temperatures ever measured since the beginning of observations.

The monthly mean temperature in Poland was significantly below normal by -2.5°C. The anomalies were smaller in the Northwest and larger in the Southeast, where the station Lesko recorded the largest deviation from normal by –4.8°C. A snow cover existed during the whole month. Sometimes, snowdrift caused trouble on roads. Only in W-Poland the snow depth was less than 10 cm (see fig. 0.10). The highest snow cover in the lowlands of Poland increased up to 50 cm at station Suwalki. In the mountains, the snow cover exceeded 50 cm at the end of the month, engendering most dangerous avalanche situations. Four persons died in the Tatra Mountains and one tourist in the Sudety Mountains in avalanches on December 31.

December was the coldest month of the year in Lithuania with a country-wide mean air temperature of –5.6°C, which is 3.2°C below normal. It was one of the ten coldest months of December on record in the past century. In the first half of December snowfall was mostly insignificant, but then became steady and formed a snow cover of 18–41 cm at the end of the month in many places. At station Nida, the snow cover accumulated up to 60 cm. The monthly amount of precipitation was close to normal in most parts of the country, except at the seaside, where it was up to 140% of normal.

In Latvia, the already existing snow cover was replenished during December and increased up to 40-50 cm at the end of the month. Maximum snow depths were recorded from stations near the Baltic Sea. Heavy snowfall and snowdrift made roads impassable at times in many parts of the country. In Estonia, a minimum temperature of –34.6°C was measured on December 25. The month

brought a new record of sunshine duration by 53 hours.

December was the coldest month of the year in Belarus (see fig. 7.1). Generally, the coldest month in Belarus shifted from January to December during the last decades. This is evident from table 12.1.

In Ukraine, the monthly mean temperature was 4°C-5°C below normal, which is extremely low for the whole period of observations.

	I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII
1881 - 1990	-6,7	-5,9	-1,6	5,8	13	16,2	17,8	16,5	11,9	6,2	0,7	-4,0
1989 - 2001	-3	-2,6	0,8	7,8	12,8	16,5	18,2	17,1	11,7	6,6	0,2	-3,8

Table12.1 : *Monthly mean temperatures in Belarus in °C for two differents reference periods*
From: Hydrometeorological Centre of the Republic of Belarus

At station Brezová pod Bradlom in Slovakia, a maximum snow cover of 39 cm was measured in December. This was the highest value observed in the Slovakian lowlands since 1921.

After the first week of the month, December turned out to become extraordinarily cold in Hungary (see fig. 0.6). The absolute monthly minimum temperature was below -15°C at all stations of the country except for Sopron, while in most parts of western Hungary this value was even below -20°C. The lowest daily minimum temperature was measured in Orosháza by –26.1°C on December 25.

Cold arctic air masses also affected Yugoslavia in December. Consequently, mean monthly temperatures dropped below normal by deviations of –2.3°C...-5.7°C. As an example, fig. 12.1 shows the daily mean temperatures of the month at station Sombor compared to normal. The coldest part of the country was the North with minimum temperatures below –22.0°C. This December was one of the seven coldest in Belgrade since the beginning of observations 113 years ago.

In The Former Yugoslav Republic of Macedonia, the national monthly mean temperature was extremely below normal by -5.8 °C.

The weather station on the island of Jan Mayen, Norway, measured a maximum temperature of 12.3°C on December 14. This is the highest temperature measured at the station in December since the start of observations in 1921 (the old record was 8.0°C from Dec 16, 1997). It was also the highest temperature measured at the station during 2001.

In Iceland, the first decade of the month was very stormy and a fishing boat was lost at sea, only one man was rescued. On the evening of December 13, the temperature at a coastal station in the north (Sauðanesviti) reached 18.4°C, which is a new absolute maximum in December for the whole of Iceland. This temperature is 1°C higher than the absolute maximum of the whole year 2001 in Reykjavík. Until Christmas, the weather continued to be very warm, but a cold snap during the last week of the year prevented a new monthly mean temperature record being set.

The drought in Switzerland south of the Alpine ridge continued throughout the month. These conditions engendered severe danger of forest fires. A remarkable cold spell occurred on December 13. Therefore the lowest December temperatures since 1962 were registered in the highest regions of the mountains, e.g. –30.7°C at the station Jungfraujoch.

Drought conditions prevailed also in Italy throughout the month, including the Alpine region and the Po valley. About 60% of the meteorological stations recorded a precipitation much below normal. The mean monthly temperature was below normal mostly in southern Italy and in the islands.

In Slovenia, the monthly mean air temperature was well below the average of 1961–1990. The anomaly in the Julian Alps was –4°C and in other parts of the country between –3°C and –1°C. The national precipitation amount was far from normal. No station recorded more than 60 % of the normal value. In Zgornjesavska valley, the precipitation rate was less than one fifth of the norm. Although the snow cover was not very deep, it was quite persistent and the number of days with snow cover mostly exceeded the

long term average. In the high mountains, the snow cover was not so deep as usual in December. In correlation with a low precipitation rate, sunshine duration was above normal everywhere in the country (see fig. 12.2). The central part of Slovenia got significantly more sunny weather than the mountain and coastal areas. Ljubljana enjoyed 86 hours of sunny weather, the normal is 37 hours.

In Turkey, the month was rather cold (country-wide monthly mean temperature 1°C below normal) and very wet (country-wide precipitation rate 190% of normal). A lot of extreme weather events occurred throughout the month in different places all over the country. Heavy rains, strong winds, snow storms and severe cold caused flooding and damage of houses and agricultural areas, destruction of transportation devices on land and at the seaside and the loss of lives.

In Cyprus, December was very wet with a monthly precipitation amount above twice normal. Heavy showers and flooding in various periods during the month, especially in the first week, accompanied by gale force winds and severe hailstorms, caused damage to agriculture and properties and also caused a lot of inconvenience to the population. Damage was also caused to boats and fish farm establishments at sea. However, rainfall was very beneficial to the water resources of the island.

December was cool and rainy in Israel. Rainfall amounts in most parts of the country were 120%-160% of normal. The most intense rainfall occurred on December 3-6 with 100 mm-150 mm in northern and central Israel. The coastal plain near the Carmel region received 200 mm-250 mm, and in Zikhron Yaakov there were more than 300 mm. Within two days (December 3-4) Zikhron Yaakov received 285 mm. In the last 90 years, in all parts of Israel, there were only 3 times in which larger amounts of rainfall were recorded for two successive days. A record hourly rainfall was recorded in Zikhron Yaakov with 75 mm in one hour on December 4. As a result of the heavy rains there were floods in the area as well as in other parts of the country. One person died, many homes were evacuated and there was large damage to roads and to agriculture. In the entire month there were 425 mm of rain in Zikhron Yaakov, the rainiest December since the beginning of measurements in 1915 (see fig.12.3).

Snowfall and strong winds restricted transport in Armenia on several days in the second half of the month in Armenia. In Tashir, wind velocities of 84-90 km/h were observed lasting for more than 10 hours on December 18; gusts were up to 122 km/h.

In the territories of Krasnodar and Stavropol, Russian Federation, heavy snowfall formed a snow cover in the period from December 18 to the end of the month. Black ice and hoar-frost affected transportation facilities and power lines. On December 24, melting snow and rain engendered the flooding of several localities.

In Sweden, the month started very mild. But from December 20 on, very cold air dominated the weather for the rest of the year. Heavy snowfall and temperatures close to zero caused serious problems to energy supply and traffic. Especially the south-western part of Sweden was affected; there, up to 15,000 families were without electricity after Christmas. New records of December minimum temperatures were set in Vänersborg (-25°C) and Visby (-22°C) in southern Sweden, stations with more than 100 years of observations.

In Denmark, December was near normal except the last 10 days of the month, which were dominated by frost and at times heavy snowfall.

In Germany, the month was rather cold, especially in the second half. At station Oberstdorf, -30°C was measured at the surface of the snow cover in the night of December 23-24. In the funnel-shaped mountain valley of Funtensee, -45,9°C were recorded in the same night. During the period from December 15-29, snowfall and freezing rain lead to numerous accidents and chaos on roads and motorways all over the country. E.g. on December 21-22, circa 100,000 drivers and passengers spent the night in their cars on a 150 km stretch of a motorway in Bavaria. Aviation and railway traffic was also blocked as a consequence of fresh fallen snow up to 70 cm. In eastern parts of the country, strong winds of about 100 km/h engendered snow drifts forming a snow cover up to 2 m on December 24-25.

In the Netherlands, the lowest temperature of the year was –17.0°C, recorded from station Nieuw Beerta on December 23. On December 28, a gust of 158 km/h was recorded at the coastal station IJmuiden.

In Luxembourg, a new record of sunshine duration for the month of December was set by 91.4 hours.

Activities and Results of European Climate Centres

Report on ECSN activities

by: Walter Kirchhofer, *MeteoSwiss*

- **General remarks**

The EUMETNET Council has designated MeteoSwiss as Responsible Member for the EUMETNET ECSN Programme, starting on 1 January 2001, with Dr. Walter Kirchhofer as Programme Manager.

The ECSN Advisory Committee (EAC) elected Volker Vent-Schmidt as new Chairman of EAC.

The third ECSN-Workshop on Climate Databases has taken place in Langen, Germany, 12-13 November 2001, focussing on climate data exchange and data quality. Since the EUMETNET project UNIDART (Uniform Data Request Interface) is considered to be a suitable project to develop an infrastructure for a border-crossing exchange of climate data, UNIDART was the

main discussion topic. A list of requirements has been prepared for the realisation of the pilot phase and further steps of UNIDART.

At the thirteenth Session of the WMO Commission for Climatology (CCl) in Geneva, 21 to 30 November 2001, a part of the session was devoted to scientific lectures, including a presentation of the main activities of the EUMETNET ECSN Programme.

- **European Climate Assessment (KNMI)**

In the European Climate Assessment (ECA) project the temperature and the precipitation climate was analysed for WMO Region VI, putting particular emphasis on changes in daily extremes. ECA aims at applying uniform analysis methodologies to daily observational series from as many European meteorological stations as possible. About 35 countries participate in the project and the data set contains data from over 200 stations. The project focuses on the twentieth century from 1901 to 2000. The Final Report will be published in spring 2002.

- **Generate Climate Monitoring Products (DWD)**

The status of the project Generate Climate Monitoring Products (GCMP) has been reviewed and a proposal was elaborated concerning the continuation of the project up to the end of the year 2003. It is obvious that European Meteorological Services should provide first hand information about climate variation and derived products for monitoring purposes. With this in mind the project GCMP was started, aiming at developing, generating and distributing standardized climate monitoring products on a monthly as well as on an annual basis. Monthly mean temperatures and anomalies, precipitation and anomalies, satellite cloud cover, and quite a number of other example products are already contained in the clearly structured mechanism on a test version of the GCMP Web pages.

- **Climate Atlas of Europe (Meteo-France)**

The project Climate Atlas of Europe is established for a duration of three years, starting on the 1st of January 2001. The Atlas will contain monthly normal values for precipitation, temperature, wind and sunshine duration and additional statistical information for these parameters and for the occurrence of phenomena such as fog, thunderstorm, hail and snow. The computation period will be 1971-2000. In a first step the Atlas will be made available without maps and implemented as a CD-ROM data base with visualization tools.

- **GIS in Climatological Applications (ZAMG)**

National Meteorological Services are facing many problems in their work which can be solved

more easily with the application of Geographic Information Systems (GIS) tools. Substantial advances in deriving information of various kinds from different sources have been achieved until now. The ECSN activitiy in this field has pushed forward a new action in the framework of COST, namely COST-719: The Use of GIS in Support of Climate Monitoring, Climate Data Quality Control and Climate Information. Therefore the ECSN project Geographic Information Systems in Climatological Application was terminated with a Final Report and followed up by COST-719.

- **ECSN Climate Dataset (KNMI and DNMI)**

The ECSN project Climate Dataset (ECD) is closely related to the project European Climate Assessment. The main objective of the ECD project is the preparation and the distribution of climate data sets on the daily amount of precipitation and daily temperature (minimum, mean, maximum) for the period 1901-2000 via CD-ROM and Internet.

The Bulletin is a summary of contributions provided by the National Meteorological Services.
The author does not warrant, guarantee or make any representations regarding correctness, accuracy,
reliability, or any other aspect regarding characteristics or use of the information presented.

Foreword

This 9th edition of the Annual Bulletin on the Climate in WMO Region VI – Europe and Middle East – for 2002 was enabled by national contributions from the Meteorological and Hydro-Meteorological Services in WMO Region VI.

The Call for Input was answered directly by 80% of the 49 member countries. Additionally, WMO Secretariat provided the editor with all national contributions to the WMO Bulletin article on consequences of abnormal weather in 2002 from the WMO Regional Association .VI Thus, even more information could be used for the compilation of this edition, leading to a percentage of 86 of represented member countries. More than 3 quarters of possible national reports were sent in the most preferred way, which is email including attachments or server addresses.

The bulletin elaborates on a very interesting climatological year. A long lasting period of positive temperature anomaly began in the middle of January and dominated the regime of monthly mean temperatures all over Europe. This period ended between August and October, depending on the specific area. Outside this period, relatively cool and sometimes extremely cold weather conditions prevailed in most countries with some exceptions.

Another characteristic and dramatic feature of the year was continuously intense rain fall in central eastern Europe for quite some days in August with disastrous consequences to the infrastructure of wide areas, especially in Austria, Czech Republic and eastern Germany. Hundred thousands of people have been directly involved in this natural catastrophe. A special article on this extreme climatic event is included in this Bulletin.

Other special reports in this edition have been contributed by the ECSN Programme Manager and the Meteorological Observatory Hohenpeißenberg.

On this occasion, I want to thank all, who contributed to this paper by reports and practical support. I am especially thankful to the German Meteorological Service for the co-ordination, the editorial review, publishing and distribution of this Bulletin.

Daniel Keuerleber-Burk
Acting President of WMO Region VI

Outstanding Events and Anomalies in 2002

Temperature

- **A very cold start of the year, followed by a long lasting period of positive anomaly from the middle of January into autemn nearly all over the Region**
- **Extremely mild February in central and eastern Europe**
- **Hottest summer since the beginning of observations in a large area around the Baltic Sea**
- **Extremely cold in eastern Europe at the end of the year**

Precipitation

- **Wet summer in central Europe with record breaking daily rainfall rates in August leading to disastrous flooding in Austria, Czech Republic and eastern Germany**
- **Long lasting drought in the Baltic countries and Belarus in late summer**
- **Extremely wet in the Caucasus at the end of the year**

Wind

- **Strong winds in northern Europe during the last days of January causing lots of life losses and material damage**
- **Stormy weather with lots of damage in many European countries at the end of October**

Annual Survey

Temperature deviations from the long term annual average were mainly positive all over the Region up to about +2.5ºC except for some places in Turkey and parts of northern Russia with slightly negative anomalies. Typical values of the yearly mean temperature compared to normal are presented for example by fig. 0.1.

Scandinavia and great parts of central and eastern Europe had a long lasting period, i.e. from the middle of January until September, of continuously positive monthly temperature anomalies (e.g. see fig 0.2 and tab. 7.1).

Additionally, there were some record breaking observations. At Weather Ship "Mike" (66ºN, 2ºE), operated by Norway, the mean air temperature for the months April to July was the highest ever recorded since the start of the series in 1948; with a time delay of one month, the mean sea surface temperatures were also extremely high. The number of days with snow cover in Iceland was reduced to about two thirds of normal. The mountain range of the High Tatras in Slovakia had the warmest year since 1951; as in other European countries, it was one of the warmest in more than 100 years, illustrated by figs. 0.3-0.5. In the Middle East, the positive temperature anomalies prevailed also, as can be seen from the example of extreme temperatures in fig. 0.8.

1951.	12,6

***Fig. 0.5:** The ten warmest years in Zagreb since 1862*
From: Meteorological and Hydrological Service, Croatia

Precipitation was above normal in central, north-western and south-eastern Europe except for an area in and around Hungary. Significant deficits to the mean annual accumulated precipitation occurred also near the coastal areas of the Biscay, in the Southeast of Spain, around the middle and northern Baltic Sea as well as in Russia, Turkey and other parts of the Middle East. The surplus precipitation in other parts of the Region as well as the deficits generally did not miss the normal by more than ±50%.

Nevertheless, some records of the yearly precipitation sum were broken; e.g. at station Kvisker, Iceland, the annual total exceeded the previous maximum of 4335 mm (1997) by 7%. This is 36% above normal.

Drought conditions in the Caucasus lasting on from former years, were soothed after the winter months (see figs. 0.6, 4.1, 12.2).

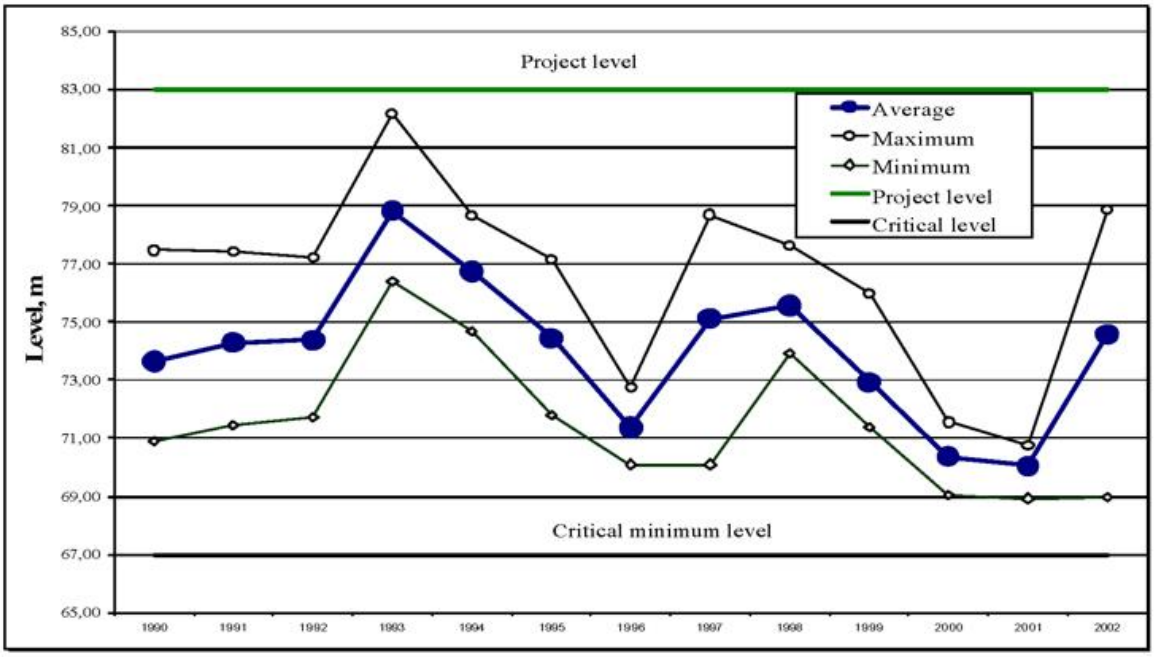

Fig. 0.6: *Annual average, minimal and maximal levels of Mingechevir Water Reservoir, Azerbaijan*
From: Ministry of Ecology and Natural Resources of Azerbaijan

Wind force again caused a lot of damage in the Region, especially at the end of January in northern European countries. But there is also the phenomenon of a considerable decrease of the annual mean wind speed in Belarus during the last five decades (fig. 0.7).

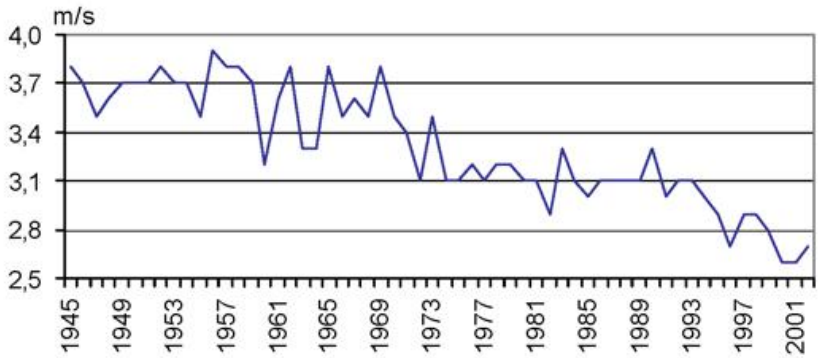

Fig. 0.7: *Mean annual wind speed in Belarus since 1945*
From: Hydrometeorological Centre of Republic Belarus

Seasonal Survey

Winter 2001/2002 was generally mild in terms of mean temperatures above normal except for areas around the Adriatic and the Black Sea. A zone of high positive temperature anomalies is stretching from the British Isles over central Europe to Belarus and central Russia (see figure page 11 above). A remarkable feature was a period of extremely high temperatures starting around the middle of January and lasting for several weeks (see e.g. figs. 1.1 and 1.2). Northern Scandinavia and especially Svalbard had extremely mild winter season. There were many areas with extremely low precipitation. Most of the Iberian peninsula and southern France received less than 50% of the usual precipitation in the reference period. This situation and partly even worse was given in parts of Italy, south-eastern Austria, some Balkan countries, especially Romania, and the Ukraine (see figure page 15 above).

Spring 2002 was generally warmer than normal. The highest positive temperature anomalies up to +3°C were observed in a coherent area of parts of Sweden, Finland, Poland, the Baltic countries and Belarus (see figure page 12 above). It was the warmest spring in a century in Lithuania. The spatial distribution of the seasonal precipitation totals looks rather patchy all over the Region. There are many centres of relatively high and low precipitation rates against normal (see figure page 15 below). The long lasting drought in southern France ended in May. Despite some local relief in March the drought situation in Romania continued and even worsened till the end of the season.

Summer 2002 was warmer than normal nearly all over the Region (see figure page 13 above). In Lithuania, Latvia, Sweden (see fig. 0.9) and in parts of Norway it was the hottest summer since the beginning of observations. Areas of minimum precipitation were the southern Iberian peninsula and central Russia (see figure page 16 above). Other countries like Denmark and Hungary experienced a mixture of intense rainfall with flooding as well as drought periods. Intense and continuous rain over central eastern Europe did not only lift the water balance of the whole season, but firstly caused catastrophic damage to the infrastructure and to people in Czech Republic, Austria and eastern Germany in an extent, that was not known before (see special report on pages 55-62).

Autumn 2002 had negative temperature anomalies in north-eastern Europe with a centre in Finland. Else there were seasonal mean temperatures mostly above normal with relatively high deviations in England, Iceland and the adjacent seas. Maximum temperature anomalies of about +3°C were observed in the Caucasus area (see figure 14 above). It was the third wettest fall across England and Wales as a whole since 1766. Additionally, central Europe as well as Portugal, Greece, the Ukraine and southern Russia received much more precipitation compared to the reference period 1961-1990 (figure page 16 below).

***Note**: Plus signs in figures on pages 11-14 below indicate anomalies exceeding the 98th percentile of a modified 2-parameter gamma distribution fitted to 1961-1990 data (Horton et al. 2001)*

Monthly Surveys

January 2002

- **After a cold start in the very first days of the year, generally warmer than normal in the northern and south-western Region, extremely mild in central Russia**
- **Cold in the south-east with a centre of negative temperature deviations from normal in Turkey**
- **Extremely dry in a zonal belt from the Biscay over the Alps and the Carpathians to the Ukraine as well as in the southern parts of Italy and Spain**
- **Severe storms in northern Europe during the last days of the month**

In Iceland, some meteorological records were broken. The absolute maximum temperature in Reykjavik was +10.6°C and thus the highest temperature ever measured there in January. A relatively warm period during the first three weeks of the month was the reason for the absence of a snow cover in the southern and western lowlands of the island, which is a highly unusual situation. A new national record of 24 hr precipitation was set on January 10, when 293.3 mm were measured at Kvisker. This record exceeds the previous one by 50 mm, measured in 1979 at the same station.

In the U.K., a 31 day period of extremely mild weather started on the 13th of the month, which never before was observed in the Central England Temperature series (fig. 1.1). In the Netherlands, the lowest temperature of the year, -11.9°C, was observed at station Hupsel on January 4. One week later, a period of positive temperature anomaly up to +9°C began and lasted for 5 weeks (fig. 1.2), similar to the situation in the U.K..

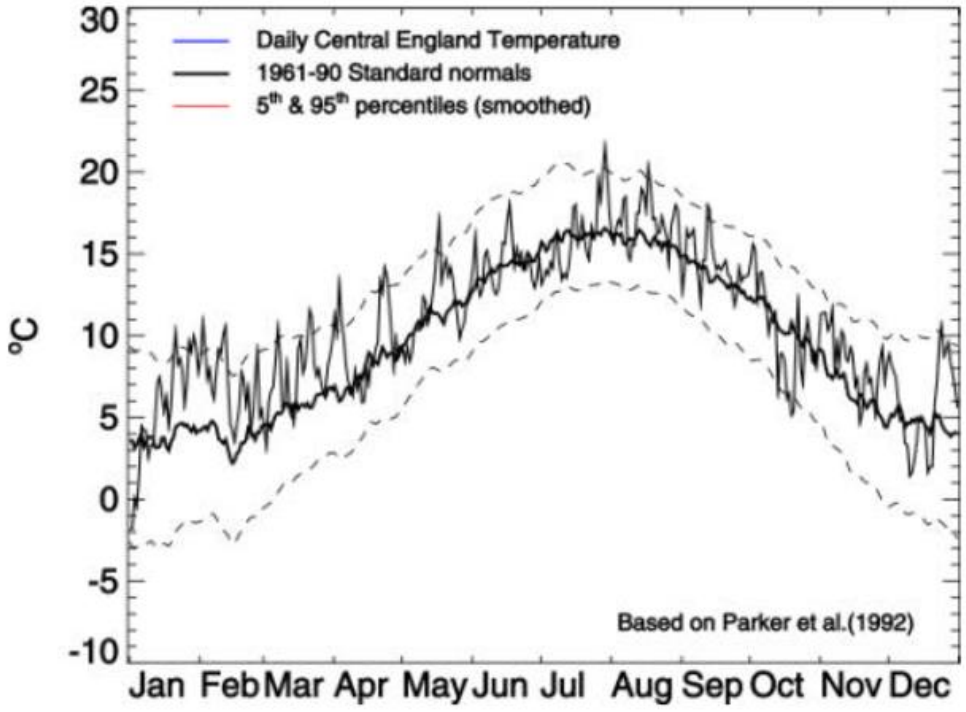

Fig 1.1: *Central England temperature, daily values 2002*

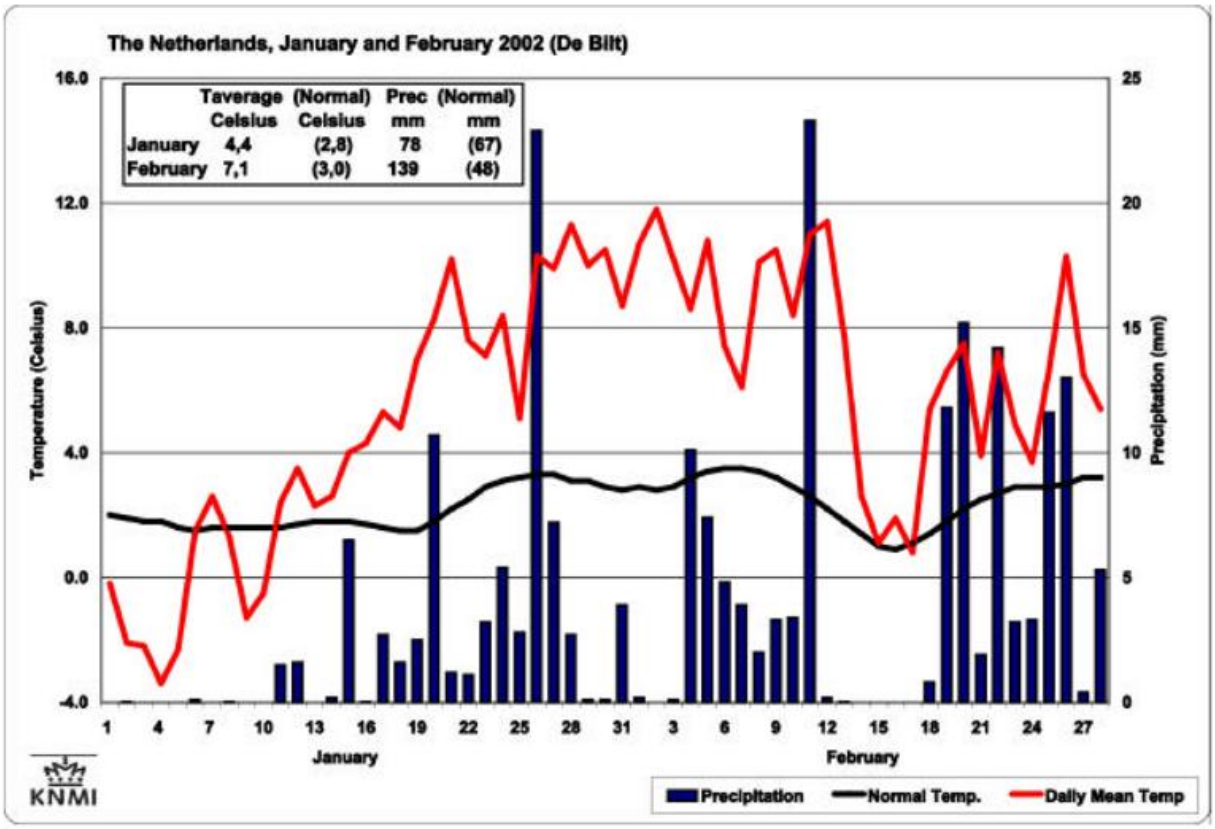

Fig. 1.2: *Daily precipitation and daily mean temperature at Station De Bilt, The Netherlands*
From: The Dutch Royal Meteorological Institute, KNMI

During the last decade of the month, some national records of maximum temperature were broken, especially on January 29 in Austria (+20.5°C, Eisenstadt), Hungary (+20.0°C, Máza), Slovakia (+20.3°C, Bratislava) and on January 30 in Germany (+21.0°C, Altenstadt). Also in La Coruña, Spain, a new record of T_{max} was set in a series of more than 100 years.

Strong winds up to Hurricane force affected N-Europe in a belt from the British Isles over northern Germany and Poland to the Baltic States within the last week of the month.

England and Scotland suffered from heavy damage to traffic and power lines, caused by strong winds, which were up to 190 km/h in the Scottish Highlands. In Husum, Germany, a wind energy converter crashed on January 29, while maximum wind speeds of more than 150 km/h were observed.

The lowest temperatures of the year in Ireland were measured on January 1, namely –8.0°C air temperature at Mullingar and –12.5°C grass minimum temperature at Kilkenny. Strong winds were observed during the last days of the month; Malin Head measured the highest gust of the year, 159 km/h on January 28.

Considerable damage occurred during stormy weather in the centre and the north of Belgium, accompanied by floods in the provinces of Brabant and Luxembourg on January 26-28.

The year started extremely cold in France, whereas the end of January was particularly mild.

Like in many other countries, in Germany very cold weather at the beginning of the year turned into extremely mild conditions at the end of the month. From January 6-7 freezing rain in many parts of the country caused thousands of accidents on roads with 120 people injured and 3 deaths. A period of very strong winds from January 26-29, especially in the northern parts of the country with maximum gusts up to 169 km/h (Brocken), caused floods in coastal areas, disruption of traffic and power lines, and lots of damage to houses and forests.

Stormy weather was also reported from Denmark on January 28-29.

In Norway the month was generally warmer than normal and precipitation was above normal for most of the country. The lowest temperature of the year was -40.6ºC, measured in Kautokeino in Finnmark County on January 24. The station Glomfjord in Nordland County received a precipitation amount of 134.6 mm on January 11, which is the highest diurnal value of all weather stations in Norway for 2002.

A new national record of daily precipitation was set in Sweden, when Katterjåkk got 104 mm. This precipitation came down as rain at a station where the normal temperature for January is -12°C.

Precipitation in Finland was generally well above normal.

In Lithuania the year started with cold frosty weather combined with heavy snowfalls and blizzards. Minimum temperatures in most regions fell down to minus 22 – 27°C. After the first 5 days, frost conditions weakened and the mean daily temperatures became unusually mild, so that the monthly mean temperature resulted to +3.8°C above normal. Precipitation in January was in excess of normal and amounted to 68 mm, which is 162% of normal. In the first five-day and the third ten-day periods, the weather was very windy. The strongest wind was observed in western Lithuania with gusts above 120 km/h on January 29. The wind broke many trees, disrupted power lines, and damaged two ships in the port of Klaipeda.

Very cold weather dominated the first days of the month also in Poland with temperatures below –30°C in the Carpathian Mountains on January 4. In the second half of the month, the wintry conditions turned into very mild weather, which made the snow cover completely disappear. Cracow had a maximum temperature of +13.1°C on January 29 and the countrywide monthly mean temperature rose to +1.2°C. The national precipitation rate was 121% of normal with considerable spatial variation. For example, station Wroclaw received only 70% of normal. The economically most unfavourable weather was observed at the end of the month, according to an exceptionally active westerly circulation. From January 25-31 violent storms and thunderstorms caused a lot of material damage all over the country and the loss of 6 lives.

In Belarus the year started with very mild weather and a monthly mean temperature anomaly of +4°C.

Slovakia had very dry conditions. The precipitation total was 61% of normal; which was the lowest monthly mean of the year.

Also in Slovenia, the month was exceptionally dry. The mean precipitation rate was less than 50% of the long term average. In some places in the north of the country, precipitation rates were even below 10% of normal. Accordingly, the sunshine duration was well above normal. Some areas, like Ljubljana's and Celje's basin, received more than twice the usual sunshine duration. As in many other countries, the month had a cold start and ended with significantly mild weather.

The same conditions were valid for Hungary; where in some places the maximum temperatures exceeded +18.0°C at the end of the month.

In Serbia and Montenegro January air temperatures were within the normal limits, and precipitation was scarce.

The first three days of the year were very cold in Bulgaria with temperatures down to –22.2°C in Sandanski. Due to heavy snowfall and frost more than 200 accidents occurred in the northeast of the country, 3 people froze to death.

In Portugal the monthly average temperatures exceeded their means for the period 1961-90, while the monthly precipitation totals were below normal.

The NW of Spain as well as in the Canary Islands experienced extremely mild weather conditions.

In Turkey two significant weather events occurred at the beginning of the month. Strong winds caused damage to houses, forests and power lines in Kayseri on January 4. Two days later, heavy snowfall cut traffic lines in the area of Yozgat.

January in Armenia was dry and mild.

A tornado affected the west coast of Cyprus on January 4**.** Another unusual event was snowfall in the western coastal area of the island on January 7. Heavy snowfall continued in the Troodos range on January 9 and disrupted traffic lines to many mountain villages.

The weather in Israel was cool and rainy. In some parts of the country rainfall was twice normal. The most significant rainfall event occurred on January 6-9 with 100-180 mm measured in the northern and central parts of the country. This event included snowfall on the mountains, mostly on January 7, when 30 - 35 cm of snow were measured at Har Kenaan.

Snowfall occurred also at areas with an altitude of only 300-400 m above sea level, an unusual event in Israel. Areas at a higher altitude reported more than 1 m of snow.

February 2002

- **Positive temperature anomalies all over the Region except for Iceland and Greenland**
- **Extremely mild in eastern Europe**
- **Extremely wet in central and north-eastern Europe, very dry in southern Europe and the Middle East**

Iceland experienced the coldest February in Reykjavík since 1935 and in Akureyri since 1973. Except for a damaging northerly storm on February 2-3, the weather conditions were favourable during the month.

In Norway the monthly mean temperatures and precipitation totals were well above normal for almost the whole country.

Finland had a wet February, as well as Denmark, where a precipitation rate of more than 200% from normal was recorded.

In Ireland, it was one of the wettest months of the year relative to normal. In addition, a combination of heavy rainfall, strong winds and in particular an exceptionally high tide brought significant coastal flooding on February 1st. Monthly mean temperatures were over two degrees higher than normal in places.

It was a particularly wet month in the U.K. too. North-western England and northern Wales had its highest rainfall, 155 mm, in the 130 year record of the month.

In France, the weather was extraordinarily mild. The long term temperature averages were exceeded all over the country with maximum anomalies of more than +4°C reported from the northern areas. The maximum wind gusts of the year, 144 km/h, were recorded on February 4 at Cap-de-la-Hève and also on February 21 at Cap-Béar.

At station Uccle, Belgium, the monthly mean temperature was significantly above normal. At the same station, the monthly precipitation total was extraordinarily high (see fig. 2.1): 168 mm are equal to 317% of normal and the highest amount since observations started in 1833. Consequently, serious damage was caused by floods in many parts of the country on February 13 and during February 25-28. The mean monthly wind speed was relatively high; 5.3 m/s were measured at Uccle, which is 1/3 above normal.

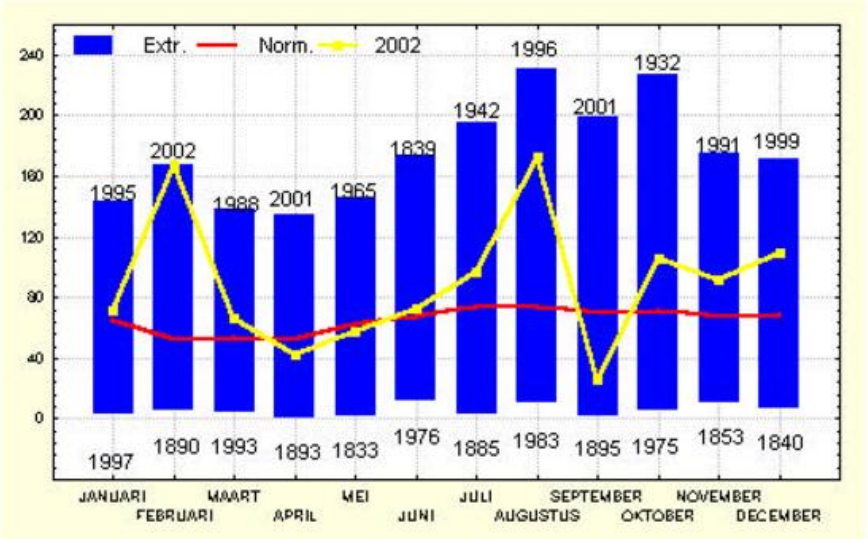

Fig 2.1: *Monthly precipitation totals in mm station Uccle, Belgium. Normal and extreme values since 1833*
From: Royal Meteorological Institute, Belgium

The month was the second warmest February since 1901 in the Netherlands. The countrywide monthly mean temperature was 7.1°C and thus +4.1°C above normal. On February 2 a maximum of 15.5°C was measured, the highest temperature ever recorded so early in the year. The month was also extraordinarily wet. The precipitation total averaged over the country was 147 mm, which is 313% of normal. In De Bilt, the second highest monthly precipitation total was observed since 1901. However, the monthly sum of sunshine duration ended up within the top 10 since 1901. Hourly average wind speeds of 88 km/h and more were reported on February 26.

The weather in Germany was extremely mild and wet. In the series of spatial monthly means it was the second warmest and third wettest February since 1901. Intense precipitation led to high waters in rivers of western Germany with flooding on February 12-14 and 25. Heavy snowfall and freezing rain caused hundreds of accidents on slippery roads all over the country during February 19-24. Motorways around Berlin were blocked by overturned trucks on February 19-20. On February 22 stormy winds up to 115 km/h caused snowdrift on Heligoland. A whirlwind damaged more than 100 houses near Münster on February 23. Winds of hurricane force with gusts up to 180 km/h paralysed public life in Schleswig-Holstein on February 26-27.

The monthly mean temperature of Vienna, Austria, was +5°C above normal and is the second highest value in the time series since 1775.

It was the month with the highest temperature anomaly of the year in Poland. Averaged over 8 stations, the deviation from normal was +4.7°C. The spatial distribution of deviations showed a remarkable positive gradient from the western to the eastern parts of the country. A snow cover in the lowlands, which often existed in former years, was absent throughout the month. On February 2 the maximum temperature in Wroclaw came up to 15.8°C. February was also the wettest month of the year with a countrywide precipitation rate of 220% compared to normal. Locally, precipitation rates up to 400% were observed, e.g. in Plock. On February 12 thunderstorms combined with hail and intense rainfall caused severe damage to houses and power lines of more than 60 villages in NE Poland. On February 27 thunderstorms and winds of hurricane force affected the city of Cracow.

In Lithuania the mean monthly air temperature was +1.8°C, which is +6.4°C above normal. Over the past century, February had been warmer only in 1925, 1989 and 1990. Precipitation was in excess of normal and amounted to 74 mm, which is 247 % of the long term average.

In Belarus, a sequence of daily mean temperatures =0°C continued throughout the month, which normally starts to happen 6 weeks later.

The monthly mean temperature in Slovakia was well above normal and exceeded the long term average up to +5°C in the north-eastern part of the country. Precipitation totals were exceptionally low.

Temperature anomalies in Slovenia were above +1.6°C everywhere and up to +4°C in the eastern parts of the country. The month was unusually cloudy at the coast, in the Karst and some other places, where the sunshine duration merely reached half the normal. Snow depths in the mountains were relatively small. On Kredarica, the snow depth was up to 75 cm, which is lower than any February record of former years.

In Serbia and Montenegro, the extreme positive deviations of the monthly mean temperatures from normal were up to >+6°C similar to those of other east European countries. Even higher deviations from normal were recorded for the mean daily maximum temperatures (see fig. 2.2). At the same time, considerably lower precipitation amounts than normal were registered. In the eastern parts of the country the deficit was over 90%.

The month was extraordinarily mild in Romania. Temperature anomalies were positive all over the country and up +8°C (see fig. 2.3).

In Bulgaria, the month was very mild with mean temperatures of +3...+7°C above normal and dry with precipitation rates from 3...54% of normal. Nevertheless, on February 24-25 stormy winds and wet snow fall caused damage of power lines and interrupted transportation to and in the mountain areas.

The weather in Portugal was rather mild and dry. The monthly precipitation totals were below 50% of normal.

Rather mild and relatively dry weather prevailed also in Cyprus and in Israel, where it was the warmest February since 1977.

Armenia had a temperature anomaly of more than +4°C.

The monthly mean temperature in Azerbaijan, calculated from 15 stations, was 4.6°C above normal, which statistically occurs every 35 years.

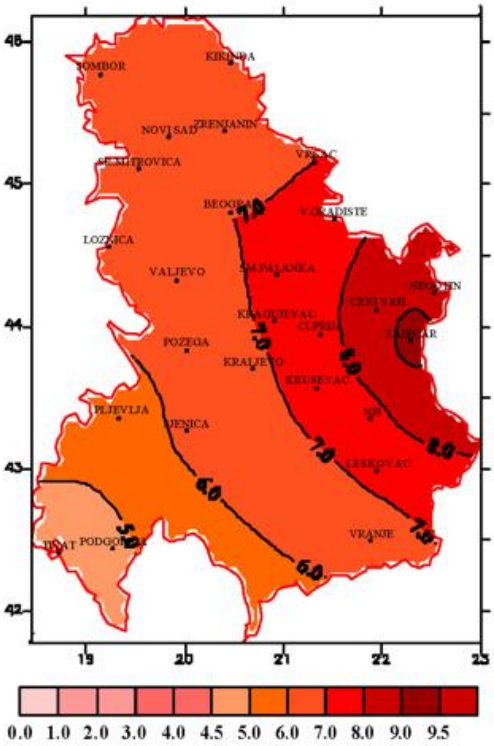

Fig 2.2:

Maximum air temperature anomaly (°C) distribution in February 2002 in FRY (now Serbia & Montenegro)
From: Federal Hydrometeorological Institute of Yugoslavia

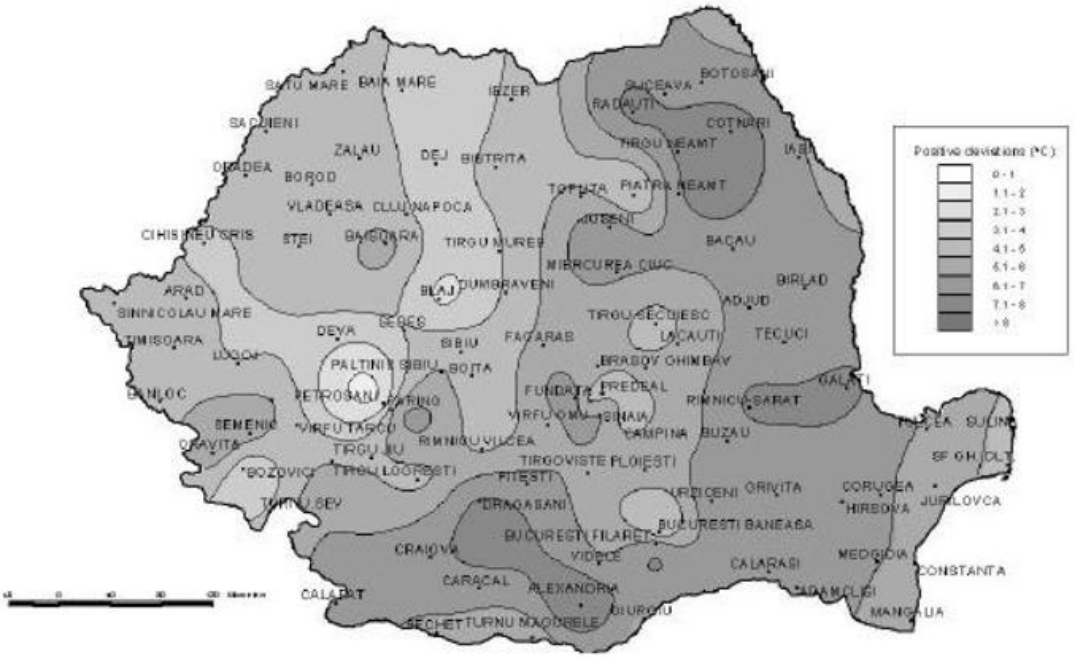

Fig 2.3: *Deviation of mean temperatures against the climatological norm in Febrary 2002, in Romania*
From: National Institute of Meteorology and Hydrology, Romania

March 2002

- **Warmer than normal everywhere except for Iceland, Svalbard and Acores; extremely warm in eastern Europe**
- **Extremely dry in coastal areas of the Greenland Sea, the North Sea, the Biscay, the Tyrrhenian Sea, the Adriatic Sea, in central Ukraine and parts of Russia**

The monthly mean temperature in Sweden was well above normal, especially in the south-eastern parts of the country. The maximum temperature was 21.4°C at station Oskarshamm, which means the 2nd highest national record of the month ever made before.

In the Netherlands March was very sunny and ended in the top 10 since 1901. Hourly average wind speeds of 10 Beaufort (24.5 m/s or higher) were reported on March 9.

In Belgium, the monthly mean temperature was well above normal. A tornado like whirlwind affected the area of Eupen. on March 18.

In Germany the monthly mean temperature was +2°C above normal and the precipitation rate 10% higher than the long term average. However, during the period of March 19-23, intense rainfall together with snow melt in the mountains led to high waters in the rivers of southern Germany together with flooding of cities, e.g. Heidelberg and Passau.

The countrywide temperature anomaly in Poland was +2°C, while the overall precipitation total was near normal. On March 7 intense advection of polar-maritime air lead to strong winds up to 97 km/h in Krakow causing lots of damage.

The month was very dry in Slovakia. The countrywide precipitation totals were only 2 thirds of normal.

The anomaly of the monthly mean air temperature in Slovenia was statistically significant with +3°C above normal. Precipitation totals did not reach the normal rate at any station. Sunshine duration was well above normal everywhere in the country, large basins in the central part of Slovenia got about 60 % more sunny weather than in the long term average.

In Romania monthly temperature anomalies were up to +4°C. At the end of the first decade of the month, the most serious event occurred along the track of gradually intensifying winds up to 145 km/h, when thousands of trees were uprooted and forest fires broke out, especially in the eastern parts of the country.

In Bulgaria, the month was mild and very wet. The deviation of the monthly mean temperature from normal varied between +2°C and +4°C. The monthly precipitation totals were from 250% up to 444% of normal. During the period of March 23-26, strong winds combined with intense rain and snowfall caused the interruption of traffic and power lines, especially in the mountain areas. Landslides were triggered. A bus with passengers was overturned on the road to Varna by wind force on March 25. The ports of Burgas and Balchik were closed for some time.

The monthly mean temperature in the mainland of Portugal was +1.2°C above normal, while precipitation totals reached 130% of the long term average amount.

On March 14 a tornado with gusts up to 149 km/h affected the area of Extremadura, Spain. Intense rain over Santa Cruz de Tenerife, Canary Islands, caused several mortal casualties and heavy material losses; the precipitation total in 24 hours was 232.6 mm with the maximum intensity of 27.1 mm in 10 minutes.

In the area of Konya, Turkey, frost and storm damaged crops and houses as well as telecommunication and power lines on March 22-23.

Monthly temperatures in Cyprus were well above normal. On March 20 a severe hailstorm in the south-eastern part of the island and a thunderstorm in the western part of the central plain on March 28 caused fatal some accidents.

The month started extremely warm and dry in Israel with temperatures of +6...+9°C above normal. The heat-wave reached its peak on March 11 with temperatures of more than 35°C in the coastal plain. In Tel Aviv 36.4°C were reported, and this was the highest temperature in March since the beginning of measurements at this station in 1950. The second part of the month was cool and rainy, but only the northern parts of the country received rainfall amounts larger than normal with a surplus between 20% and 60%. Other

parts of the country received only 50% to 80% of the long term average rainfall.

The mean monthly temperatures in Armenia were up to +4°C above normal.

Relatively low snow depths compared to previous years were recorded from the mountain areas in Azerbaijan. These circumstances caused a dramatic decrease of water resources and endangered the ecosystem of river Kura, which is the main waterway of the country. The monthly mean temperature was countrywide +4.5°C above normal. The statistical recurrence period of such an event is more than 100 years.

April 2002

- **Slightly to moderately warmer than normal except in south-eastern Europe and most parts of the Middle East, extremely mild in Svalbard.**
- **Seriously dry in central France and north-eastern Europe, extremely wet in north-eastern Greenland and around the furthermost eastern Mediterranean compared to normal.**

Iceland had relatively mild weather except for a bad snowstorm in the north and northeast during the last week of April.

In Norway, the month was a lot warmer than normal for the whole country and precipitation below normal for a greater part of the country. On the island of Svalbard the monthly mean temperature exceeded normal by more than +5°C.

Sweden had fairly dry weather conditions. It was still drier in Finland with a precipitation deficit of more than half of the normal rate.

The weather in Belgium was dominated by two different circulation types importing cool and dry continental as well as mild and humid maritime air. These conditions resulted in monthly mean values of the air temperature and precipitation totals near normal. However, sunshine duration at station Uccle was 35 h higher and thereby 22% above the long term average.

In France it was very dry with monthly precipitation rates below 50% of normal in the central part of the country. The monthly mean temperatures were up to +2°C above the long term averages.

Portugal had a precipitation deficit of about 50%, while the monthly mean temperatures stayed slightly above normal.

In Germany, the monthly mean temperature was slightly above the long term average, while the overall precipitation nearly reached normal. Stormy winds with gusts of hurricane force damaged houses, trees and cars in Düsseldorf on April 29.

The mild winter and favourable conditions at the beginning of spring caused a very early start of vegetation in Poland. For example in Cracow the blossoming of bird cherry (prunus padus) was observed very early on April 12; the first blossoms of lilac (syringa vulgaris) appeared on April 28. The monthly mean temperature was slightly above and the precipitation total near to normal.

Weather conditions in Lithuania where rather dry. The mean precipitation amounted to 24 mm only, which is 57 % of normal.

The mean air temperature in Slovenia was very close to the long term average. The anomaly was within the normal variability. The countrywide precipitation total exceeded normal, some places received more than twice the average precipitation amount of the reference period.

On April 7-8, a cold front passed over Serbia and Montenegro and brought an intensive drop of temperatures. At that time morning frost brought great damage, especially to agricultural areas in the north-east of the country. However, the overall temperature anomaly was slightly positive.

In Bulgaria the monthly mean temperature deviation was down to –2°C from normal. There was a 14 day period of hoar-frost, while thunderstorms occurred on 12 days including 7 days with hailstorms.

The monthly mean temperatures in Cyprus were below normal. Precipitation totals exceeded normal significantly. In the south-eastern part of the island, a severe hailstorm damaged potato plantations on April 1. A tor-

Monthly Surveys April / May 2002

nado crossed the western part of the island on April 19.

The month was cooler than normal in Israel with rainfall amounts reaching 150%-250% of normal and a small number of sharav (local term for Sirocco) events.

In Armenia the monthly mean temperature was moderately below normal, while the precipitation total exceeded the long term average by more than 50% (see fig. 4.1).

Frequent rains and hailstones caused severe damage to agriculture and hindered the work in the fields.

The monthly mean temperature in Azerbaijan was slightly below normal and only 1°C higher than in the month before; normally, this difference is +5.5°C. The precipitation total was 65% above the long term average (see fig. 12.2).

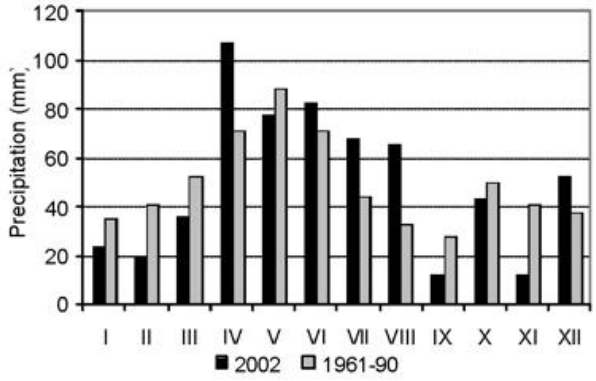

Fig. 4.1:

Monthly precipitation totals in Armenia compared with 1961 - 1990 means

From: Department of Hydrometeorology of the Republic Armenia

May 2002

- **Significantly warmer than normal in Scandinavia and eastern Europe**
- **Very wet in the coastal areas of the north-western Mediterranean, extremely dry in the eastern Balkans and around the Aegean Sea**
- **Lots of damage to local infrastructure in many countries as a consequence of strong winds, intense rainfall and thunderstorms**

In Iceland, the month was sunny and mild in the south and west, but damp and cool in the north-east. In Ireland it was very wet and dull except in the north.

The month was warmer than normal for the whole of Norway and substantially warmer for a greater part of the country. Precipitation amounts were below normal for most of the country. The southern and southeastern part, however, received a lot more precipitation than normal.

The monthly mean temperature at Uccle, Belgium, was +0.7°C above the norm and the precipitation rate 80% of normal. A violent storm in the eastern provinces occurred on May 9.

In France a very hot period happened in the middle of the month, and highest temperatures established new maximum records for the month, e.g. 34.2 °C in Biscarosse on May 16; the previous record was 33.1°C. Three days before, an intense squall line, locally called "Galerne", had crossed the south-west of France from the Basque country over Landes to north of Bordeaux with gusts up to 133 km/h.

The mainland of Portugal had a negative temperature anomaly of -0.7°C. The same deviation from normal was observed for the monthly mean minimum temperature, which was positive for nearly all other months of the year (see fig. 5.1). Very dry weather conditions caused a countrywide mean precipitation rate of about 50% from normal.

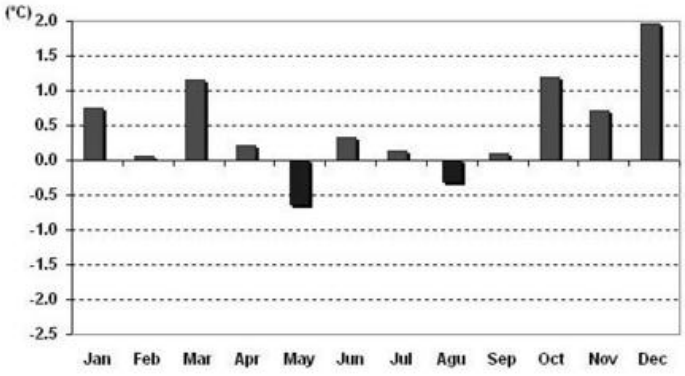

Fig. 5.1:
Mean monthly minimum temperature anomalies, differences from 1961-90

From: Instituto de Meteorologia, Portugal

In Germany the monthly mean temperature was +1.7°C above normal and the precipitation total only slightly above normal. During the course of an extensive thunderstorm along the Elbe river, 6?000 lightnings per hour were registered and numerous houses were set on fire in the night of May 11-12. Another extreme weather event happened during May 18-19 in Bavaria, when widespread thunderstorms caused the interruption of traffic and power lines, burning down of farmhouses, flooding, mudflow and landslides. Similar damage occurred to an area in and around Berlin on May 23-24, again as consequence of thunderstorms.

A severe cold spell occurred in Lithuania on May 19-21 with morning frosts down to – 6 ^{0}C, damaging lots of early vegetables. The precipitation total was merely 32 mm, which is 62 % of normal. In some places, e.g. Vilnius, the month was the beginning of a drought episode with a relative humidity of the air below 30% for 31 consecutive days. Additionally, the monthly sunshine duration was 341 h, which is 82 h above normal.

In Poland the whole month was frost-free. On May 4 the maximum temperature came up to 30.2°C in Krakow. The mean temperature anomaly in Poland was +3.2°C with a spatial variation from +2.0°C to +3.8°C. This large positive anomaly of temperature was caused by a very active southern circulation. The overall precipitation rate was 105% with great spatial differences. Monthly totals in deficit were observed in Lower Silesia with less than half of the normal rate, while in mountain areas precipitation amounts exceeded 250% of normal. During a thunderstorm on May 5, an petrol depot caught fire near Katowice. At the occasion of another thunderstorm near Krakow on May 27, intense precipitation of 133 mm in one hour occurred including hailstones of hen's eggs size. A bridge near Kielce was destroyed by flooding of the river Kamienna after intense rainfall on May 28-29.

The month was very warm in Slovakia. Temperature anomalies were generally above +2°C and exceeded +3°C in some parts of the country.

Slovenia experienced also positive temperature anomalies up to around +3°C, which were statistically significant at most stations. The precipitation was below normal over most of the country combined with a 20% surplus of sunshine duration over the long term average.

In Bulgaria, the temperatures were about and above the norm. In many regions precipitation was below the norms. Hailstorms occurred on 11 days and 17 days with thunderstorms. Heavy rainfall (145 mm in 24 hours) caused floods in the historical capital Veliko Turnovo on May 30.

Although the countrywide mean monthly precipitation total was well below normal, two serious flooding events occurred in Turkey causing lots of damage to agriculture and urban areas: one in Elazig on May 15 and the other one in Istanbul on May 26.

The average temperature was around normal in Cyprus. Severe hailstorms in the area south of Nicosia caused damage to agriculture on May 2. Heavy thundery showers in the afternoon of the 14th caused flooding in the western parts of the town of Nicosia.

In Israel it was the coolest May of the last 10 years. In Azerbaijan the temperatures were slightly below normal (-0.3°C) and the precipitation total ended up in 183% of the long term average.

June 2002

- **Very warm in southern Europe, Greenland and Scandinavia**
- **Very wet in the British Isles, around the north-western Mediterranean and the northern Baltic Sea**
- **Dry in Portugal and south-eastern Europe**
- **Many thunderstorm events, squalls and tornadoes with lots of damage**

Föhn situations produced very high and record-breaking temperatures at several locations in Greenland.

A 'heat wave' in south-western Iceland lasted during the period from June 3-16. The temperature in Reykjavik reached 22.4°C on June 11, exceeding +20°C for the first time in any month at that location since 1995. In Reykjavik, June was the warmest month of the year, wich is highly unusual; last time it happened before was in 1898. It was the warmest June in Reykjavik since 1941. The warm period ended abrubtly on the 17th of June, when an unseasonally fierce northerly storm hit the country, with heavy precipiation in the north and east and snowcover down to sea level in the northeast.

The highest daily sunshine duration of the year in Ireland was measured at Valentia Observatory on June 6. It was the highest daily value since 1989. The monthly mean temperature was slightly below and the overall precipitation rate well above normal.

In Norway the month was much warmer than normal for most of the country. The highest air temperature of the year was 32.5ºC measured at station Høylandet-Drageidet on June 9. The mean air temperature at Weather Ship 'Mike' was 11.4°C, which means a new record since the beginning of observations in 1948; the mean sea surface temperature was 11.8°C and record breaking as well. For a greater part of the country, the precipitation was less than normal, but the western and southern part of Norway received more precipitation than in the long term average.

Due to a rainy latter part of the month, the precipitation totals in Finland were well above normal in most parts of the country. In Denmark several tornado-like waterspouts caused considerable damage.

The month started cool in France and ended record breaking warm. In Luxembourg, the weather was very warm and dry. The monthly mean temperature was more than 2°C above and the precipitation rate less than half of normal.

In Belgium, the monthly mean temperature was well above normal. The absolute extreme temperatures of the month (minimum as well as maximum) at station Uccle had significant positive deviations of more than +3°C against the long term averages. A tornado affected the country on June 4. Two more events of stormy weather with flooding occurred on June 14 in the central and on June 20 in the eastern provinces.

The monthly mean temperature in Germany was +2°C above normal and the countrywide precipitation rate 80% of the long term average. From June 17-19 several places had 'Tropical Nights' with minimum temperatures above 20°C up to 24°C. New local records were set in some cities with maximum temperatures up to 39°C. There were 3 episodes of widespread thunderstorms with disastrous consequences to the local infrastructure: in the south of the country from June 5-7 and June 19-24 and also in the north-west from June. 15-18. Additionally, several whirlwinds affected different areas, e.g. the city of Wittenberg on June 12 (see fig.6.1.).

In Poland, the monthly mean temperature was 1.3°C above normal. In Wroclaw the maximum temperature reached 33.3°C on June 19. The monthly mean precipitation amounted generally to 84% of normal and was even less than 60% in western parts of the country. However, some heavy local rainfall occurred in the second week of the month. The worst event among thunderstorms and heavy downpours was connected to a local tornado on June 13, that destroyed 50 buildings in villages near Czestochowa.

Fig. 6.1: *Consequences of a local tornado in Wittenberg on June 12, 2002*
From: Photo Quelle: http://www.wittenberg.de

Frequent showers ended a drought period in Lithuania and raised the monthly amount of precipitation close to normal and in excess of it at some places. The sunshine duration was 299 h, which is 20 h above normal.

The monthly mean temperature of Vienna, Austria, came up to 20.6°C, which is the highest since 1811, when it was 22.0°C. On June 6-7, intense rainfall of about 200 mm per day caused disastrous floods in Lower Austria. Thunderstorms with heavy rain caused floods in Carinthia on June 17. Heavy thunderstorms with hail were the reason for widespread damage in and around Klagenfurt on June 23-24.

In Hungary a hot spell started in the middle of the month and lasted for about 10 consecutive days. Thus, drought conditions were triggered for most parts of the country. The maximum temperature was higher than 35°C in southern places on 3 days. The annual absolute maximum of 38,4°C was measured in Békéscsaba on June 24.

The temperature anomalies in Slovenia were between +1.9 and +3.6°C and statistically significant everywhere. In the course of a heat wave the highest temperatures of the year were recorded at many stations and the monthly mean temperatures were the highest of the last fifty years in many places. Precipitation was distributed unevenly in time and space, as it is usually the case in summer; the overall monthly average was near to normal.

The month was significantly warmer than normal in Romania with deviations of more than +2°C above the long term averages. The countrywide precipitation rate stayed in deficit.

The monthly mean temperatures in Bulgaria were above normal from +1°C to +3°C. There were thunderstorms on 22 days of the month, including 6 days with severe hailstorms. The diameter of hailstones were up to 5 cm (see figs. 6.2, 6.3), hitting more than 1000 cars in the capital of Sofia. The estimated damage of about 1.5 million € was also caused by flooding of some cities.

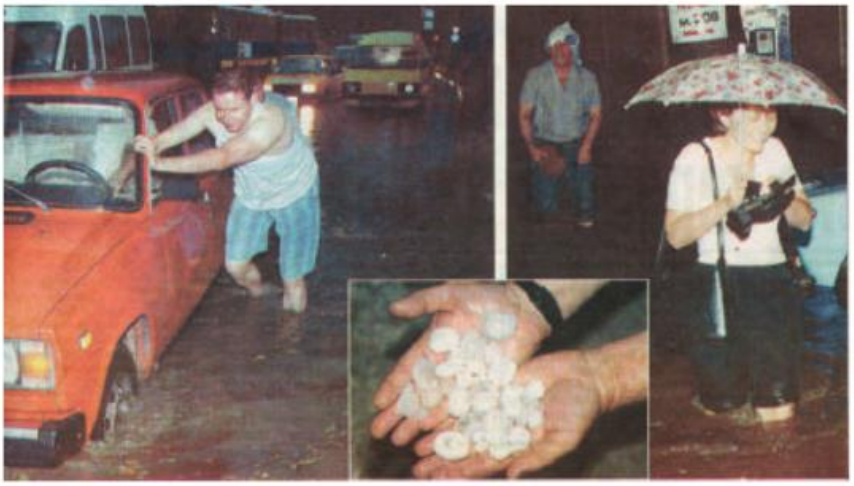

Fig. 6.2:

(Photo: Press Photo BTA Bulgaria)

Squalls and tornadoes with gusts of more than 100 km/h were observed in western and central parts of the Ukraine on June 24. The agriculture and national economy suffered considerably, there were a number of victims.

In Portugal the temperature was again fairly above the long term average, especially the mean maximum temperature exceeded the normal value by +1.7°C. Precipitation totals continued to stay below normal.

The month was very hot in Spain. New records for monthly mean temperature were set at Madrid and in the Balearic Islands within series of more than 100 years.

Although the monthly mean temperature was just +1.0°C above normal, Cyprus experienced severe heat wave conditions.

In the province of Giresun, Turkey, heavy rainfall triggered flooding of several locations on June 20.

During most days of the month temperatures were lower than normal in Israel. However an extreme sharav event occurred on June 7-9. Temperatures reached 43°C to 45°C in the coastal plain.

In Azerbaijan, the monthly precipitation total, averaged over all stations, was 152% of the normal rate. A thunderstorm with hailstones having a diameter of more than 2 cm. occurred on June 16.

July 2002

- **Temperature anomalies generally increasing from west to east**
- **Very dry on the Iberian peninsula, mixed precipitation pattern else**
- **Lots of extreme weather events in central Europe**

In Iceland and Ireland the month was rather dull, but in other respects close to average.

The monthly mean precipitation rate in England and Wales was 150% of normal. It was the summer month with the highest rainfall amount in that area and the only one with precipitation above normal (see table 7.1).

Month	CET 1961-1990	CET 2002	EWP 1961-1990	EWP 2002
January	3.8	5.5	91	87
February	3.8	7.0	65	115
March	5.7	7.6	74	53
April	7.9	9.3	62	48
May	11.2	11.8	65	81
June	14.2	14.4	65	57
July	16.1	16.0	62	93
August	15.8	17.0	77	76
September	13.6	14.4	78	41
October	10.6	10.1	87	144
November	6.5	8.5	92	176
December	4.7	5.8	96	148
Year	9.5	10.6	914	1118

***Tab. 7.1**: Monthly Mean Central England Temperature and England and Wales Precipitation data for 2002*
From: U.K. MetOffice Hadley Centre of Climate Prediction and Research

In the Netherlands, the highest temperature of the year was 34,9 °C, reported from station Westdorpe, located in the south-western part of the country.

The monthly mean values of temperature and precipitation were slightly above normal in Belgium. However, there were some extreme weather events: a violent thunderstorm in the centre of the country caused local flooding with severe damage at many places on July 20; an even more spectacular event occurred on July 30, when locally more than 100 mm rain fell during the course of widespread thunderstorms in central and north-eastern parts of the country.

In France it was mostly cool. However, a hot spell prevailed at the end of month. There were several severe thunderstorm events with heavy rain and hail on July 15 (evacuation of campers and damage to vineyards in the department Var), on July 17 (land- and mudslides in Savoie), on July 22 (people wounded by hailstones with diameters up to 2 cm in Isère), on July 29 (heavy damage caused by hailstones in Ariège), and on July 30 (railways closed and damage to houses in the north-east).

The monthly mean temperature in Germany was moderately above normal, while the overall precipitation total reached 140% of the long term average. From July 9 until the end of the month, a lot of extreme weather events like thunderstorms with hail, heavy downpours and whirlwinds occurred in many parts of the country; e.g. strong winds up to 152 km/h caused the death of 7 people in and around Berlin on July 10-11.

Vehement and intensive showers released considerable landslides in the area of Salzburg, Austria, on July 9. A lot of buildings in Upper Austria were heavily damaged by landslides and hail on July 13. The showers during the night to July 17 lead to catastrophic situations in Carinthia. Simultaneous showers caused floods in Lower Austria and lead to devastation in the vineyards of the Wachau area as well.

Temperature anomalies in Poland varied from +1.1°C to +3.2°C, while the countrywide precipitation rate was 79% of normal and locally down to 31%, e.g. in Warsaw with a monthly total of 22 mm. However, a lot of extreme weather events occurred in different parts of the country during the month, namely on July 1, 3-4, 7, 10, 14-18 and 21, marked by thunderstorms, downpours, hail, flooding and strong winds up to hurricane force. The worst case was reported from July 4, when a tornado like wind damaged a forest area of about 12 000 ha near Pisz.

Everywhere in Norway, the month was much warmer than in the long term average. Precipitation totals were above normal except for the middle part of the country,.

The month was generally very warm in Sweden with numerous and partly heavy thunderstorms.

Two violent local thunderstorm events occurred in southern and central parts of Finland on July 4 and 5. Accompanying downbursts cut trees and caused considerable economic losses to forest owners.

The month was very warm in Latvia with mean temperatures of about +3°C above normal. Connected to the passage of a cold front, a whirlwind with gusts up to hurricane force affected the capital of Riga as well as southern and central parts of the country on July 4; a lot of trees were downed and uprooted, causing the interruption of traffic and power lines.

In Lithuania the countrywide mean monthly air temperature was +3.2°C above the long term average and the precipitation rate 91% of normal. The highest temperatures were recorded on July 30-31 and reached 30-35°C. On the days of July 4, 19, 20, and 31, squall events with maximum wind speeds of 115 km/h, combined with thunderstorms and local-scale showers, caused a considerable number of injuries to persons and a lot of material damage.

The month was very warm in Slovakia with temperature anomalies from +2.2°C to +3.5°C. The countrywide precipitation total was 139% of normal. Significantly high daily precipitation amounts were reported from July 13, when in the western and central parts of the country more than 50 mm rain fell at 17% of the stations. Landslides were observed locally in the Hron river basin as a consequence of repeated heavy precipitation; stations Jarabá and Pohronská Polhora received monthly precipitation totals of 331 mm and 284 mm respectively.

In Slovenia the monthly mean temperature varied from close to normal on the coast up to more than +2°C above the long term average in the north-eastern parts of the country. Precipitation was distributed unevenly in time and space; the monthly totals were in the range from less then 75% up to more than 150% of normal. The number of days with thunderstorm was above normal all over the country, especially in the second half of the month..

The monthly mean temperature in Hungary was +2.5°C above normal. In the capital and in the south of the country, the maximum temperauture was often higher than 30°C. From the middle of the month a rainy period started and lasted until October (see fig. 7.1). At station Mátraszentlászló, the second highest monthly precipitation total of 328 mm was measured since 1951.

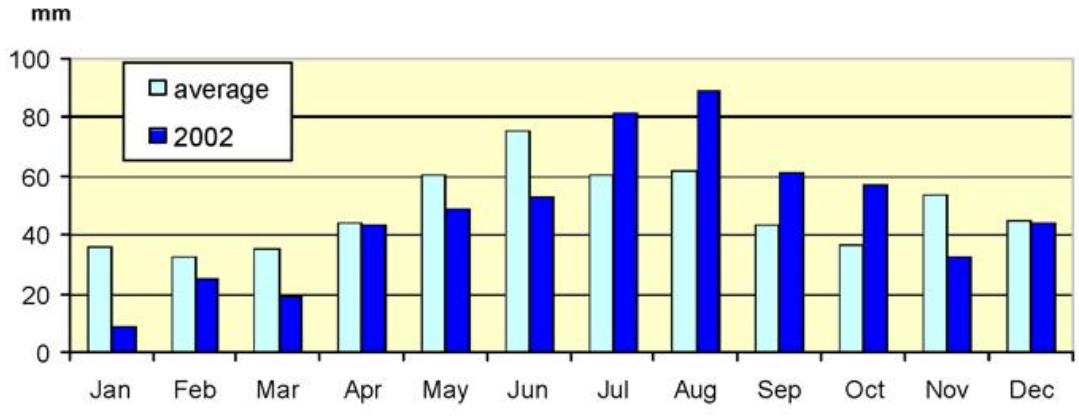

Fig 7.1 *Monthly precipitation sum (mm) in 2002 and between 1961 and 1990 in Hungary*
From: Hungarian Meteorological Service

In Romania, temperature and precipitation anomalies were significantly above normal.

In Bulgaria it was relatively warm with monthly temperature anomalies of +1.2°C to +3.4°C. There was a period of intense rainfall during the last week of the month, that raised the precipitation total to more than twice normal. The number of days with thunderstorm came up to 25. A whirlwind caused damage of about half a million Euro in some villages near Plovdiv on July 17.

The month was unusually wet on the Balearic Islands, Spain. The station Palma de Mallorca received a record breaking monthly total of 57.5 mm rain.

The north-western parts of Italy were affected by heavy showers during July 13-15, when 67 mm rain fell at station Turin and 73 mm in Rome. Four people lost their lives in the floods.

Cyprus had a monthly temperature anomaly of +1.3°C and suffered temporarily from heat wave conditions.

Heavy rainfall followed by flooding caused the death of 27 people in Rize, Turkey, on July 23, and total material losses of about 17 million Euro in the county of Cayeli. Not far away, at Oltu, another extreme rainfall event combined with flooding occurred on July 31 and caused considerable damage of houses and crops.

The month was very hot in Israel. The most extreme temperatures were recorded on the last 2-3 days of the month, e.g. 47.4°C in Eilat on July 31. In Bet Dagan it was the hottest July since 40 years (fig. 7.2).

Azerbaijan had a relatively hot month with an average temperature of +2.1°C above normal. Maximum temperatures were up to 42°C and caused human health problems in some areas.

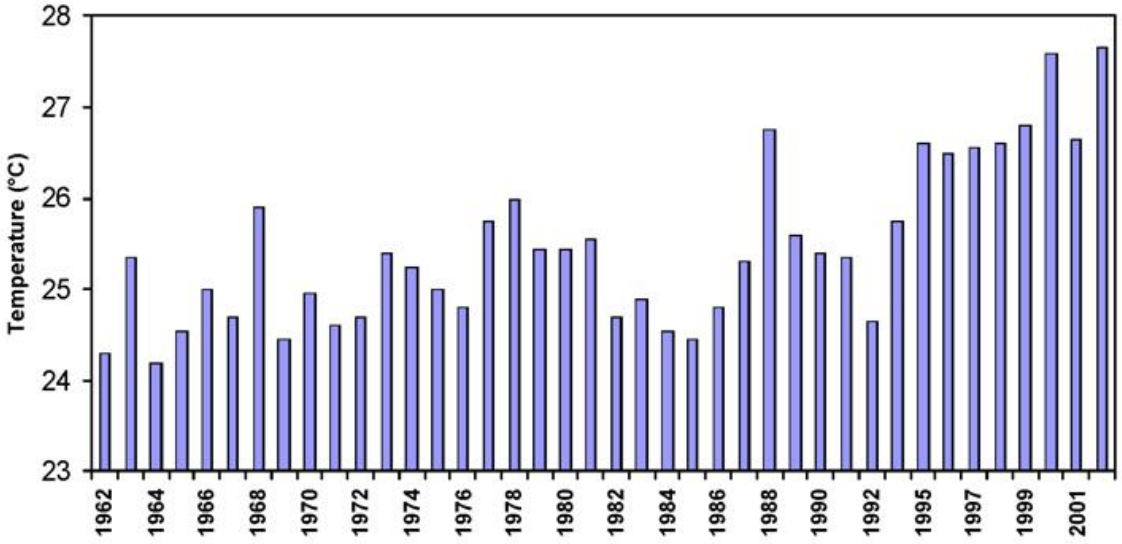

Fig. 7.2 *Mean Daily Temperature in July Bet Dagan (Central Coastal Plain) 1962-2002*
From: Israel Meteorological Service

August 2002

- **Catastrophic flooding in many parts of eastern central Europe because of long lasting intense rainfall**
- **Extremely hot in Scandinavia and the Baltic countries, very cool in northern Russia**
- **Extremely dry around the Baltic Sea and in the southern Iberian Peninsula, unusually wet in south-eastern Europe**

In Iceland, the month was rather dull and damp, but in other respects close to average.

The highest temperature of the year in Ireland was 25.6°C, measured at Clones on August 5. Precipitation totals were well below normal throughout the country.

On August 1, the north-eastern part of England experienced its highest daily rainfall total since records began in 1931 with 61mm, the highest daily regional mean value on record for any month in any England and Wales area. This was a convective rainfall event and some places within the region received much more than this.

The first week of the month in Denmark was dominated by some intense thunderstorms, causing flooding and lightning. The number of lightning strokes was 2-3 times higher than normal. After this episode, a dry period started and lasted on for several weeks with the main focus on the eastern parts of the country.

In Norway, the precipitation total was well below normal except for Troms County in the northern part of the country and some coastal areas. The month was also much warmer than normal for the whole country.

The month was generally very warm in Sweden with numerous and partly heavy thunderstorms. The most exceptional thunderstorm caused flash floods on the island of Orust along the west-coast during the night of August 1-2; private measurements showed that 180-200 mm had fallen on western parts of the island during around 10 hours with horrifying thunder. All roads in the area were disrupted and many houses damaged by water, erosion and lightning

A drought period started on August 3 in Latvia and lasted on over the end of the month. It was the second warmest and the absolute driest August ever recorded. The countrywide precipitation rate was only 4% of normal (fig. 8.1). The heat and drought engendered many forest fires.

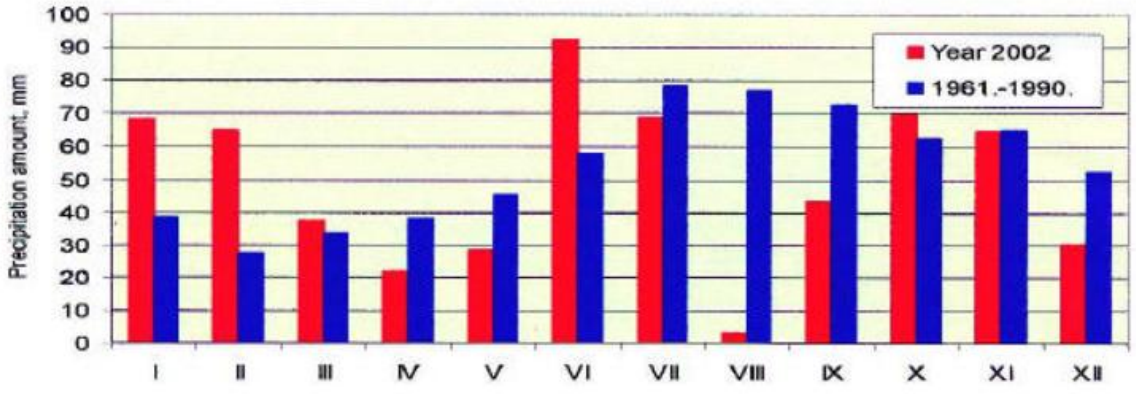

Fig. 8.1: *Monthly precipitation Latvia, actually and for the reference period 1961-1990*
From: Latvian Hydrometeorological Agency

The month was very hot and dry in Lithuania with a mean temperature anomaly of +3.7°C and an overall precipitation total of only 11 mm, which is 14 % of normal. Some stations did not receive any rain during the month. The mean relative humidity was 65% and thus 13 percentage points below normal. The sunshine duration summed up to 351 h; this is 107 h above normal. The soil surface temperature was up to 55°C, and the soil temperature at 20 cm depth reached 22 °C. During the whole month, a disastrous drought affected the country, especially in its eastern parts,. It was the longest and most severe drought since 1992. On August 4, the forest fire index reached its highest level in eastern Lithuania and gradually spread over most parts of the country.

It was the warmest summer month in Poland with a temperature anomaly of +3.1°C, calculated from 8 stations. The mean precipitation total was 119% of the normal rate with a large spatial variability. There was a general increase of precipitation totals from north to south., e.g. 7mm (11% of normal) on Hel, 141mm (240%) in Warsaw, and 275% of normal at station Jelenia Gora in the south-west. A lot of heavy rainfall events were connected to thunderstorms, mainly in central and southern parts of the country. Warsaw experienced catastrophic downpours on August 5. Great damage occurred also at the slopes of the Sudety Mountains, especially in Walbrzych, where the daily precipitation total amounted to 179 mm on August 31.

In the Netherlands, some locations were hit by heavy showers at several times and thus received 3 to 4 times the normal amount of monthly precipitation. In a substantial part of the country, 50 mm or more rain fell on August 24. Station Weesp near Amsterdam recorded 101 mm. At station Eext in the northern part of the country, a new national record of 295 mm for the month was measured; the old one (292 mm) dates back to 1942 at station Voorthuizen.

The monthly mean temperature in Belgium was well above normal, although precipitation rates were generally high and reached 273% of normal at station Uccle. At the same station, the monthly mean wind speed was only 2.3 m/s and thus the lowest monthly mean of the year and 26% less than the long term average of 1878-1986. However, quite a lot of violent storm events were recorded during the month; the most remarkable ones on August 24 and 27 were combined with daily precipitation sums of 100 mm and more in the south-western parts of the country.

The monthly mean temperature in Germany was +2.3°C above normal and the overall precipitation total reached 155% of the long term average. A lot of extreme events occurred during the month. Thunderstorms with intense rainfall and hail caused severe damage in nearly all parts of the country on August 1-2, e.g. the streets of Dresden were covered with a 5 cm layer of hailstones, 65 mm of rain fell in Hamburg within 45 minutes flooding streets and buildings, a whirlwind near Lüneburg removed the roofs of several houses and turned over some cars within a minute. Another period of heavy rains with flooding, especially in northern and southern areas, lasted from August 5 to 8. The most severe event was the period of intense rain on August 10-13 with catastrophic consequences to the south-eastern part of the country. A new record of 312 mm precipitation in one day was set at station Zinnwald. The flooding of the Elbe river and its tributaries caused damage to urban and rural areas at an extent not known there before for natural reasons. 20 people died and the material losses were estimated to thousands of million Euros (see special report on pages 55-62). Again, on August 20, 25 and 27-29 thunderstorms with heavy rains and hail caused a lot of damage to people and infrastructure by flooding, lightning and wind force at many places throughout the country.

Extremely high precipitation hit the Czech Republic in the periods of August 6-8 and 11-13 (figs. 8.2, 8.3). The passage of two distinct depressions and their frontal systems over central Europe caused disastrous floods, one following the other in a very short time. Both depressions hit the country with their rainiest sectors, the area to the WNW from the centre of the depression. Moreover, both of them moved very slowly, which extended the period of continuous rainfall. The precipitation was markedly intensified by the windward effect of the mountains. In the Novohradské hory Mts. and the Cesky Krumlov area 130-250 mm of rain fell within the two days between August 6 and 8, which is 150-200 % of August's normal. The highest precipitation totals for the two days were measured at station Staré Hute, 254.3 mm, and Podhorská Ves , 277.7 mm.

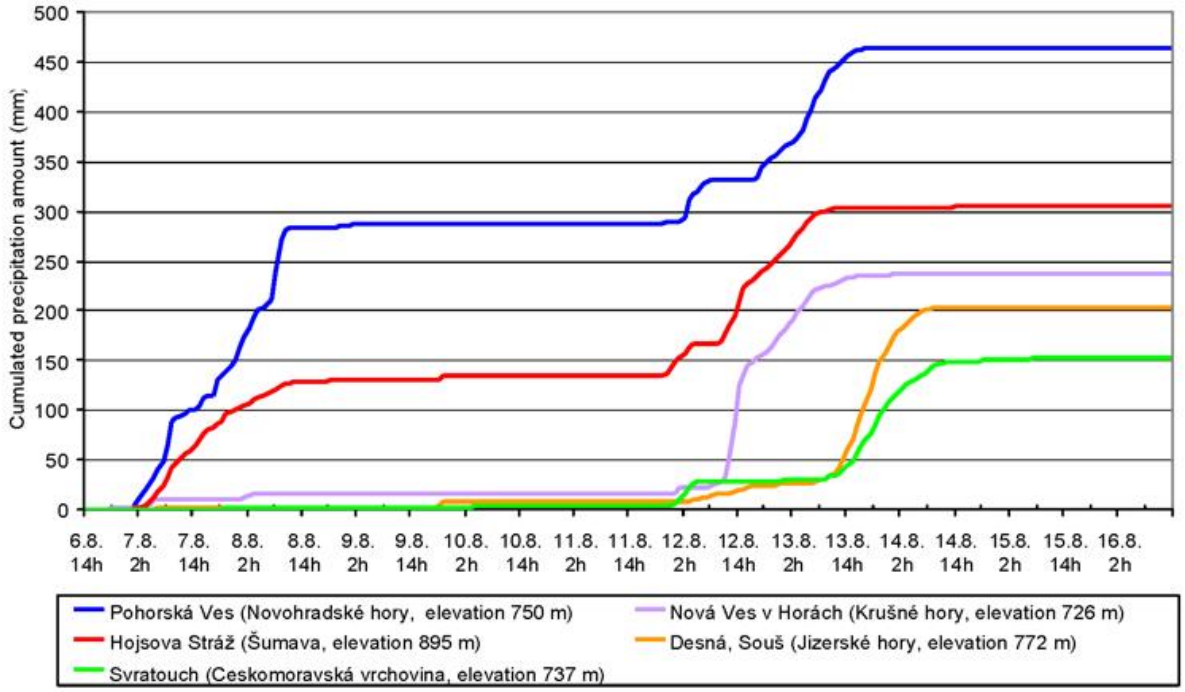

Fig. 8.2: *Cumulative hourly precipitation amounts on selected stations of the Czech Republic*
From: Czech Hydrometeorological Institute

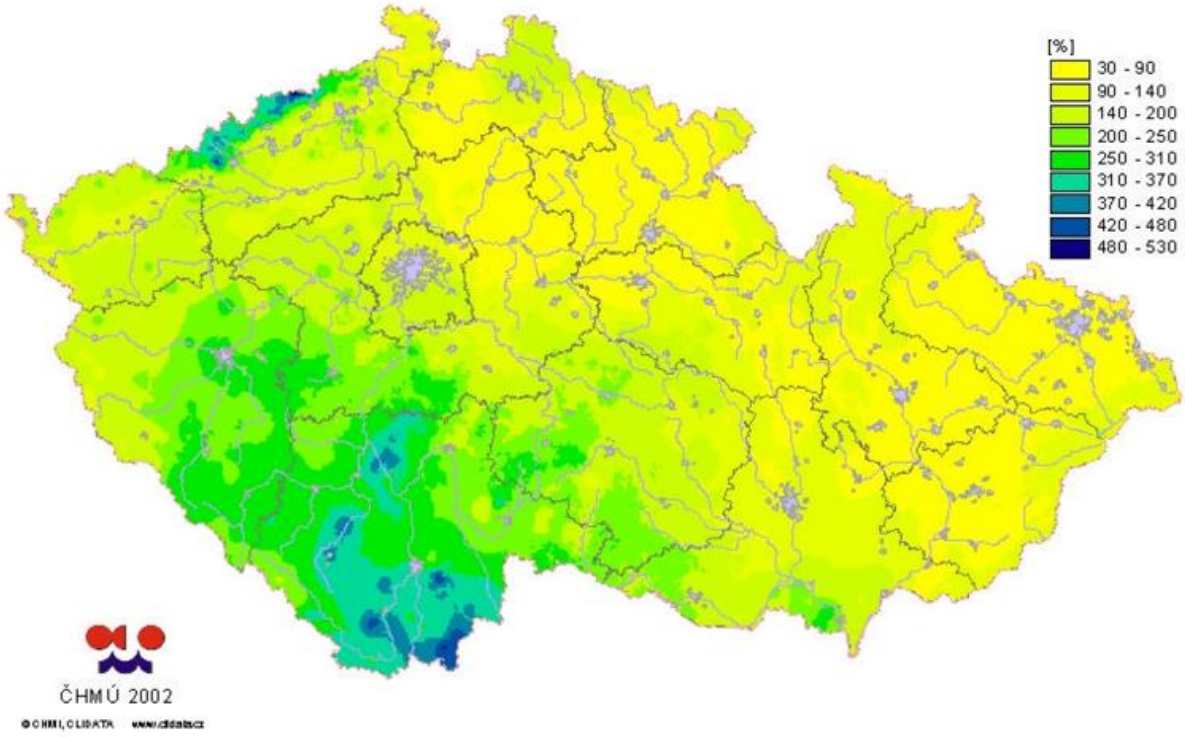

Fig. 8.3: *Anomaly of the precipitation amount on August 6 to 15, 2002 in the Czech Republic (% of August's normal 1961-1990)*
From: Czech Hydrometeorological Institute

On August 12-13 meteorological stations in Krušné hory Mts. and Jizerské hory Mts. recorded daily precipitation amounts of more than 200 mm and two-days' amounts greater than 300 mm. Most was measured at Cínovec, 312 mm in one day, which is the second highest value in history. The 2-days' total on Cínovec, 380 mm, is the highest one ever observed. The whole amounts of water, which fell in the Labe catchment (area of 49?033 km^2) was 6.948 km^3. The first rain period caused the big flood in southern and south-western Bohemia. The second one resulted in terrible floods in the whole Vltava and Ohre catchments. The Vltava river culminated in Prague on August 14 at noon at a level of 782 cm and a discharge of 5?200 m^3/s. This is the highest ever evaluated discharge in the Vltava in Prague in the history of routine observations, which matches a recurrence time of 500 years. On Vltava's left bank near the Charles Bridge the water level was 140 cm above the mark made in 1890 and even 55 cm above the mark of 1784. During the floods 18 people were killed, many houses destroyed, traffic and communication lines damaged as well as bridges, factories and field crops, a lot of animals died. The economical losses were estimated to billions of Euros, the highest damage to this region in written history.

The month was characterized by unusual high precipitation amounts in Austria. More then 300 percent and up to 400 percent of the average monthly total were recorded from many places There were mighty showers during the periods of August 6-7 and August 11-13 leading to disastrous high water-situations. Station Freistadt received a monthly precipitation amount of 405 mm and on August 7 a daily amount of 172 mm. At Linz–Hörsching a new extreme monthly total of 351mm was recorded. Particularly villages and towns along the rivers Inn, Enns and Danube were affected by the floods. The province of Salzburg was declared as disaster area. The total losses were estimated to 1 Billion Euro.

In France, the month was relatively cool; the precipitation regime included heavy rainstorms and came up with an overall total well above normal. Additionally, low sunshine duration was reported.

On the mainland of Portugal, the mean monthly temperature as well as the precipitation total were moderately below normal.

On the mainland of Spain, the monthly precipitation rate varied from about 200% of normal in the north-east to zero in the south-west. The monthly precipitation total at Palma de Mallorca in the Balearic Islands reached record-breaking 119.3 mm.

Northern and central Italy was affected by strong winds and flooding. A peak of 106 km/h was registered at Verona. In the period from August 26 to 29 some violent thunderstorms occurred at Turin with a precipitation total of 138 mm, Brescia (166 mm) and Rome (54 mm). The estimated economic losses were about 200 million Euro, due to damage to agriculture, mostly to viticulture.

In Slovakia, it was the wettest month of the year with a precipitation total of 159% of the normal rate. The combination of long-lasting and heavy precipitation caused numerous flood situations. The sum of material losses was estimated to 41 million Euro.

The heavy rainfalls of August 6-7 over Bavaria and Austria caused extreme flooding of the Danube in Hungary during the following days. The same cyclone carried an extreme rainstorm to the reservoir of the rivers Sajó and Hernád with the consequence of floods in that area.

In Slovenia, the monthly mean temperatures were generally above normal up to about +1.5°C. Precipitation was distributed unevenly in time and space. At the beginning of the month, abundant rainfall in the area of Goriška contributed substantially to the excess of the monthly precipitation total of about 40 % above normal. In Vipava valley the monthly precipitation accumulated to more than 200 % of the normal rate. In the Julian Alps cloudiness was above normal, and consequently the sunshine duration reached only ¾ of the long term average.

The beginning of the month in Serbia and Montenegro was characterised by very intensive rainfall, when in several days the precipitation amount was higher than the long term average total for the whole month in some areas. There was a remarkable increase of the monthly precipitation rate from west to east ranging from a little less than 100% up to more than 300% in south-eastern part of the country. Simultaneously, sunshine duration was below normal everywhere in the country and down to 44% of normal at station Pozega. In Belgrade the monthly sum of sunny hours was the lowest since 1975 (see fig.8.4).

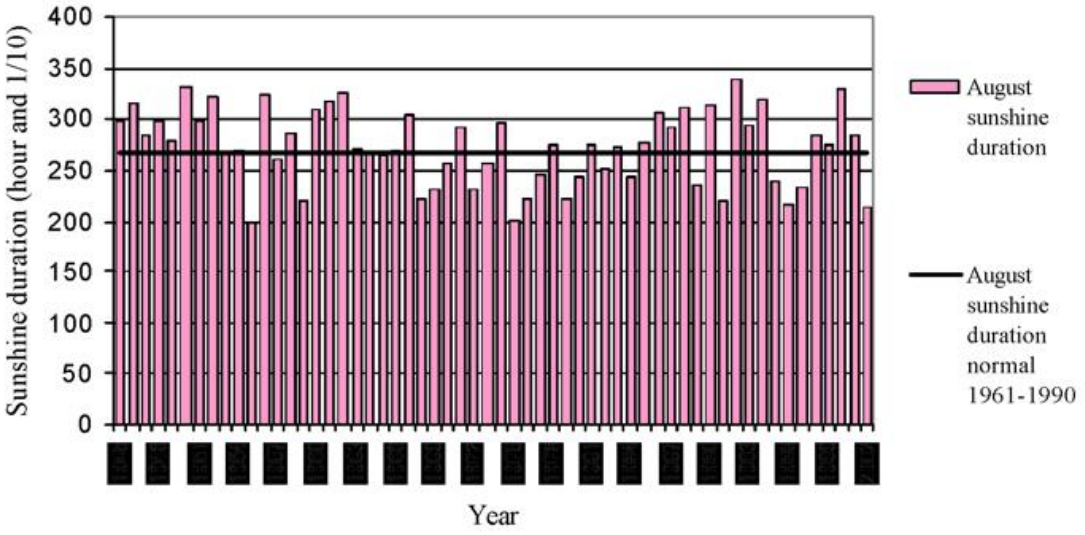

Fig. 8.4: *Sunshine duration in August in Belgrade between 1945 and 2002 and the August mean of 1961-1990.*
From: Federal Hydrometeorological Institute of Yugoslavia

Precipitation totals in Romania were in excess to normal due to torrential rainfalls, frequently accompanied by hail. A whirlwind behind a passing cold front caused severe damage to the town of Facaieni in the south-eastern plain during the night of August 11-12; three people died, houses and crops were destroyed and a lot of trees were uprooted.

In Bulgaria, the month was less warm than normal. The precipitation amounts varied in most areas between 120% and 250% and were up to 355% of the normal rainfall rate in the north-eastern part of the country. There was a great number of thunderstorms, 2 people and a sheep herd were struck by lightning. Rural and urban areas suffered from significant damage to power and traffic lines as well as to houses, especially in and around Sofia on August 7-8 and in Plovdiv on August 12.

Unusually heavy seasonal rains and thunderstorms occurred on August 25-30 in Greece, resulting in floods over the Ionian Mainland, Athens-Attiki and islands of the North Aegean.

In Turkey, heavy rainfall, partly with hail, caused flooding with severe damage to private and public property including buildings, crop fields, transportation facilities and power lines in the provinces of Kocaeli on August 4 and Erzurum on August 27.

The monthly means of temperature and the precipitation total were slightly above normal in the Ukraine. During a period of intense rainfall in Crimea on August 7-9, heavy downpours summed up to more than 100 mm at some places and caused the flooding of houses and railways and the damage of power lines.

In Russia, the Black Sea coastal area was heavily affected by rainfall on August 5-8. Torrential rains totalled 35 mm of precipitation in Novorossisk on August 5 in 30 minutes and 57 mm in Anapa on August 6 in one hour. Thousands of homes were flooded and many of them destroyed. Traffic and power lines were damaged causing the interruption of public transport and energy supply.

In Armenia, rains with thunderstorms and hailstones were frequently observed, causing significant damage to agriculture. Precipitation totals were generally rather high and exceeded 400% of normal in the north-east of the country.

The month was very wet in Azerbaijan with an overall precipitation total of nearly 200% of normal. On August 19 and 27-28 local torrents and floods were observed in rivers of the northwestern part of the Major Caucasus leading to a lot of damage to crops and farms.

Cyprus suffered from some heat waves, although the monthly mean temperature of the island was only moderately above normal.

In Israel, the month was fairly warmer than usual, but not as extreme as the month before.

September 2002

- **Much warmer than normal from the north-western to the south-eastern edge of the Region**
- **Cooler than normal from central to southern Europe and in north-eastern parts of the Region**
- **Extremely wet in the western part of the Iberian Peninsula and in a belt from the western Alps over the Balkans into Turkey**
- **Very dry from the western Mediterranean over western France, the British Isles and southern Scandinavia to the Baltic countries and Belarus**

In Greenland föhn situations gave very high and record-breaking temperatures at several locations.

In Ireland, the month was drier than normal everywhere and very sunny.

Denmark experienced an ongoing drought nearly throughout the whole month, especially in the eastern parts of the country.

The month was warmer than normal for most of Norway. From the Lofoten area and northwards, the monthly mean was below normal. The precipitation was approximately 50% of the normal rate in the southern part of the country, in the mid part near to normal and in the northern part up to 150 % of the long term average.

The period of temperatures warmer than normal lasted on in southern and central Finland, whereas the rest of the country was colder than normal.

The drought period in Latvia, ending in the middle of the month, resulted in minumum water levels in rivers, close to the lowest in1993 over a long term observation period (see fig.9.1).

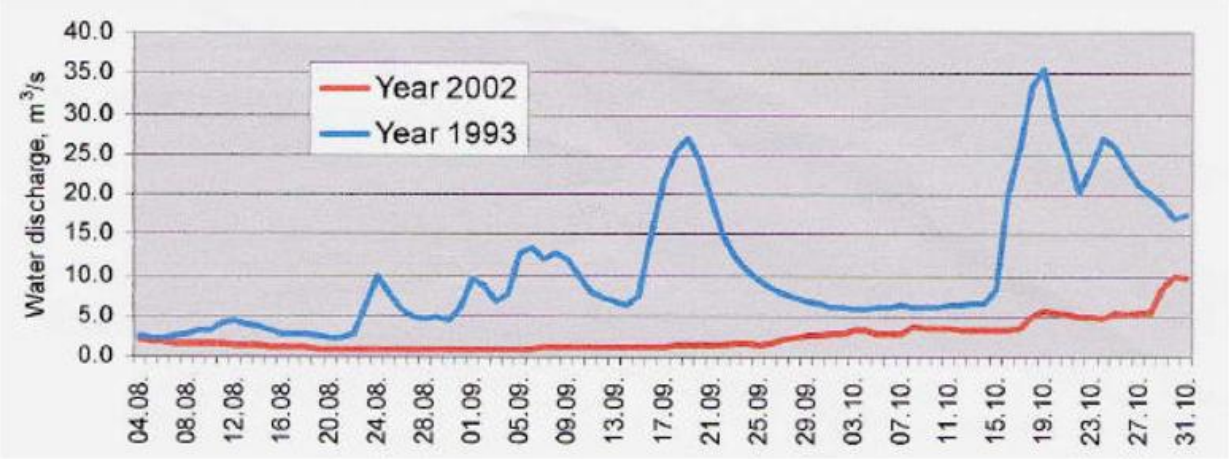

Fig. 9.1: *Water discharge of the Barta river during low flow period of 2002 (lower curve) compared to 1993 of average runoff (upper curve)*
From: Latvian Hydrometeorological Agency

The drought in Lithuania ended with rainfall and inflow of cool air by September 9 – 22. It was the longest and most severe drought since 1992 and lasted for more than 60 days in some areas. The countrywide monthly precipitation total was 41 mm, which is 60 % of the normal rate.

The continual precipitation deficit since March intensified the drought situation in Belarus. Consequences were obstructions to river traffic, damage to agriculture and an increasing risk of forest fires.

The monthly precipitation total in Belgium was below 50% of the long term

average (fig. 2.1), while the temperature was close to normal. The mean wind speed was about 85% and sunshine duration near to 90% of normal.

In Luxembourg the month was very sunny with 62 hours more sunshine than normal.

In Germany the monthly mean temperature as well as the precipitation total were nearly identical to the averages of the reference period 1961-1990. But there was a remarkable meridional trend from relatively warm and dry weather in the north to cool and wet conditions in the south of the country. Thunderstorms with heavy rains of up to 70 mm in less than 1 hour caused flooding of cities in southern Hesse, northern Bavaria and in Saxony on September 9-10. Snowfall occurred in places down to 400 m above sea level on September 24-25 in southern parts of the country leading to many accidents on roads and fallen trees; a closed snow cover appeared in Munich for the first time in this month since1931.

The monthly mean temperature in Poland was moderately above normal by +0.5°C; negative deviations were observed in the southern and positive ones in the northern parts of the country. The first frost of the season occurred in Suwalki with a minimum temperature of –1.7°C on September 24. Precipitation totals were generally 90% of normal with a great local variety, e.g. Szcecin received 140% of the normal rate whereas the total precipitation amount in Suwalki was only 20 mm, which equals 39% of the long term average. Strong mist was observed in central and eastern areas on September 5.

Catastrophic floods occurred in south-eastern France on September 8-9. Exceptional rainfall affected the Languedoc area. In the department Gard daily precipitation amounts exceeded 500 mm during this event. The highest values recorded during this spell were 687 mm in Anduze and 514 mm in Alès (s. fig. 9.2). 23 people died and one was reported missing.

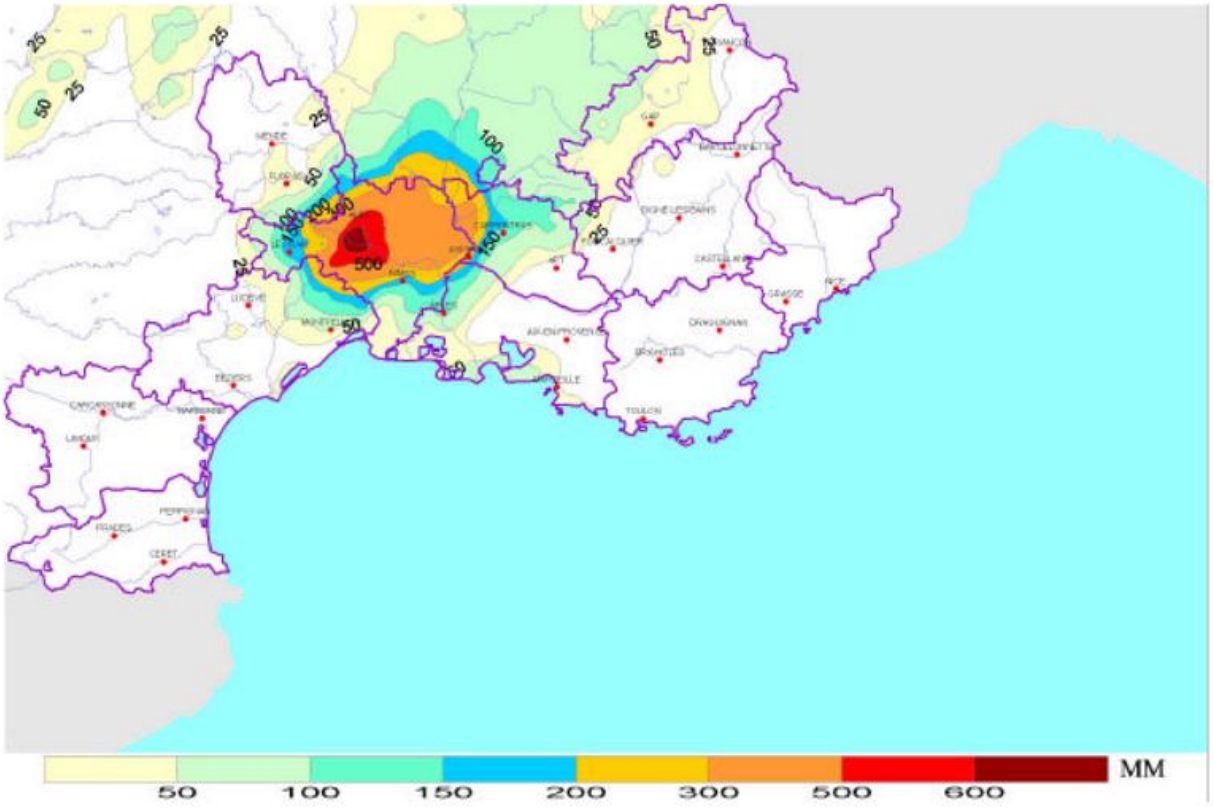

Fig. 9.2: *Precipitation totals from 8th to 9th of September 2002*
From: Météo France

In Portugal the month was cool and rainy. The monthly mean temperature deviation in mainland Portugal was –1.0°C from normal; and the deviation of the monthly

mean maximum temperature even –2.0°C. The monthly precipitation total on the mainland was about 260% (s. fig. 9.3). In southern areas the monthly precipitation amount was 7 times higher than mean value of 1961-90. The large precipitation amounts that occurred during this month caused significant damage in agricultural activities, e.g. tomato production was reduced to about 20% of the previous year's harvest.

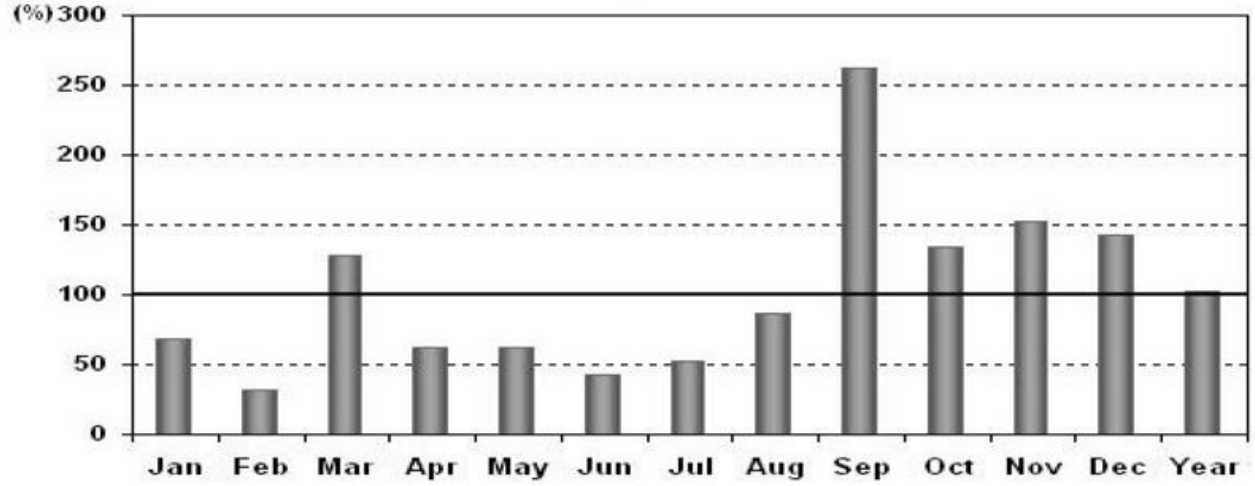

Fig. 9.3: *Monthly precipitations totals in percent of normal (1961-1990) in Mainland Portugal in 2002*

From: Instituto de Meteorologia, Portugal

The monthly mean temperature in Slovakia was slightly below and the precipitation total near to normal.

In Hungary, the monthly mean temperature was 0.4°C below normal and the monthly precipitation total 135% of the long term average. The maximum of the daily precipitation total, 141 mm, was measured in Gagybátor on September 9.

The month started relatively warm in Slovenia, but became cooler after the first ten days with the result of a monthly mean temperature moderately below normal. Precipitation was distributed unevenly in time and space. The normal monthly total was exceeded on the coast and almost everywhere in the southern part of the country, elsewhere precipitation was below normal and down to less than 70% of the long term rate in some places.

In Serbia and Montenegro, the deviation of the mean monthly temperature was negative and the precipitation total was above normal in the whole country

In Bulgaria, the month was cool and extremely wet. The monthly precipitation rate varied from about 200% of normal up to 788% at station Krumovgrad. A severe hailstorm and heavy rainfall on September 25-26 caused great damage to agriculture, communication and power lines as well as to transport facilities.

In Greece, it was the wettest month since 50 years in some areas. The monthly precipitation totals were generally around 200 % and up to more than 500% of normal at some places. E.g. station Lamia received 88,0 mm of rain, which is equivalent to 506% of the normal monthly precipitation sum. Other stations recorded even higher amounts, but with a lesser percentage of normal.

Heavy rainfall and storm affected the area of Trabzon, Turkey, on September 17. Buildings and streets were flooded, roofs torn off, trees broken and road traffic interrupted.

Very heavy rains were observed in the Crimea, Ukraine, on September 16 with precipitation amounts of 31-85 mm in 4-9 hours, and at some places of 120-150 mm in 12 hours. The Crimean economy suffered considerable damage.

Heavy rainfall caused flooding of the tributaries to the Samur river at the northern Caucasian ridge in the Russian Federation on September 19-20; in consequence mudflow damaged roads, bridges and power lines. In North Osetiya, the Kolka Glacier collapsed on September 20 and triggered an avalanche of ice and debris that buried small villages including 6 holiday complexes, killing dozens of people.

Although the monthly precipitation total was only 52% of normal in Azerbaijan, there were torrential downpours of short duration flooding the rivers in the area of Quba/Khachmaz on September 14 and of Balaken/Sheki on September 19.

The month was warmer than normal in Israel. A significant sharav event occurred on September 29-30 with temperatures reaching 37-38°C in the coastal plain and in the northern Negev.

October 2002

- **Very cold in Scandinavia, extremely dry in its central part**
- **Wet in a broad belt from the British Isles over central to eastern Europe**
- **Violent storms in many parts of Europe at the end of month**

The month was very warm in Iceland except for the last week which was unusually cold, as the new absolute temperature minimum testifies. The new national minimum temperature record for the month was reached, when -22.3°C was measured at lake Myvatn in the north-eastern inland on October 28. The previous record was set in 1957 by -21.6°C. It was also one of the two sunniest months of the year relative to normal.

In Ireland, it was one of the wettest months of the year relative to normal and a little cooler than normal over most of the country. The highest daily rainfall on record, 80.0 mm , was measured at Rosslare on October 24. The strongest winds of the year were measured during late October.

The period beginning on October 20 saw the highest 7-day running precipitation total in Northern Ireland, U.K., since records began, 114mm falling over this time.

The month was very cool and rainy in Denmark. Stormy weather on October 27-28 caused the loss of one person.

In Norway, the monthly mean temperature was well below normal for the whole country. At some places the anomaly was down to -4°C. The monthly precipitation was below normal for most of the country but parts of the southernmost region received up to 205% of normal.

An exceptionally early snowstorm hit southern Sweden on October 18-19, and a new record snow depth for this month in southern Sweden was noted close to Ulricehamn with 48 cm. More than 20 000 households were without electric supply, as wet snow broke down birches that still had leaves.

In Finland, the month was very cool and dry with temperature deviations of more than -4°C from normal and precipitation totals below 50% of normal.

A violent storm struck the Netherlands on October 27. The storm was the most severe in 12 years. Highest gusts up to 148 km/h were measured in the south-west of the country. The maximum hourly wind speed reached 101 km/h in the western coastal zone. Public life was disordered and material damage was substantial, 4 people were killed. Another extreme event was a downburst causing extensive damage in the province of Limburg on October 16.

In Belgium, the monthly mean temperature was near to normal and the precipitation total about 50% above the long term average. Stormy weather conditions with thunderstorm and hail prevailed on October 25-27 and caused lots of damage including the death of 4 people in different parts of the country.

During stormy weather in Luxembourg a maximum wind gust of 116 km/h was measured on October 27.

An intense storm hit northern France also on October 27: The wind speed exceeded 100 km/h and highest gusts of 130 km/h and more were recorded on exposed coasts (see for example fig. 10.1) with the consequence of several casualties.

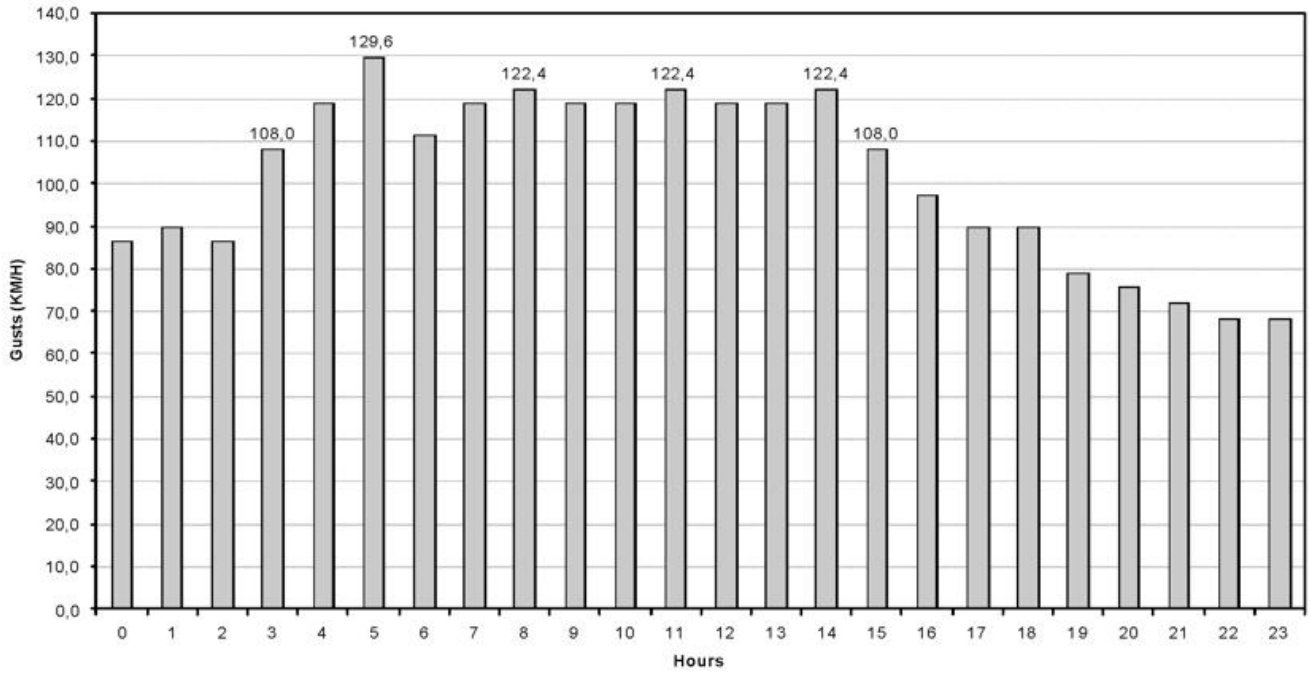

Fig. 10.1: *Hourly maximum wind gusts on 27-10-02 in Cap de la Hague (Manche)*
From: Météo-France

It was the first month of the year with a countrywide negative temperature anomaly in Germany, -0.8°C. A local record for the coldest October 13th since more than 100 years, 4.0°C, was set in Hamburg. The overall precipitation total was 106.4 mm and thus exceeded the normal value by 91%. It was the 10th wettest October since 1901. Three major storm events affected the country on October 22-23, 25-26 and 27-28, especially in the low mountain ranges with winds of hurricane force. During the latter event highest gusts were observed at the mountain stations Fichtelberg (183 km/h) and Brocken (176 km/h) and in Gütersloh (148 km/h). Severe damage occurred to all kinds of transportation facilities, to houses and church towers, wind generators and power lines. Twelve people were killed and 50 injured.

In Belarus, the monthly precipitation total was about 280 % of the average rate of 1961-1990 (fig. 10.2).

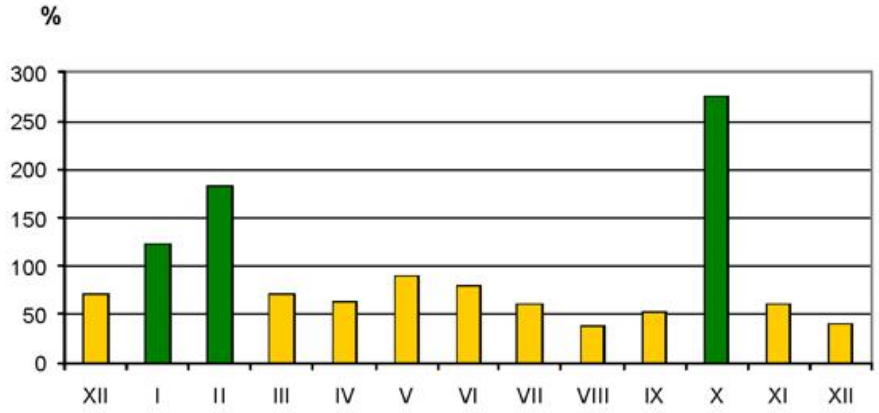

Fig. 10.2: *Monthly precipitation total in % with reference to the period 1961-1999*
From: Ministry of Natural Resources and Environment Protection, Belarus

Strong winds affected Austria north of the main Alpine ridge on October 26-28. In Upper Austria numerous trees were uprooted on October 27 and several streets were blocked. One day later in Tyrol gusts up to 140 km/h caused traffic obstructions, the destruction of power-lines and the damage of houses and cars.

The countrywide monthly mean temperature anomaly in Poland was –1.2°C and the overall precipitation total 208% of normal. It was the wettest month of the year except for February. Station Chojnice received even 300% of the long term average precipitation. Strong winds with gusts up to 101 km/h were observed on October 27-28.

The mean monthly temperature in Lithuania was 4.5°C and thus 2.7°C below normal. The monthly amount of precipitation was abundant with 123 mm, which means 203 % of normal. The rains were very welcome for the national agronomy.

In Latvia the monthly temperature anomaly was nearly down to –4°C and the precipitation total about 110% of normal.

In the mainland of Portugal the monthly mean temperature anomaly was +0.4°C and the precipitation total about 130% of normal. Heavy rain caused floods in Lisbon on October 8. Thunderstorms with heavy rain, strong winds and hail caused the flooding of roads and the damage of houses, forests and power lines in central parts of the country on October 29.

A tornado was registered at Lladux, Spain, on October 21.

In the Ukraine the monthly mean temperature was close to normal, while the precipitation amount summed up to 200% of the long term average.

In Romania, it was moderately cooler than normal and very wet. The countrywide precipitation total was about 200% of the long term average

The month was very rainy in Bulgaria with precipitation rates of generally around 200% of normal and particularly of 400%-500% in the north-east of the country.

Cyprus had only 29% of normally 33 mm precipitation. The monthly mean temperature was +1.2°C above normal. A water-spout turned into a tornado over land in the western part of the island on October 8 and caused injuries of people while damaging touristic installations. Heavy thundery showers in the area of Nicosia on October 14 caused flooding and fire from lightning.

The most significant weather event in Israel occurred on October 15 and it included severe hail, intense thunderstorms, heavy rain and strong winds in the central coastal plain. Very large hailstones caused severe damage to homes, cars and trees. In some places the size of the hailstones was 4-5 cm and even more. On October 30-31 heavy rains, 40-50 mm, fell in the Negev Desert causing floods in the area.

November 2002

- **Very cold and dry in northern Scandinavia**
- **Very mild from Svalbard, Greenland, and Iceland over the British Isles and France to the Alps and the northern Balkans**
- **Very wet over the British Isles, the western Alps and southern parts of Italy and Greece**
- **Intense Alpine foehn event in the middle of the month**

In Iceland it was very mild with monthly mean temperatures of +3°C and more above normal. The snow cover was far below normal in most parts of the country. The eastern parts of the country received exceptional precipitation. A new absolute monthly total record was established, as the accumulation approached 1000 mm at two stations in the east. This case is exceptional, as the stations involved have average annual totals of less than 1500 mm. Although a few roads were blocked by local flooding and debris flows and a house was hit by a landslide, the total damage was relatively small considering the circumstances.

Relative to normal it was one of the wettest months in Ireland with serious flooding in both rural and urban areas. The monthly mean temperatures were over two degrees higher than normal in places.

In Norway the month was colder than normal for the whole country In the northern and southern mountainous terrain the anomaly was about –4.0ºC. In the eastern part of the country the precipitation was above normal but well below else.

Sleet and icing events accumulated heavy loads on trees in some areas of southern and south-eastern Finland. Consequently many of these trees were cut and caused considerable economic losses to forestry.

The month was relatively mild and wet in Belgium. There was one major event of heavy precipitation with flooding in the south-eastern part of the country on November 10-11.

In Luxembourg, the monthly mean temperature was +2.3°C above normal.

The monthly mean temperature in Germany was 5.5°C and thus +1.5°C above normal. The precipitation total amounted to 111 mm, which is 168% of normal and the third wettest November since 1901. Heavy snowfall up to 10 cm caused a lot of accidents on roads in the eastern parts of the country on November 4. Intensive rain on November 11 triggered flooding of the river Rhine and some of its tributaries. Three foehn events with gusts up to 250 km/h at the mountain station Zugspitze caused severe damage to the infrastructure in the foothills of the Alps on November 14-16, 21 and 25.

Temperature anomalies in Poland varied from –0.6°C in Szczecin up to +3.2°C in Lesko with a clear gradient from north to south. In Krakow a maximum temperature of 20.3°C was measured on November 16. The countrywide monthly mean temperature came up to +0.9°C above the long term average. The overall precipitation total was 87% of normal with a spatial variation of values below 60% in the eastern and above 200% in the western parts of the country. Strong foehn winds caused a lot of damage to the forests of the Tatra National Park on November 15. Maximum gusts were up to 108 km/h in Zakopane and 130 km/h at the mountain station Kasprowy Wierch.

The month started very cold in Lithuania and became much warmer in its second half resulting in a monthly temperature anomaly of -0.3°C. Precipitation amounted to 34 mm only, which is 52 % of normal.

Belarus had a temperature anomaly of +0.5°C and a precipitation deficit of 40%.

The month was very mild in France with temperature anomalies between +3°C and +3.5°C. Exceptional rainfall affected the southern and central eastern parts of the country on November 13-17; cumulated precipitation exceeded record values for November. Thunderstorms with intense rain caused floods in eastern areas on November 23-24, people were evacuated in the departments Var, Vaucluse, Drôme and Ardèche. At Cap-Béar close to the Mediterranean sea shore the maximum wind gust of the year, 144 km/h, was recorded on November 7.

During a powerful foehn situation in Austria on November 14-16 new records of absolute maximum temperature for the month were registered, i.e. 21.5°C in Klagenfurt and 22.8°C in Graz. The previous records were 18.6°C and 19.7°C respectively and date back to 1963. This foehn episode was accompanied also by strong winds with gusts of about 150 km/h. Severe damage occurred to the infrastructure and forestry in the area of Salzburg, The material losses were estimated to 95 million Euro.

The first third of the month in Slovenia was slightly colder than normal, but then it became exceptionally mild. The monthly temperature anomalies in the lowland resulted in values between +3°C and +5°C; during the last 52 years the monthly mean air temperature was higher only in 1963. A stormy southerly wind blowing between November 14 and 16 caused severe damage to houses and forests.

The weather in Hungary was mixed between the first snowfall on November 4 and a succeeding late Indian summer with daily maximum temperatures above 15°C everywhere in the country. Local records of the maximum temperature were set at stations Keszthely, 23.9°C, and Fonyód, 24.0°C on November 15. The daily mean temperature in Budapest was above 18°C for 5 consecutive days, which is without precedence in the last 50 years. The countrywide monthly mean temperature came up to be +3.2°C above the average of the reference period 1961-1990 (see fig. 11.1).

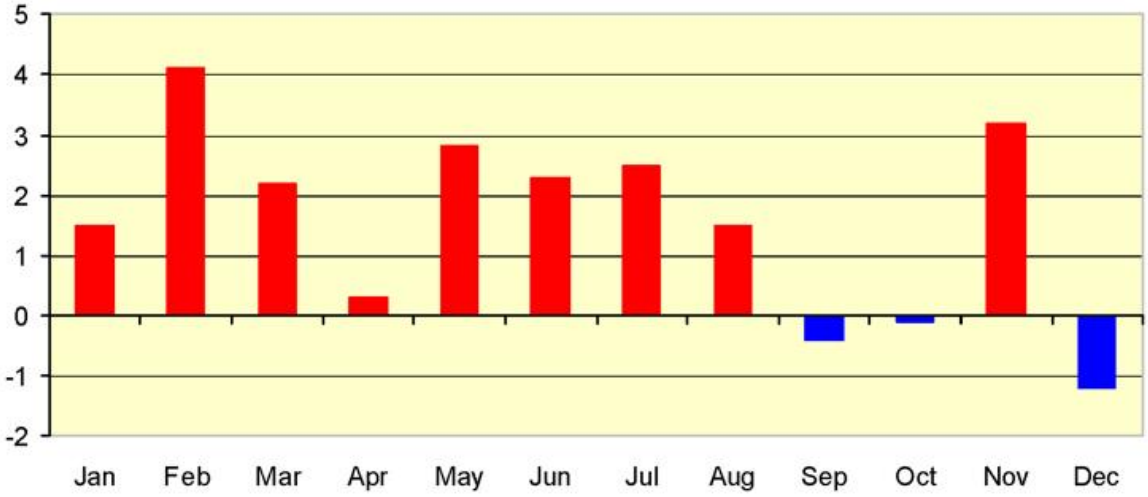

Fig. 11.1: *Monthly temperature anomalies in Hungary in 2002 (reference period 1961-90).*
From: Hungarian Meteorological Service

Extremely high mean monthly temperatures and very low precipitation amounts characterised the weather in Serbia and Montenegro.

In Romania the month was very mild with significant positive temperature anomalies.

Italy was hit by some intense weather events with flooding. During a violent thunderstorm in Tuscany on November 1, a precipitation amount of 104 mm was measured at Grosseto. In the period of November 22-30, intense precipitation occurred in the north-western part of the country. The largest precipitation amount of 300 mm in this episode fell at the Pass of Giovi near Genoa at 475 m above sea level. The damage to agriculture has been estimated to about 350 million Euro. In the same period, fifteen houses were destroyed by landslides following the flood and one person died.

In Cyprus, the month was very warm and extremely dry.

On the occasion of an hailstorm in the area of Antalya, Turkey, greenhouses and plantations of citrus fruits were heavily damaged on November 22.

The month was warm and dry in Israel. In most areas rainfall amounts were only 50% of normal. There were long periods of hot and dry weather with temperatures reaching more than 30°C.

The month was very dry in Armenia with a general precipitation rate of only 30 % of normal.

In Azerbaijan, the month was significantly warmer and drier than usual. The temperature anomaly was +2.8°C and the precipitation totals varied from 25% to 49% of normal.

December 2002

- **Extremely mild in Greenland, Iceland and Svalbard, very mild also in south-western Europe**
- **Very cold in eastern Europe and parts of the Middle East, extremely cold and wet in the Caucasus**
- **Extremely dry from Scandinavia over Poland to the Ukraine and central Russia**

Some foehn situations in Greenland yielded very high and record-breaking temperatures at several locations.

In Iceland it was one of the warmest December months on record in most parts of the country. At a few stations the previous record holder, December 1933, was surpassed. The absolute maximum temperature in Reykjavik in December was 12.0°C, the same as the previous record. The snowcover in the north of th island was the lowest on record for this month.

The monthly average temperature in Norway was below normal for the whole country except for some coastal areas in Finnmark County. In southern parts of the country the anomaly was –3°C to –4°C. The monthly precipitation amount varied from near normal to well below normal. Coastal areas in the southern part and the north-eastern part received nearly 100% while coastal areas in the western part received only 25%. Due to a blocking situation in northern Europe in the end of the year, the station Finsevatn recorded the highest air pressure, 1058.7 hPa, ever measured in this month in Norway. on December 8. Extremely high temperatures were observed in the Svalbard area during December 3-8. All regular weather stations recorded temperatures higher or equal to the previous December records. The maximum temperature of 7.9 °C at Svea Gruber on December 7 is the highest December temperature ever measured in Spitsbergen.

The month in Denmark was mild in the beginning, but then the weather became cool and dry with easterly winds and without any snow.

The unusually cold weather in Sweden culminated with –41°C close to Jokkmokk in Lappland on December 24.

In Finland the month was clearly colder than normal in the whole country.

Many areas in the U.K. experienced flooding at the end of the month following heavy rainfall that started on December 26 and lasted into the next year.

The monthly mean temperature in Belgium was moderately above normal, while the precipitation total clearly exceeded the long term average. Intense precipitation with flooding occurred on the occasion of two major events: in west Flandres on December 5 and in the south-eastern part of the country on December 29-31.

In Germany as a whole the temperature anomaly was slightly negative and the precipitation total nearly reached the normal amount. But there were considerable differences between the very cold and dry northern and the mild and wet southern parts of the country. A cold spell on December 9-11 made some lake surfaces freeze and enabled the harvest of frozen grapes for the making of sweet wine; three people froze to death. Freezing rain and snowfall caused chaos with many accidents on roads and motorways during two other weather events in the north and the east of the country, namely on December 13-18 and 23-26.

In Poland it was a typical cold winter month with a temperature anomaly of –4.1°C. According to a rather low precipitation rate of 51% of normal the snow cover was rather poor. Deep frost of nearly –30°C was observed in the valleys of the Carpathian Mountains on December 26. Icing made a lot of problems on the roads on December 29.

The weather in Lithuania was determined by anticyclones in northern latitudes. This circulation pattern led to very low temperatures, 5.5°C below normal, and scarce precipitation, less than 50% of the normal rate.

The weather conditions in Latvia were very cold with a temperature anomaly of –5°C and dry with a precipitation rate below 60% of normal.

The monthly mean temperature anomaly in Belarus was down to nearly –6°C, while the precipitation total was below 50% of normal.

The month was extraordinarily warm in all parts of France, especially at its end. New records were reported like a daily maximum temperature of 24.7°C in Herrère on December 23 and a daily minimum temperature of 11.9°C in Saint-Yan on December 27. The month was characterised also by a large deficit of sunshine duration: in Dijon with only 3.05 hours between December 1 and 15, it was the lowest sunshine duration for this period since 1947.

The month was unusually warm in the west and south of Austria. The monthly mean temperature in Bregenz reached 4.4°C, which is the highest observed value since 1880, when it was 5.1°C.

The month was very cold in Slovakia with temperature deviations down to –3°C below normal at some stations in the central and eastern part of the country.

In Hungary the monthly temperature anomaly was –1.2°C, while the precipitation total nearly reached the normal amount. The lowest temperature of the year, -28.3°C, was measured in Zabar on December 26.

The monthly mean temperature in Slovenia was clearly above normal with highest anomalies up to +3°C near the coast. Precipitation was abundant at some mountain stations, but scarce at other places like Potorož at the coast with less than 40% of normal.

In Serbia and Montenegro it was a typical winter month with clearly negative temperature anomalies. A snow cover was formed in the second part of the month

The month was very cold in Romania with a temperature anomaly of –2.6°C.

The month started mild and rainy in Bulgaria. After the first week temperatures dropped down to –18°C and snowstorms with gusts up to 86 km/h caused significant damage in the eastern part of the country. Electric power supply was interrupted, hundreds of car accidents occurred on slippery roads, 10 people died.

The monthly average temperature in Portugal was well above normal essentially due to the positive anomaly of about +2.0ºC of the minimum temperature. The precipitation rate was about 140% of normal. Heavy rain and strong winds occurred, mainly in the northern parts of the country on December 25-27. Water levels rose about 7 meters higher than normal in Douro River and 5 meters in Tâmega River. The swell of the river basins caused several floods that submerged roads, dislodged people and led to the interruption of railway traffic. The sea weather conditions forced the closure of several harbours in northern and central coastal zones.

The month was cool and rainy in Israel. Rainfall amounts were 150%-200% of normal and there was a large number of rain days. In the northern and central parts of the country there were 12 succesive days of rain from December 15-26, which is a unique event in Israel.

Unstable weather conditions including thunderstorms with hail prevailed in Cyprus. The monthly precipitation was well above normal, while the monthly mean temperature was near to normal. A tornado caused damage to homes and greenhouses in the western coastal area on December 6. Another tornado in the western part of the central plain again caused damage to farms on December 8. On the same day a very severe hailstorm in the southeastern part of the island caused extensive damage to buildings, cars and farm land. Flooding occurred in the towns of Nicosia, Larnaka and Limassol and land slides in mountain areas.

In Turkey it was very cold, especially at the end of the month. At 75% of 110 stations the long term record of minimum temperature was broken within the last ten days of the month.

The month was extremely cold and dry in the Ukraine. The temperature anomaly was down to about –7.5°C and the precipitation rate was only 40% of normal.

The monthly mean temperatures in Russia were very much below normal, especially the southern areas experienced anomalies down to -8°C. Strong winds with gusts up to 137 km/h in combination with low temperatures caused severe damage to the city of Novorossisk at the Black Sea. One vessel sank and another one stranded because of ice formation. Throughout the month the danger of avanlanches continued in the northern Caucasus area. The situation culminated to the end of the month, when seven people died and several villages were cut off in a series of avalanches.

In Armenia the month was very cold and snowy. The monthly temperature anomalies were generally about -4°C, in Ararat and Sunick valleys down to –8°C. In Yerewan the absolute minimum temperature reached -28^{0}C and -32^{0}C in Ararat town. It was the coldest December since the beginning of observations in 1954. Temperatures dropped down

especially in the second half of the month (e.g. see fig. 12.1). The period with temperatures below -14°C lasted for about 150 hours in Ararat valley and caused significant damage to vineyards and orchards. Material losses are estimated to 30 million Euro. The precipitation totals were about 200% of normal, in Ararat valley even up to 300%. A snow cover was established everywhere with a depth varying from 20 cm up to 50 cm in mountain areas.

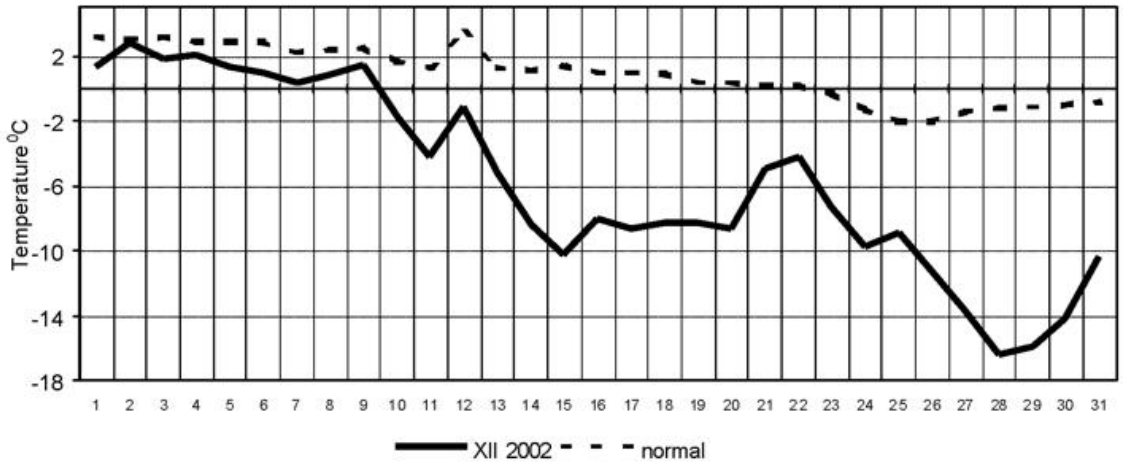

Fig. 12.1: *Daily mean temperature in December 2002 and normal values in Yerevan*
From: Department of Hydrometeorology of the Republic of Armenia

Abnormal cold and wet weather conditions prevailed in Azerbaijan. The monthly mean temperature deviation from normal was -4.3°C, which statistically occurs once in 86 years. Frost periods were accompanied by strong northerly winds and the daily mean temperature dropped down to 9°C below normal on some days. The lowest daily mean temperature in Baku was –2.9°C on December 25. The absolute minimum temperature was measured in Nakchivan on December 28, -30°C. This is 5°C lower than the absolute minimum temperature within the last 100 years. A stable snow cover appeared all over the country. The cold weather conditions caused difficulties in energy supply, 11 people died. The monthly precipitation total as a mean value of all stations was 253% of normal (see fig. 12.1). The precipitation in Baku amounted to 183.9 mm, which is 5.7 times the monthly and 74% of the annual long term average at this station.

Activities and Results of European Climate Centres

The Century Flood of the River Elbe in August 2002:
Meteorological Conditions and Climatological Aspects

By: Bruno Rudolf and Joerg Rapp, Global Precipitation Climatology Centre (GPCC)
German Meteorological Service, Offenbach/Main, Germany

1 The Flood

The meteorological cause of the catastrophic floods along the Danube and - in particular – the Elbe rivers in August 2002 was an extraordinary weather situation with various meteorological factors leading to such extreme precipitation as has never been recorded before in Germany. In parts of the Erzgebirge (mountain range between Germany/Saxony and Czech Republic) more than 300 mm fell in one day, and even in the region north of the low mountains more than 150 mm fell over a widespread area in 24 hours, and in the Berlin area approximately 100 mm were recorded.

The extreme precipitation was followed by a very quick rise in the water levels of the Elbe tributaries, in particular the rivers which drain the Erzgebirge to the north. The water level of the Elbe subsequently reached a maximum mark, which had not been recorded for centuries. The total economic damage resulting from the August flood (the Czech Republic: € 3 billion, Austria: € 3 billion; Germany: € 9.2 billion) represent a new European record for flood damage.

Floods never have merely one single cause, therefore it is important from the point of view of climatological research to examine more closely the individual meteorological factors leading to the flood. Only in comparison with the climatic temporal-spatial precipitation distribution it can be assessed how extraordinary and extreme the meteorological conditions for this event really were.

2 Synoptic description of the weather situation

An essential cause of the catastrophe was the transport of cold maritime air from the Icelandic-Greenland area to the western Mediterranean Sea days before, where on 10 August a well-defined upper-air trough was formed. Dynamic lifting processes led to a rapid fall in air pressure in front of this low over Upper Italy, so that in the night of 11 August over the northern Adriatic Sea a so-called Vb-low was formed. The low included extremely moist and warm Mediterranean air into its circulation, a process that was decisive for the precipitation potential that later existed over Central Europe.

The low subsequently moved on "a Vb-track" north-eastwards (Figure 1), whereby its cloud structure was increasingly transformed into a vortex. At this time high-reaching frontal cloud bands with heavy rainfall, which also included thunderstorm cells, were already lying over the southern side of the Alps and over the Alps themselves. By 12 August the low had moved towards the Czech Republic, strengthening all the time, and later reaching Saxony. On the northern and western side of the low an expanded and strong lifting was connected to a divergent upper current, whereby persisting and abundant large-scale precipitation was initiated. Due to stable high pressure areas over eastern and western Europe the low finally became almost stationary and pivoted itself to a certain extent exactly over the eastern part of Germany. The atmosphere here was supplied again and again with warm and very moist, unstably layered Mediterranean air, which experienced a large-scale lifting, condensation and immediate raining out.

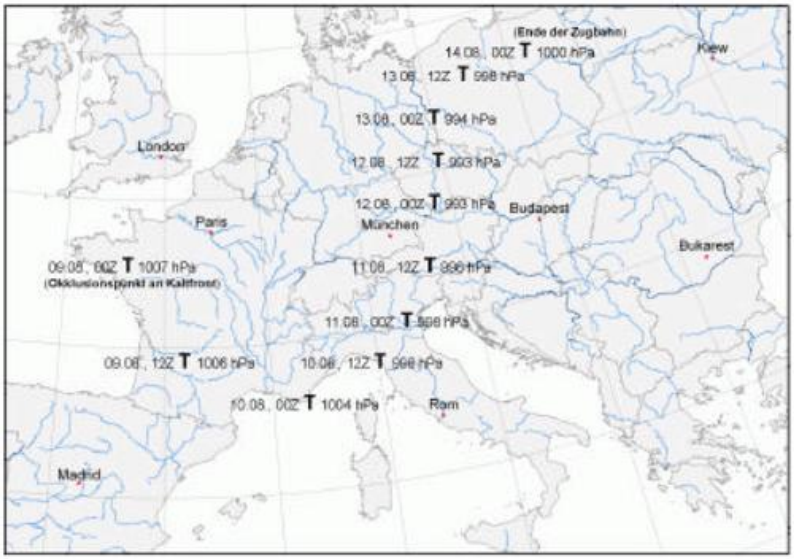

Fig. 1:

Track of the "Vb-low" with indication of the core pressure.

The situation was intensified by the fact that on 12.08.2002, in the region of the Erzgebirge, due to the fall in pressure in the east and the increase in pressure in the west a strong pressure gradient developed, which resulted in a freshening, stormy north-west wind in this mountainous area. As a consequence, the air mass saturated by water vapour was orographically lifted in the Erzgebirge area, which led to extraordinary heavy precipitation.

The impact of at least five meteorological factors upon one another led to the catastrophic flood:
The (1) large-scale, strong and quasi-stationary lifting area was connected with the development of the Vb-low, and is to be classified as an essential synoptic precondition of the heavy precipitation. The large-scale constellation of pressure and airflow over Central Europe changed only very slowly. Warm and very moist air was guided from the Mediterranean and Black Sea via the typical Vb-track, water vapour saturated and with an extended (2) very high liquid water content, a necessary condition for record precipitation, which is naturally fulfilled much better in summer than in winter. (3) Convective precipitation processes in the moist-unstable air mass further east constituted a considerable additional effect locally. Essentially more significant, however, was the (4) additional orographic lifting windward of the Erzgebirge due to a reinforcement of the pressure gradient in the rear of the low. Finally the (5) already deeply water saturated ground and the relatively high water level of many rivers due to the heavy rainfall in the weeks before was responsible for the explosive nature of the Elbe flood, particularly since this river drains - contrary to most of the other rivers - the whole mountain range and not only one side.

On the basis of a synopsis and an interpretation of the observation material available (total precipitation measured at stations, other weather observations, radar and satellite images, lightning echoes etc.), the following estimation of the causal proportions of the various precipitation mechanisms can be made:

- Stratiform (scaled) precipitation — 2 thirds
- Convective precipitation (showers, thunderstorms) — 1 third
- Orographic intensification along the mountains — doubling of the totals

The extremely high diurnal precipitation and the devastating flash floods caused by it, which affected the places in and close to the Erzgebirge, resulted thus above all from the lifting at the northern edge of the mountains. Over all, the precarious flood situation along the Elbe and its larger tributaries with flooding in many places and towns was due to the combination of the five causes described above.

3 Observed precipitation data

The extreme dimension of the flood disaster was thus based also on the soil moisture saturation resulting from the rainy weather before. Figure 2 shows on the left the precipitation totals for the period 6 - 8 August. The rainfall first centred on Upper Austria with amounts of more than 100 mm which led to heavy flooding along the Danube, but it also rained considerably (20 to 30 mm) in the Erzgebirge. Some days later the heavy rainfall expanded northwards to include the Czech Republic, Saxony and Brandenburg. In the period 10 -13 August, 100 mm were exceeded over widespread areas, with many places in the Erzgebirge reaching the 200 mm threshold (Figure 2 on the right).

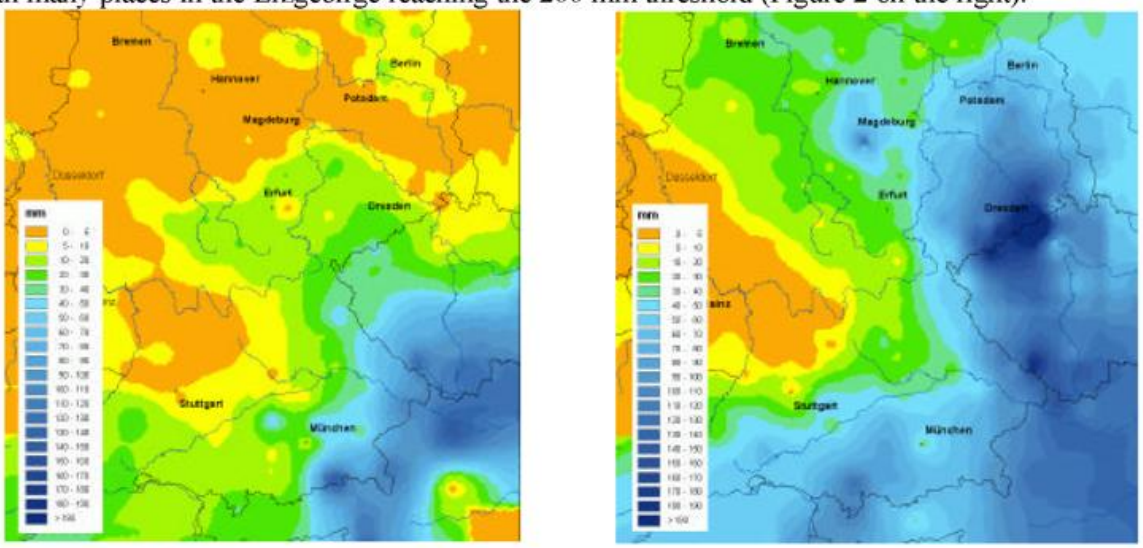

Fig. 2: *Precipitation totals of the periods 6 - 8 August (left) and 10 - 13 August, 2002 (right).*

Zinnwald-Georgenfeld even reported 380 mm of rain. 312 mm fell on one day alone (06 to 06 UTC the following day), or even 353 mm if the reference interval is shifted by three hours (03 to 03 UTC). Radar-based precipitation estimates showed even a maximum of 400 mm/24h. Table 1 shows further impressive individual values of the total precipitation measured. For example, in Dresden, 158 mm fell in 24 hours. The record precipitation also led to unusually high monthly values, which in the areas concerned varied mostly between 150 and 300 mm, which constitutes 200 to 350% of the rain which normally falls in the month of August (reference period 1961-1990).

Tab. 1: *Measured precipitation totals for various periods in August 2002 and August normals.*

Station name	Station height ab. msl (m)	Geogr. latitude (deg:min)	1 day totals 12 August 2002	3d-totals 10.-12. August 2002	August totals 2002	August normals average 1961-90	relation of August 2002 to 1961-90

Grosser Arber	1446	49:07	88.5	121.1	261.6	131	200%

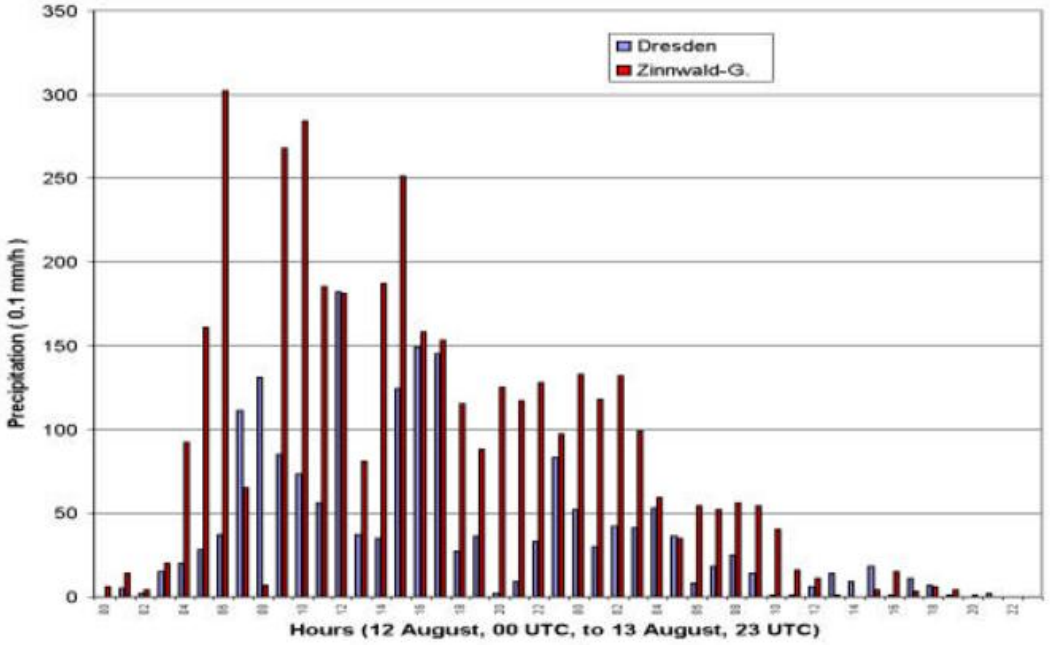

Fig. 3: *Hourly precipitation totals from 12 August, 00 UTC, to 13 August, 24 UTC.*

The exact temporal course of events on 12 and 13 August is shown in Figure 3. The severe rainfall began in the early hours of 12 August and persisted, but with high fluctuations, until the late morning of the following day. On the first day extreme hourly precipitation totals of up to 30 mm were measured in the Erzgebirge (Zinnwald-Georgenfeld), and even in the northerly foreland (Dresden) 15 mm or more fell repeatedly. By 13 August the rain intensity had decreased.

4 Climatological assessment

200 per cent of the normal August precipitation had already fallen in the first half of August 2002 in a belt reaching from Berlin and Brandenburg via Saxony to the Czech Republic. In the Erzgebirge and in the southern Czech Republic even three times the mean monthly precipitation total occurred in this time. With a maximum monthly precipitation total of 470 mm for August 2002 in Zinnwald-Georgenfeld, more than four times the normal August precipitation was measured.

The maximum of both, the regional precipitation total as well as the anomaly, cover the Erzgebirge, located in the Elbe catchment area. The belt of the unusually high monthly precipitation follows to a large extent the course of the Elbe river (Figure 4). The measurements from many stations in the area extending from Austria via Saxony to Berlin/Brandenburg resulted in the highest monthly precipitation totals ever measured in August since records began. Figure 5 shows the time series of the August precipitation for selected stations.

On 12 August 312 mm was recorded at the DWD station Zinnwald-Georgenfeld, the highest daily precipitation total ever measured in Germany. Up to then 260 mm was considered as record daily precipitation total, observed on 6 July 1906 in Zeithain, district of Riesa. The three-day (406 mm) and monthly (470 mm) precipitation totals measured in Zinnwald-Georgenfeld had, however, already been clearly exceeded in Stein, district of Rosenheim, in July 1954 with 458 mm in three days and 777 mm for the month (see Table 2).

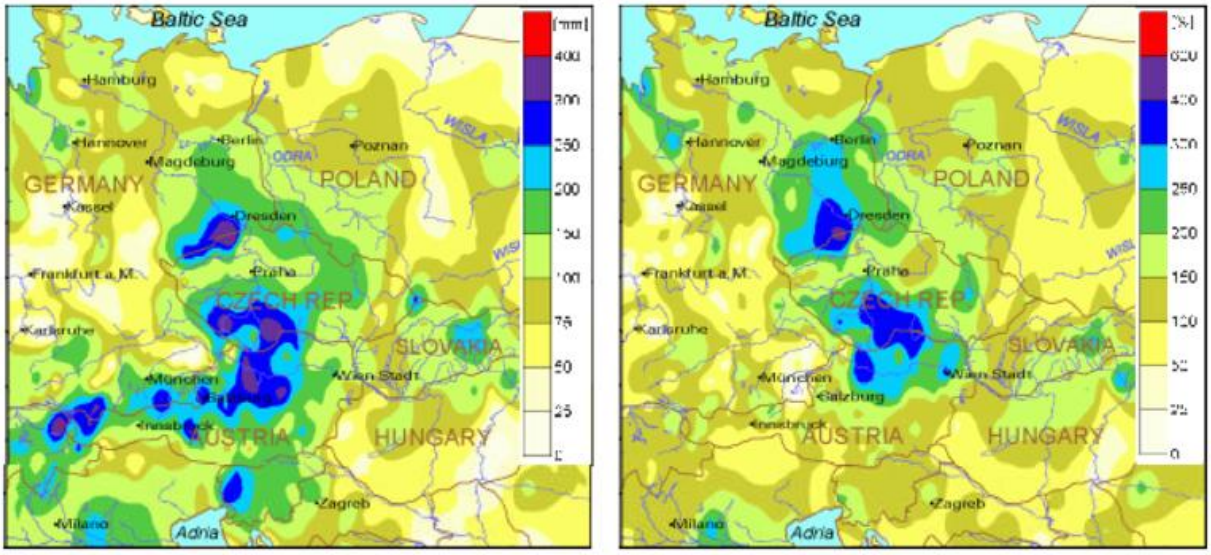

Fig. 4: *Monthly precipitation total in mm/mon for August 2002 (left) and the amount of precipitation in per cent in relation to the period 1961-1990 (right). Data base: Observations of 614 stations (left) and 415 stations (right).*

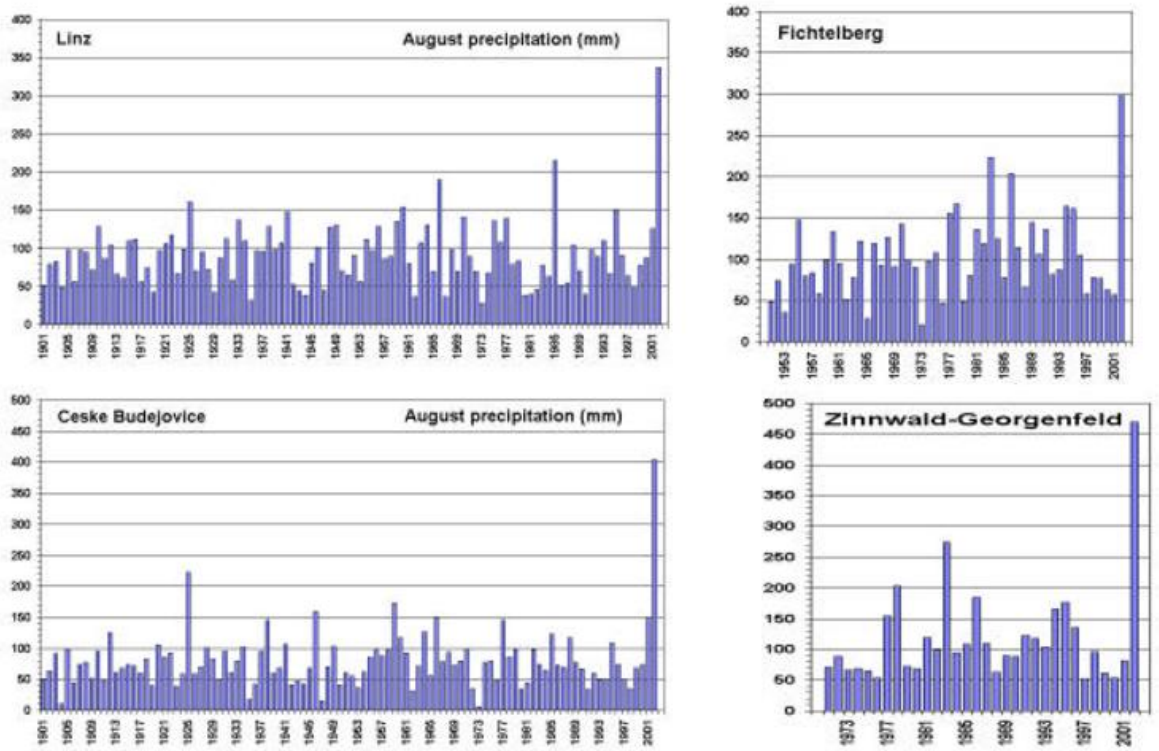

Fig. 5: *Time series of monthly August precipitation totals at the stations Linz (Danube), Ceske Budejovice (Czech Republic), Fichtelberg and Zinnwald-Georgenfeld.*

Tab. 2: *The extreme precipitation totals observed in Germany for various observation time intervals (one observational day = 06 UTC to 06 UTC subsequent day).*

interva	Precipitation depth(mm)	Station name (district / province)	Date

1 month	777	Stein (Rosenheim)	July 1954
12 months	3,661	Purtschellerhaus (Berchtesgaden)	Dec. 1943 - Nov. 1944

But even higher possible precipitation than observed has been calculated for our climate: The study "Maximierte Gebietsniederschlagshöhen in Deutschland" (Maximised Areal Precipitation Totals in Germany), carried out by the DWD (DVWK 1997), provided "a regionally adjusted maximised grid point precipitation total" of 375 mm/24h and 445 mm/72h for the eastern part of Land Brandenburg and 800 mm/24h and 1340 mm/72h for the eastern part of the Bavarian Alps. Corresponding values for the Erzgebirge area were not published. These values were estimated on the basis of the extreme values observed in the region, the regional land form (orography) as well as the most unfavourable values for humidity and wind speed. The authors of the study vote that the results represent "an approximation to the possible physical/climatological maximum" and that the calculated values will not be reached "according to human estimation", however, they also state that these values could apply to the current climate conditions only.

This restriction applies in particular to the recurrence times of heavy precipitation totals, used in applied hydrology, in particular in hydraulic engineering, which are based on observed precipitation data from the 30-year period from 1951 to 1980 (Bartels et al. 1997). The counting of the measured values (classified according to duration and total amount of precipitation) and application of a statistical extreme value distribution resulted in recurrence times for periods of up to 100 years depending on station. According to these statistics the maximum 24- and 72-hour precipitation totals observed in August 2002 at the stations Zinnwald-Georgenfeld, Fichtelberg, Marienberg and Dresden-Klotzsche are expected to occur less than once in 100 years. The DWD plans to update the atlas of recurrence times for the total period 1951 to 2000. A comparison of the results for two subperiods could then supply information on changes in extreme value behaviour, particularly recurrence times, as a result of the climate change during the second half of the 20th century. The first results of another study, independent of this project, with the few available long data series (Grieser and Beck 2003) already show that a change in the extreme value behaviour of daily precipitation totals in Germany can be proved to be significant.

In the previous considerations it had not been stressed that precipitation is not only a basic quantity in relation to time (there is no exact instantaneous recording, but only - although short - time intervals can be observed), but is also in principle an area-related quantity. Even the observation "point", i.e. the funnel of the precipitation gauge is, strictly speaking, an area. According to general technical opinion, the conventional local gauge measurements represent, in case of a suitable installation of the instrument, daily precipitation or of longer time intervals within a radius of approximately 3 km or for an area of 25 km².

In order to quantitatively assess the precipitation, which led to river floodings, it is thus necessary to determine the spatial distribution and area mean of the precipitation from the point data of the measuring networks, whereby radar images and numerical models can provide additional information. In the already above-mentioned DVWK-Study empirically computed maximised area precipitation of different duration (1, 12, 24 and 72 hours) and area sizes (25, 100, 500 and 1000 km²) separated for summer and winter conditions for Germany were mapped. With an area of 1000 km² the northern Erzgebirge falls within the classes 300 mm/24h to 400 mm/24h and/or 450 mm/72h to 550 mm/72h. The precipitation totals observed there in August 2002 show that the results of this study are by no means unrealistic.

Based on the generation mechanisms of precipitation a relationship exists between the maximum precipitation total, its duration and the spatial expansion of the affected area. To put it simply, it can be presupposed that, the longer extreme precipitation persists, the larger the affected area is. In this connection, however, different factors play a large role, firstly the regional orographic and climatic conditions in general and then, in individual cases, the weather situation.

Heavy precipitation, which leads to regional flash floods, is not at all unusual in the Erzgebirge (Marx 1966, 1966a and 1967). In the evening of 8 July 1927, for example, two unusual cloudbursts occurred over the watershed between the Mueglitz and the Gottleuba (Alt and Fickert 1936), which in the shortest time produced precipitation totals of up to 200 mm. These resulted in devastating flash floods of the rivers concerned, which were regionally limited to a small area. The precipitation responsible for the Elbe floods of August 2002 was, however, not only more intensive, it lasted considerably longer and covered - together with the Vb-cyclone moving northwards - a significantly larger area.

With respect to the overlapping of the different meteorological processes and the absolute maximum values of precipitation and river levels, the 2002 Elbe flood can be ranked to be an extraordinary event, which occurred for the first time since the 17th century, the beginning of flood registration at Dresden. Global warming and the observed increase of extreme precipitation days during the last century may indicate a higher risk for such events in future.

Report on ECSN activities

by: Walter Kirchhofer, MeteoSwiss

- **General remarks**

At the Meeting of the WMO Regional Association VI in Geneva, 3 May 2002, the ECSN activity was presented as one of the successful EUMETNET programme.

The 7th ECSN Advisory Committee (EAC) Meeting took placr at Hohenpeissenberg, Germany, 3-5 June 2002.

After the successful termination of the two projects "European Climate Assessment" (ECA) and "ECSN Climate Dataset" (ECD), a follow-up project was prepared in order to continue the ECSN activities in these fields. The project proposal "European Climate Assessment & Dataset" (ECA & D), promoted by KNMI and the ECSN Advisory Committee, was approved by the EUMETNET Council in its September meeting.

MeteoSwiss has generated a new ECSN web-site. The web-site is placed on the EUMETNET Internet server.

The second workshop of the project "Generate Climate Monitoring Products" (GCMP), hosted by DWD, took place in Hamburg, 25-27 September 2002. This GCMP workshop was an important milestone in the project development.

The Fourth European Conference on Applied Climatology, ECAC-2002, took place in Brussels, 12-15 November 2002, with the focus on "Climate related Risk Analysis and Sustainable Development in the 21st Century". The Royal Meteorological Institute of Belgium organized and hosted this successful ECAC-2002.

At the EUMETNET Council Meeting, 4 December 2002, it was decided that in the future the European Meteorological Society (EMS), in partnership with EUMETNET-ECSN, will organize the European Conference on Applied Climatology (ECAC). The next ECAC will be a combined conference "ECAC-2004 / EMS Annual Meeting 2004" in Nice in September 2004.

UNIDART (Uniform Data Request Interface) is a project to develop an infrastructure for a border-crossing exchange of climate data. ECSN is collaborating very closely with UNIDART and has prepared a list of requirements for the realisation of the pilot phase and further steps of UNIDART.

- **European Climate Assessment (KNMI)**

  In the "European Climate Assessment" (ECA) project the temperature and the precipitation climate was analysed for WMO Region VI, putting particular emphasis on changes in daily extremes. The ECA project focusses on the twentieth century from 1901 to 2000. Respecting the data policies of the participating countries, a selection of the daily series in the ECA dataset is made available to the public on a CD-ROM and through the Internet (http://www.knmi.nl/samenw/eca). With the Final Report "Climate of Europe: Assessment of observed daily temperature and precipitation extremes" the ECA project was terminated.

- **Generate Climate Monitoring Products (DWD)**

  The work on the development of the web-site "Generate Climate Monitoring Products" (GCMP) continued. In order to further improve the Internet platform, external software experts elaborated concept proposals.

  An important milestone in the project development was the GCMP workshop, 25 - 27 September 2002, hosted by DWD in Hamburg.

  Although cooperation within the project has intensified, especially due to the GCMP workshop in September, it is nevertheless indispensable to increase the number of actively participating European NMHSs to achieve sufficient regional coverage, especially concerning the national climate monitoring products.

  Implementation of the workshop results will continue. The GCMP Website will be adapted accordingly. GCMP Web manager and project partners will coordinate the filenaming and directory structure as well as information on the links of the contributions on the respective servers.

- **Climate Atlas of Europe (Meteo-France)**

  The Atlas will contain monthly normals for precipitation, temperature, wind and sunshine duration and additional statistical information for these parameters and for the occurrence of phenomena such as fog, thunderstorm, hail and snow. The computation period will be 1971-2000, and the target spatial density will be about one station per 5000 square kilometres. In a first step the contents of the Atlas project will be made available without maps.

  Metadata from all the participating countries (24) representing about 685 stations have been received, checked, harmonized and put into a single file. Among the non ECSN countries contributions have been made by Albania, Bulgaria, Czech Republic, Slovakia and Slovenia.

  Quality tests applied to the whole dataset have been engaged, revealing the detection of a large number of errors. Considering the large size of the dataset, graphical tools are necessary to assess the quality of some parameters.

- **Drought investigations (Meteo HU, PT)**

  The objectives are the following ones:

  - Evaluation and use of different drought indices;
  - Analysis of long drought index series;
  - Study of thresholds of drought indices;
  - Calculation of the spatial distribution of drought indices on different time scales;
  - Recommendation of drought indices.

  The project could not be cared permanently by a scientist. Nevertheless the project has been completed with a Final Report.

- **ECSN climate Dataset (KNMI and DNMI)**

  The "ECSN Climate Dataset" (ECD) project is closely related to the project "European Climate Assessment" (ECA). The main objective of the ECD project was the preparation and the distribution of climate datasets on daily amount of precipitation and daily temperature (minimum, mean, maximum)for the period 1901-2000 via CD-ROM and Internet. The project was formally finished with the Final Report prepared on Internet. The server is operational in the network environment of KNMI since November 2002.

Ozone Layer over Central Europe in 2002

by: Ulf Köhler, Hans Claude and Wolfgang Steinbrecht, Deutscher Wetterdienst

The total ozone column is affected by numerous processes in the atmosphere such as circulation patterns, radiative variations (e.g. 11-year solar cycle) or special events like major volcanic eruptions. Thus even annual averages are subject to large variations. In 2002 the ozone layer above Germany and also above Europe was a little bit thinner compared to the previous year. The total ozone column as a measure of ozone layer thickness was approx. 319 D.U., which is about 3% below the long term average. This deviation is not an extreme value compared with the post Pinatubo years 1992/93. **Fig. 1** clearly shows a quasi biennial oscillation in the annual means, which is superimposed onto the long term decline mainly attributed to the chemical ozone depletion by the CFCs (Chlorofluorocarbons). This oscillation is in opposite phase to the so-called QBO (**Q**uasi **B**iennial **O**scillation) of the stratospheric winds at 30 hPa in the equatorial region. Westerly winds like in 2002 cause lower ozone values at northern midlatitudes with an amplitude between westerly and easterly phase of the equatorial winds of 10 - 20 D.U..

Statistical analysis further indicates a superimposed 11-year oscillation caused by the solar cycle with minimum solar acitivity around the mid of each of the three decades combined with relative ozone minima. The last years around 2000 are marked by higher ozone (~ 10 D.U.) values compared to the mid nineties due to the recent solar maximum.

Since the very low values after the volcanic eruption of Pinatubo in 1991 there is obviously no recovery of the ozone layer back to the pre-Pinatubo values. Starting from the present low level another severe volcanic eruption of a similar magnitude like Pinatubo (1991) or El Chichon (1982) would probably cause an ozone depletion with annual averages below 300 D.U.. Even without such natural impacts very low values have to be expected, when both solar cycle and QBO are in their negative phase.

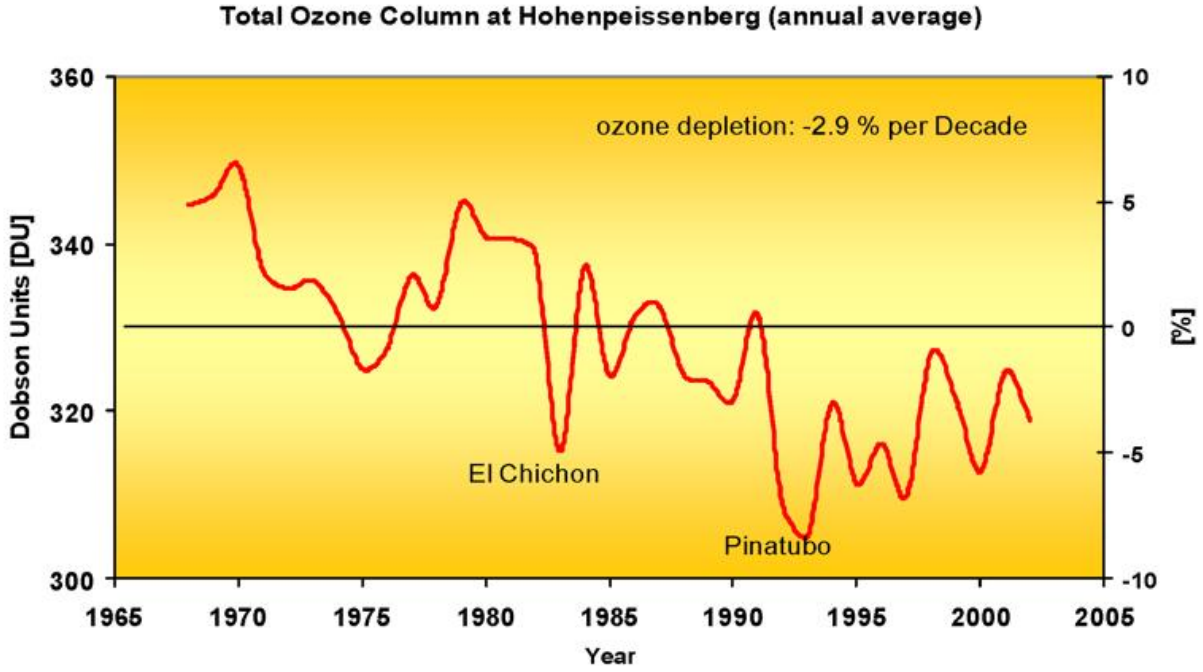

Fig. 1: *Time series of annual means of the total ozone column above Hohenpeissenberg 1967 - 2002. The relative trend of -2.9 % per decade is based on linear regression analysis.*

A detailed look at the annual course of the deviation of daily total ozone in 2002 **(Fig. 2)** draws the attention to the first part of the year. Very low values are seen, especially in February, with maximum deficits down to -30% from the long term mean. This low ozone is closely connected with special weather situations (high pressure, warm troposphere / high tropopause and cold stratosphere). In general February shows not only the largest trend with -5.2% per decade, it is additionally the only month with significantly increasing variability of the daily values. Variance has increased by 8% since 1968, whereas all other months either did not show any increasing variance or even an obvious decrease (April, May, June). The main reason appears to be the more frequent occurence of very deep ozone minima (so-called "mini-holes") with more and more low values. High ozone values do not exhibit such a significant decrease.

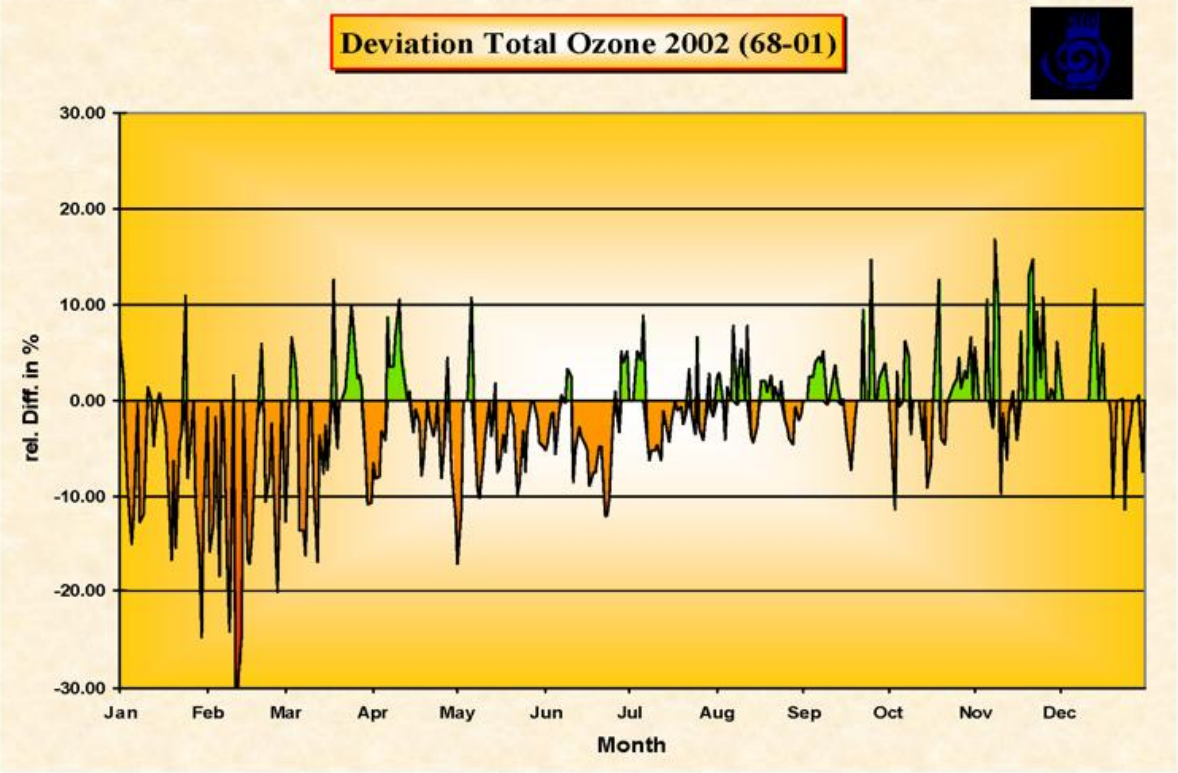

Fig. 2: *Relative deviation (in %) of the daily total ozone amount over the year 2002 compared to the baseline defined by the period 1968 - 2001 for Hohenpeissenberg (Southern Bavaria).*

Analyses of the atmospheric circulation, described by specific oscillation patterns (e.g. Arctic Oscillation AO, North-Atlantic-Oscillation NAO etc.) indicate that climate change is connected to a modified atmospheric circulation. This has substantially contributed to the more frequent low ozone values in late winter. AO and NAO, especially in February, show significant changes resulting in a prominent warming of the free troposphere over Central Europe by 3 K combined with a lift of the tropopause by 450 m and ozone decrease of about 10 D.U. since the end of the sixties.

ACTIVITIES AND RESULTS OF EUROPEAN CLIMATE CENTRES:

- Report on ECSN Activities 82
- Ozone Layer over Central Europe in 2003 84
- Hydrometeorological Conditions During the Extremely Dry Year 2003 in the Long-Term and European Context 86

Foreword

This 10th edition of the Annual Bulletin on the Climate in WMO Region VI – Europe and Middle East – for 2003 was enabled by national contributions from the Meteorological and Hydrometeorological Services in WMO Region VI.
The Call for Input was answered directly by 43 of the 49 member countries, which equals 88%. Additionally, WMO Secretariat provided the editor with all national contributions to the WMO Bulletin article on consequences of abnormal weather in 2003 from the WMO Regional Association VI. More than 90% of the national contributions were sent in the most preferred way, which is email including attachments or server addresses. It is for the first time, that this publication is completely colour printed.

The most prominent climatic characteristic of the reporting year was the extraordinarily hot European summer. New records were set up for all kinds of temperature measures at many stations and for many areas. The statistical recurrence period of such an event in central Europe is at least 500 years.

The socio-economic impact of this long-lasting heat-wave was particularly disastrous to people's health with a dramatic increase of mortality in central European countries. A special article on this extreme climatic event is included in this Bulletin.

An additional climatic feature of the Region was a significant increase in sunshine duration in most countries compared to a long-term average. Surprising was the early seasonal forming of a snow cover in October in several countries.

As in the years before, this edition includes special articles contributed by the ECSN Programme Manager and the Meteorological Observatory Hohenpeißenberg.

On this occasion, I wish to express my gratitude to all, who contributed to this paper by reports and practical support. I am especially thankful to the German Meteorological Service for the co-ordination, the editorial review, publishing and distribution of this Bulletin.

Daniel Keuerleber-Burk
President of WMO Region VI

Outstanding Events and Anomalies in 2003

Temperature

- Extremely hot summer in central Europe with serious socio-economic impact

Precipitation

- Long-lasting drought conditions in many countries
- Early autumnal snow cover in central and eastern Europe

Sunshine

- Record yearly sunshine duration in many countries

Wind

- Many local tornadoes, especially at the end of the summerly heat wave period

Annual Survey

Temperature deviations from the long-term annual average were mainly positive all over the Region except for some areas around the Black Sea. Anomalies above +1°C were registered mainly in central Europe and Scandinavia. Greenland experienced the warmest year since 1941 (fig. 0.1) with deviations from normal up to +2°C and more.

The most prominent climatic feature of the year was the record breaking long-lasting heat wave over Europe with its serious socio-economic impact, especially on human health, agriculture and the risk of forest fires. Fig. 0.2 illustrates the extraordinary jump of the mean temperature in this period against the previous records in line.

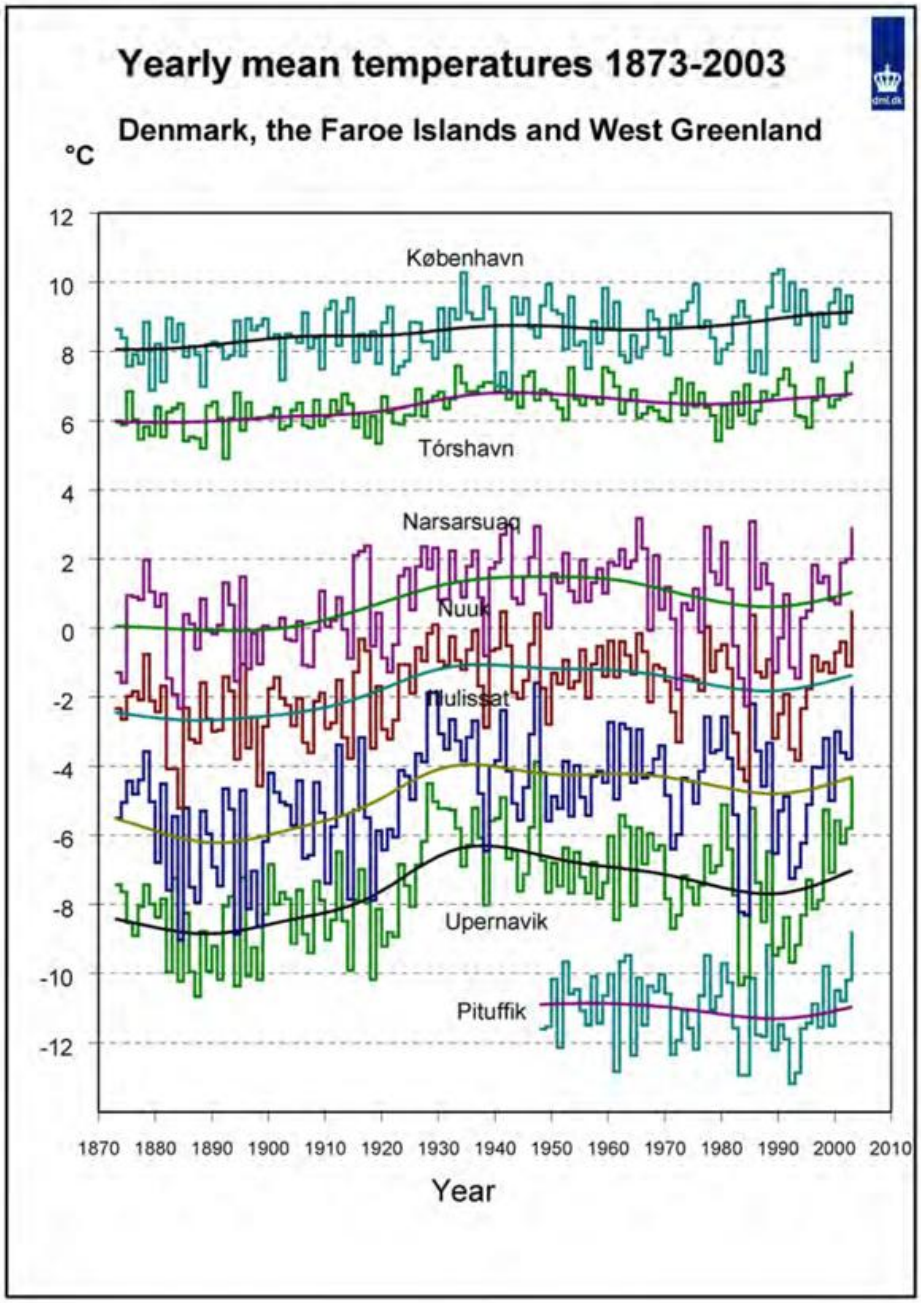

Fig. 0.1: *Yearly mean temperatures at stations in Denmark, Faroe Islands and Greenland*
From: Danish Meteorological Institute, Copenhagen

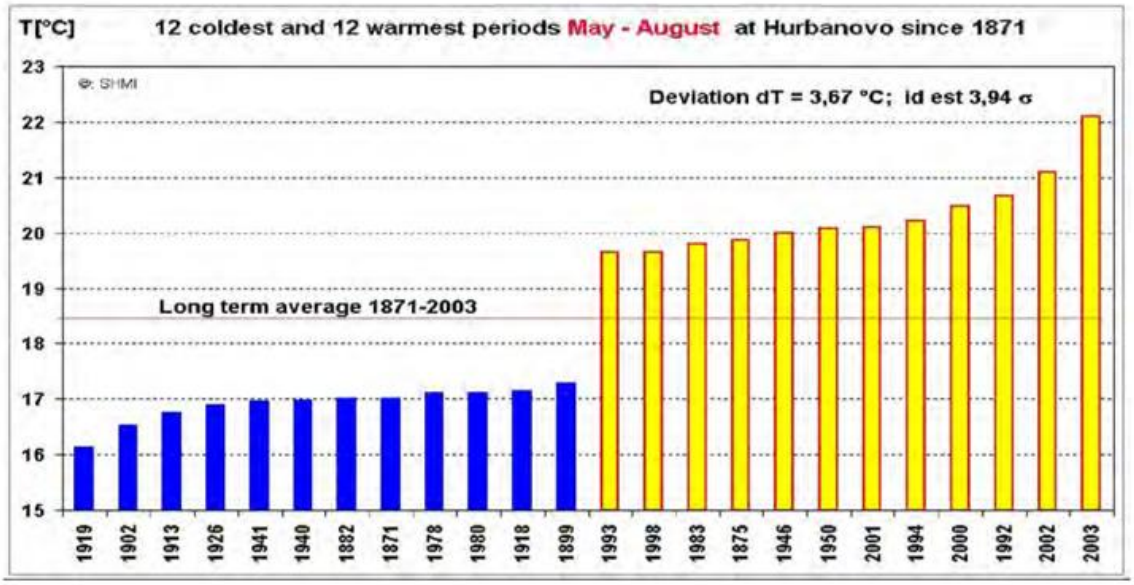

Fig. 0.2: *12 coldest and 12 warmest periods May - August since 1871 at station Hurbanovo, Slovakia From: Slovak Hydrometeorological Institute, Bratislava*

Precipitation was mainly below and up to normal in central parts of the Region and above normal in Iceland and some other parts of Scandinavia and Russia as well as in large areas of the Iberian Peninsula, coastal areas of the Mediterranean and parts of the Middle East. Figs. 0.3 – 0.5 are typical examples for the relatively smooth spatial distribution of annual precipitation rates compared to normal.

Sunshine duration was significantly higher than normal from north-western to central and eastern Europe. Every reporting country registered some record highlights in the observational series. E.g. in the Netherlands, station De Bilt measured a new record since the beginning of observations in 1901; additionally, all months except for May had a surplus of sunny hours (fig. 0.6), a characteristic, which was common also to other places in 2003.

Wind force caused a lot of damage in different countries of the Region, especially during tornado episodes and with the end of the summerly heat wave.

Seasonal Survey

Winter 2002/2003 was milder than normal in western and southern Europe. Eastern Europe and most of the Middle East were clearly colder than the long-term averages, in some areas with statistically significant deviations (see figs. page 12). An example for the wintry conditions in eastern Europe is given by fig. 0.7 with the special aspect, that the coldest period of the season is shifted back from January to December.

Precipitation was rather low in a broad zonal belt from the north of the British Isles over southern Scandinavia and large areas around the Baltic into Russia. The Alpine region suffered also from a deficit in precipitation, whereas the southern parts of Italy and the Balkans as well as Israel were much wetter than normal (see fig. page 16, upper part).

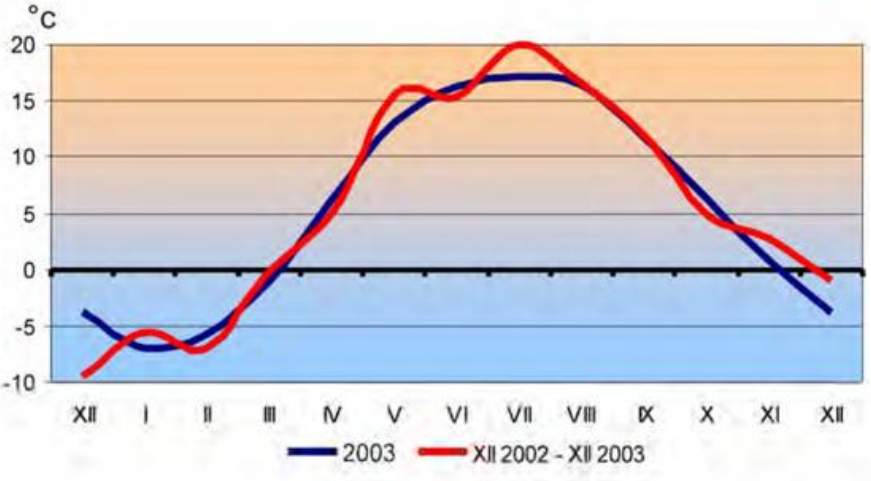

Fig. 0.7: *Monthly mean air temperatures from December 2002 until December 2003 and for the reference period 1961-1990 in Belarus*
From: Hydrometeorological Centre of the Republic of Belarus

Spring 2003 was warmer than normal in most of Europe except for an area around the south-eastern Baltic. In the Middle East the deviations of the monthly mean temperatures from normal were mostly negative, decreasing to the east and with highly significant values at the Caspian Sea (see figs. page13).

In many parts of Europe precipitation was in deficit in a broad and nearly zonal belt from the northern Iberian Peninsula over southern France, the Alps, the northern Balkans and the Ukraine into southern Russia (see fig. page 15, lower part).

Summer 2003 was extremely hot in central Europe and generally warmer than normal nearly all over the Region except for southern Russia. Statistically, it was the hottest summer in the central European countries since more than 500 years (figs. page 14). The long-term series of average summer temperatures from Vienna illustrates this outcome (see fig. 0.8).

The frequent anticyclonic circulation pattern caused also a precipitation deficit over most parts of Europe (see figs. on page 17, upper part). Together with the extraordinary heat wave, these conditions had an immense socio-economic impact, especially on human health, drought conditions for agriculture and the increase of forest fires.

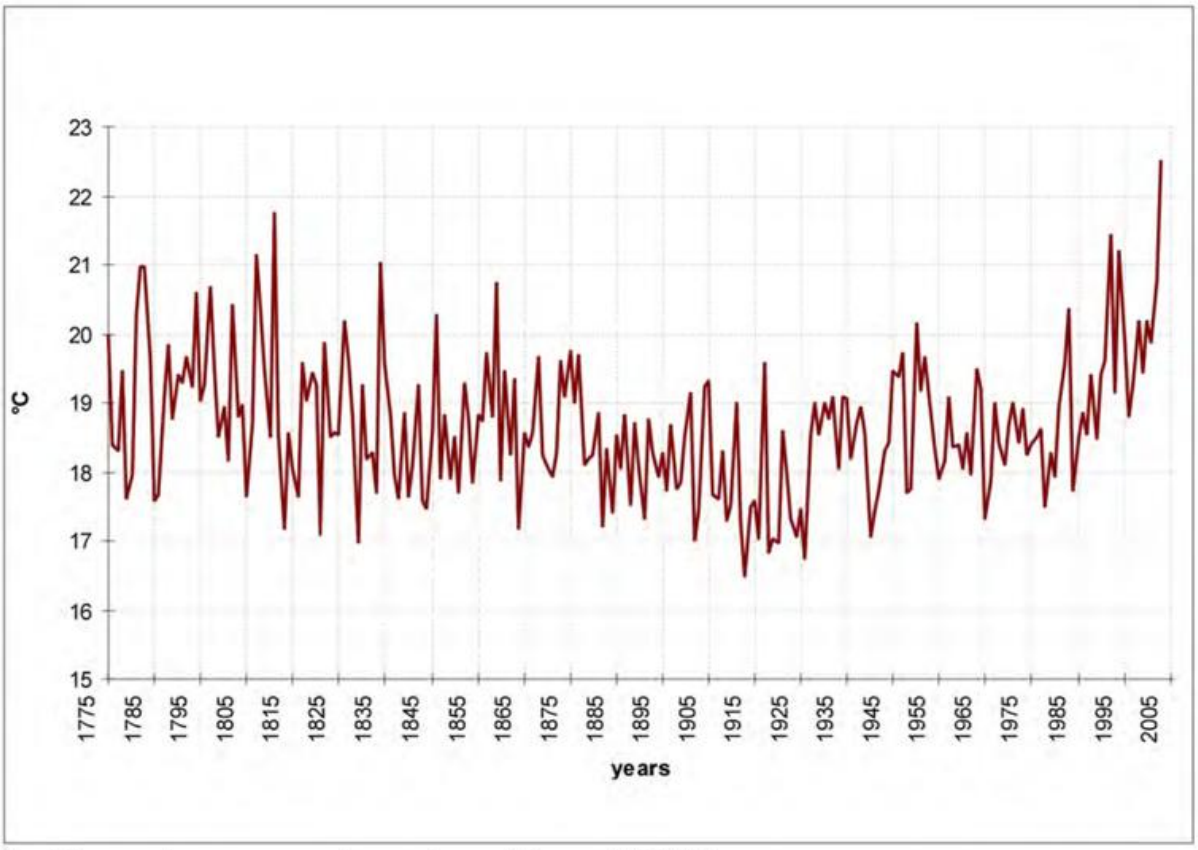

Fig. 0.8: *Average summer temperatures of Vienna 1775-2003*
From: Zentralanstalt für Meteorologie und Geodynamik, Austria

Autumn 2003 was milder than normal all over the Region except for the Alps and the Carpathians. Statistically significant positive deviations were observed mainly in the U.K. (see figs. on page 15). North-western Europe and most of Scandinavia had a precipitation deficit as well as some parts of central and eastern Europe and the coastal areas of the eastern Mediterranean. Centres of precipitation above normal were on the Iberian Peninsula, in southern parts of France and Italy, in Romania, Ukraine, in southern Russia and the north-east of Turkey (see fig. on page 17, lower part).

Monthly Surveys

January 2003

- **Unusually mild around Greenland and from the southern Balkans over Turkey into the Caucasus**
- **Much more colder than normal in northern Scandinavia**
- **Extremely wet in Portugal and The Former Yugoslav Rebublic Of Macedonia**
- **Very sunny in the British Isles and Luxembourg**

In Narsarsuaq, Greenland, the month was record breaking mild. At Nuuk Airport +15.3°C were registered during a foehn situation on January 29.

The month was rather mild and dry in Iceland and high temperatures persisted during the first part of the month, but a harsh cold spell influenced the country during January 18-23.

The month was wet and as a whole warmer than normal in the Faroe Islands, but it was cold in the end with frost and snow.

Norway had a very cold start of the year, especially in the inner part of northern Norway. The station Karasjok in Finnmark experienced the 4th coldest January since the measurements started in 1877. Other stations in Finnmark and Troms registered the month as one of the coldest in the observational series.

In Sweden, very cold weather in the first part of the month gave unusually harsh conditions for the boat traffic, especially in Lake Vänern and in the Gulf of Bothnia. A warmer latter half of the month brought some relief.

The month was rather cold in Finland with anomalies of about -4°C down to -7°C in the northernmost parts of the country. The monthly precipitation rate varied between 75% and 150% of normal in most southern and central parts of the country, whereas it exceeded 150% to the north.

After a cold start of the year in Denmark with temperatures down to -21°C and a snow blizzard, the weather changed and became mild, causing the monthly mean temperature to be approximately normal.

The year started very cold in Latvia. By January 8 all the Gulf of Riga was covered by ice. Within 24 hours the air temperature at the east coast of the Gulf of Riga rose from -32°C to -3°C due to a change of air masses on January 7.

In Ireland the year's lowest temperatures were measured during mid-January in most places. The absolute minimum air temperature of -6.0°C was recorded at station Clones on January 5 and the lowest grass minimum temperature of -12.3°C at station Kilkenny on January 4 and 5. The strongest winds of the year at almost all stations were measured during the second half of the month, but there were no exceptional storms. Station Malin Head recorded the highest gust of the year, 130km/h on January 28.

The highest U.K. temperature for the month was equalled on January 26, with Aboyne/Scotland recording a temperature of 18.3°C. Joint holder of this record is Aber/Wales, which reported a temperature of 18.3°C in both 1958 and 1971. On

January 30 bands of snow affected eastern areas, giving between 5cm and 12cm in most places. There was major disruption and gridlock on some motorways. It was the 2nd sunniest January in the 1961-2003 series for England & Wales with 70.5 hours being recorded (145% of 1961-90 average). The sunniest was 2001 with 74.3 hours.

From the beginning of the year until January 4, heavy rains engendered floods in several parts of Belgium. Thundery weather on January 28 caused damage in some places of eastern Flanders.

The monthly precipitation in Luxembourg amounted to 102.0 mm, which is 141% of normal. In spite of this, the monthly sum of sunshine duration surpassed the long-term average by 25.6 hours or 56%, which is equal to 27% of the theoretically possible insolation.

The monthly mean temperature in Germany was marginally above normal, while the precipitation rate exceeded normal clearly by 35%. Heavy rains triggered flooding in many places all over the country from January 1-4. Gusts up to 200 km/h in the area of the Black Forest and also a small tornado near the city of Ulm caused a lot of damage to people and the infrastructure. A cold spell from January 6-12 caused the blocking of traffic lines on land, at sea and in the air in the eastern part of the country; two people froze to death.

The monthly mean temperature in Poland was lower than the reference of 1971-2000 with a spatial variation from -1.6°C in the north up to -0.1°C in the south. The country wide precipitation total was slightly above normal with rates below 80% of normal in the North and above 160% of normal in the West. A snow cover appeared in the first half of the month and again at the end.

The month had the most contrasting weather of this winter in Lithuania. The first ten days were very cold with daily mean air temperatures of -21°C ... -27°C on January 6-7. The ten-day thermal anomaly reached -8.5°C, which is the lowest record except for the years 1935, 1940 and 1987. The monthly mean air temperature, instead, was -5°C and thus close to normal. The steady snow cover of the first half of the month gradually melted down with the warming weather and reappeared again on the last days of the month. The monthly precipitation amounted to 36mm, which equals 86% of the normal rate.

The month was rather mild in Belarus with monthly mean temperatures about 2°C above normal (see fig. 0.7).

During the first half of the month some very cold days occurred in the eastern part of Austria with temperatures down to -27°C. Later on, milder weather caused the monthly mean temperatures to become normal or slightly above normal. A powerful stream over western and central Europe caused severe damage and floods in some parts of the country on January 2-3; especially in Vorarlberg, Upper and Lower Austria, lots of trees were uprooted and roads and railways were blocked.

In Czech Republic, the year started in its very first hours with a remarkable drop of temperatures. Intensive cold advection from N to NE caused cooling rates of more than 20°C / 24h in many places, followed by warming at a similar scale (see example in fig. 1.1). Such temperature changes occur once per 10-20 years.

The temperature anomaly in Slovenia was within ±1°C. After a few relatively warm days in the beginning, the second third of the month was quite cold. Most of the precipitation fell in the first third of the month, while the second third was quite dry. In the lowlands the snow cover lasted longer than on the average in the reference period. Gusty north-easterly winds, called bora, were quite frequent on Karst, Vipava valley and near the coast.

After a mild start of the year in Hungary, temperatures dropped down considerably. The coldest days were January 12-13 with absolute minima below -30°C in some places.

In Croatia temperature anomalies were slightly positive and the country-wide precipitation rate was well above normal.

While the monthly mean temperature was slightly above normal, precipitation totals exceeded the averages significantly and accumulated to 154% of normal in Bosnia and Herzegovina.

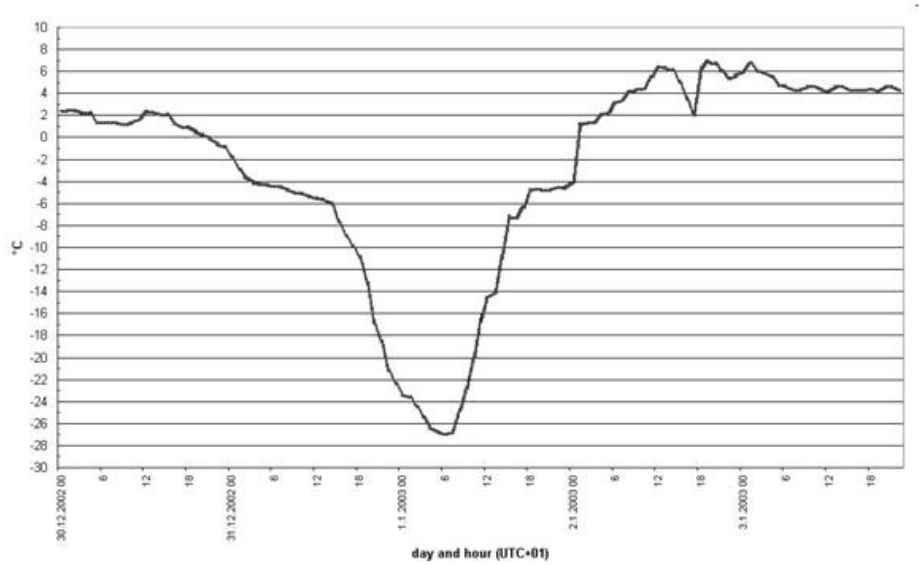

Fig 1.1: *Temperature course at Broumov station (NE Bohemia) around the beginning of the year 2003*
From: Czech Hydrometeorological Institute

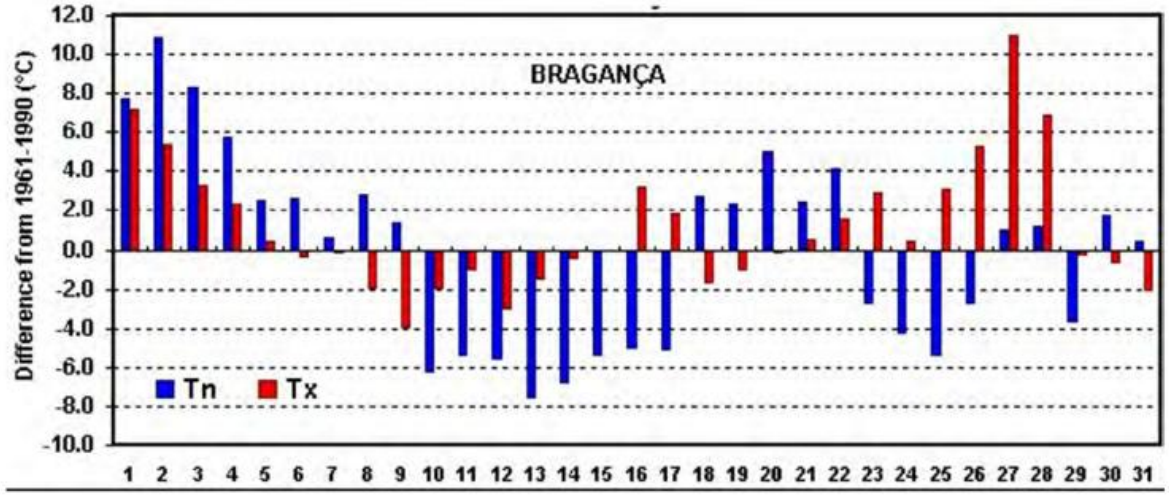

Fig 1.2: *Daily air temperature - anomalies in Bragança (January 2003)*
From: Instituto de Meteorologia, Portugal

The month was extremely rainy in the northern and central parts of Portugal. Precipitation rates were above 150% of normal, e.g. 156% in Vila Real and 210% in Oporto. The floods of the Agueda river in the central region caused great damage and 36 people were dislodged. At station Viseu precipitation amounted to 160mm in 4 days from January 1-4. This is about 95% of the normal monthly total. In spite of monthly mean temperatures close to normal, there were significant variations with time during the month (see fig 1.2).

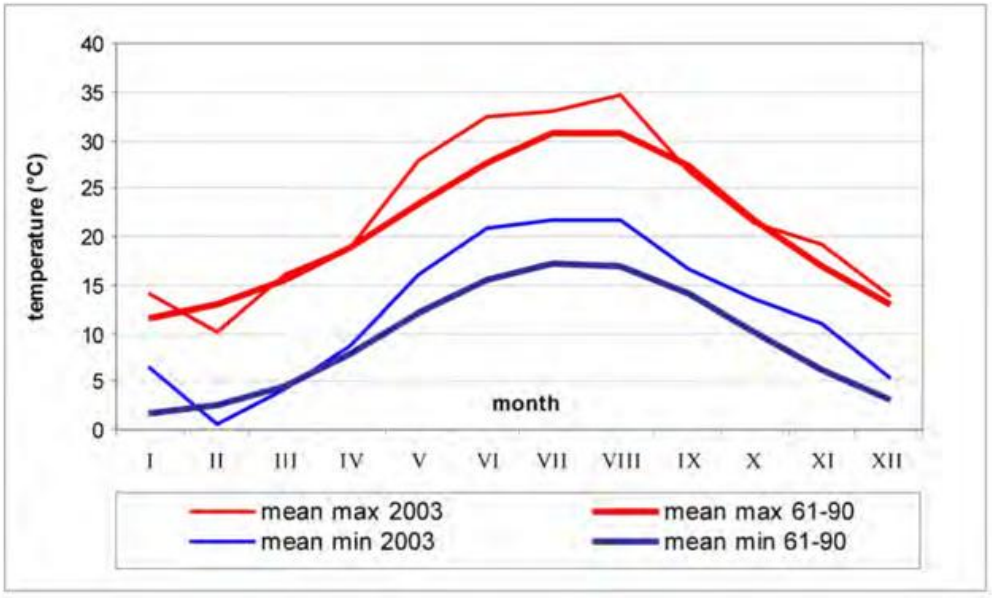

Fig 1.3: *Monthly mean of daily temperature extremes in Tirana*

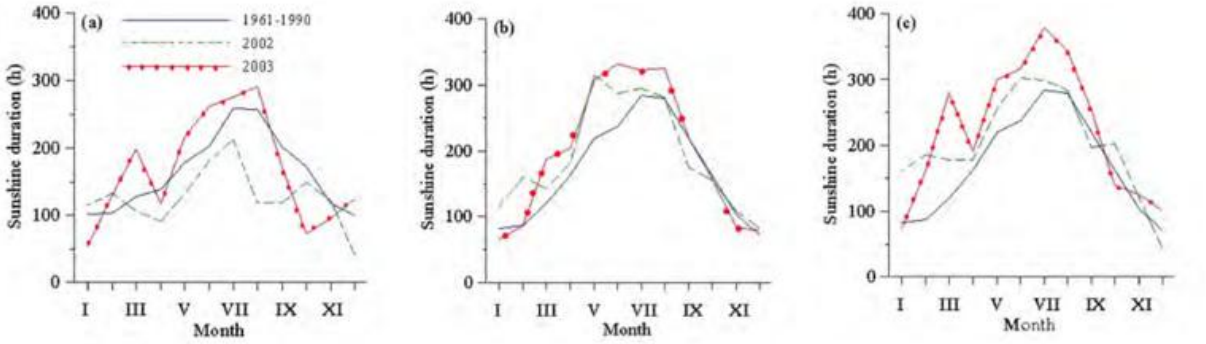

Fig 1.5: *Monthly values of sunshine duration at Cherni vrah (a), Varna (b) and Sandanski (c) in 2003, 2002 and normal (1961 - 1990)*
From: National Institute of Meteorology and Hydrology Bulgaria

The month was very mild in Albania, which is illustrated by the anomalies of the mean daily temperature extremes (fig. 1.3).

In The Former Yugoslav Rebublic Of Macedonia the monthly precipitation rate was about 200% of normal. Fig. 1.4 shows the example of station Skopje. The monthly mean tempera-tures were well above normal with an anomaly of +2.5°C at station Shtip.

The month was warm, cloudy and wet in Bulgaria with mean temperatures up to 2°C above normal and precipitation rates between 115% and 130% of normal. The mean sunshine duration was lower by about 20-30 hours compared to the long-term average (see fig. 1.5). Widespread fog occurred on 18 days of the month. On January 31, heavy rains with a daily total of 31mm caused flooding in the city of Varna.

In Turkey, January was the only month of the year with a positive temperature anomaly. Strong winds forced the closure of the harbour of Bandima at the western coast on January 12. Another storm in the area of Seydisehir/Konya destroyed a minaret and damaged homes and forests on January 26. Stormy weather on January 31 damaged the meteorological station of Giresun at the Black Sea coast. On the same day, the area of Izmir suffered from stormy weather connected with heavy rains and hail. Inside the country, drought affected the agriculture around Nevsehir.

The month was rather mild and dry in Cyprus. But on January 27, severe weather conditions connected with hailstorms and tornadoes affected the western and southern areas of the island. In Limassol, 30 people suffered from injuries, when houses, cars, power lines and telecommunication networks were damaged.

In Israel the month was warmer than average and also dry. In the northern parts of the country rainfall amounts were 70%-90% of normal and only 40%-60% in the central and southern parts. But two areas received large rainfall amounts – the western Galilee (180-220mm: 110%-120% of normal) and Tel Aviv area with 170-180mm (130%-150% of normal). More than half of the monthly total in the latter area were recorded on January 21. Almost 80mm of rain fell within two hours and that caused flooding and damage in the Tel Aviv area (fig. 1.6). Temperatures were high, especially in the first half of the month. In the coastal plain and in the Negev 28-30°C were recorded on January 11-12.

The month was warmer than normal in Jordan with a maximum temperature anomaly of +1.9°C in Amman.

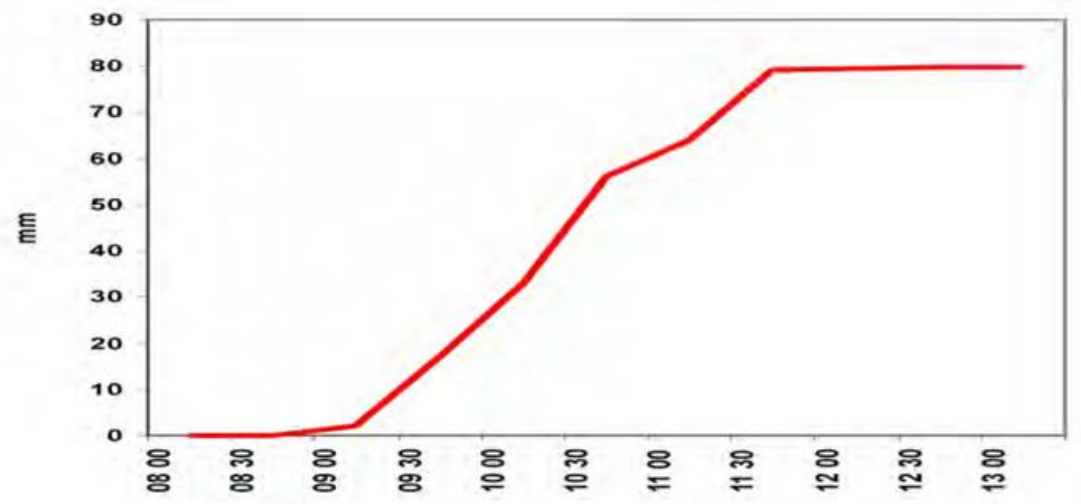

Fig 1.6: *Accumulated Rainfall in Tel Aviv on January 21 2003*
From: Israel Meteorological Service

In the first days of the year rather low temperatures were observed in Armenia, especially in Ararat valley by -19°C ...-21°C, which is 7°C to 9°C below normal. In the third decade of the month the weather turned out to become extremely mild and windy. Maximum temperatures of 17°C to 22°C were measured in some places on January 30-31. Strong winds with gusts up to 108km/h damaged electric-power transmission lines in Martuni on January 30.

February 2003

- **Extremely mild in eastern Greenland and northern Scandinavia**
- **Extremely cold in the Balkans**
- **Extremely dry in the British Isles and in central Europe, wet around western Greenland and at the southern Mediterranean coastal areas**
- **Beginning of a long-lasting drought in many countries**

The month was mild, wet and quite windy in Iceland.

In Northern Ireland, cold conditions prevailed throughout the start of the month. Snowfalls on February 1 and 2 caused widespread disruption across the province, with snow lying up to 6cm deep. It was the 2nd sunniest February in the 1961-2003 series for Scotland with 91.8 hours being recorded (143% of 1961-90 average). The sunniest was 1963 with 92.6 hours.

The month was warmer than normal in the greater part of Norway, especially in the north. In this area the lowest temperature of the year was measured on February 1 at station Karasjok with -42.5°C. At the same station the increase in mean temperature from January to February was 16.2°C. This is the greatest difference between January and February registered here. Several stations in Norway registered new maximum temperatures.

The weather ship Polarfront in the Norwegian Sea measured a monthly mean temperature of 6ºC, which is the highest for the month in the measuring series starting in 1949. The mid and southern part of Norway received very little precipitation and on some stations the monthly sum was the lowest in series starting in 1955 and 1954.

The monthly mean temperature in Finland was above normal nearly all over the country with a clear gradient of anomalies from south to north, starting with +1.1°C in Helsinki and reaching +6.0°C at station Sodankylä. The monthly precipitation was significantly below normal, especially in the south-west with less than 25% of its reference value.

In Denmark the month was considerably colder than normal and extremely dry.

The month was wintry cold and dry in Lithuania. The mean monthly air temperature was -5.6°C, which is an anomaly of -1°C. Prevalence of high pressure formations determined a small amount of monthly precipitation of merely 17mm, which is 57% of normal. Because of a thin snow cover, the ground freeze depth reached 95cm - 105cm in some regions, e.g. in Vilnius exceeding normal by 50cm.

In Latvia the monthly mean temperature was moderately below normal and the precipitation rate was very low (43% of normal). At the end of the month the river ice thickness in the eastern part of the country had reached 50 - 70 cm (150 - 200% above normal). In some places, this winter ice thickness was the greatest since records started in 1945.

In Belgium the month was slightly colder than normal and very dry. The precipitation amounts were about half of the long-term average. Sunshine duration was extremely high. At station Uccle 145h 40min of sunshine were registered during the month, which is almost twice of the long-term average and the 2nd highest record since observations started in 1887 (see fig. 2.1). A tornado hit the area of Hasselt on February 3.

In Luxembourg the month was very dry with a precipitation total of about 30% of normal and cool with a temperature anomaly of -1.2°C.

The month was colder than normal and very dry in the Netherlands. Sunshine duration was extraordinarily high; at station De Bilt 158 hours of sunshine were observed, which is about twice as normal and a new record since observation started in 1901 (see fig. 0.6).

In Germany the month was very dry and colder than normal. The monthly mean temperature was -2.1°C below normal and the precipitation rate about 40% of the long-term average. Sunshine duration was extremely high. Snowfall and ice caused many obstructions on roads in western and southern parts of the country from February 2-7; 9 people died in accidents. Railway and air traffic was also affected. In the Alpine area avalanches endangered public and private life. On February 26 freezing rain caused a lot of accidents on the roads in Rhineland-Palatinate.

The month was extremely cold in Poland. Temperature anomalies were from -2.5°C in the west down to -5°C in the south-east and in coastal areas. The country-wide precipitation rate was only 36% of normal. It was the start of a long-lasting period of insufficient precipitation causing a drought until July, especially affecting the western part of the country. Strong wind with gusts up to 100km/h occurred at the beginning of the month.

In Belarus, temperature anomalies were slightly negative (fig. 0.7), while the precipitation total marginally exceeded normal.

While the monthly mean temperatures were near normal or moderately below in France, a severe drought period started for a long duration of 8 months.

The month was very cold and dry in Switzerland. Temperature anomalies varied mostly between -2°C and -4°C. In the lowlands monthly minima of -10°C to

-19°C were recorded. At station La Brévine -35.7°C was measured on February 1. Very little precipitation fell during the month. North of the Alps a dry period lasted from February 7 - 28. In southern Switzerland only 5%-15% of the normal precipitation quantity fell. Nevertheless, enormous snow depths – up to 80cm – were registered in low regions of eastern Switzerland. Additionally, it was the second to fourth sunniest February in the Alps since 1901.

The monthly mean temperatures in Italy were below normal everywhere. In some southern parts of the country the mean daily minimum temperatures even surpassed three times the standard deviation (see fig. 2.2). The monthly precipitation rates had a very strong gradient from north to south (1% of normal at station Verona and >100% in Sicily).

The month was cold in Austria with temperature anomalies between -1°C and -4°C. It was very dry all over the country, especially in the east, where less than 25% of the normal precipitation rate was registered. In Vienna the monthly precipitation was only 1 mm, the former dryness record for February being 3mm in 1890.

The month was rather cold and extremely dry in Czech Republic. It was also the beginning of a long lasting period of dry conditions until the end of September.

It was the beginning of an excessive dry period in Slovakia lasting until August. Sunshine duration was measured between 130% and 209% of normal.

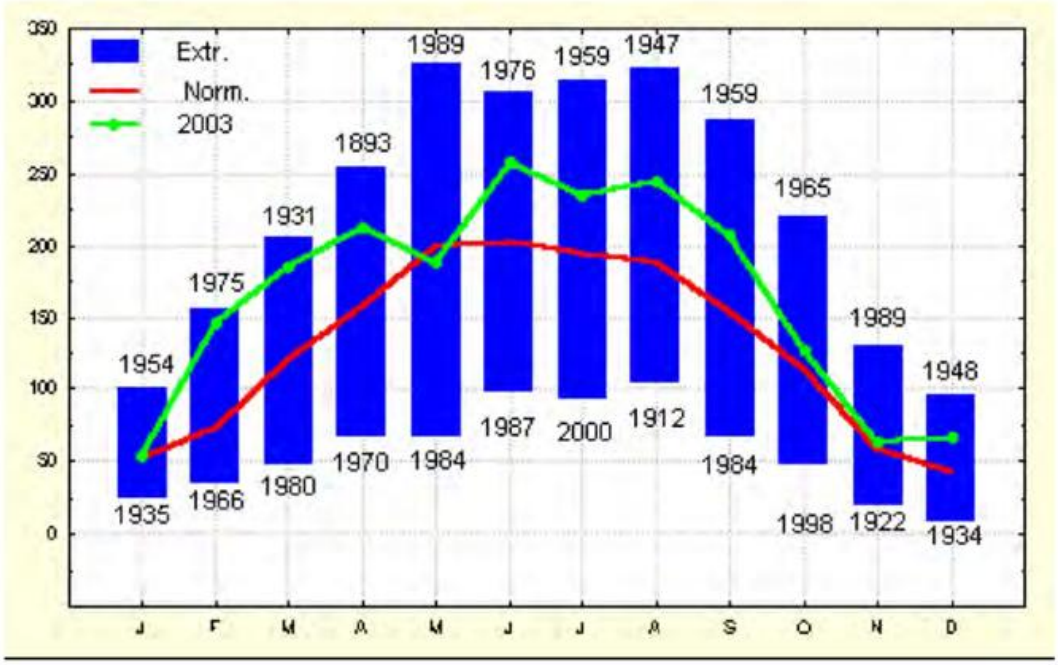

Fig 2.1: *Sunshine duration at station Uccle monthly sums of the year 2003, the reference period 1887 - 1988 and extreme values since 1887 From: Institut Royal Météorologique de Belgique*

Temperature anomalies in Slovenia were significantly below normal down to deviations of -5°C in some places. Most of the precipitation fell during February 4-5. The second third of February was quite dry and the last third completely dry. Sunshine duration everywhere exceeded normal by at least 20%. Near the coast sun was shining 232 hours, which is 93% above normal. A snow cover, although not being very deep, persisted over the whole month.

In Croatia it was very cold and dry. The monthly mean temperature anomaly was below -3°C and the precipitation rate about 50% of normal.

The month was extremely cold in Hungary with a temperature anomaly of -5.2°C (see fig. 2.3). Heavy snowfalls occurred in the whole country except of the most western parts. As a consequence, 45 settlements with 35000 people became isolated due to the snow. With the end of these snowfalls in the first half of the month a long lasting drought period started (see fig. 3.3).

It was extremely cold and rather dry in Romania. The monthly mean temperature was -4.4°C below normal and the precipitation deficit nearly 30% compared to the long-term average. It was the start of a series of relatively dry months until June inclusively.

It was the coldest month of the year in the Ukraine with temperature anomalies from -2°C to -4°C generally and locally even down to -9°C. The absolute minimum of air temperature was recorded as -34°C.

The month was extraordinarily cold and dry in Bosnia and Herzegovina. Temperature anomalies were below -4°C and the precipitation total about half of normal.

The month was very cold in Serbia and Montenegro with a great number of freezing days with ice and snow cover. The daily minimum temperatures in Belgrade were always below normal (fig. 2.4).

It was the coldest month in Albania since the beginning of observations with temperature anomalies down to -5.5°C.

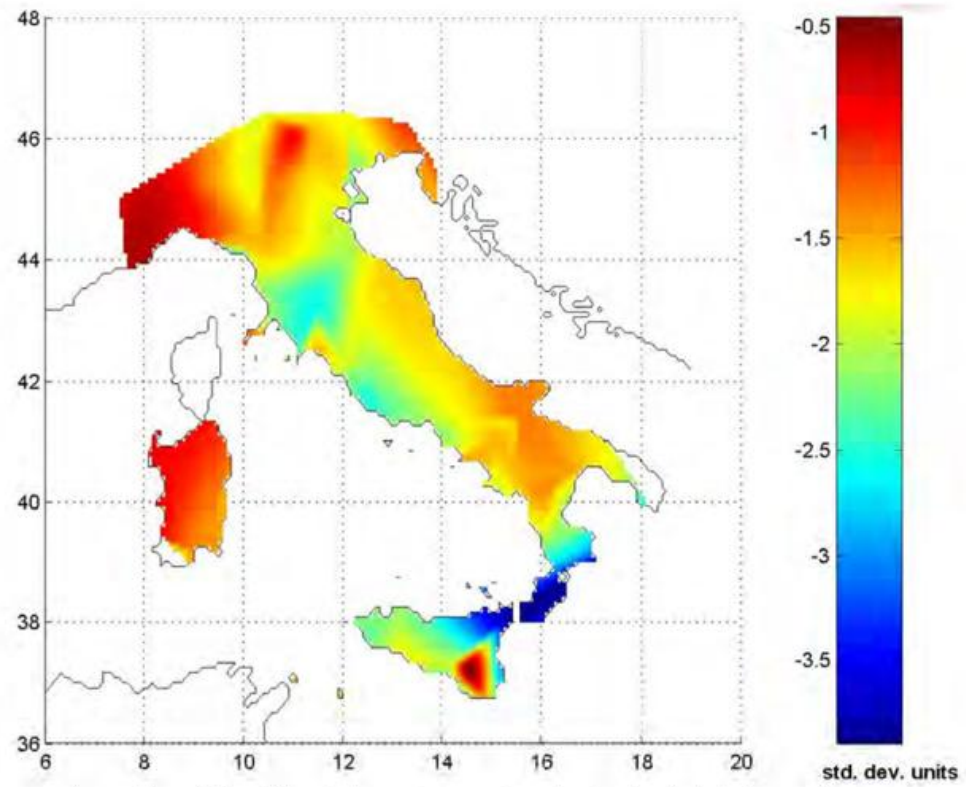

Fig 2.2: *Anomalies of the daily minimum temperature in standard deviation units*
From: Ufficio Generale per la Meteorologia, Italy

The month was extremely cold and very dry in The Former Yugoslav Rebublic Of Macedonia. Temperature anomalies varied from -3.0°C down to -5.2°C (see fig. 2.5). Precipitation rates were about 50% of normal (e.g. see fig. 1.4).

The month was extremely cold and significantly dry in Bulgaria. Temperature anomalies were below -4°C and the

precipitation totals about 20% less than the multi-annual averages. There were 20 ice days (i.e., the daily maximum air temperature is below 0°C) in the northern part of the country and about 4-7 ice days in the south. Snow fall and strong winds on February 1-2 caused snowdrifts amounting up to 1.5m mainly in the eastern regions of the country. Many roads were closed, 44 villages were without electricity and 4 people died. The harbours and airports of Varna and Burgas were closed.

Heavy showers and thunderstorms affected the western part of Greece on February 5 leading to local floods around Epiros with destructive consequences to roads and agriculture and the loss of one life. Heavy showers and thunderstorms again, this time mainly in Cyclades on February 17-18, led to floods with landslides and destruction of roads and plantations. Extreme 24h rainfall amounts were measured in Mykonos (89.8mm) and Paros (121.4mm); both records exceeded by far the mean monthly precipitation sums of 59.8mm and 49.0mm respectively.

In Turkey the monthly mean temperatures were well below normal in most places. The country wide precipitation total exceeded normal by approximately 60%. Strong winds affected the south-western coast on February 2; station Dalaman was damaged by a water spout. Stormy weather in the western

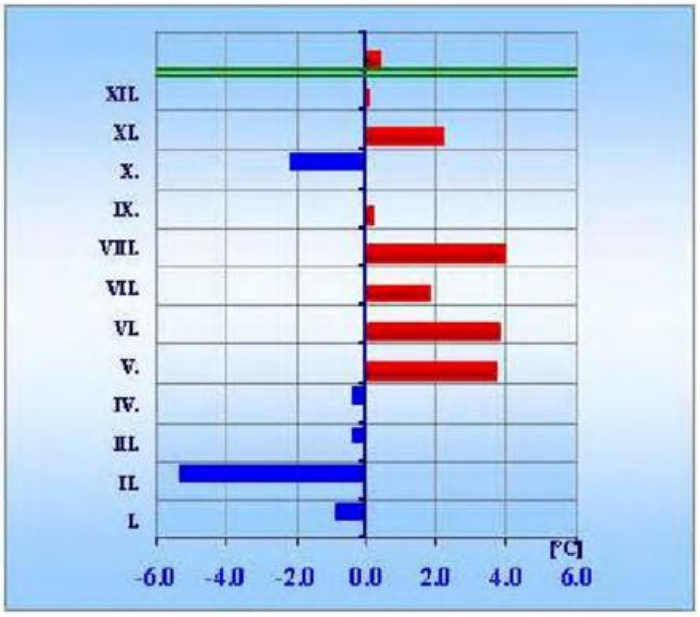

Fig 2.3: *Anomaly of the countrywide monthly mean temperatures 2003 (°C) in Hungary*
From: Hungarian Meteorological Institute

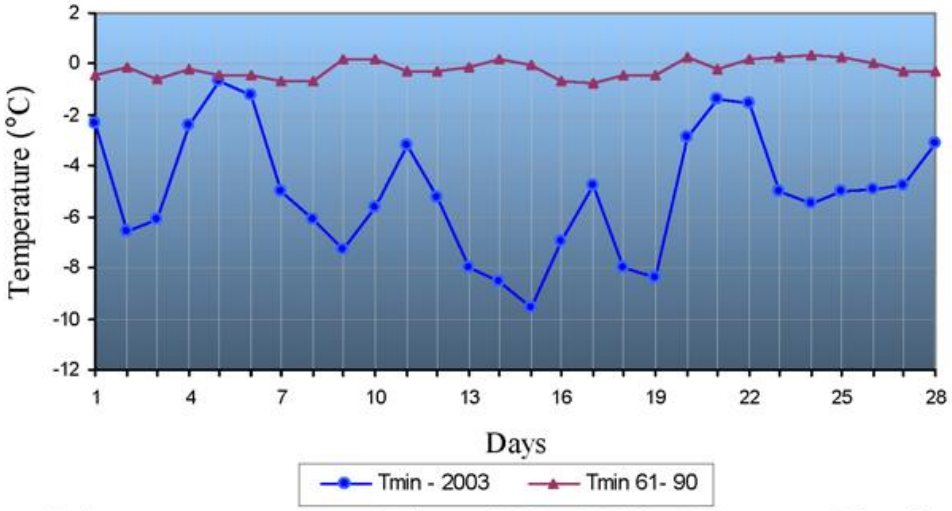

Fig 2.4: *Daily minimum temperature in February 2003 and 1961 - 1990 means in Belgrade*
From: Republic Hydrometeorological Service of Serbia and Montenegro

part of the country caused a lot of damage on February 5; the seaways into the Bosporus and Izmir harbour were stopped. A snow storm on February 18 was the reason for the death of some people in traffic accidents and the subsequent breakdown of public transport in the main roads of Istanbul. An avalanche caused the death of some people and livestock and the collapse of houses in Elazig on February 24.

The month was rather cool and wet in Cyprus. Heavy rains combined with local hailstorms occurred all over the island on February 12. Cars were carried away by floods and one car driver was drowned in the area of Nicosia. Heavy snowfall occurred in the Troodos area on February 24-25 cutting off some villages from the road network. Snowfall occurred also in areas with lower elevation, including Nicosia in the central plain and Pafos on the west coast.

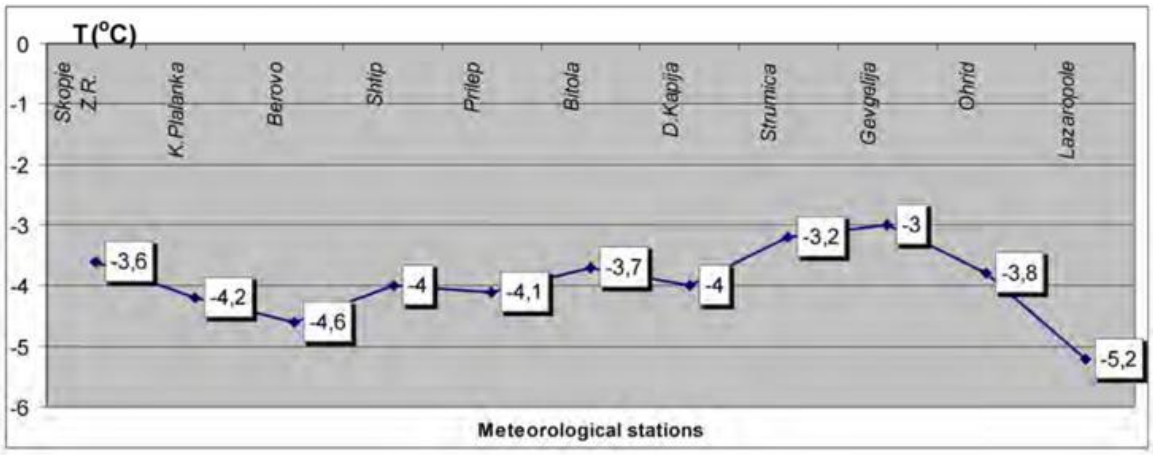

Fig 2.5: *Anomalies of the air temperature in February 2003, Macedonia*
Reference period is February 1961 - 1990
From: Hydrometeorological Service of Republic Macedonia

The month was cool and very rainy in Israel. In the northern and central parts of the country rainfall amounts were 150-300mm and thus 200%-350% of normal. It was one of the two rainiest months since the beginning of measurements at many

stations. These large precipitation amounts resulted in flooding of agricultural areas and in road closures. Most stations in the northern and central parts of the country recorded 22-23 rain days, which is 2-3 times as normal. The most significant rain period was from February 18-28 with 11 successive rain days. This period was very cold with temperatures of 3°C to 5°C below average. On February 24-26 large amounts of snow were recorded in the mountains. The heaviest snowfall occurred in the central mountains causing many road closures. In Jerusalem 25cm of snow were recorded. Snow continued to cover the ground for almost one week.

A snowstorm affected Jordan on February 24-26 (see fig. 2.6). Snow accumulated over most parts of the country with elevations above 600m. Snow depth at station Ras Muneef in the northern region was 90cm, while it was between 5cm and 70cm in the other regions. The snowstorm caused a temporary power outage in Amman and other cities. A lot of damage occurred to agriculture and forestry. It was the 2nd wettest month along the record in most parts of the country with monthly precipitation rates of 200%-350% of normal. Station Salt in the central region recorded the extreme 24h rainfall amount of 145mm on February 25.

The first decade of the month was very warm in Armenia. The precipitation total all over the country exceeded normal by 20%. Only 6 days of the month were without precipitation. Snowfall occurred country wide and continuously from February 19–22. In Yerevan 133% of the monthly normal precipitation amount fell within 62 hours.

Fig 2.6:

Snowstorm near Amman on February 24 - 26
From: Jordanian Meteorological Department

March 2003

- **Much more warmer than usual in western and northern Europe, extremely mild in north Scandinavia**
- **Very cold around the Black Sea**
- **Extremely dry in the British Isles, around the Baltic Sea as well as in central Europe, Italy and most parts of the Balkans**
- **Very wet in Gibraltar, Malta and the islands and coastal areas of the south-eastern Mediterranean**

In Iceland the month was very mild everywhere with heavy precipitation in the southern part of the country.

The monthly mean temperature of 6.8°C at station Kirkja in the Faroe Islands was record breaking high since the observations started in 1873.

In Ireland the month was moderately warmer than usual with a total precipitation well below normal.

The monthly mean temperature all over the U.K. was 2.0°C above normal. The temperature at Altnaharra (Scotland) rose from -9°C to +18°C on March 17, the greatest diurnal rise in temperature for Scotland in March. The country-wide precipitation rate was 59% of normal. The month was very sunny across all parts of the country with many station records broken. The overall long-term average of sunshine duration was exceeded by 57%. Northern Ireland, Scotland and England&Wales also experienced their sunniest March in the 1961-2003 series.

In Norway the month was warmer than normal in the whole country and especially in the inner part of Finnmark. Coastal areas in Troms and Finnmark received 300%-500% of the monthly normal precipitation. The station Nordreisa-Øyeng in Troms recorded 169mm (483% of normal), which is the highest sum for March at this station since measurements started in 1895. The highest daily precipitation amount for the whole year (107.8mm) was measured at station Mandal in the southern part of the country on March 6.

In Sweden the monthly mean temperature was above normal everywhere with a strong gradient from south to north. An anomaly of +5.3°C was registered at station Haparanda. Precipitation was below normal nearly all over the country.

The month was warmer than normal practically in whole Finland with the largest positive deviations of >4°C from the long-term mean in the north-western part of the country. Most parts of southern and central Finland had precipitation less than normal. The monthly precipitation in the south-west was less than 25% of its reference value.

In Estonia the weather conditions were relatively mild and extremely dry.

The weather in Latvia was rather mild and extremely dry. The area of ice coverage of the Baltic Sea was at its maximum of 232,000km² on March 5 (fig.3.1).

In the Netherlands temperature anomalies were about +2°C and the precipitation rates near half of normal. Station De Bilt recorded 199h of sunshine, which is the maximum since observations started in 1901 (see fig. 0.6).

In Belgium the monthly mean temperatures were about +3°C above normal, whereas precipitation had a deficit of about 35%. Sunshine duration at station

Uccle exceeded the very long-term average of 120 h (reference period 1887-1988) by 55% (see fig. 2.1).

In Luxembourg the weather was mild and dry. Temperature anomalies were > 3°C and the precipitation deficit was $^1/_3$ of the normal amount.

The month was rather mild, dry and very sunny in Germany. The overall monthly mean temperature anomaly was +1.8°C and the precipitation rate merely 50% of normal. A local tornado damaged houses and garden sheds near the city of Ulm on March 2-3. Freezing rain caused 410 accidents with cars in Berlin in the morning of March 3.

The monthly mean temperature in Poland was slightly below normal. The weather was variable with the first decade as the coldest period of the month; the warmest was at the end of the month with maximum temperatures >20°C in the south-western part of the country on March 27. Precipitation was rather low. The monthly total was merely 60% of normal and varied between 25% in the north and north-east and 75% in the south.

The weather in Lithuania was changeable. The first ten days as well as March 21-22 were the coldest with little precipitation. The lowest temperature had been falling down to -17°C. In spite of this the mean monthly air temperature was plus 0.5°C with a +1°C anomaly. The monthly amount of precipitation varied from 3mm to 20mm, which means 6% - 55% of normal. The snow cover melted by the middle of the month. The sunshine duration amounted to 150 - 200 hours (45 - 70 h above normal). Ground freeze was deepest in the beginning of the month, gradually thawing by 20 - 40cm from the surface while remaining deep to 80cm at some places.

Drought conditions in France continued all over the month with positive temperature anomalies up to >3°C and precipitation rates below 50% of normal in most parts of the country.

In Switzerland the month was very mild with temperature anomalies between +2.5°C and +3.5°C. It was also very dry. The precipitation rate in the western part of the country was 20%-30% of normal, in the south and south-east 0%-10%. In the lowlands north of the Alps the relative humidity of the air was 60%-65%, thus the lowest monthly average for March since records started in 1901. It was the sunniest March since 1953 with more than 200 hours of sunshine in large areas. In the Alps it was the second sunniest March with respect to the period 1901-2003.

The month was relatively warm and dry in Austria with less than 25 percent of normal precipitation amounts in the southern parts of the country.

In Slovenia the monthly mean air temperature was above normal with anomalies up to +2.5°C. Extremely dry weather persisted during the month. Less than 20% of normal precipitation was observed, half of the territory got less than 5% of normal. Sunshine duration exceeded the long term average for at least 30% everywhere in the country.

In Croatia the month was clearly warmer than normal and extremely dry. The precipitation deficit at station Zagreb was 86% (see fig. 3.2).

In Hungary it was extremely dry, while the monthly mean temperature was slightly below normal (figs. 2.3 and 3.3).

The month was cool and dry in Moldova with temperature anomalies of about -2°C and precipitation rates of 35% from normal.

The month in Portugal was characterised by mean maximum and minimum temperatures well above normal. Significant positive anomalies of the daily minimum air temperature were recorded during almost all the month and for all stations, for example in Oporto and in Faro there were many days with anomalies between +5°C and +6°C. The anomalies of daily maximum air temperature, especially in the northern and central regions were from +8° to +10°C. The monthly precipitation amounts were close to normal almost all over the country.

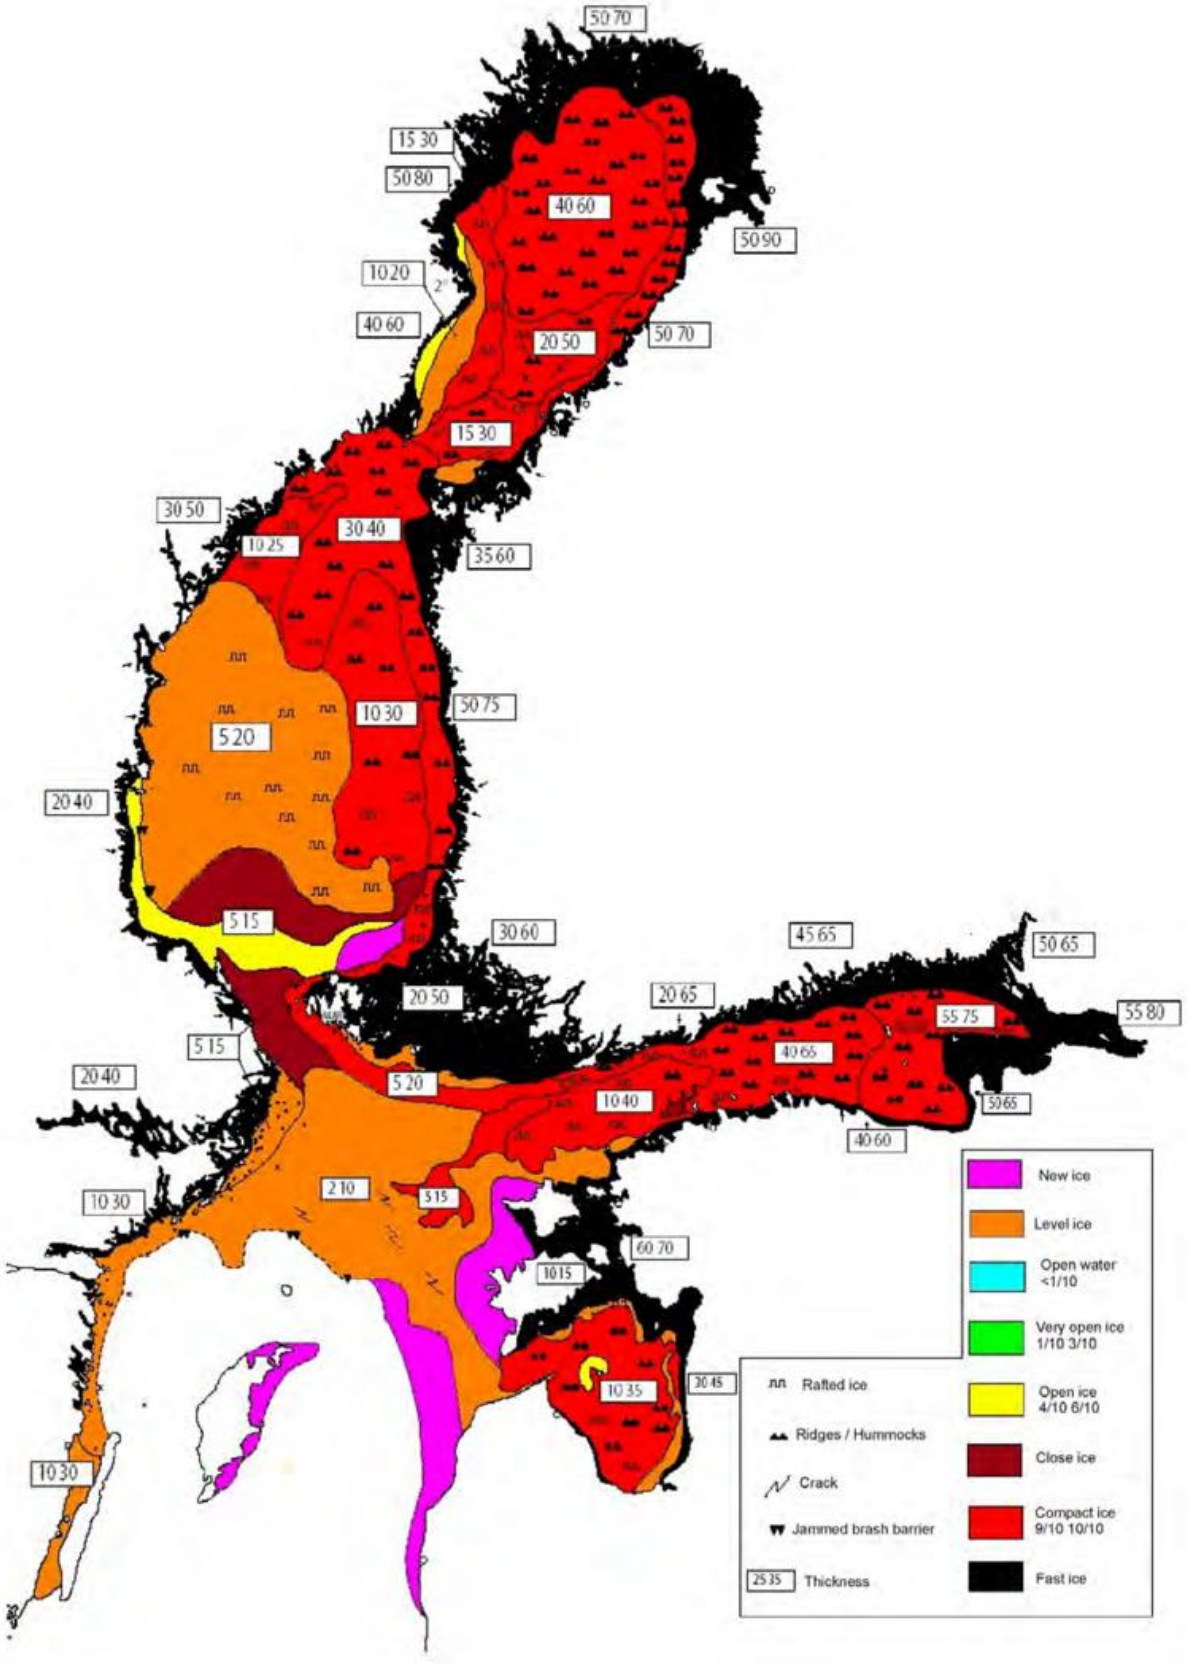

Fig 3.1: *The area of ice coverage of the Baltic Sea at its maximum, year 2003*
From: Latvian Environmental, Geological and Meteorological Agency

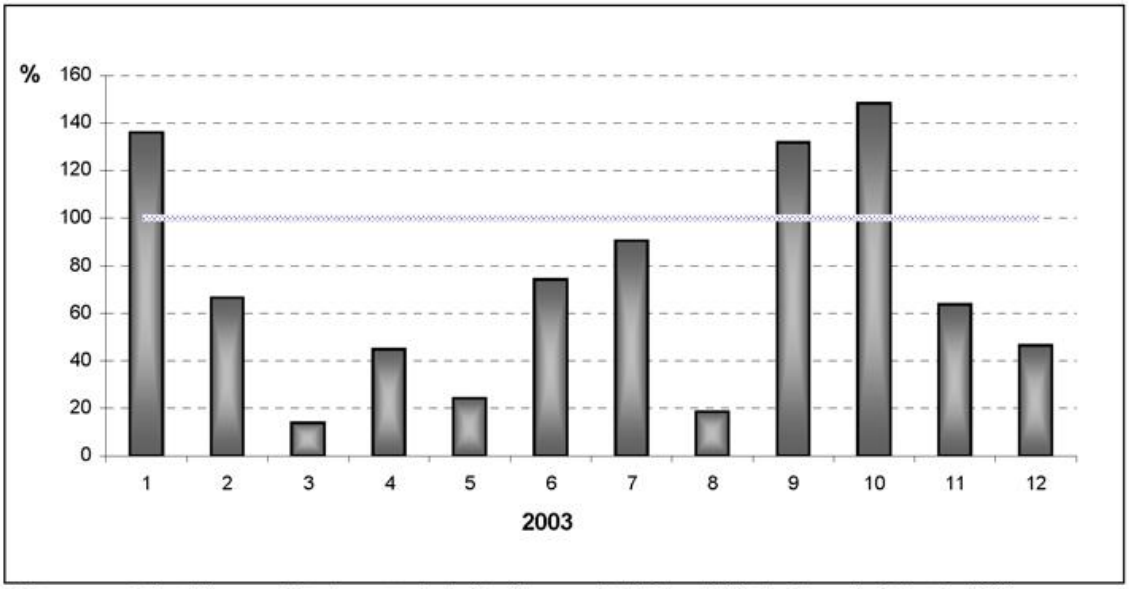

Fig 3.2: *Monthly precipitation totals in % of normal (1961 - 1990) in Zagreb Gric, in 2003*
From: Meteorological and Hydrological Service, Croatia

Temperature anomalies in Spain were generally positive and centered in the north-west with maxima of >2.5°C. Precipitation was unevenly distributed over the peninsula. Except for a zonal belt including Madrid, precipitation amounts were below normal.

Gibraltar received 148mm of precipitation during the month, which is nearly twice normal.

While temperatures were close to normal in Bosnia and Herzegovina, precipitation had an enormous deficit of about 80% of normal.

In Serbia and Montenegro temperature anomalies were mostly negative, but close to normal everywhere. Precipitation amounts were extremely low in the whole country; the deficit varied from about 60% to more than 95% (see fig. 3.4). In mountainous areas a snow cover remained during the whole month.

It was the driest of all months since the beginning of observations in Albania.

In The Former Yugoslav Rebublic Of Macedonia the month was moderately cool and extremely dry with nearly no precipitation.

The month was rather cold and extremely dry in Bulgaria. Temperature anomalies were about -2°C. In the north of the country the precipitation rate was 25% and in the south only 3% of normal (fig. 3.6). There were 40-60 hours more sunshine during the month than usual (fig. 1.5). Fog was observed all over the country on March 1-4 and 10-11.

Fig 3.3:

Monthly precipitation average (%) in 2003 (green boxes) compared to the reference period (red line) in Hungary
From: Hungarian Meteorological Institute

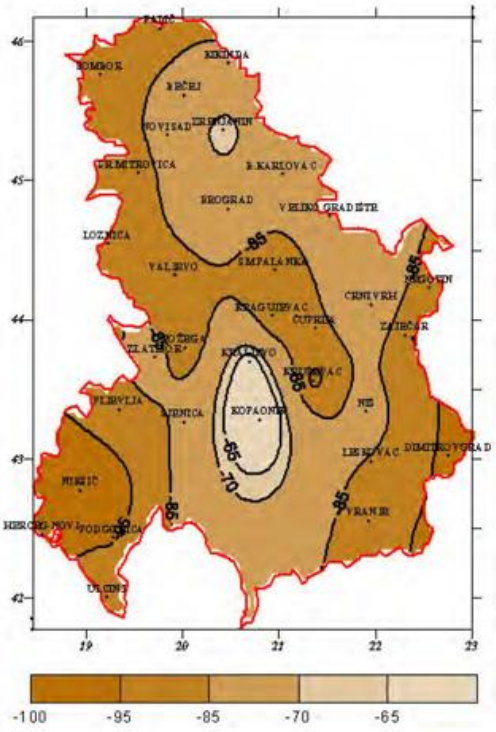

Fig 3.4:

Precipitation amounts deficit (%) distribution in March 2003
From: Republic Hydrometeorological Service of Serbia

In Greece the weather was cooler than normal everywhere and very dry on the mainland. Station Heraklion in Crete had a precipitation rate of 166% compared to normal. Strong north-easterly winds of 75-100km/h prevailed on March 16-17 over the western and southern part of the country and caused the destruction of house shelters and agricultural infrastructure in Peloponnesus and particularly in the city of Kalamata, from where maximum gusts up to 141km/h are recorded. Station Kythira measured a maximum wind force of 133km/h and Athens 93km/h.

In Turkey the monthly mean temperatures were significantly below normal with anomalies down to -3°C. Precipitation amounts were unevenly distributed over the country with dryness in the north-western parts and precipitation rates exceeding normal in the southern and eastern areas. During a storm event 3 minarets were destroyed in Yalvac/Isparta on March 25. On the same and the next day again stormy weather caused a lot of damage in some places at the southern coast.

In Cyprus the month was relatively cool and very wet. The monthly mean air temperature was 1.5°C below normal and the precipitation total exceeded the long-term average by 55%. In the areas west and south of Nicosia hailstorms caused damage to houses and agricultural plantations on March 11; hailstones had a diameter of 1 cm and accumulated to a height of 15cm in some places. Thunderstorms combined with hail and snowfall in the mountains occurred on March 18 in various areas of the island.

The month was cool and very rainy in Israel. Precipitation amounts were 150%-250% of normal. In the north it was the rainiest March in the last 30-40 years (fig.3.6). Most of the rainfall occurred in the period of March 18-26. In the northern and central parts of the country 150-250mm were recorded. March 25 was one of the coldest days in the past 3-4 months, with significant amounts of snow in the northern mountains at an altitude above 1000m. Severe hail and lightening activity occurred on March 24-25 causing some power failures.

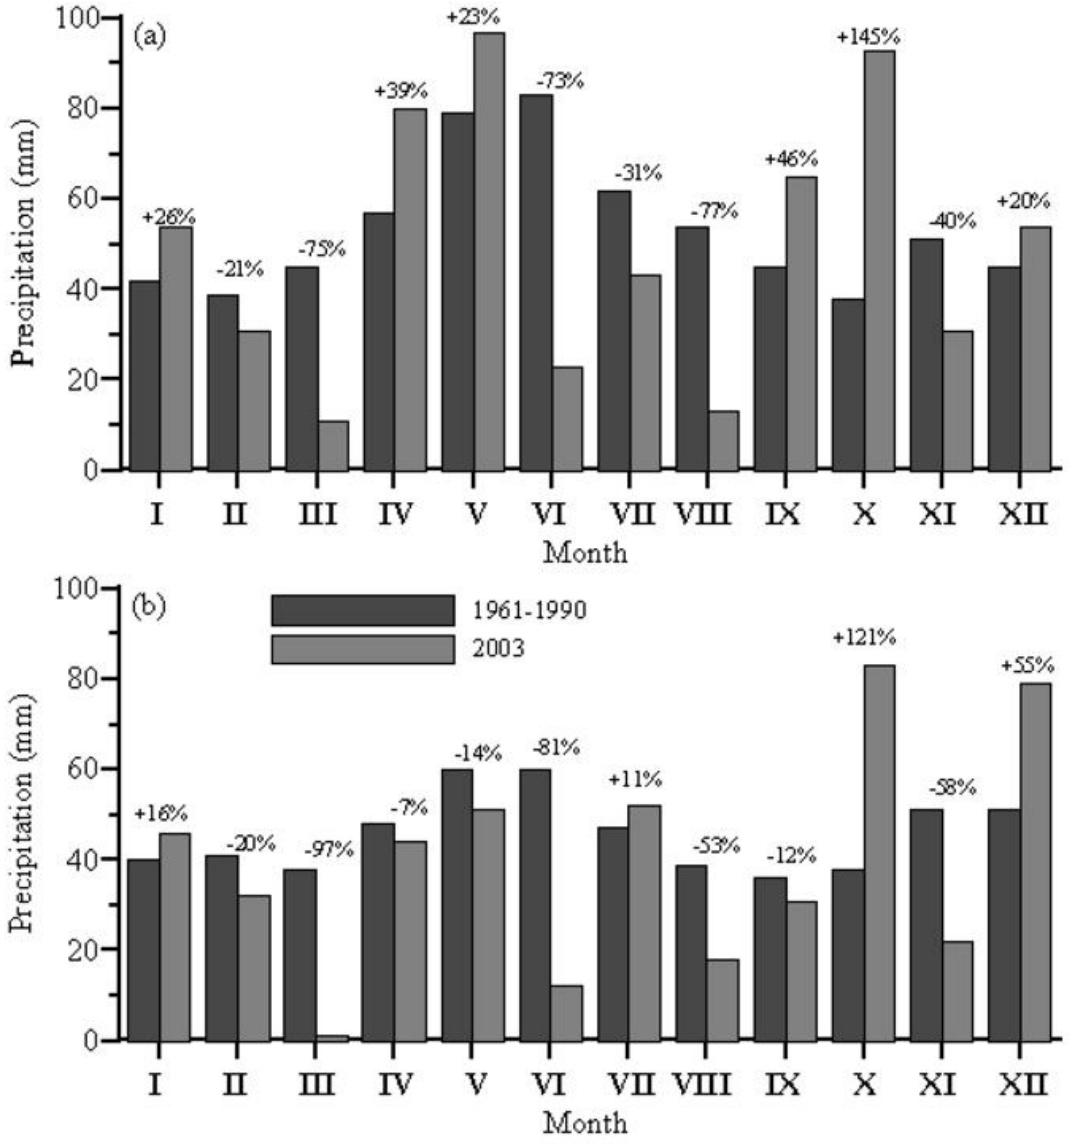

Fig 3.5: *Monthly precipitation in north Bulgaria (a) and south Bulgaria (b) in 2003 and departures (in %) relative to normal (1961 - 1990)*
From: National Institute of Meteorology and Hydrology, Bulgaria

The month was cold and wet in Armenia. Temperature anomalies were between -2°C and -3°C and the amount of precipitation exceeded normal significantly (see fig. 3.7). Most extreme weather conditions like snowfall, blizzards, strong winds and low visibility were observed within March 19-26. Continuous snowfall during 9 hours led to a snow cover of 91cm in Aparan on March 19. A blizzard occurred on March 26 in Jemuk and lasted for more than 20 hours producing a snow cover of 118cm. At the end of the month, advection of cold air masses from the north made temperatures fall down to -18°C ... -25°C in hilly and mountainous regions.

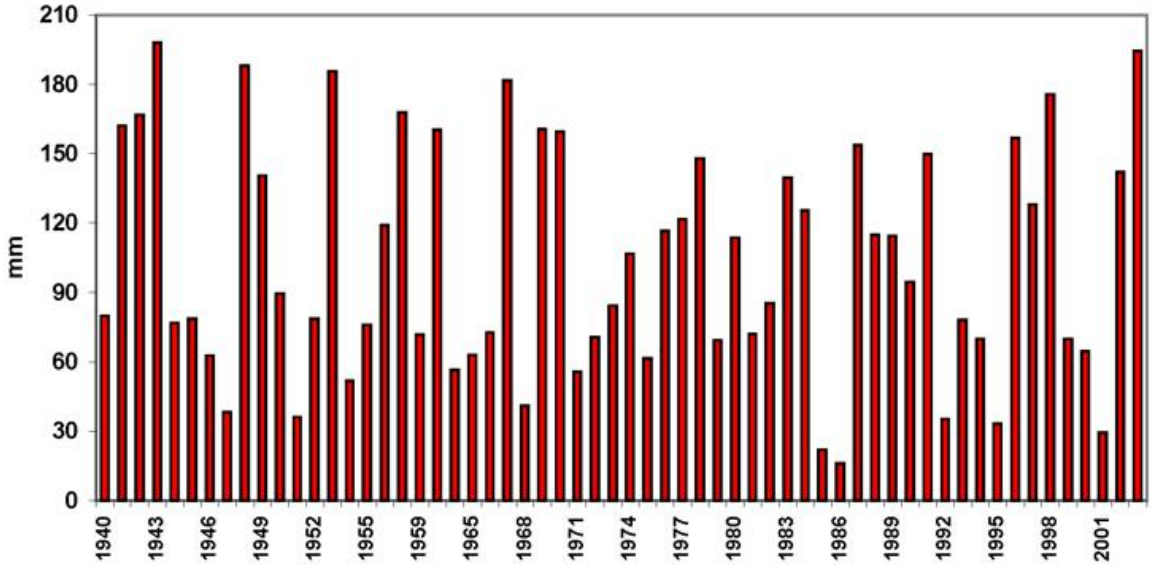

Fig 3.6: *Rainfall amounts in Har Kenaan in March 1940 - 2003*
From: Meteorological Service Israel

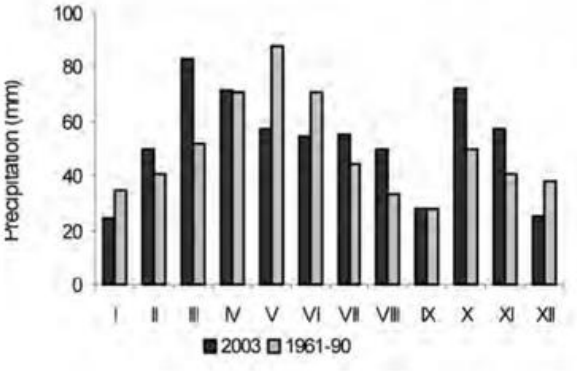

Fig 3.7:

Monthly precipitation totals in 2003 compared with 1961 - 1990
From: Hydrometeorological Instiute, Armenia

April 2003

- **Very dry in most parts of central Europe and in northern Scandinavia**
- **Very mild in south-eastern Greenland, Iceland , Norway, the British Isles and France**
- **Very cold around the Bosporus**

It was the second warmest April on record in Iceland, 1974 being somewhat warmer. It was also dry in most regions except of the south-west. A new absolute temperature record for the month, namely

21.4°C, was reached at Hallormsstaður in the eastern inland on April 19.

Record breaking high temperatures were registered at different places in the Faroe Islands. The monthly mean temperature of 7.7°C at station Kirkja on the island Fugloy equals the record of station Sandur on Sandoy from 1974. The maximum temperature 19°C was measured on April 17 on Fugloy.

Southerly winds brought extremely high temperatures inland to the U.K., with Wolverhampton reaching 27.3°C on April 16. This was the highest April temperature in the UK since 16th April 1949. Records were broken in many places. April 16 brought the highest maximum temperature on record in the 1878-2003 Central England series (fig. 4.1). A heat wave also occurred in Scotland from April 15-18 as the anticyclone over Scandinavia returned westward giving warm southerly winds. It was sunny everywhere, and the temperature reached 26.9°C at Lochcarron on the 17th, a new record April temperature for Scotland (the previous highest being 26.7°C at Dollar in 1870). Over Northern Ireland, April 16-17 were very warm days everywhere with day-time temperatures recording values around 10°C above the average for this time of year. Indeed some areas broke their highest temperature record for April on the 17th. 22.8°C was recorded in the north at Portrush on April 17. Both Scotland and Northern Ireland had their warmest April in the areal series back to 1961.

In Norway the month was warmer than normal in the whole country, especially in the western part. The Easter Days were very warm in the southern part of the country with fair weather. The western part was very dry, receiving only 25-50% of the normal precipitation amount. Svinøy Lighthouse outside mid-Norway received only 8.1mm, which is the lowest sum for April ever measured at this station since observations started in 1955.

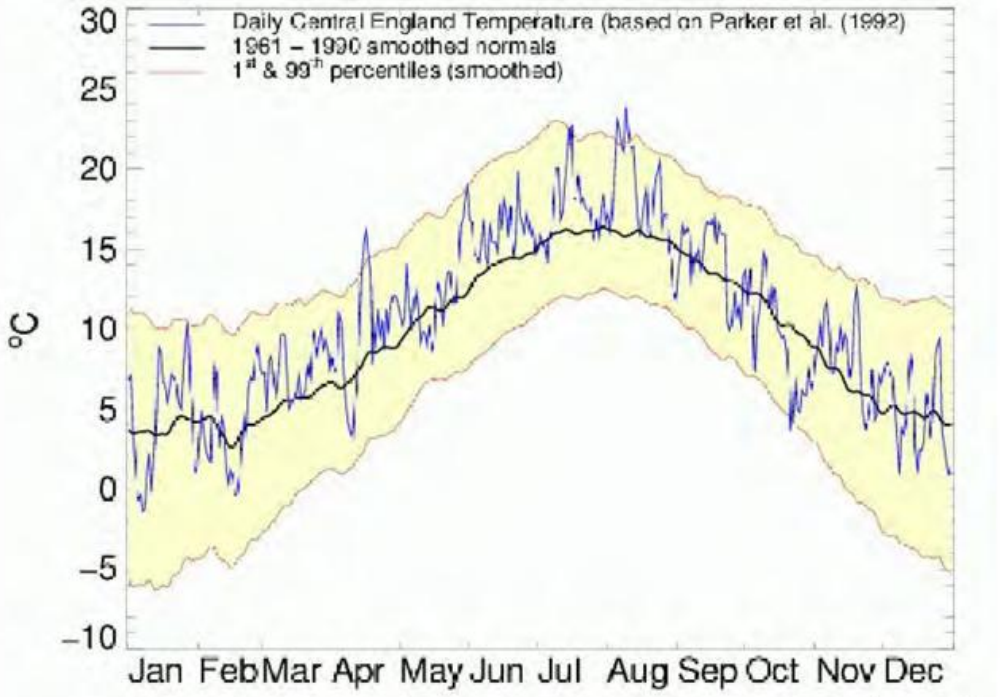

Fig 4.1: *Daily Central England temperature (°C) for 2003, normal 1961-1990 and 1st and 99st percentiles for each day of the year*
From: Met Office, U.K.

In Denmark, the month was warmer and had more sunshine compared to the long-term averages. It was also very dry with about half of the normal precipitation. The phenological phase leafing of the beech

was observed, which is rather new to the country in this month.

The Azores Islands were affected by lows which caused heavy rainfall and winds with very strong gusts. Particularly on April 11-12, strong winds with gusts exceeding 130km/h over all islands and up to 159km/h in S. Jorge, associated with a heavy swell of more than 12m, caused damage estimated at €1.7 million in 1,545 farms (especially in gardening, vine, beet and tobacco) and €187,000 in power supply. Scheduled flights were suspended.

The month was warmer than on the long-term average and extremely rainy in the mainland of Portugal. The precipitation amounts were well above normal in almost all territory, especially in the coastal northern, the central interior and the southern regions and also in the Lisbon area.

Temperature anomalies in Belgium were clearly positive, while the precipitation total had a deficit of more than 10%. Sunshine duration was extremely high; at station Uccle it was 212h and thus exceeded the long-term average by 34%. Heavy rains and strong winds caused flooding over dry ground in the northern part of the country on April 26.

In Germany the country-wide monthly mean temperature was about 1°C above normal, while the total precipitation reached only $^2/_3$ of the long-term average. Freezing rain and snowfall in the early morning of April 7 caused a lot of accidents and obstructions on roads in eastern and southern parts of the country. Heavy rains engendered flooding of streets and houses near the city of Aachen on April 26.

The monthly mean temperature in Poland was close to normal, but the field of anomalies had a clear gradient rising from south-east to north-west. The first two decades were very cold with negative minimum temperatures almost over the whole country. Temperatures gradually rose in the second half of the month with maximum temperatures exceeding 28°C in some parts of the country. Precipitation was still insufficient in a large area with 30% of normal in the west. Snow fell in the first half of the month and snow cover achieved depths of 30cm in the east.

In Lithuania the first ten-day period of the month was the coldest since 1965 with an anomaly of -3.8°C. It caused a snow cover of 10-19cm depth at some places. Frozen ground thawed by mid-April; very active and changeable synoptic processes determined unsteady and chilly weather. The mean monthly air temperature was 4.9°C, which equals an anomaly of -0.5°C. The monthly amount of precipitation was 38mm and thus close to normal in most places and up to 1.5 times normal at the seaside.

In Latvia the monthly anomalies were moderate. The mean temperature was -0.9°C below the reference and the precipitation rate 118% of normal.

In the first half of the month cold air characterised the weather conditions in Switzerland. Temperatures dropped to -8°C in the lowlands. Station Davos recorded -14.7°C; only April 1913 was even colder since the year 1901. A snow cover up to 10cm formed in the lowlands from April 9-11. In large areas significant precipitation deficiencies occurred, particularly on the southern slope of the Alps.

It was extremely cold in Austria during the first days of the month. At the station Innsbruck in Tyrol, a record minimum temperature of -9.6°C was measured on April 8; the previous record was -6.5°C in 1929. At the end of the month strong south-westerly winds brought very warm air to the area. From the city of Salzburg to eastern Austria new all-time maximum values of temperature occurred, reaching 31°C in Salzburg on April 30. Precipitation again was below 75 percent of normal amounts in large parts of the country.

In Slovenia, the first decade of the month was significantly colder than usual. The rest of the month was warmer than on the average in the reference period and the

monthly mean air temperature was very close to normal. The mountain observatory Kredarica recorded the lowest air temperature of the month, -20.3°C, on April 7. Precipitation showed the typical pattern brought by south-westerly upper level winds. Most of the precipitation fell on the mountain ridges of the Julian Alps. Sunshine duration in the high mountains was slightly below normal, the lowland got more sunny weather than usual. The Goriška region got about one third more sunny weather than on the average in the reference period.

While the monthly mean temperatures in Croatia were close to normal, it was very dry with precipitation totals below 50% of normal.

Extremely high temperatures in Hungary at the end of the month did not prevent the monthly mean from staying slightly below normal (see fig.2.3). The country-wide precipitation total was only 40% of normal; therefore, drought conditions continued.

In Romania the monthly temperature anomalies varied from -1°C to -2°C. The country-wide precipitation total reached 85% of normal.

In Bosnia and Herzegovina the mean monthly temperature was slightly below normal, while the precipitation total was merely 45% of normal.

The weather in Serbia and Montenegro was characterised by extreme temperature variations. During the first decade, absolute minimum temperatures were unusually low. By the end of the month extremely high temperatures were registered. At eight stations in Serbia, records of absolute temperature maxima were broken. The highest temperature recorded from Belgrade was 32.2°C, the previous absolute maximum being 30.9°C in 1926. In Montenegro an absolute maximum temperature of 29.6°C was measured at station Berane. The spatial distribution of precipitation amounts was uneven.

In Macedonia the month was rather cool and dry. Temperature anomalies were about -2°C and precipitation rates clearly below normal.

The month was cold in Bulgaria with temperature anomalies about -2°C. The average monthly minimum air temperature was lower than 5°C, which is not typical for this month. The cool weather limited the crop growth and the development of winter crops. In south-western Bulgaria frost damage from 50% to 100% of the flowers of cherry, peaches and apricot trees was registered. Precipitation in the Danube plain was about 40% above normal; daily precipitation amounts of more than 30mm were measured on April 12-13, e.g. 46mm in Lovech, 52mm in Orjahovo and 56mm in Belogradchik. Long lasting and pouring precipitation during the above-mentioned days caused slips of rock masses which closed the road Sofia-Samokov. There were more than 35 road accidents for a day in Sofia because of intensive precipitation. In the low parts of the country a snow cover with a height of 2-6cm was formed, which is not typical for the season.

The weather in Moldova was cool and dry. The deviation of the monthly mean temperature from normal was about -2°C and the precipitation total amounted to 85% of normal.

The temperature anomalies in Greece were negative all over the country. Precipitation rates had a clear gradient from north-west to south-east; while station Kerkyra received 50% of normal precipitation, Heraklion on Crete registered 200%.

In Turkey the month was generally colder than normal. The overall precipitation total exceeded the long-term average by 50%. Frost and hail damaged beets and flowers of trees at different places during the month.

The month was dry and cooler than normal in Israel. Yet very high temperatures were recorded due to a sharav event on April 4-5. Temperatures reached 38-40°C in the coastal plain and 40-41°C in the Negev. In the last 40 years such temperatures were recorded only once (1979) in the beginning of April. Most of

the rainfall occurred in the second part of the month but they amounted only to 60%-80% of normal.

After a very cold start of the month in Armenia mean daily temperatures rose to +3°C ... +7°C above normal on April 5-6, in valley regions even to +11°C above normal. Maximum temperatures in Sunik and Ararat valleys were up to 29°C. On the same days strong winds with gusts up to 104km/h caused a lot of damage to houses, forests and power lines in Martuni.

May 2003

- **Extremely warm in south-eastern Europe**
- **Extremely dry in the western Iberian Peninsula, the southern Alpine area and around the Black Sea**
- **Very wet in southern and north-eastern Scandinavia**

The first 6 days of the month were very cold in Iceland, with some setbacks for the unusually early vegetative growth. After that the temperature was generally above the average. The monthly temperature average in Reykjavík was almost the same as in April and in Akureyri May was colder than April, the first time since 1979.

The month was very wet in Ireland with precipitation rates exceeding normal by more than 50%, while temperature anomalies were moderately above the long-term average.

In the U.K. the monthly mean temperature was 1.0°C above normal, while precipitation exceeded the monthly reference of 1961-1990 by 37%. Sunshine duration was slightly below normal. During the first week of the month, four depressions moved north-east close to the north-west of Scotland. In the west there were strong winds at times, with a gust of 108 km/h at Barra in the early hours of May 8.

The month was warmer than normal in northern Norway and near normal or below in the middle and the south. A greater part of the country received more precipitation than normal. Some places in the south have not measured more precipitation in this month for the last 50-130 years; e.g. Oksøy Lighthouse measured 184.3mm (267% of normal), which is the highest value observed in May at this station starting in 1870.

The overall monthly mean temperature in Sweden was moderately above normal and the total precipitation exceeded normal clearly. A thunderstorm killed two men when a lightning stroke triggered the explosion of a petrol deposit close to Sala on May 21.

The country-wide monthly mean temperature in Finland was moderately above normal. Precipitation was abundant, so that in some western, central, and north-western parts of the country the monthly precipitation was at least 300% with respect to its reference value.

In Belgium the monthly climate parameters of mean temperature, precipitation and sunshine duration were not far away from their long-term averages. In spite of this, thunderstorms and hail caused considerable damage in different places on May 2 and 30.

In Germany the monthly mean temperature was 2°C above normal. A heat wave affected Bavaria and Saxony on May 5; a maximum temperature of 33°C was

recorded from Leipzig. The overall precipitation total reached 95% of normal, but the spatial distribution was uneven (see fig. 5.1). Three major thunderstorm events in southern and south-western Germany combined with hail, lightning, flooding and local tornadoes caused lots of damage and obstruction on May 8-9 , 19 and 30.

In Denmark the monthly mean temperature was near to the long-term average, while precipitation amounts were about 200% of normal.

It was the month with the highest positive temperature anomaly in Poland (together with November, see fig. 5.2). The spatial distribution of temperature was diverse. At the end of the month, maximum temperatures exceeded 30°C in some parts of the country. Rainfall was generally lower than average. It was mostly accompanied by thunderstorms, so its spatial distribution was very diverse: in the western and central parts precipitation was below normal (even less than 20%) and above normal in the north and south (up to 185%). The most intense rainfall was observed late May with daily sums exceeding 50mm.

In Lithuania the weather was changeable with warm periods in the first half of the month and in the middle of the third ten-day period, but colder else. The monthly mean air temperature was 12.9°C with an anomaly of +1.0°C. Precipitation amounted to 34-65 mm and thus was near normal in most parts of the country while reaching 70-104mm in eastern and some southern areas. The monthly sunshine duration amounted to 270-305h at the seaside, which is 10-40h above normal and to 210-250 h in the other parts of the country (20-40h below normal).

Temperature anomalies were moderately positive in Latvia, while the precipitation rates exceeded normal significantly. The Gulf of Riga was not completely clear of ice until May 4, which is 20 days later than normal.

The month was very warm in Belarus (see fig. 0.7). Precipitation was significantly above normal (fig. 5.3).

Drought conditions continued in France except of the northern parts of the country.

In Portugal the month was moderately warmer than usual and extremely dry in almost all parts of the country. In some stations the monthly totals were the lowest values ever registered in this month.

In Spain a long lasting period of extraordinarily high temperatures started in the middle of the month.

In Italy the month was rather warm and also very dry, especially in the northern and central parts of the country.

The month was very warm in Switzerland. Temperature deviations from normal were 2-3°C in the north and 3-4°C in the south. It was the warmest May south of the Alpine crest since 1868. In large areas significant precipitation deficits arose, particularly on the southern slope of the Alps.

The monthly temperature anomalies in Austria varied from 2°C to 4°C, making May 2003 one of the warmest ever since the beginning of observations. In Vienna the month had been warmer only in 1797 (18.1°C) and 1811 (18.4°C) compared to 17.9°C in 2003.

It was extraordinarily warm and relatively dry in Slovakia. Monthly mean air temperatures were up to +4°C above normal and the highest since 1961. The daily maximum temperatures were also very high, but the extreme values of the year 2000 were not overcome. In mountainous regions the mean monthly minimum air temperature was the highest since 1961.

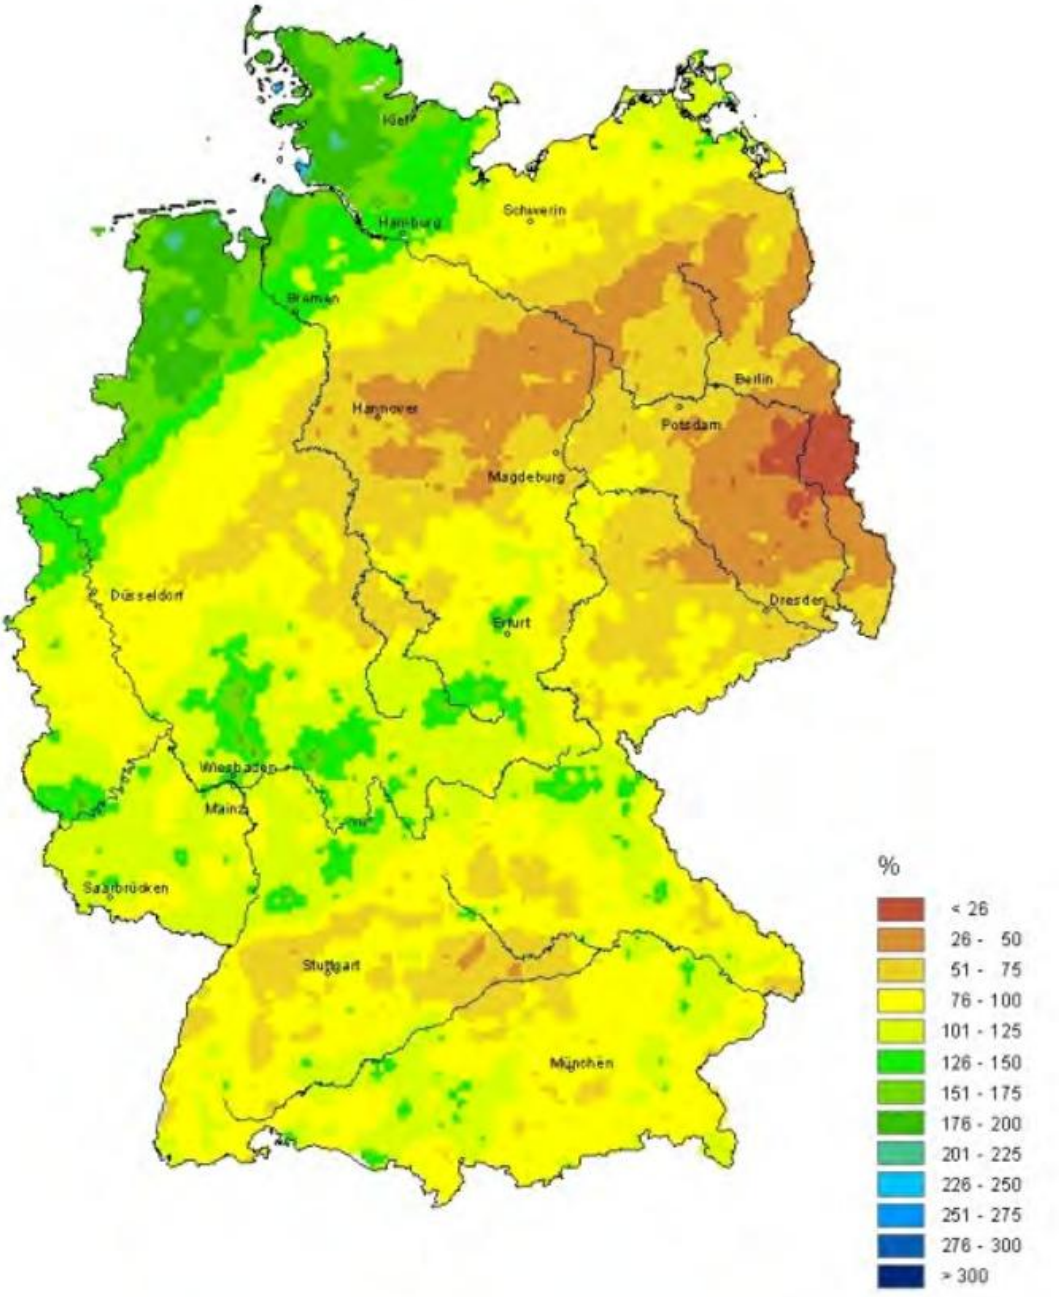

Fig. 5.1: *Precipitation distribution for Germany in % of normal (reference period 1961-1990), May 2003*
From: Deutscher Wetterdienst, Offenbach

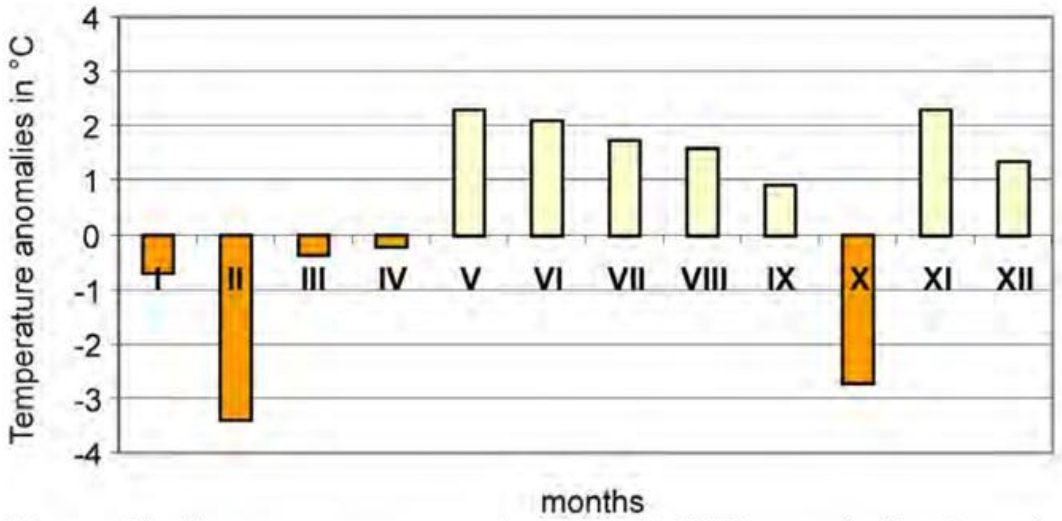

Fig. 5.2: *Monthly mean temperature anomalies in Poland in 2003 (average for 14 stations, reference period 1971-2000)*
From: Institute of Meteorology and Water Management, Poland

The month was extremely warm and very dry in Hungary (see figs. 2.3 and 3.3). The country suffered from a serious drought. The water level of the Danube was very low, only 80cm against 857cm in the same month of the previous year.

In Slovenia, the monthly mean air temperature was well above normal with anomalies up to more than 4°C. It was the warmest May of the last fifty years in Ljubljana and Dolenjska. Lack of precipitation was the other characteristic feature for the whole country. The first third of the month was almost completely dry; the second and last third brought local precipitation with large spatial variability. Sunshine duration exceeded normal everywhere. On the coast 15 % more sunny weather occurred than on the average in the reference period, in the Goriška region even 50% more than usually.

In Croatia the month was extremely hot with temperature anomalies above +4°C. Precipitation was rather low with rates of less than 50% in many places.

In Bosnia and Herzegovina the country-wide temperature anomaly was +3.7°C. The total precipitation reached only 60% of normal.

The month was very hot and dry in Serbia and Montenegro. Temperature anomalies reached +4°C and more. Registered temperatures for almost all stations were the highest in the past 40 years. The number of tropical days was exceptionally high including a ten day series in the first half of the month. Total precipitation amounts were far below the long-term averages in most parts of the country.

The month was very hot in Romania. Temperature anomalies were up to 5°C and more in some areas (see fig. 5.4). It was very dry almost all over the country with precipitation rates of less than 50% of normal in many places.

Moldova experienced an extremely hot and dry month (fig. 5.5). Temperature anomalies exceeded normal from 4.0°C to 5.5°C almost all over the country, which was observed for the first time in the last 100 years. The country-wide precipitation rate was below 20%. These drought conditions caused massive economical damage, especially to agriculture. Additionally, a cold front accompanied by squalls and hail showers affected some areas on May 29; houses and roads were inundated, roofs and power lines destroyed, crops damaged and two people died near Chisinau and in the Ungheni district.

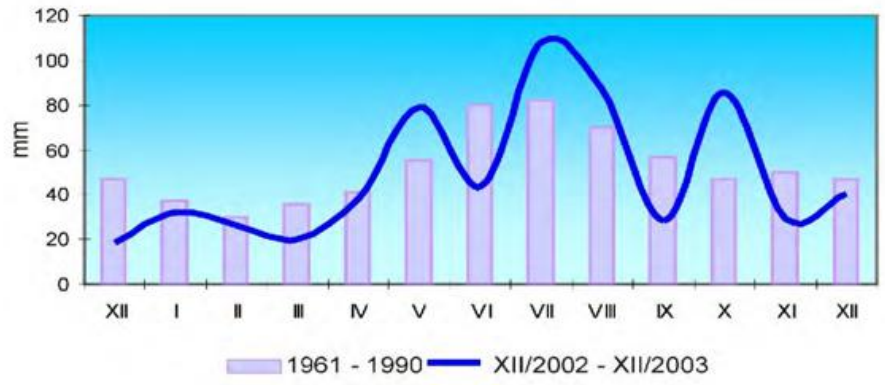

Fig. 5.3: *The monthly precipitation for 2003 and the average long-term precipitation (1961-1990) of Belarus*
From: Hydrometeorological Centre of the Republic of Belarus

In Ukraine the month was very hot and dry. Temperature deviations from normal ranged between +3.5°C and +4.7°C. The drought, that started in most parts of the country one month before, continued.

Albania experienced the start of an unprecedented heat wave lasting until August (see fig. 1.3). In this month of May a maximum anomaly of +7°C was registered in the mountain zones.

The month was very warm in Bulgaria with temperature anomalies ranging from +2.2°C in the south to +3.0°C in the north of the country. In 20-25 days the maximum air temperatures were higher than +25°C. The country-wide precipitation total was near to normal, but in the north precipitation was 23% higher than the long-term average and in the south 14% below. Extreme daily rainfalls above 30mm were registered between May 21 and 31 at different places. In the Rhodope mountains heavy rains activated landslides on May 29. Hailstorms were observed on 11 days of the month.

Temperature anomalies in Greece were clearly above normal everywhere, while precipitation was distributed unequally. Heavy showers and thunderstorms occurred during the period of May 29-30 affecting the southern part of the country, mainly Cyclades and Crete. Station Ierapetra recorded a daily rainfall amount of 113.4mm on May 29, whereas the long-term average is 21.9mm. These storms led to floods with destructive results to roads and agriculture; one person died.

In Turkey the month was clearly warmer than normal. Except for the south-western coastal area precipitation was in deficit. Drought affected agricultural sites especially in the area of Tekirdag in the second half of the month. A hailstorm damaged fruit trees and crops near Bursa on May 24. Heavy rains caused flooding of roads, bridges and crops in coastal areas near Iskenderun on May 31; two people drowned.

The month was very much warmer than usual in Cyprus with a temperature anomaly of +3.1°C. The total precipitation was only $^1/_3$ of normal. Dense fog occurred on May 20 with visibility reduced to 200m. After two days with dust, thunderstorms combined with heavy rains and hail engendered floods in the area of Nicosia causing damage to premises.

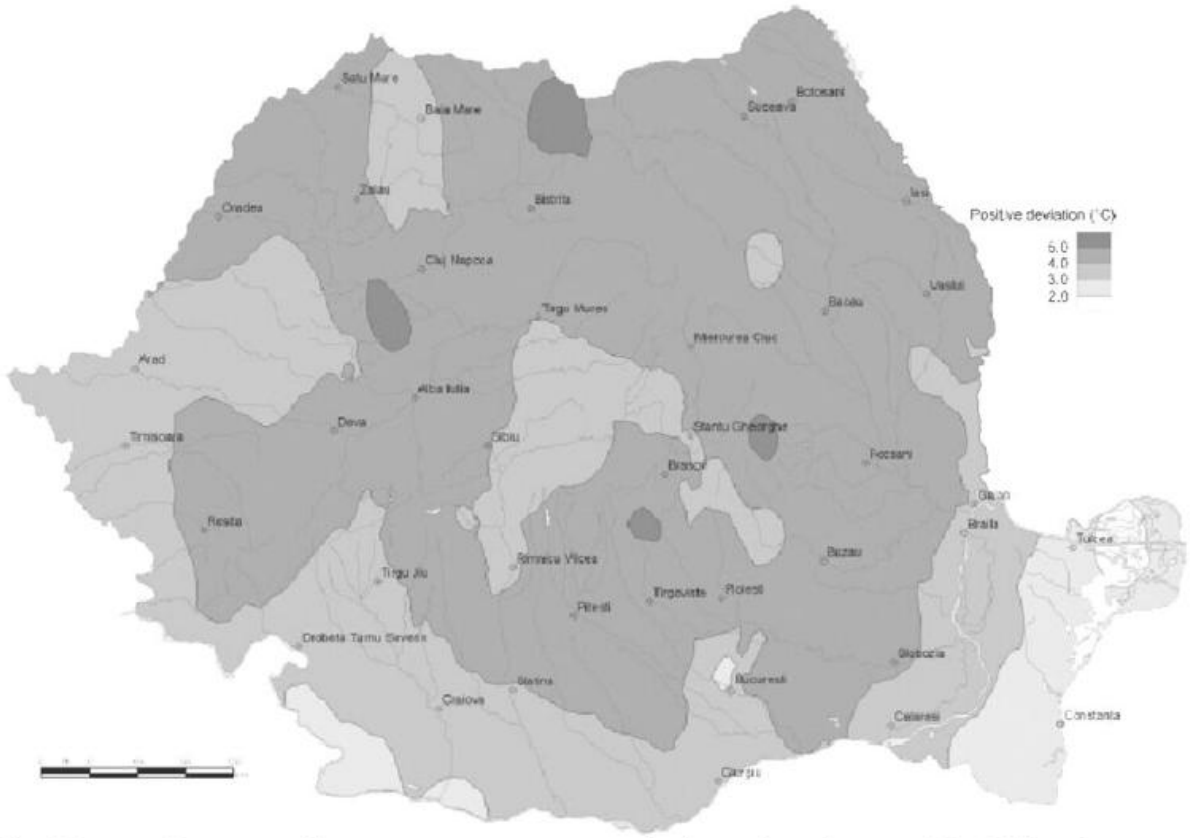

Fig. 5.4: *Deviation of the mean temperature against the climatological norm in May 2003, in Romania*
From: National Institute of Meteorology and Hydrology

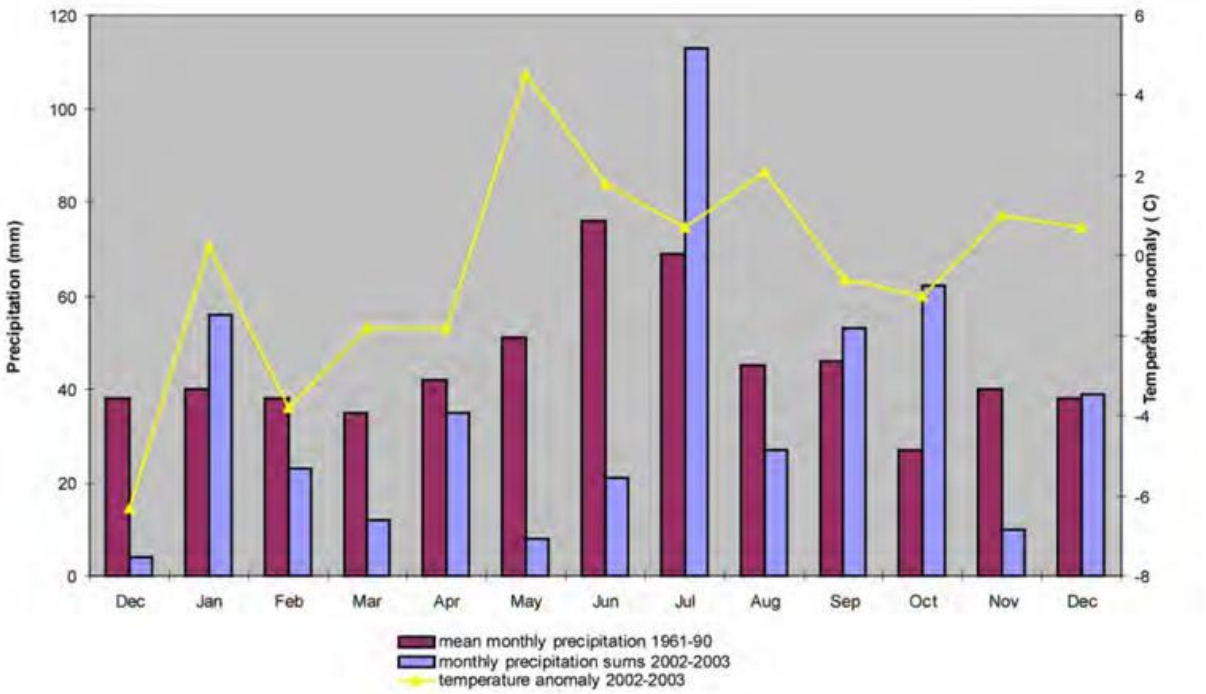

Fig. 5.5: *Monthly area average precipitation and temperature anomalies in Republic of Moldova*
From: State Service Hydrometeo of Republic of Moldova

In Israel it was very hot with monthly mean temperatures of 3°C to 4°C above normal, and at most stations this was the hottest May since the beginning of measurements (see e.g. fig. 5.6). The first part of the month was characterised by

successive hot days. Sharav events with maximum temperatures up to 39°C in the coastal plain and in the Negev occurred on May 4 and 8 - 10. The second part of May was slightly less warmer, but the hottest day of the month was recorded on May 29 with 41°C to 43°C in the coastal plain.

The month was very hot and dry in Jordan. The mean maximum and minimum temperature at the Amman airport had anomalies of +4°C and +2.3°C respectively (see fig. 5.7).

While the monthly mean temperature was near normal in Armenia, the country-wide precipitation total was much below the long-term average (see fig. 3.7). In spite of this, continuous snowfall during 9 hours occurred on May 9 in Goris and produced a precipitation amount of 23mm. A thunderstorm in Ashotsk on May 20 caused the death of one person.

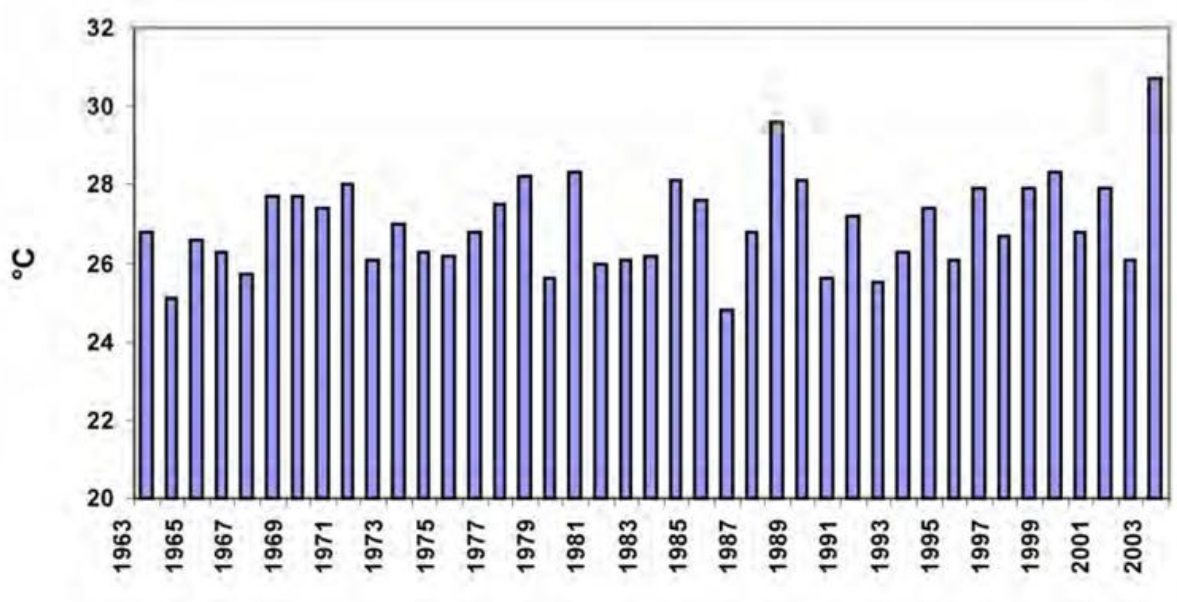

Fig. 5.6: *Mean daily temperature in May; Bet Dagan (Central Coastal Plain) 1963-2003*
From: Israel Meteorological Service

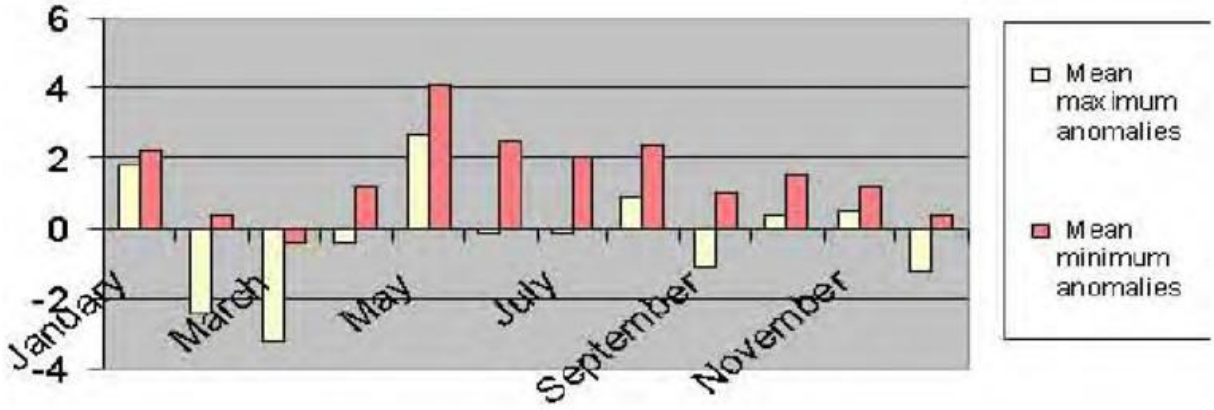

Fig. 5.7: *Mean maximum and minimum anomalies for the year 2003; Amman Airport*
From: Jordanian Meteorological Department

June 2003

- **Extremely hot in central Europe, especially in the Alpine region**
- **Very dry in the southern parts of France and the Iberian Peninsula as well as in eastern Europe and northern Turkey**

The month was relatively warm all over Iceland, but quite wet in the south and east. In Reykjavik it was about as warm as June 1941 which is the warmest on record.

The monthly mean temperature in Ireland was moderately above normal, while the precipitation total clearly exceeded the long term average. A daily fall of 63.7mm at Valentia Observatory on June 9 was its highest daily amount for June since records began in the area in 1892. In spite of this sunshine duration was generally above normal and daily values of more than 15 hours were measured at a few stations during the last week of the month. Station Malin Head measured the year's highest daily sunshine, 16.0 hours, on June 29.

In the U.K. the monthly mean temperature anomaly was +1.9°C and the precipitation total close to normal. The Midlands and south-eastern England had thundery showers on June 1, with station Shepshed recording 39mm in 1 hour. Widespread storms with some flash flooding affected eastern and south-eastern England early on the 2nd, 60mm being reported from St Leonard's on the south coast. During June 17 heavy thunderstorms tracked north-eastwards over much of England. The rain was torrential in places, with flooding and lightning strikes disrupting railway networks in the north-east. 24mm of rain fell in an hour at Coningsby in eastern England.

In Norway the month was warmer than normal in most parts of the country. Precipitation was well below normal in the north and more than normal in the west as well as in some parts of the south-east. Here, stations Rygge (41.6mm) and Sarpsborg (39.3mm) noted new diurnal maxima for the month on June 24.

In Finland the month was cooler than normal, especially in the eastern part of the country, where the deviations came down to -4°C. The monthly precipitation was fairly close to normal in the southern and central areas, but mainly below normal more northwards and in some parts even less than 25% rain fell compared to its reference value.

The month was relatively warm and dry in Belgium with temperature anomalies mostly between +3°C and +4°C and precipitation rates about half of normal. The monthly sunshine duration at station Uccle was 258.2 hours, which is 28% above the long term average of the years 1887-1988 and 40% above normal with reference to 1961-1990. In spite of this some extreme weather events with a varying composition of heavy rains, hail, thunderstorms and strong winds including a local tornado occurred in different parts of the country on June 1-3, 8, 10 and 14.

The month was relatively warm (anomalies about +2.5°C) and dry (precipitation rates near half of normal) in the Netherlands.

In Luxembourg the month was very hot and dry with temperature anomalies up to +5°C and precipitation rates about 60% of normal.

In Germany the month was extremely hot, sunny and dry. The monthly mean temperature exceeded normal by 4°C, thus being the hottest June since 1901. A maximum temperature of 33.7°C was recorded from Munich on June 12, which is the highest value ever measured there on that day since the beginning of observations 130 years ago. The country-wide precipitation total was only 65% of the long term average. In spite of this many extreme weather events with serious

consequences (local tornadoes, heavy rains, thunderstorms, hail, flooding, land slides) occurred in different parts of the country throughout the month.

The monthly mean temperature in Poland was higher than normal by up to 3°C. Only the north-eastern region was close to the long-term average. The western and southern parts of the country were the warmest with maximum temperatures exceeding 33°C. The annual sums of precipitation calculated for 14 Polish stations reached only 45% of the 1971-2000 normal (see fig. 6.1). Very warm and dry weather engendered soil drought and decrease of water levels in rivers and reservoirs.

Weather conditions in Lithuania were variable during the month. The first ten-day period had been warm and dry under anticylonic influence. Then, the circulation gradually changed and northerly winds prevailed leading to the cooling down of the weather and the arrival of rain. The resulting monthly mean temperature was 15.1°C, which means an anomaly of -0.3°C. The mean monthly precipitation amounted to 59mm equaling 87% of normal. The month saw 12 days with thunderstorm and 8 days with a wind speed exceeding 54km/h and gusts up to 80km/h. Sunshine duration amounted to 290 – 340 hours (25 – 60h above normal).

In Belarus the month was moderately cooler than usual and significantly dry (see figs. 0.7 and 5.3).

The month was very hot and mainly dry in France. Temperature anomalies ranged generally from +4°C to +5°C. Except of some places in the north and north-east the monthly precipitation rates were below normal and even down to zero in southern parts of the country.

In Portugal the month was very warm with a mean air temperature of 21.7°C on the mainland, 2.5°C above the 1961-1990 normal. However, in the north-east, the southern coastal zones and the inner southern region, it was extremely warm. In some southern areas the mean maximum air temperature was above 40ºC. The monthly mean of Tx was 28.5ºC with an anomaly of about +3°C, corresponding

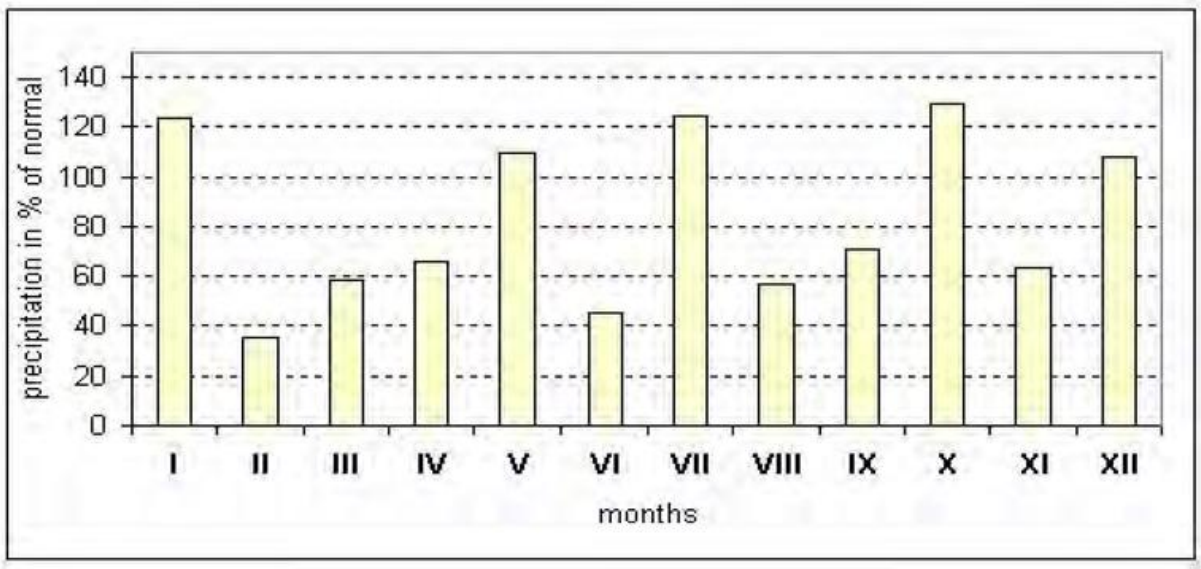

Fig. 6.1: *Monthly precipitation totals in Poland in 2003 in percent of 1971-2000 mean (average for 14 stations)*
From: Institute of Meteorology and Water Management, Poland

to the 3rd highest value since 1931 (higher values: 29.0ºC in 1976 and 28.8°C in 1996). The mean minimum air temperature was 15.0ºC, 1.6ºC above normal, corresponding to the 3rd highest value of the series (higher values: 15.1ºC in 1996 and 1981). Tab. 6.1 shows the number of days with a minimum air temperature of ≥20ºC

(tropical nights), and maximum air temperature equal or above 25ºC (summer days) and 30ºC (tropical days). The month in Portugal was also characterised by values of precipitation near the 1961-1990 normal in the northern region and below in the rest of the country. However, in the northern region precipitation occurred mainly on the last day of the month. For example in Bragança, the monthly total was 38mm (the mean 1961-90 is 39mm) with 31mm on June 30; in Vila Real the monthly total was 40mm (the mean 1961-90 is 53mm) with 34mm on June 30.

In Spain the monthly mean temperature was about 3.5°C above normal, the highest absolute anomaly since more than 40 years (fig. 6.2); new records were set up for more than 70% of all stations since the beginning of observations. The greatest deviations from normal occurred in Catalonia, in the north-east and the Balearic Islands with more than 2ºC above the previous record. At some locations new records were also set for the absolute maximum temperature. A tornado of an estimated intensity F3 on the Fujita scale appeared in the Ebro Valley on June 23 leaving behind a trace, that was 10km long and 400m wide.

In Switzerland, the monthly mean temperatures exceeded normal by 5.5-7.5°C, thus being about 2°C hotter than the hitherto warmest June of 1822. In the lowlands it was the hottest of all months since records started in 1753 with mean temperatures of 21-25°C. Only 20-50% of the normal precipitation quantities fell in many parts of the country. It was the sunniest June at least since 1976, in the south since 1945 and partly the sunniest June in the north since records started in 1901. Sunshine duration was generally between 290 and 330 hours.

In Austria the temperature anomalies ranged from +3.5°C to +6°C. It was the warmest June since the beginning of meteorological measurements in all parts of the country. In Vienna and Krems-münster with series since the eighteenth century, the warmest June before had been in 1811. In 2003 the

Stations	Minimum T >= 20°C		Maximum T >= 25°C		Maximum T >= 30°C	
	June 2003	Mean 61-90	June 2003	Mean 61-90	June 2003	Mean 61-90
Viana do Castelo	4	0.3	14	10.3	6	3.7
Braganca	2	0.1	23	13.5	13	3.5
Vila Real	2	0.3	19	16.3	7	5.3

Tab. 6.1: *Number of days with minimum and maximum temperature equal or above defined limits*
From: Instituto de Meteorologia, Portugal

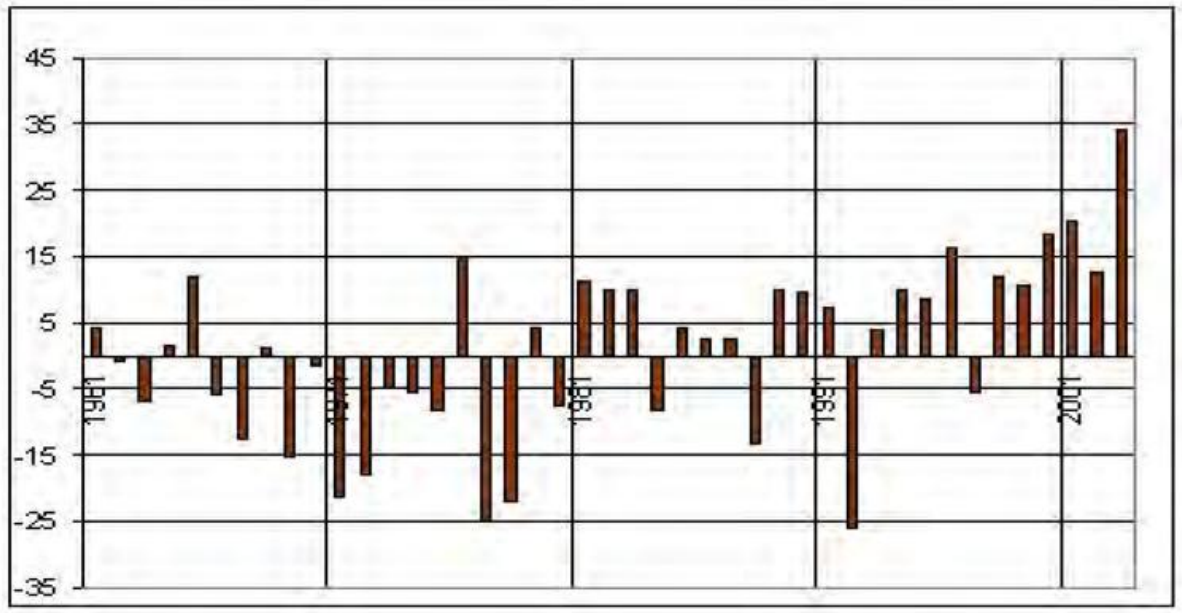

Fig. 6.2: *Deviation of average temperature (in tenths of °C) over the Spanish peninsular territory in June (reference 1971-2000)*
From: Instituto Nacional de Meteorologia, Spain

monthly average in Vienna was +22.4°C (+22.0 in 1811) and +21.2°C in Krems-münster (+20.8 in 1811).

It was the warmest and driest month in Czech Republic since 1961 with the highest positive monthly temperature deviation of +4°C. Drought conditions continued.

The month was very warm in Slovakia with temperature anomalies of about +3°C. It was also very dry with precipitation rates far below normal.

In Slovenia it was the warmest June since the beginning of observations and it was almost as hot as it was in the warmest month in the records which is August 1992. The mean monthly temperatures were 4.5°C to 6°C above the 1961-1990 normal (see fig. 6.3). Everywhere record numbers of days with at least 30°C were registered, in Ljubljana and Novo mesto 16, in Murska Sobota 15, in Portorož 20 and in Bilje 23. At many sites the highest temperatures on record for the month occurred, in Ljubljana 35.6°C, in Murska Sobota 36.0°C and 37.0 C in Vipava valley. Sunshine duration everywhere exceeded normal by at least 100%. On the coast sun was shining 310 hours which is 15% above normal. Kredarica got 229 hours of sunny weather, 39% above normal. Goriška region and Maribor got 40% more sunny weather than on the average in the reference period. Precipitation was clearly below normal everywhere except for Zgornjesavska valley. Only one quarter of normal precipitation fell in the Goriška region, Štajerska and Prekmurje got around one third of normal.

The month was extremely hot and generally very dry in Croatia. The temperature anomalies were ≥+3.8°C everywhere and up to +6.6°C at station Bjelovar (fig. 6.4). Although there were some isolated places, especially in coastal areas, with a monthly precipitation rate above normal, most stations had a considerable deficit in rainfall.

The month was very hot and dry in Hungary. Temperature anomalies ranged from +3°C to +5°C. The daily mean temperature was higher than the long term average of the month every day. More than two thirds of the month the daily temperature maxima were higher than 25°C. The precipitation total was 33% of the normal amount (fig.3.3). The drought had a serious impact on agriculture with 50% lower crops of rape and a minimum yield of

wheat in the last 5 years. Fruits and vegetables needed watering.

In Bosnia and Herzegovina the monthly mean temperature, calculated from 12 stations, was 21.3°C , thus being 4.6°C above normal (reference period 1961-1990). The analogously determined monthly precipitation total was 65mm, which is equal to 68% of the normal amount.

Almost all stations in Serbia and Montenegro registered the highest temperatures in the past 40 years, and for some stations it was the hottest June ever, as long as measurements started (see e.g. fig.6.5). The number of tropical days in row from June 12-21 was exceptionally high. Total precipitation amounts in most of the country were far lower than the long term averages.

In Romania it was rather warm with temperature anomalies about +3°C and very dry with only $^1/_3$ of the monthly normal precipitation.

Drought conditions in Moldova continued (see fig. 5.5).

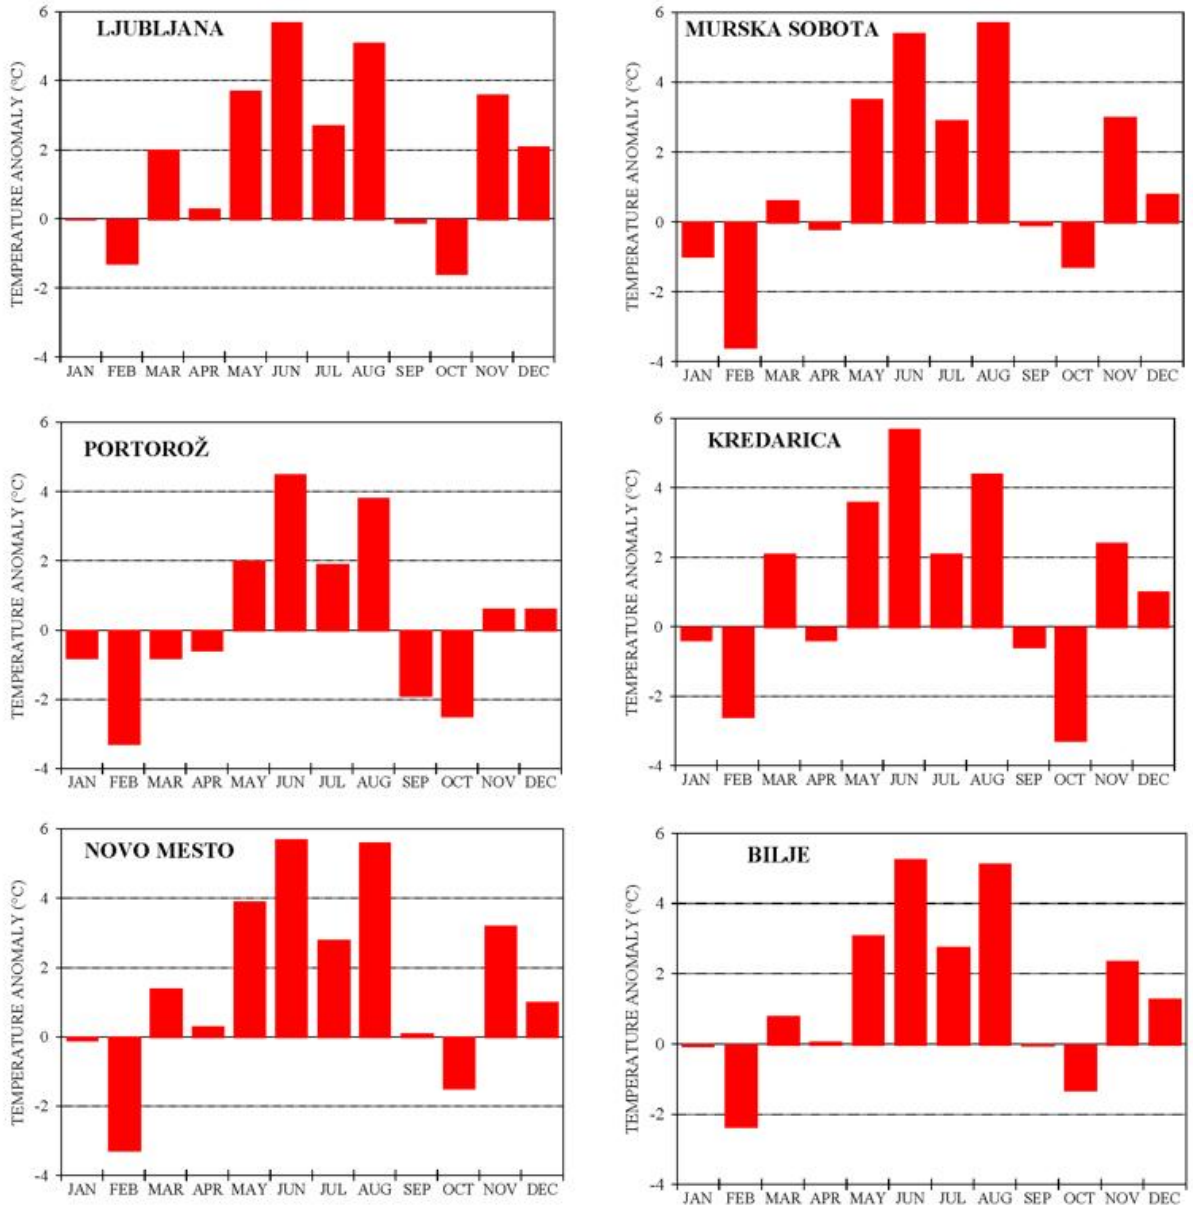

Fig. 6.3: *Mean monthly temperature anomaly in the year 2003*
From: Environmental Agency of the Republic of Slovenia

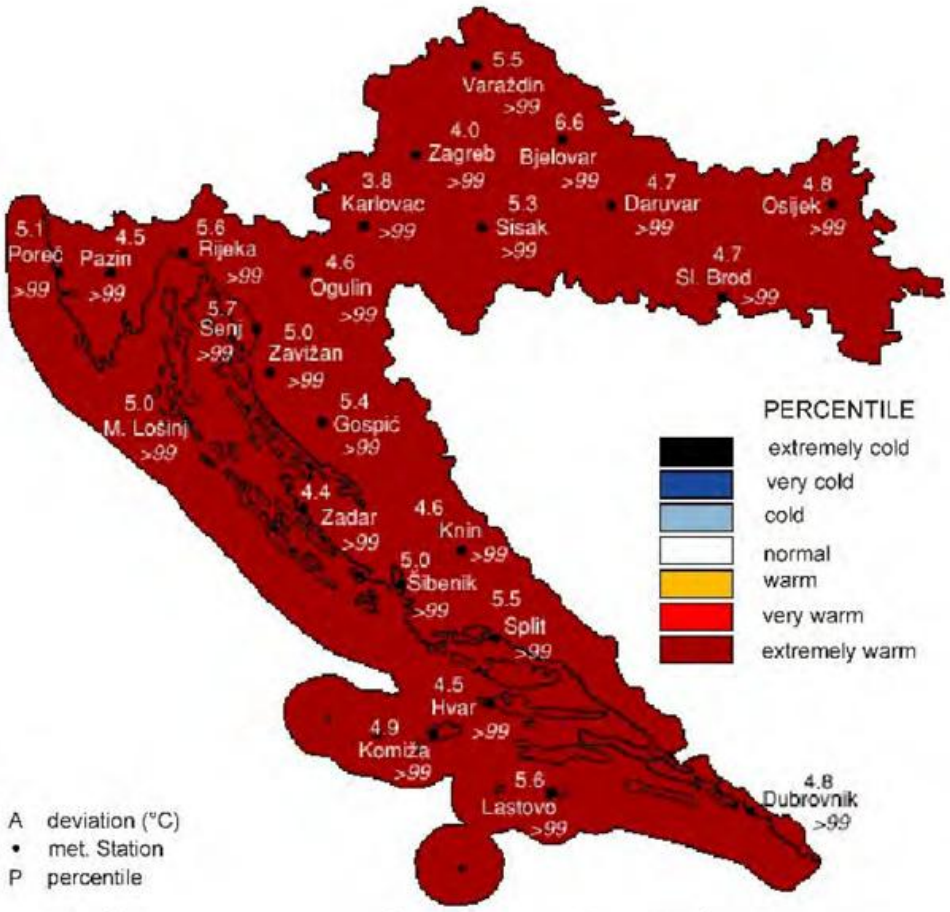

Fig. 6.4: *Monthly air temperature anomalies in Croatia in June 2003,from normals 1961-1990*
From: Meteorological and Hydrological Service Croatia

In Italy the month was rather hot, especially in the northern and central parts of the country with temperatures up to six standard deviations above normal. A mean daily minimum temperature of 20.8°C was registered in Cagliari, the previous record being 17°C from 1999.

The heat wave in Albania continued all over the month. The mean minimum temperatures reached up to 5°C above normal (fig. 1.3) and the anomalies of the monthly mean were even up to 7°C in the lowland zones. The monthly mean temperature was higher than for any June of the reference period 1961-1990. The precipitation total was merely half of normal.

In Macedonia the weather conditions were rather warm and wet with temperature anomalies about +3°C and precipitation rates clearly above normal.

In Bulgaria the monthly average air temperature was about 3°C higher than the long-term averages. It was a very dry month with precipitation rates of only 20-30% of normal. Sunshine duration was 30-50 hours higher than the averages. Intensive and wide-spread hailstorms were observed on June 8 and 16. Thunderstorms were registered in 18 days during the month. A man was killed by a lightning stroke.

In Greece the month was much warmer and in most places drier than normal. Unusual high seasonal maximum temperatures of 7°C - 10°C above the long term averages were reported from many areas of the country in the period June 13-15 (see table 6.2).

In Turkey the month was clearly warmer than normal and mostly dry except of the south-western coastal areas and eastern parts of the country. Heavy rains

on June 17 caused flooding in the area of Yalvac/Isparta. One person died and two were injured from river overflow; 12 houses, livestock and agricultural plantations were damaged.

From: Hellenic National Meteorological Service

In Cyprus the monthly mean temperature exceeded normal by 1.1°C. The overall precipitation amounted to 16.8mm, which is only 3% of the year's precipitation total, but 280% of the month's normal. Heavy rains and thunderstorms occurred on June 2. Fog in the area of Nicosia appeared on June 9. Severe heat wave conditions occurred occasionally during the second fortnight of the month. The airport of Larnaka was closed for four hours because of dense fog in the morning hours of June 30.

The monthly mean temperature in Armenia was 0.5°C below normal. Sudden drops of temperature in mountainous regions led to air and ground frost down to -2°C on June 6-7 and 25-26, which is a rare phenomenon for this month. For the last 100 years frosts were not observed in the third decade of June. Significant damage was done to the agriculture. The monthly precipitation total was only about 2/3 of normal (see fig. 3.8).

Kazakhstan experienced several mudflows in the mountain rivers close to Almaty. Fortunately, they did not reach the city, but they caused great damage to the economy of the country. Road bridges, highways, houses and schools in settlements had been ruined, areas under crops and livestock had been destroyed; some people were killed. The economic damage from one such mudflow is estimated to about 2 million EUR.

July 2003

- **Generally warmer than normal all over the Region except for the south-west and the south-east**
- **Hot in northern Scandinavia**
- **Extremely dry in the western and eastern Mediterranean areas**

There were several magnificent days in Faroe Islands with sunshine and clear skies from morning to evening, among them July 17, when the record breaking maximum temperature of 26.3°C was registered at Vaga Floghavn.

It was a very warm month across all parts of the UK, with the Northern Isles around 3°C higher than their average temperature. Wisley, southwest of London, recorded 33.6°C on July 15 and Maidenhead, west of London, had its hottest July day since 1976. However, Atlantic depressions to the north-west brought an unsettled spell with rain bands depositing copious amounts in places, especially over southwest England, Wales and the Midlands between July 24 and 26. Cardinham in Cornwall received 58 mm in 12 hours ending 0900 GMT on July 25.

The monthly mean temperature in Norway as a whole was 3.1°C higher than the long-term average. It was the warmest July since the measurements started in 1867, the former record being from 1901 of nearly the same order. 38 Norwegian weather stations got new temperature records for this month, most of them situated along the coast from south to north. The greatest positive departures from normal were attained in mid–Norway with 4°C to 5°C. Several coastal stations in the south experienced minimum temperatures above 20°C the night before July 17. At Oslo-Blindern the minimum this night was 20.7°C which is the second warmest measured here since the start in 1937. The

monthly mean for the air temperature (13.1°C) and sea surface temperature (13.4°C) measured at the weather ship "M" in the Norwegian Sea were both the highest for July in the series starting in 1949.

Temperature anomalies in Sweden were generally positive varying from about 1°C in the south up to 4°C in the northern part of the country. Precipitation was also very variable. Heavy rainfalls in the province of Småland caused considerable damage to farms and villages on July 2-6. Monthly totals reached locally 3-4 times the normal amounts with a maximum of 297mm close to Oskarshamn. In Lönneberga many houses were overflowed by water and millions of SEK had to be paid by insurance companies. At station Kalmar a new daily record was set with 73mm during a night-time thunderstorm on July 30. Private measurements recorded up to 115mm south of the city.

In Finland it was very hot compared to the long-term average. Temperature anomalies were about +4°C all over the country. In combination with a relatively high humidity, these weather conditions caused problems to the health of the population. The monthly precipitation rates varied spatially from $^1/_3$ in the south to more than 100% of normal in the northern parts of the country.

The temperature anomalies in the Netherlands were about +2.0°C. Precipitation was rare and reached only about 40% of normal.

In Belgium the monthly temperature anomalies were about +2°C and precipitation close to normal. In the area of the province of Luxembourg a thunderstorm with strong winds and hail caused a lot of damage on July 21. Two more extreme weather events connected with thunderstorms occurred in the province of Brabant on July 1 and 26.

Luxembourg had monthly temperature anomalies of about +2.5°C and a precipitation total of ¾ of normal.

In Germany the country-wide temperature anomaly was +2.3°C and the overall precipitation rate 89% of normal. At station Karlsruhe a maximum temperature of 37.9°C was measured on July 20. There were 3 episodes of thundery weather combined with strong winds and heavy rains causing lots of damage to public and private life: from July 16-17 in western and southern parts of the country, from July 20-24 in the west and the north and on July 27 again in the south, especially in Bavaria.

Positive temperature anomalies continued in Poland throughout the month with values of ≥1°C in the south and >3°C in the north-east. Heat waves occurred in the second half of the month with maximum temperatures up to 36°C. Precipitation was related to thunderstorms in most cases and variable across the country. Torrential rains with daily sums above 50mm were noted as well as hailstorms and strong winds with gusts up to 32m/s. In spite of locally high rainfalls soil drought and decreasing water levels still were observed.

The month was very warm in Lithuania with a mean air temperature of 20.1°C, which is 3.4°C above normal. The country-wide precipitation total was 79mm and thus close to normal but with a very uneven distribution in space and time. The precipitation was mostly of a downpour nature and the monthly amount varied locally from 30mm to 146mm. In the first half of the month most frequent and abundant rainfall occurred in the eastern regions originating from cyclones moving northward. The second half of the month passed under prevailing influence of anticyclones. The third ten-day period of the month was very hot with a mean air temperature of 22.5°C, which is an anomaly of +5.3°C. Station Palanga received 60mm of rain in 2 hours on July 26. The number of days with thunderstorm was counted as 22.

Latvia experienced the second warmest July ever recorded. The monthly mean temperature was 3.3°C above normal (see fig. 7.1) and surpassed only in 2001 by 0.1°C.

The month was very warm in Belarus with temperature anomalies of +2.5°C and more. The country-wide monthly mean reached the limit of 20.0°C, which normally occurs only once in ten years,

	XII 2002	I 2003	II 2003	III 2003	IV 2003	V 2003	VI 2003	VII 2003	VIII 2003	IX 2003	X 2003	XI 2003	XII 2003	Year 2003

Fig. 7.1: *Monthly temperature anomalies and precipitation rates in Latvia 2003*
From: Latvian Environmental, Geological and Meteorological Agency

but actually it was the third time in a row. The total precipitation was 133% of normal.

The monthly temperature anomalies in France were generally positive and ranged from west to east between about +1°C and +3°C. Precipitation rates had a strong gradient from south-east to north-west and varied within the limits from zero (Ajaccio/Corsica) up to 200% of normal.

The month was rather hot in Switzerland with a temperature surplus of 2-3°C. Precipitation was below normal and drought conditions continued.

The monthly mean temperature in Slovenia exceeded normal significantly (fig. 6.3) in spite of being lower than in the month before. It was the warmest July since more than 50 years in several areas. The number of hot days varied from 11 to 24 at different places. The precipitation totals exceeded normal only in the Julian Alps and the Zgornjesavska valley with more than 200mm. The coastal zone and the Karst were the driest areas where less than 20 mm fell. Unusually high temperature, lack of precipitation in most parts of the country and sunnier weather than on the average enhanced drought.

In Croatia the monthly mean temperature anomaly was +2.3°C and precipitation reached 90% of normal.

In Bosnia and Herzegovina the monthly mean temperature was 2.1°C above normal, while the precipitation total reached only 64% of normal.

At the end of the month extremely heavy downpours fell especially in the northern part of Hungary. A maximum daily rainfall amount of 177mm was registered at station Kompolt on July 29. This was enough rain for the area, but the rest of the country continued to suffer from serious drought conditions.

The monthly mean temperature on the Spanish mainland was clearly above normal, but not as excessive as in the month before. Monthly precipitation amounts varied from 92 mm in the north-west (La Coruna) to zero in the south-east (Almeria, Alicante).

It was very warm in Italy with temperatures anomalies above +2°C and up to +4°C. A daily maximum temperature of 40.4°C was registered in Piacenza on July 11. The spatial distribution of precipitation was variable. Some areas in the south had no or nearly no rain, while station Pisa received the normal rate.

A heat wave episode affected Greece on July 4-5, especially the mainland and the Ionian islands. The maximum daily temperatures were ≥40°C.

In The Former Yugoslav Rebublic Of Macedonia the month was clearly warmer than normal with temperature deviations between +1°C and +2°C. It was also extremely dry.

It was the sunniest month in Bulgaria with average air temperatures above normal. Precipitation was near to normal in the south and 50% of the average in the north. Thunderstorms were observed on 19 days and in combination with hail on 10 days. The most widespread events occurred on July 4–5 and led to damage in 12 counties; in Sofia the thunderstorm was combined with intensive rainfall and hailstones of walnut size and caused significant damage to cars and properties.

Moldova had a monthly temperature anomaly of +0.7°C and a high precipitation total of 112mm, which is equal to 164% related to the long-term average (see fig. 5.5).

In Turkey temperature anomalies were generally positive up to 2°C. Precipitation rates were less than 25% in large central and western parts of the country leading to serious drought conditions.

In Jordan the highest maximum temperatures of the year were measured at the stations Amman and Aqaba on July 6, namely 37°C and 44°C respectively.

The monthly mean temperature in Armenia was 0.4°C below normal. A cold spell occurred in the second half of the month. During a thunderstorm in Jajur on July 18 hailstones with diameters up to 5cm caused considerable damage to the agriculture.

The mean monthly temperature anomalies in Kazakhstan were from -2°C down to -4°C. The monthly precipitation rates varied between 200% and 500% of normal. In Almaty the air temperature at night dropped down to 8.3°C on July 29, which is 3°C below the previous absolute minimum of this day noted in 1938. The decrease in air temperature was accompanied by frequent precipitation, quite often as rain showers. More than 20 rainy days were observed during the month. Frequent and abundant rains caused the overflow of moraine lakes in the Zailiysky Alatau mountain ridge in 3000m asl, and consequently triggered mudflows in the mountain rivers close to Almaty. They were not catastrophic and did not reach the city. As an example, fig. 7.2 shows a ravine of river Left Talgar after the mudflow with a cleft reaching 7m. The mudflow volume amounted to 500 000m^3 and blocked the river-bed of Left Talgar along a distance of 900m; a lake had been formed at an elevation of 2500m asl.

Fig. 7.2:

Ravine of the Left Talgar river after the mudflow 2003
From: Hydrometeorology and Environmental Monitoring Agency, Kazakhstan

August 2003

- **Extremely hot in central Europe**
- **Generally warmer than normal all over the Region except for some places in Russia**
- **Very dry in and around the British Isles, southern Spain, northern Italy, many areas in the Balkans and most of Turkey**
- **Record warm sea surface temperature in the Norwegian Sea**

The south and the eastern coastline of Greenland had relatively high temperatures with anomalies of ≥2°C. A foehn situation at Nuuk Airport made the air temperature rise up to a maximum of 24.1°C on August 26.

The month was unusually warm in Iceland. In the south and the west it was the warmest August since the beginning of observations, in the north-eastern inland only August 1947 was warmer and in the eastern coastal regions it was the third warmest on record. Precipitation was slightly above normal for the whole country.

The month was particularly warm in Ireland relative to normal. Almost every station recorded its highest temperature of the year during early August, when maxima touched 30°C in parts of the west. The highest observed temperature of the year was 30.3°C at station Belderrig on August 8.

The monthly mean temperature in the U.K. was 2.3°C above normal and the total precipitation only 28% of the 1961-1990 average. A heat wave affected the country from August 3 to 12. Faversham, southeast of London, recorded the UK's highest ever temperature with 38.5°C on August 10, passing the previous highest of 37.1°C set

at Cheltenham on 3rd August 1990. Greycrook set up a new Scottish record reporting 32.9°C on August 9, passing the previous high of 32.8°C set at Dumfries on 2nd July 1908. The month was also very dry across England & Wales with about 21 mm recorded; this is the 6th driest August in the 238-year series. The driest was 1995 with about 9mm.

The month was very warm and rather dry in Denmark, introducing many days with high water temperatures along the Danish coastline. Maximum air temperatures were up to 32°C.

In Norway the month was warmer than normal in the whole country, especially along the coast. The highest temperature, 33.1°C, was measured on August 10 at Nesbyen in the SE. The weather ship at station "M" in the Norwegian sea experienced the highest monthly mean both for air temperature (13.2°C) and sea surface temperature (14.1°C). Precipitation showed great differences from region to region. In the central parts of the country the monthly and daily precipitation was of record quantity; some stations received extreme diurnal amounts on August 14-15, leading to local flooding; e.g. station Atndalen-Eriksrud measured 116.5mm on August 15. In the southernmost parts of the country, precipitation was much below normal.

Monthly temperature anomalies were moderately positive everywhere in Sweden. Relatively large amounts of rain fell in the middle part of the country, especially during a thunderstorm sequence from August 13-15. Close to Sundsvall more than 130mm of rain fell within two days interrupting the railway traffic occasionally. Unusually many tornadoes were reported, especially on August 31. The most damaging tornado struck the outskirts of Falkenberg in the province of Halland on August 26.

The month was moderately warmer than normal in most parts of Finland with temperature anomalies at about +1.5°C decreasing slightly from south to north. The monthly precipitation rates varied in most parts of the country between 50% and 150% increasing from west to east.

In the Netherlands the period from the beginning of the month until August 13 was marked by a heat wave. In Arcen in the south-eastern part of the country 12 consecutive tropical days were recorded. On three days, the temperature rose among other stations in Arcen to 37°C or higher; on August 7 even to 37.8°C. These readings are among the highest ever recorded in the Netherlands.

The month was relatively hot in Belgium with temperature anomalies above +3°C. The highest temperature was measured with 38.6°C in Aubange on August 8. Precipitation totals were somewhat below normal and most of the rain fell during the last 4 days of the month. Sunshine duration was significantly above the long-term average, as can be seen from the example in fig. 2.1. Thunderstorms on August 28-29 caused damage in different parts of the country.

In Luxembourg temperature anomalies were up to +6°C and precipitation rates about $^2/_3$ of normal.

The month was extremely hot and very dry in Germany with a country-wide temperature anomaly of +4°C and a precipitation deficit of more than 50% of the normal rate. It was the hottest and sunniest August since observations started more than a century ago. During the night of August 8 to 9 a record high minimum temperature of 26.7°C was measured and repeated on August 12 at station Weinbiet. The absolute temperature maximum of 40.2°C was reached and repeated at station Karlsruhe on August 9 and 13. Agriculture suffered from a continuous drought. A small tornado damaged a farm near Barntrup in Westphalia. A hailstorm with strong winds caused much damage to the area of Rosenheim in Bavaria on August 18. Thunderstorms in combination with heavy rains, strong winds and hail affected different parts of the country on August 28-29, especially in Saarland, Rhineland-Palatinate, at Lake Constance and in Berlin.

The month was very hot and still dry in Czech Republic. The country-wide temperature anomaly was +3.6°C. The warmest day of the year was the August 13, when at station Klementinum in Prague a temperature of 36.8°C was measured, which is the highest temperature there in August since 1775. The temperature maximum on this day was 39.5°C, recorded from the NW part of the country and only 0.7°C less than the absolute national temperature maximum. The highest daily average temperature was measured at station Vlkonice and it was 30°C on the same day.

The month was generally warm and dry in Poland (see figs. 5.2 and 6.1). Temperature anomalies varied from +1°C up to +2.5°C. The warmest parts of the country were the west and the south, the coolest north and NE. The monthly precipitation rates were less than 50% of normal and even below 10% at some sites, but close to normal in the central and north-eastern parts of the country. Thunderstorms with intense rain exceeding 40 mm daily and wind gusts above 20m/s were observed. As a consequence of precipitation shortage and intense evaporation, soil and hydrological drought deepened.

In Lithuania the monthly mean temperature moderately exceeded normal by +0.8°C. The country-wide monthly precipitation total was 94 mm and thus 124% of normal. The first half of the month was dry and warm everywhere, while the second one was rainy and chilly. The highest air temperatures in the first five days reached 27–33°C. Because of the lack of moisture, some Lithuanian regions encountered drought conditions lasting until mid-August. The lack of moisture had originated 885 forest fires burning down 436 ha of forestry and causing lots of material damage. In contrast to this, the second half of the month saw heavy rainfall in many places. Generally, the weather was unfavourable for agriculture: Deficient humidity was posing drought danger for some regions in the first half of the month, and rain was impeding harvest in its second half.

In Latvia the monthly mean temperature was slightly above normal, while the precipitation total exceeded the long-term average significantly (see fig. 7.1). August 21-31 was the rainiest third decade of August since the start of regular precipitation measurements. The amount of precipitation in this decade was between 2 and 3.5 times greater than normal. Continuous rainfall resulted in the loss of almost half of the grain crops. Agricultural losses were evaluated at 80 Million EUR.

In France the record hot summer culminated in this month with temperature anomalies up to +6°C and fatal consequences to people's health. A very long period of anticyclonic situations over western Europe was topped by heated air coming from the south and leading to a stabilisation of the lower atmosphere up to 5000m. The nearly total lack of thunderstorms is a clear illustration of that. The warming up of the lower atmosphere is also visible from the monthly temperature anomaly of more than 4°C at the 850hPa level. Precipitation was mostly far below normal except for some places. Especially during the period of August 1-18 the country suffered from an extraordinary heat wave (see e.g. fig. 8.1). Fig.8.2 provides the daily average temperature time series for Paris, showing the upper decile being surpassed on twelve successive days from August 4 to 15 . The effects were devastating: the National Institute of Public Health reported an official figure of 14,802 additional deaths for the period of August 1-20.

In Switzerland the month was extremely hot everywhere and mostly very dry. It was the warmest month of August since observations started in 1753, surpassing the previous records from 1991/1992 by 1-2°C. Temperature anomalies were from 4°C up to 6°C. In the lowlands, the monthly mean temperatures were 24°C - 30°C and the mean of daily maxima reached 34°C – 37°C. An extraordinary heat wave lasted from

August 4 to 13. The highest temperatures ever measured in Switzerland were recorded from station Grono on August 11: minimum 24.8°C, mean 32.7°C, maximum 41.5°C. Drought conditions continued with serious consequences for the agriculture. In a series beginning 1901, it was the sunniest August together with August of 1962 in the central and eastern parts north of the Alps.

The monthly mean temperatures in Austria were from 3°C to more than 5°C above normal. With 23.6°C in the very long series of Vienna it was the 3rd warmest August after 1807 (24.8°C) and 1992 (24.2°C). August 13 was the hottest day of 2003; the air temperature rose up to 39°C in Zwerndorf in Lower Austria and brought new record values in some towns where measurements reach back only to 1948. Duration of sunshine was more than 300 hours in eastern parts of the country. In Vienna 323 hours of sunshine were registered, which is 76 percent of the possible local sunshine and 16 hours more than the old record from 1992. Because of dry weather conditions, forest fires broke out in different parts of the country between August 21 and 25.

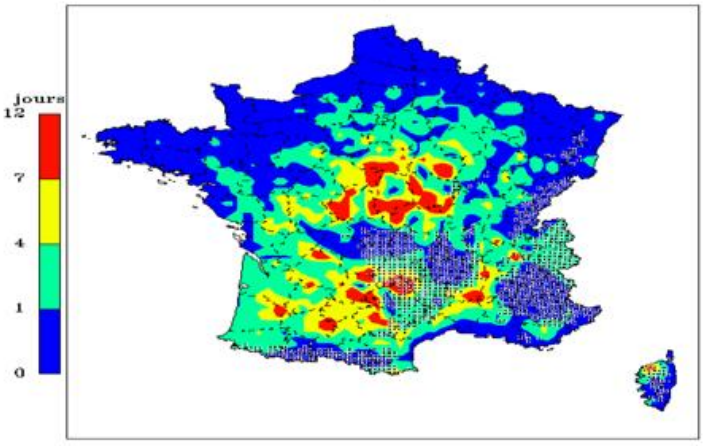

Fig. 8.1:

Number of days with Tx>40°C over the period August 1 to 18, 2003. Red areas indicate a range from 7 to 12 days
From: Météo-France

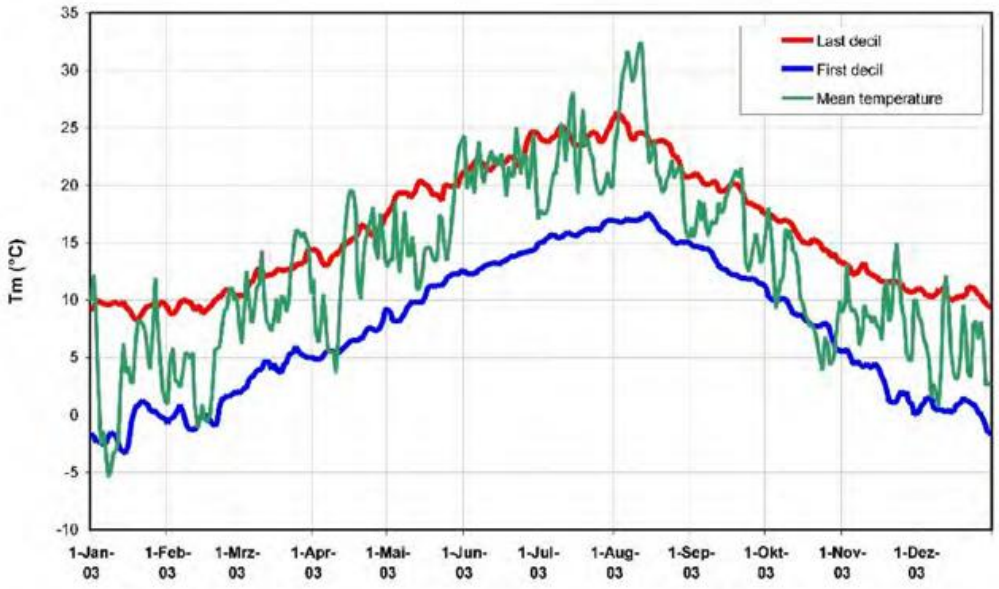

Fig. 8.2: *Daily Paris average temperature time series (geen) compared with the upper (top/red curve) and lower (blue curve) deciles*
From: Météo-France

In Slovakia the month was generally warm and dry with temperature anomalies of about +3°C and precipitation rates below half of normal, thus prolonging the drought conditions.

In Hungary the month was 4ºC warmer than the long term mean (fig. 2.3). Due to a long-lasting anticyclonic situation the precipitation was far below the mean value in the whole country (fig. 3.3). East of the Danube the amount of monthly precipitation was lower than half of the mean value. 250 hectares of agricultural fields were destroyed by fire.

The month was exceptionally warm in Slovenia. The normal monthly mean temperatures were exceeded by at least 4°C everywhere in the country. In many places new records of the highest absolute temperatures in August were set. Hot days with a maximum daily temperature ≥30°C were exceptionally frequent; e.g. 30 in Portorož and 29 in Vipava valley. Unusually high temperature, lack of precipitation in most parts of the country and sunnier weather than on the average enhanced drought almost throughout the country. Locally, some severe thunderstorms with strong wind, gusts and hail caused a lot of damage. During the last weekend of the month, exceptionally abundant precipitation affected Zgornjesavska dolina. On August 31 a strong wind, so-called tramontana, damaged some boats on the coast.

The month was extremely hot and very dry in Croatia. In Zagreb the monthly mean temperature exceeded normal by more than 5°C and the monthly precipitation total was less than half of the long-term average.

In Bosnia and Herzegovina the month was very hot and extremely dry. The country-wide temperature deviation from normal was +4.2°C and the overall total precipitation only 24% of normal.

The month was extremely hot in Serbia and Montenegro. Deviations of the monthly mean temperatures, the maximum and minimum temperatures from the average values ranged from +4°C to +6°C. In the whole country the daily maximum air temperatures were almost continually higher than 30°C and at the end of the month at some stations even higher than 40°C. The number of tropical and summer days as well as the number of tropical nights was much higher than the long-term averages. Climatic conditions were worsening because of the lack of precipitation. At many stations there was no precipitation at all during the month.

In Romania the month was generally warm with temperature anomalies up to >3°C and dry with a country-wide precipitation total less than $^1/_3$ of the normal rate.

It was a hot month in Bulgaria. The number of days with maximum air temperatures higher than 30°C was more than 20, and 35°C were exceeded on 5 days. The monthly temperature anomalies were near +3°C. The month was also very dry, especially in the north of the country. In spite of this, high daily precipitation amounts were measured at some stations (Targovishte - 52mm, Shumen - 45mm). Thunderstorms were observed on 20 days and mainly local hailstorms on 9 days. Some of them caused flooding and considerable damage to several places including Sofia on August 10, 20 and 22. The very hot days (August 13-15, 18-19, 22-25 and 28-31), where in some weather stations absolute records of maximum air temperatures were reported, affected human health and triggered car crashes and fires.

The monthly mean air temperature in Mainland Portugal was 25.1°C, which is 3.2°C above normal, resulting in the warmest month since 1931; the mean maximum air temperature was 32.2°C, with an anomaly of about +3.6°C; the mean minimum air temperature was 18.0°C, +2.9°C above the average of 1961-1990 (fig. 8.3). Both temperatures correspond to the highest values recorded since 1931. The first two weeks of August were extremely hot and an extraordinary heat wave affected the mainland (fig. 8.4). Comparative weather conditions were not ever been

reported before. The highest maximum temperature was 47.3°C, observed at station Amareleja on August 1, while the highest minimum temperature was 30.7°C, recorded at Portalegre on the same day. During the period of this heat wave, mortality of people increased by more than 40%. The number of forest fires in this month was 65.

In Spain temperature anomalies were positive in most of the Peninsula and in the Balearic Islands. In a few places new records for the whole series of observations were set. In the first half of the month a persistent heat wave affected the country. The threshold of 40°C was surpassed in Córdoba on 14 days and in Badajoz on 5 days. Even usually temperate regions such as Galicia had to endure spells of more than 35°C of maximum temperature for several days. A thunderstorm with hailstones of tennis-ball size caused considerable damage to the town of Alcañiz on August 16. A squall

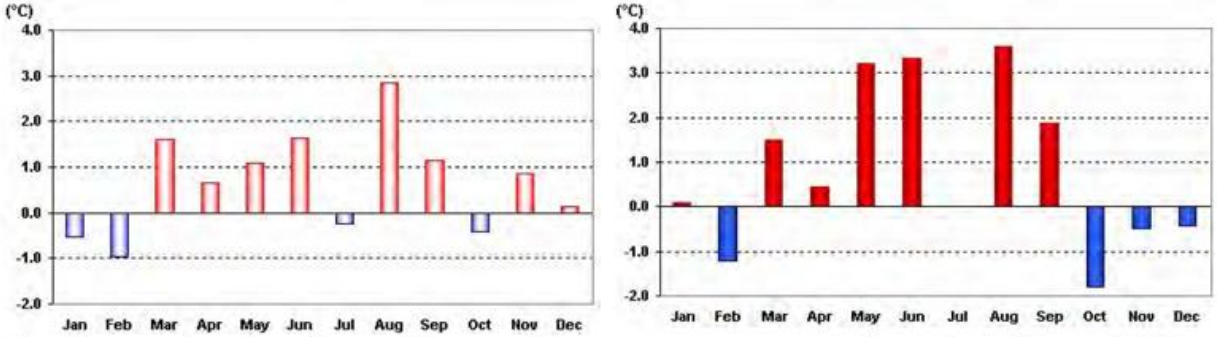

Fig. 8.3: *Anomalies of the monthly means of daily extreme temperatures in the mainland of Portugal, 2003*

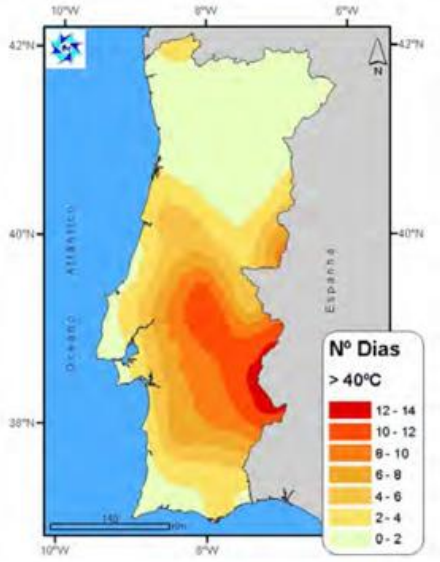

Fig. 8.4:

Number of days with maximum temperature above 40°C in the period from August 1-14
From: Instituto de Meteorologia, Portugal

line produced winds up to 180km/h north-east of Barcelona on August 17.

Temperature anomalies in Italy ranged from about +2°C in the south up to more than +6°C in the north. The monthly precipitation rates varied from below 10% of normal in the north to nearly 50% in most places in the southern parts of the country.

Temperature anomalies in Albania were up to +4°C (see fig 1.3), while the precipitation deficit continued; station Tirana received only 10% of normal (fig. 8.5).

In Greece the month was generally warmer than normal with temperature anomalies up to >3°C at some places. A heat wave affected the country at the end of the month, when daily maximum temperatures were up to 40°C and even more.

In Turkey the month was clearly warmer than normal everywhere and mostly very dry.

The month was hotter than normal in Israel.

In Syria, maximum temperatures of 2-3°C above normal in combination with increased humidity of the air caused health problems to many people.

In Armenia temperature anomalies were moderately positive up to about 1.5°C. The country-wide precipitation total exceeded normal by 50% (fig. 3.7).

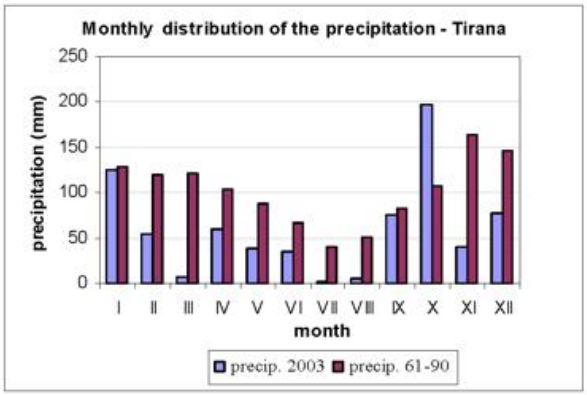

Fig. 8.5:

Monthly distribution of the precipitation at station Tirana
From: Hydrometeorological Institute, Albania

September 2003

- **Moderate monthly temperature anomalies all over the Region, positive in the north-west and negative in large areas to the south-east**

- **Patchy distribution of precipitation rates over the Region with contributions above normal mainly in southern countries**

In Iceland the month started with warm and favourable weather, but a cold spell arrived by the middle of the month. There was an unusually early snowfall in some parts of the north, the snow covering the ground completely in Akureyri on September 18, the earliest autumn snow cover at that location since 1940, when it occurred on September 7.

A thunderstorm near Pollathomas in Ireland on September 19 produced a 3-hour fall of over 80mm rain, resulting in locally devastating floods and landslides. The picture of the Shannon radar illustrates the rainfall intensity in the vicinity of the Pollatomish Mountains (fig.9.1).

The monthly temperature anomaly in the U.K. was +0.9°C and the precipitation rate 54% of normal. In southern England, Boscombe Down had its coldest September night since 1931, with a temperature of -0.1°C on 24th. Redhill, south of London, recorded a low of -2.8°C on the same night. In south-eastern England, temperatures fell by 10°C in less than an hour in many places as a cold front moved southwards on September 22.

The month was 1-2°C warmer than normal in southern Norway while the northern part of the country had mean temperatures near normal. The monthly precipitation in parts of the Troms and Nordland counties was

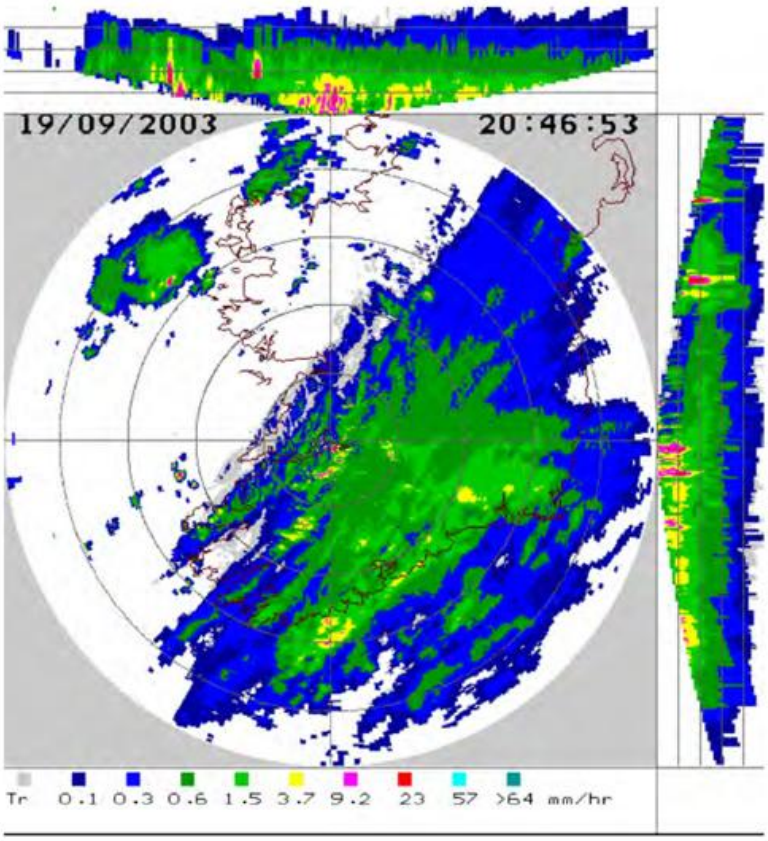

Fig. 9.1:

Shannon radar image illustrating the rainfall intensity in the vicinty of the Pollatomish Mountain on September 19
From: Irish Meteorological Service

record high. 6 stations experienced new records. The recurrence period for such quantities in this area in September is approximately 50-100 years.

The weather in Denmark was relatively mild and dry.

In Sweden the month was generally warmer than normal with temperature anomalies up to ≥+2°C in the central part of the country. The monthly precipitation amounts were less than normal everywhere with rates below 25% of normal in the south increasing northward up to 95%.

The monthly temperature anomalies in Finland were mostly positive and up to +2°C except for the northernmost area. The month was very dry in southern and central parts of the country, especially in the south-west, where it was less than 25% of its reference value. On the contrary the north was quite wet with precipitation above normal.

In Belgium, the monthly mean temperatures were moderately above normal and precipitation near to half of normal. At station Uccle sunshine duration exceeded the long-term average by 54 h or 35%. The monthly mean wind speed was 9 km/h and thus reduced to 75% of the average from the reference period 1878-1986 at the same station.

In Luxembourg the monthly mean temperature was clearly above normal and the precipitation total below half of the long-term average.

In Germany the month was relatively warm, dry and very sunny. The country-wide temperature anomaly was +1°C and the precipitation total 80% of normal. Heavy rains in the area north of Stuttgart caused land slides and obstruction on roads, flooding of city streets and lifting of duct covers on September 9. Strong winds including local tornadoes caused a lot of damage to forests, houses and traffic installations at several places in the north of the country. During heavy thunderstorms near the middle Rhine valley houses, barns and people were hit by lightning strokes on September 22-23.

The long lasting drought in Czech Republic ended at the end of the month.

The month was relatively warm in Poland with a temperature deviation of +1°C from normal (fig. 5.2). There were observed very cold spells as well as hot periods. At the beginning of the month, minimum temperatures fell even below 0°C, but during the second half, maximum temperatures reached 31°C in the south. Precipitation sums were generally lower than normal (fig. 6.1) except for northern and central parts of the country. In the east less than 30% of the long-term average rain fell. Thunderstorms with downpours, above 50 mm daily in mountains, and wind gusts accompanied warm weather in the end of the month. Sunny and in many places rainless weather caused continuing drought.

The monthly mean air temperature in Lithuania was 12.8°C with an anomaly of +0.9°C. The weather had most often been determined by anticyclones and morning frost occurred after 14 nights during the month. The mean monthly precipitation amounted to merely 39mm or half of normal. Sunshine duration was 190 – 240 hours, thus exceeding the normal values by 40 – 70h.

In Belarus temperatures were close to normal (fig.0.7) and precipitation clearly in deficit (fig. 5.3).

Drought conditions in France continued until the end of the month, especially in northern parts of the country. Apart from obvious impact on water resources and agricultural yields, the soil drought had a severe impact on foundations of houses: thousands of houses and buildings spread over two thirds of the country suffered from cracks of the walls or ceilings, many doors and windows could not be shut any more.

In Portugal the monthly average temperature was above and the precipitation amounts were below the 1961-1990 normal in almost all parts of the country.

The monthly mean temperatures in Austria were near normal and precipitation rates varied from less than 25% of normal in eastern Tyrol to more than 125% in parts of Lower Austria.

In Slovenia the monthly mean air temperature was close to the 1961–1990 normal, the anomaly was small and mostly negative. There was more sunny weather than on average in the reference period. More precipitation than normal fell on the coast and over the eastern half of the country. Significantly less rain than on average fell on Karst and Vipava valley.

In The Former Yugoslav Rebublic Of Macedonia the monthly temperature anomalies were about -1.5°C and the precipitation totals near half of normal.

It was a relatively cold, rainy and cloudy month in Bulgaria. The monthly average air temperatures were about 1°C below normal. In the north of the country precipitation rates exceeded normal by about 45% and in the south they were slightly below the long-term average. The Black Sea coast received unusual high amounts of rainfall up to 250% of normal. Daily rainfalls in some locations were also very high, e.g. in Shabla 151mm, Spasovo 85mm and Dobrich 57mm.

A cold spell on September 4 in Greece made the maximum temperatures of the day stay below normal by 4°C to 8°C. Nevertheless, the country-wide monthly mean temperature was near to normal.

In Turkey the monthly mean temperatures were not far from normal with anomalies in the range of ±1°C. The monthly precipitation amounts varied from <10% of normal on the western coast up to 200% in the eastern parts of the country. A frost event damaged vegetables in the area of Nevsehir on September 6. During a storm on the western coast roofs and tiles from houses were displaced, minarets were destroyed and trees were broken in Ayvalik on September 11.

It was the coolest September since 1997 in Israel.

In Armenia the monthly mean temperature and the total amount of precipitation (see fig. 3.7) were close to normal.

October 2003

- **Very cold in central Europe and southern Scandinavia**
- **Very wet in south-eastern Europe, over the Alps and the western Iberian Peninsula**
- **Early seasonal snowfall in several countries**

The monthly mean temperatures in Iceland were moderately above normal. The precipitation was in deficit and amounted to only about half of the reference value.

It was the only month of the year in Ireland with a negative temperature anomaly. The lowest air temperature of the year at station Kilkenny was -4.7°C and recorded in late October during a spell of exceptionally cold weather. Precipitation of more than 60mm fell over the Dublin area between October 21 and 23, accompanied by almost continuous hail and thunderstorms.

In the U.K. the monthly temperature anomaly was -1.3°C and only 57% of the monthly precipitation was observed. Nevertheless, there was 34mm of precipitation at Charterhall in Scotland on October 21, and snow fell above about 200 metres asl. There was 7cm of snow lying at Glenlivet. Southern areas of England had heavy thundery showers on October 22, sleet and snow fell widely, and Dartmoor in the south-west had a covering above 300m. Both Scotland and England&Wales had their sunniest October in the 1961-2003 series.

The month was colder than normal over the greatest part of Norway. In southern parts of the country monthly anomalies were -2°C to -4°C and new absolute minimum temperatures for October were observed at several places. At station Sande-Laukollmyr the minimum temperature was -17.0°C and at station Hovden–Lundane -18.9°C on October 23. These are the lowest temperatures ever measured in October in the two counties, where these stations are located, since measurements started in 1867. The southern part of the country received less precipitation than normal. The monthly precipitation was only 20-30 % of the normal in the eastern counties and in parts of West-Norway.

The month was cold and sunny in Denmark with frost dominating during night time. At station Copenhagen the monthly temperature anomaly was -3.2°C and the precipitation total merely half of normal.

In Sweden a cold spell brought several new minimum temperature records in the southern part of the country. In a more than 100 years' long series new October records were set, e.g. in Örebro (-12.8°C), Göteborg (-8.5°C) and Halmstad (-9.6°C).

In Finland it was colder than normal almost in the whole country due to the very cold latter part of the month. The largest deviations, more than 2°C below normal were found in the south-west and in the north-western tip of the country. The monthly precipitation was close to or above normal in most parts of the country. The only exception was in the south-western coastal areas, where the monthly precipitation varied between 50% and 75% with respect to its reference value.

In Belgium it was very cold with precipitation slightly below normal. At station Uccle the monthly mean temperature had an anomaly of -2.6°C compared to the long-term average of 1833-1985 and of -3.0°C against the reference period 1961-1990. The mean daily minimum temperature was only 4.0°C at that station, thus being even 3.2°C below the long-term average and

the 3rd lowest value in the series since 1833. Stormy weather caused damage to several places in western Flanders on October 7.

The month in Germany was rather cold with an overall temperature anomaly of -3.1°C, with more sunshine than normal and a precipitation total exceeding the reference by 32%. Extreme weather affected western and southern parts of the country on October 7; thunderstorms with hail, intense snowfall, heavy rains and strong winds caused a lot of damage to properties and obstruction on roads. Stormy weather and snow fall again caused traffic obstruction in the island of Usedom and in western and southern parts of the country on October 23-24. The two nights from October 23-25 also brought new records of minimum temperature, e.g. -10.6°C at station Fassberg in the Lüneburg Heath (1.8°C below the old record) and -12.7°C at station Oberstdorf; privately operated stations measured extreme temperatures even below -20°C in the near Alpine area.

In Poland the month was very cold (fig. 5.2). Deviations of the mean monthly temperature from the long-term average achieved -4°C in the western and -2°C in the eastern and northern parts of the country. The minimum temperatures fell often below 0°C, but in some places and days also the maximum temperatures were negative. Precipitation was above normal (fig. 6.1), exceeding 200% in some places. Early in the month there were daily rainfall amounts of ≥40mm. The rich precipitation had a positive impact on soil moisture and water resources. Mountainous areas in the south received a snow cover.

Low pressure formations with frequent precipitation determined the weather in Lithuania. The first ten-day period was relatively warm while the second one was much colder and the third one turned out to become the coldest. There was little sunshine, only half of normal at some places. The monthly mean air temperature was +4.9°C with an anomaly of -2.3°C. It was raining/snowing almost every day. The monthly precipitation amounted to 84mm, 140% of normal. The seaside area encountered 10 windy days with maximum wind speeds reaching 86km/h.

In Latvia the month was rather cold with an anomaly of -2.1°C and a precipitation total slightly above normal (see fig. 7.1). Heavy snowfall led to a snow cover of 39 cm depth in Riga in the morning of October 27 and caused transport problems (fig. 10.1) and many accidents with injured people. It was the deepest snow cover in October for both Riga and the whole country. However this first seasonal snow did not last for long. Due to a sharp rise in temperature it had all melted by October 29.

The month was much cooler than normal in Belarus (fig. 0.7). The country-wide precipitation total exceeded the reference by about 80% (fig. 5.3). The early formation of a temporary snow cover, lasting for 20 days of the month, was the distinctive special feature of year.

In Switzerland it was the coldest October north of the Alps since 1974 with temperature anomalies of -2°C to -3°C. The period from October 23-26 was extremely cold. Snow fell in the north of the country on October 23. For the first time since 1974, a snow cover appeared in the northern and eastern lowlands in October. Zurich had its first ice day for October since records began in 1864 with a maximum temperature of -0.3°C. At some places of the Jura significantly lower minimum temperatures were recorded on October 25 and 26, namely -16.1°C in La Chaux-de-Fonds and -23.2°C in La Brévine, thus being the lowest temperatures measured so far in October since 1901 with -8.8°C and -14.7°C respectively. It was the only month with abundant precipitation north of the Alps; near the Austrian border the precipitation rate reached 250% of normal.

The month was cold and in large parts of Austria very wet. Monthly precipitation amounts reached 200 to 300 percent of normal in the provinces of Vorarlberg and Tyrol. A new record daily amount of 127mm of rain was measured in Bregenz

on October 5. Heavy snowfall formed the earliest snow-cover ever in eastern Austria from October 23 to 24, including the towns of Vienna, Graz and Eisenstadt. In the following clear night at many places in Austria temperatures dropped to new all-time minimum values for October,

Fig. 10.1:

Snow cover in Riga on October 27 2003
From: Latvian Environmental, Geological and Meteorological Agency

e.g. down to -13°C in Mariapfarr in the province of Salzburg.

In Slovakia an unusual early snow cover appeared on October 10 in the south-western part of the country and reached a depth of 6cm to 9cm. It was the earliest seasonal appearance of a snow cover since the beginning of observations in 1921.

In Hungary it was rather cold (fig. 2.3) and wet (fig. 3.3). The month began with summerly warm days but cooled down later. The daily maxima dropped down to values between +1°C and -4°C on October 24. The precipitation was much more than the average and snowfall occurred on October 23-24 which caused a snow cover of 10cm or more in the plains. It was the earliest snow cover in the last 100 years.

The monthly mean temperature in Slovenia was generally below normal with anomalies mostly between -1°C and -2°C. In the north-western part of the country the temperature anomaly was statistically significant; in the Julian Alps the mean temperature was 3.3 C lower than the average of the reference period. Most of the country got more precipitation than on the long-term average. It rained in the first and the last third of the month, while it was dry in between. An unusual phenomenon was the building of a snow cover on October 24-25. A snow cover in October has not been observed in Ljubljana since 1970.

In Croatia the month was rather cool and rainy. At station Zagreb Grič the temperature anomaly was -1.8°C and the monthly precipitation rate 148% of normal.

In Bosnia and Herzegovina the month was relatively cool and very rainy. The monthly mean temperature, calculated from 12 stations, was 1.2°C below normal and the mean precipitation rate at the same stations 201% compared to the reference period 1961-1990.

The month was extremely rainy in Serbia and Montenegro. The precipitation total was two to four times higher than normal.

In Romania the month was cooler than normal and extremely wet. The country-wide temperature anomaly was -1.4°C. The overall precipitation total summed up to 255% of normal and varied throughout the country between 150% and 275%.

In Moldova the month was cool with temperature anomalies below -1°C and very wet with precipitation rates of more than 200% of normal (see fig. 5.5).

In Albania it was the wettest month of the year instead of November according

to the reference period 1961-1990 (see fig. 8.5). The actual monthly precipitation rates varied from 150% up to 300% in several mountain areas in the south-east and north-east of the country.

The monthly mean air temperatures were about normal in south Bulgaria and above the averages in the north. Precipitation was 220-240% of normal. During the passage of a cold front strong winds combined with heavy rainfall and snowfall caused damage to electricity supply and roads in the southern part of the country on October 8-9. Downpours at the northern Black Sea coast caused local flooding and activated landslides. Sunshine duration was 30-50 hours lower than normal (fig. 1.5).

Temperature anomalies in Greece were generally positive and increasing from north to south up to about +3°C. There was also a strong meridional gradient in precipitation rates rising from <50% in the south up to 200% in the NE. Heavy showers and thunderstorms affected the north-western part of the country with floods, landslides and damage to roads and agricultural sites on October 24. On that day extreme rainfall occurred at the stations Aktio and Arta in Epiros, when amounts of 100mm respectively 189mm poured down in 24 hours; the affiliated monthly reference values are 104.1mm and 94.6mm respectively.

In Portugal the month was cooler than normal with temperature anomalies of about -1°C and very wet with precipitation rates up to >200% of normal.

The month was relatively warm in Turkey. Precipitation was unevenly distributed with a surplus in the north and in deficit in the southern part of the country. Stormy weather with heavy rains caused a lot of damage to the north-western coastal areas and to the central northern province of Corum on October 9. Another extreme weather event occurred in the eastern province of Erzurum on October 28, when heavy snow fall led to disruption of water supply, energy and telephone lines.

The monthly mean temperature in Cyprus was 1.3°C above normal and the mean precipitation rate only 42% of the reference value 32.7mm. Heavy rains and thunderstorms, some of them combined with hailstorms and flooding, caused a lot of damage all over the country, especially in the areas of Larnaka, Troodos and Limassol on October 1-2. Strong winds occurred in the area of Pafos causing damage to properties on October 28.

The month was warmer than normal and dry in Israel. Most areas received 5-15mm, which is less than 40% of normal. The only exception was severe rainfall on October 1 in a small area in the north of Hula Valley: 65-75mm of rain fell within 1-2 hours causing local flooding in the area.

In Armenia the month was characterized by unusually warm weather. The monthly mean temperature exceeded normal by 2 - 4°C, although there was a significant cooling down during the last days of the month. Maximum temperatures were ≥30°C and up to 33°C at station Kapan. The monthly precipitation total all over the country was 140% of normal. (see fig. 3.7). At some places 32 - 42mm rain fell on one single day, equaling 100-120% of the monthly normal precipitation.

November 2003

- **Generally milder than normal except for some areas in the south-east of the Region**
- **Much drier than normal in parts of Scandinavia, in large areas of central and eastern Europe, and in western Turkey and Cyprus.**
- **Extremely mild in Norway**

The month was moderately milder and wetter than normal in Iceland. The first days of the month were rather cold with snow in the north, but the second week was unusually warm.

In the U.K. the monthly mean temperature was 1.9°C above normal, whereas the country-wide precipitation total equalled the 1961-1990 average. In Scotland, November 6 and 7 were exceptionally warm and sunny with the temperature rising to 20°C at Aultbea on the 7th. This was just short of the highest temperature recorded in Scotland in November, 20.6°C at Edinburgh in 1946. After a very dry year so far, some locations south-west of London recorded over 75mm of rainfall in a 48 hour period between November 21 and 23. This exceeds the average for the whole month. Northern Ireland had the sunniest November in its 1961-2003 series with 76.6 hours.

In Norway the month was warmer than normal in the whole country and set some new records. The monthly mean temperature at Torsvåg Lighthouse in the north was 5.1ºC, which is 3.5ºC above normal and the highest November temperature since the measurements started here in 1933. Tromsø with measurements since 1920 noted 2.4ºC, which is the same as the record from 1999 with 3.5ºC above normal. In southern parts of the country the monthly mean was 4°C to 5ºC above normal. A special Foehn situation occurred on November 6 with extraordinary air temperatures for the month. At station Tafjord 21.8ºC was measured, which is a new national absolute maximum for November. 34 other stations got new November maxima as well. In central parts of the country, the monthly precipitation amounts were only 10-20% of normal. This is about the second or third driest November month from the measuring series in this area.

The month was very cloudy and consequently relatively mild in Finland, the monthly mean temperature being in most parts of the country ≥2°C above normal. The largest deviations, close to 4°C above normal, occurred in the north-east. The monthly precipitation varied between 50% and 125% of its reference value in most parts of the country.

In Belgium the monthly temperature anomalies were ≥+2°C and the precipitation rates near to normal. A tornado affected the province Hainaut on November 3.

The month in Germany was mild with a temperature anomaly of about +2°C and dry with an overall precipitation rate of nearly 60% of normal. A local tornado carved an aisle of 20-30m width through the town of Kirchhain in Hesse on November 3, displacing roofs from houses and destroying wooden cabins.

The month was relatively warm and dry in Poland. The monthly mean temperatures exceeded normal by 1.5°C in the north-west and 3.5°C in the south-east. In the end of the month maximum temperatures in the south exceeded 17°C. The monthly precipitation sums were generally lower than normal. The southern part of the country got less than 50% of its normal precipitation. In the second half of the month intense rain occurred with daily sums exceeding 20mm.

In Lithuania the weather was medium warm and moist in the first and the third decade of the month and much colder in the second ten-day period. The third decade was the warmest with maximum air temperatures rising up to 7 – 11°C. The mean monthly air temperature was 3.7°C with an anomaly of +1.7°C. The month was rather dull; sunshine duration summed up to merely 10 – 25 hours and only 1 – 3h in the northeast border regions, which is the shortest sunshine duration in this part of the country since 1961. Precipitation was very diverse, from 50% to 150% of normal. The mean monthly precipitation amounted to 46 mm or 71% of normal. There were 12 days totally with fog in most regions and the occurrence of freezing rain and hoarfrost.

In Switzerland the month was especially mild in the mountain areas with positive temperature anomalies of 2.0°C-3.5°C. South of the Alps it was the first month of the year with more precipitation than normal.

Temperature anomalies in Italy were generally positive and higher than 2°C at many places in the north. Precipitation was below normal in the central part of the country, but near to or above normal else and locally even >200% in the north and in Sicily.

The monthly mean air temperature in Slovenia was above normal. The anomaly was statistically significant. In high mountains it was 2.4°C, in low land between 2.0°C and 3.6°C. The highest daily maximum temperature was recorded on November 1; in some places more than 20°C were observed, the warmest was station Črnomelj with 22°C. The monthly precipitation amounts were unevenly distributed with rates above and below normal.

In Croatia the month was very mild with temperature anomalies about +3°C and a precipitation total of nearly $^2/_3$ of normal.

In Bosnia and Herzegovina the monthly mean temperature was 7.5°C and thus 2.1°C above normal. On the average of 12 stations, precipitation amounted to 83mm, which is 73% of the normal rate.

In Serbia and Montenegro the month was significantly warmer than the long-term average. There was a precipitation deficit in the whole country except for the south of Montenegro.

In Romania the month was milder than normal with a country-wide anomaly of +1.4°C and relatively dry with a precipitation rate of 68% against the reference.

The air temperatures in Bulgaria were 1°C higher than normal. The month was relatively dry with precipitation 40-60% of the normal rates. There were significant daily precipitation amounts, 60-85mm on November 29 and 30, which caused flooding of the river Arda in the region of the Rhodope mountains. Sunshine duration was less than normal. Fogs were registered on 22 days – mainly in north Bulgaria. The temperature alteration between warm and cold in combination with wet and foggy weather created appropriate conditions for flue outbreaks in more than 8 cities.

In Portugal the monthly mean air temperatures and the precipitation amounts were above the 1961-90 normal.

The mean monthly temperatures in Greece were clearly above normal, whereas precipitation rates varied from <15% to >150%. Unusually high seasonal maximum temperatures were recorded from all over the country on November 2; the highest temperature measured was 32°C at station Heraklion, being 12°C above the long-term average of the period 1955-1997.

In Turkey the temperature anomalies were near to normal. Except for the east, the month was rather dry, especially in the western central part of the country. The country-wide precipitation total reached about 70% of normal. Nevertheless, heavy rains affected the area of Mugla in the south-west and caused flooding of houses, depots and agricultural plantations on November 6.

Cyprus had a monthly temperature anomaly of +1.1°C and a precipitation

deficit of 57% compared to the reference value 53mm. Heavy rains in combinations with strong winds caused floods and a lot of damage in the area of Limassol on November 9.

The month was warm and dry in Israel. Rainfall amounts were 60%-80% of normal in the northern parts of the country and 40%-60% in the central parts. In the last 8 years November was warm and dry 6 times, and 2 times, 1997 and 2001, temperature and rainfall were close to normal. Only in 1995 November was cool and rainy. There was a warm spell at the beginning of the month; in the coastal plain 31-33°C were recorded and in the mountain areas 28-30°C, an unusual event in November.

December 2003

- **Very mild in the north-eastern Region**
- **Moderate positive temperature anomalies in central Europe**
- **Mainly drier than normal except for the Baltic countries and coastal areas around the North Sea and the Mediterranean**

The month was rather mild and wet in Iceland, but the weather was mainly pleasant. The south-west was hit by a paralyzing snow storm of a short duration on December 29.

In the U.K. the monthly mean temperature as well as the precipitation total had marginal positive deviations from normal. A deep depression formed over the U.K. on December 20 bringing widespread heavy rain. The low moved east to Denmark during next day allowing cold northerly winds with heavy wintry showers in its rear. High ground in the north and north-west including Wales received snow cover as did the north-eastern coastal counties. Early on December 22 more snow fell in eastern counties and some roads became blocked. 80 mm precipitation was recorded in 18 hours at Shap Fell in north-western England on December 26.

The monthly temperature anomalies in southern Norway were from +3°C up to +5°C. In the northern part of the country the monthly mean temperature was a little above or near normal. Precipitation was above normal for the whole country and up to 2-3 times of normal in the north. Continuous heavy rain in the north-west part resulted in sums over 3 days up to 245.3mm on December 17-19. Strong northerly winds of hurricane force affected the western coast and even the capital of Oslo with gusts up to 108km/h on December 4-5. During this extreme weather event platforms on the continental shelf recorded wave heights of about 10 m and even more in the episodes of December 15-16 and 25.

In Denmark the month was mild with occasional frost and snow especially in the days before Christmas. But the weather changed and Christmas eve was mild and grey with very few places still covered by snow. A strong northerly storm damaged the environment in the northern parts of Fyn and Nordsjælland on December 5-6.

In Sweden stormy weather caused prolonged disruption of electricity supply for 100˙000 households in the middle of the country during December 5-6. Another storm event in combination with wet snow caused again long-lasting failure of electric

power for about 80˙000 households in the southern part of the country on December 21-22. Christmas was characterised by rapid changes in temperature and large amounts of rain and later snow in the south-west.

In Finland the month was warmer than normal almost everywhere with the largest temperature deviations, close to 4°C above normal, in the eastern parts of the country. The monthly precipitation rates were above normal with values exceeding 150% of their reference in the south-west, in some eastern areas as well as in the north. An exceptional high number of days with winds of at least strong gale strength was observed in the maritime regions. Within these episodes sleeting and icing events accumulated heavy loads on power lines in some areas of the north-east and caused interruptions in power supply.

In Belgium temperatures and precipitation amounts were near normal. The monthly sunshine duration at station Uccle exceeded the long-term average (1887-1988) of 43 hours by 55% (fig. 2.1).

The month in Germany was generally mild, dry and sunny with a temperature anomaly of +1°C and an overall precipitation deficit of 20% of normal. Nevertheless, there were several extreme weather events in different parts of the country. Strong winds with gusts of more than 150km/h caused lots of damage to the infrastructure and together with heavy snow-fall and ice on roads led to numerous car accidents with a considerable number of deaths and many injured people, especially in the northern lowlands and in western parts of the country, but also in Thuringia and Bavaria, on December 5-6, 11-12, 15-16 and 21-23.

The month in Poland was milder than normal by 1°C in the south-west and 2°C in the north-west of Poland. Maximum temperatures exceeded 12°C in the south and south-west. The second half of the month was colder with minimum temperatures below -10°C in the south and the formation of a snow cover. Precipitation was close to normal but varying across the country from 55% of normal in the south-east to 148% in the north-west.

The weather in Lithuania was influenced by eastward moving cyclones coming from west or south-west and therefore relatively mild. The daytime temperatures were predominantly positive. The monthly mean air temperature was 1.0°C with an anomaly of +3.4°C. There were only three days of the month without precipitation. The precipitation total amounted to 63mm, which is near normal. However, several regions received 94–104 mm of precipitation, which is over 150% of normal. The seaside encountered wind speeds exceeding 54km/h for as many as 20 days in total with gusts up to 94 km/h.

In Latvia the month was extremely mild with a country-wide temperature anomaly of +3.8°C and a precipitation total slightly above normal (see fig. 7.1).

In France temperature anomalies were generally positive up to about +1.5°C. The monthly precipitation rates were unevenly distributed from less than 50% in northern areas up to 200% in the south.

During the month southern Switzerland received abundant precipitation with 200-300% of normal. North of the Alpine ridge much lower amounts were registered; the west and the south-west received only 20-50% of normal.

The monthly mean temperatures in Austria varied from normal to 3°C above normal in the western and south-western parts of the country, while precipitation increased from 50% of normal at lake Constance to 180% in north-eastern Lower Austria. Heavy snowfall, gusts and thunderstorms caused a lot of car accidents leading to obstructions on motorways in Upper and Lower Austria and around Vienna on December 15. On the next day thunderstorms and strong winds damaged forests and power lines and led to the blocking of roads in Carinthia.

In Slovenia the mean air temperatures had anomalies between +0.5°C and +2°C against the 1961-1990 reference. The limit of 2°C was exceeded only in the capital Ljubljana and on the coast. Precipitation was

variably distributed with rates significantly below normal and above at other places. Most of precipitation was concentrated in the last third of December. A snow cover in the lowlands was built up in the second half of the month, its maximum depth remained mostly below 10 cm. There was much more sunny weather than on the average in the reference period, especially in the Ljubljana basin.

The temperature anomalies in Croatia were mostly positive and ≥1°C mainly in the western and <1°C mainly in the eastern and southern part of the country. Precipitation was below 50% of normal in the east and up to normal in the west.

The monthly mean temperature in Bosnia and Herzegovina was 1.0°C and thus slightly (+0.4°C) above normal. The monthly mean precipitation amounted to 57mm, which is 58% of normal.

In Serbia and Montenegro the monthly mean temperatures were close to normal and precipitation amounts less than the long-term average in the whole country. A snow cover formed on December 7 in mountainous areas and remained until the end of the month with a maximum depth of 60cm measured on December 26 on Kopaonik.

In Bulgaria the month was cooler than normal by 1°C in the south and by 0.5°C in the north. Minimum air temperatures were lower than 0°C and -5°C in 20-25 days and 5-10 days, respectively. There were 2-5 ice days during the month. Precipitation exceeded normal by 20% in the northern and by 55% in the southern part of the country. Pouring rain and succeeding snowstorms with precipitation amounts of ≥100mm on December 23-24 caused flooding in Kardjali as well as interruptions of the electricity supply in many villages. The road traffic before Christmas was embarrassed and stopped in some locations. There were many road accidents, 124 cases alone in Sofia. Fog was observed on 23 days, long-lasting in most areas; the Sofia airport was closed several times during fog episodes.

Two extreme weather events were reported from Turkey. Heavy rains engendered flooding of houses and agricultural areas in and around Ceyhan on December 16. Strong winds caused the interruption of power lines and damage to houses and trees in Demirci one day later.

In Cyprus the monthly mean temperature was slightly above normal by 0.4°C, whereas precipitation amounted to 127.3mm or 121% of normal. A tornado occurred in the western area of Limassol causing damage to houses on December 4. Thunderstorms and a tornado occurred in the area of Larnaka in the morning of December 26 causing damage to properties. Floods occurred in the area of Larnaka on December 3, 4 and 15.

Temperatures were close to normal in Israel. Rainfall spread was not homogeneous – rainfall amounts were above normal in the northern parts of the country and in some areas of the coastal plain, and below normal in other parts of the country.

Activities and Results of European Climate Centres

Report on ECSN activities 2003

by: Walter Kirchhofer, MeteoSwiss

- **General remarks**

The EUMETNET Council has decided that in the future the European Meteorological Society (EMS), in partnership with ECSN, will organize the European Conference on Applied Climatology (ECAC). ECSN will remain responsible for the scientific part. The first combined conference ‚EMS4/ECAC5" will take place in Nice, 26-30 September 2004.

The fourth ECSN Climate Database Workshop on Data Management and Data Quality has taken place in Helsinki, Finland, 19-20 May 2003. The workshop continued the series of ECSN Workshops to consolidate the network among climate database experts.

The project Drought Investigations (Meteo HU, PT) was terminated with a Final Report in March 2003. The objectives of this project have been the following ones: evaluation and use of different drought indices, analysis of long drought index series, study of thresholds of drought indices, calculate the spatial distribution of drought indices on different time scales, and recommendation of drought indices.

Within the European Integrated Project ‚ENSEMBLES", the Work Package WP 5.1: ‚Development of high-resolution observational datasets for Europe" was proposed by KNMI in connection with MeteoSwiss and ECSN.

The 8th ECSN Advisory Committee (EAC) Meeting has taken place in Toulouse, France, 24-26 September 2003.

At its 19th Meeting the EUMETNET Council agreed to continue the Optional Programme ECSN for a third phase of three years, starting on1 January 2004. MeteoSwiss was unanimously selected to be the Responsible Member for ECSN with Dr. Walter Kirchhofer as Programme Manager.

- **European Climate Assessment & Dataset (KNMI)**

The paper ‚Homogeneity of 20th Century European Daily Temperature and Precipitation Series" has been published in the International Journal of Climatology.

A document was prepared that describes the technical work of the ECA&D project and its infrastructure (www.knmi.nl/samenw/eca). The document provides an overview of how the ECA&D work is embedded in KNMI, and forms the core of the documentation of the ECA&D system as developed in the project (database, quality control procedures, extremes analyses and website).

The results of the homogeneity analysis of ECA series were presented at the fourth seminar for homogenization and quality control in climatological databases in Budapest in October. The results of the trend analyses of indices of extremes based on the ECA dataset

were discussed at the Norwich meeting of the CCl/CLIVAR working group on Climate Change Detection and Monitoring Indices in November.

The experiences gained over the past years in using indices to analyse changes in extremes were shared with the participants of the CLIPS RA VI workshop in Erfurt (Germany) as part of a training session. As a follow-up, the countries in WMO Region VI that are not yet registered as project member were invited on an individual basis to become participant.

- **Generate Climate Monitoring Products (DWD)**

According to the decisions of the second GCMP workshop in Hamburg, and on request by the project leader, several countries offered to include European and National monitoring products of their Services in the GCMP Web site. Appropriate links to the respective servers have been set up by the GCMP Web master. Efforts were concentrated on the transformation of the GCMP Web site into a quasi operational mechanism. The number of countries contributing to the GCMP web site continued to increase up to eight NMHSs. It should be noted with acknowledgement that in spite of commercial constraints the participants make their contributions timely and freely available to the other NMHSs and to the public via the GCMP web site.

Taking into account the findings of the second GCMP workshop, special emphasis was put on monitoring products of temperature and precipitation. Moreover the layout and navigation were revised and adapted. Thus with the completion of the project a quasi operational Internet platform is at hand, accessible under the URL http://www.gcmp.dwd.de, displaying European and national climate monitoring products on a regular basis.
In order to fully reach the project goals it is important to obtain a good coverage of the European region with national climate monitoring products. Therefore efforts are continued to enhance the number of actively participating European NMHSs.

- **Climate Atlas of Europe (Météo-France)**

The "Climate Atlas of Europe" will contain monthly normals for precipitation, temperature, wind and sunshine duration and additional statistical information for these parameters and for the occurrence of phenomena such as fog, thunderstorm, hail and snow.

After the database, including the metadata, were considered as final, a set of yearly maps has been drawn.

All the information has been provided to the subcontractor in charge of the CD Rom. The priority assigned to the subcontractor was to realize first a web site from which all the information is available to all participants for a final check of both data and language text.

The draft CD-ROM has been presented at the last ECSN Advisory Committee Meeting. It includes all expected functionalities. The database including metadata will be accessible to anyone having the ACCESS software. It is reminded that it contains data from more than 700 stations from 24 countries, with up to 43 parameters.

A CD-ROM comprising the French and the English versions of the software has been made.

Ozone Layer over Central Europe in 2003

by Hans Claude, Ulf Köhler and Wolfgang Steinbrecht, Deutscher Wetterdienst

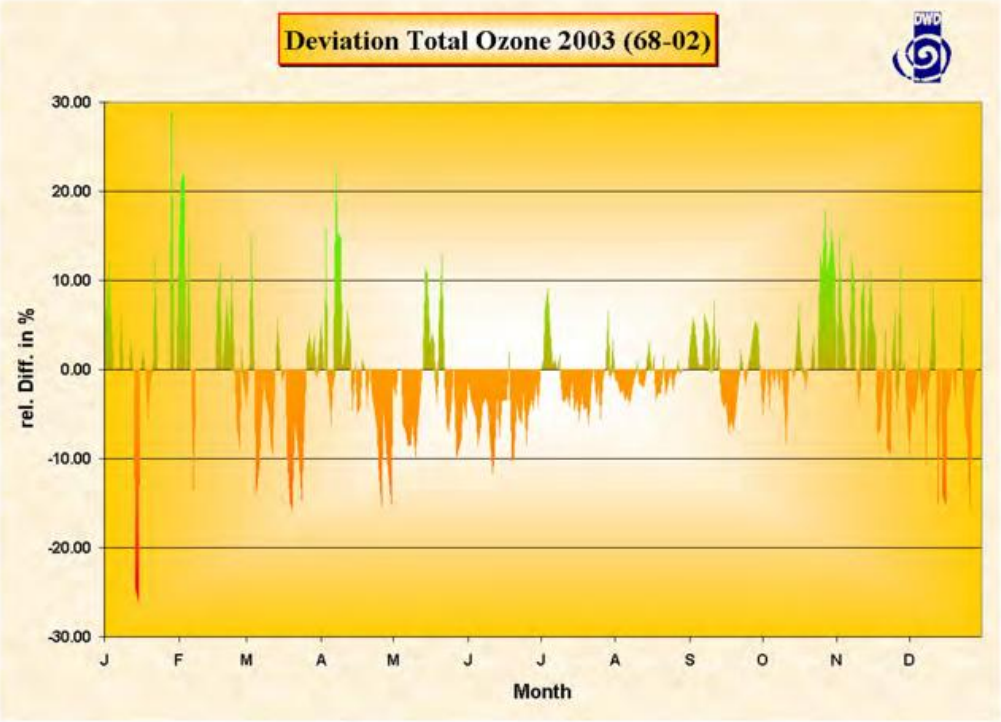

Figure 1: *Relative deviation of total ozone daily means from the climatological long-term mean. Measurements are from the year 2003 at Hohenpeissenberg (47.8°N, 11.0°E).*

The dominant meteorological feature of 2003 was the extremely warm summer in Central Europe, with record temperatures from June to August. At northern mid-latitudes, the lower stratosphere, and thus the total ozone column, is affected by tropospheric circulation patterns. Therefore, this extreme summer with frequent and persistent high pressure systems over Europe should be reflected in low total ozone. Indeed, Figure 1, showing the percentage deviation of total ozone from the long term mean, does indicate a long period of negative deviations from May to August. However, different from the extreme tropospheric temperatures, the total ozone values in the summer of 2003 were not extraordinarily low compared to previous years (e.g. compared to 2000). The frequent and persistent high pressure was only one of many factors affecting total ozone. By itself, it would have resulted in very low total ozone. However, other natural factors like the 11-year solar cycle, the Quasi-Biennial Oscillation (QBO), or variations in the global meridional Brewer-Dobson circulation also influence total ozone at northern mid-latitudes. They have masked the effect of the extremely warm summer of 2003.

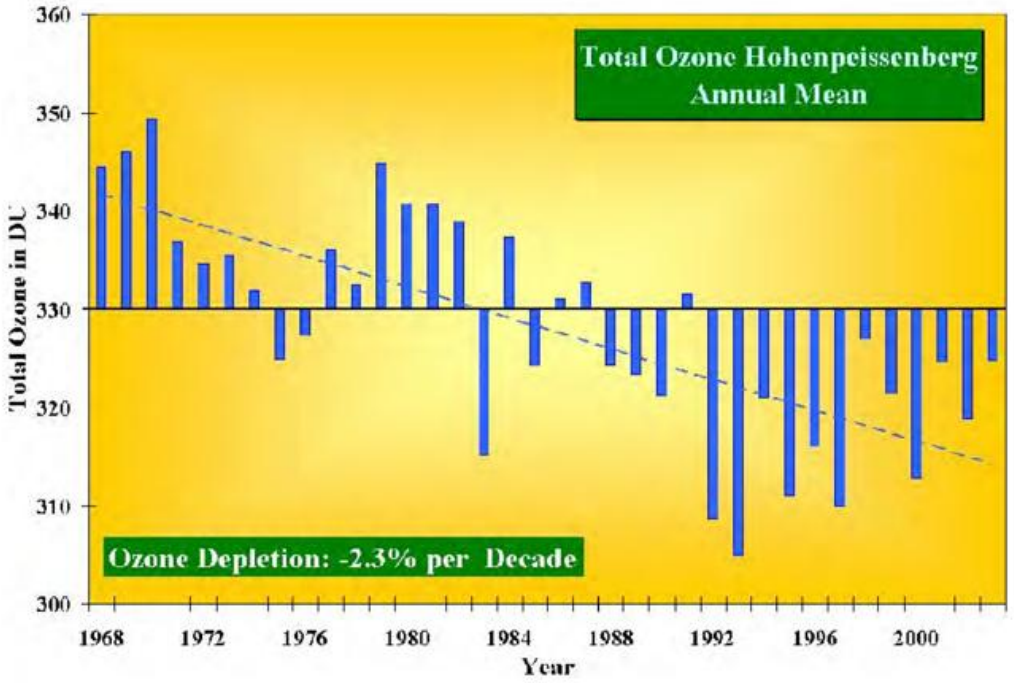

Figure 2: *Annual means of total column ozone above Hohenpeissenberg since 1968.*

The time series of annual means, given in Fig. 2, also does not show extremely low total ozone in 2003. Since the record low values of 1993, two years after the Mt. Pinatubo volcanic eruption, total ozone has been increasing from about 305 Dobson Units (DU) to more than 320 DU. Are these 10 years of rising total ozone level a conclusive indication for a beginning recovery of the ozone layer? The answer is no. While measurements of stratospheric chlorine loading do show a levelling off or even a slight decrease in recent years, the positive influence on total ozone levels is still small, probably less than 5 DU. This is much smaller than recent ozone increases related to other, natural, factors: The gradual disappearance of the Mt. Pinatubo aerosol cloud has increased total ozone by 10 to 30 DU since 1993. Changes in the phase of the Arctic Oscillation also resulted in ozone changes between +5 and +15 DU since the early 1990s. Given these large natural background variations, the small signal of a possible beginning recovery cannot yet be detected in total ozone data.

In order to see positive effects from the Montreal Protocol, which has undoubtedly achieved a beginning decrease of stratospheric chlorine levels, we should look at ozone levels in the upper stratosphere. There, ozone is controlled to a larger degree by photochemical reactions. The number of influences is smaller and better defined than for total column ozone.

First indications of the expected recovery should appear earlier there than in total ozone. Note, however, that the contribution of this region to the total ozone column is very small.

This evolution of upper stratospheric ozone between 35 and 45 km altitude, near Hohenpeissenberg, i.e. over Central Europe, is given in Figure 3. The long-term decline of upper stratospheric ozone by -10% to -15% since 1980 is clearly evident. It is caused by increasing chlorine from man-made sources. Other factors influencing ozone levels in the upper stratosphere are the 11-year solar cycle and the QBO. Their effects on ozone have been estimated and eliminated for Figure 3.

The recent ozone anomalies in Figure 3 show no clear indication of ozone levels above the long-term trend line. There are only inconclusive signs for a levelling off or a slight increase, which would indicate a beginning recovery. The situation is clearer in other parts of the world: Data from near-tropical Hawaii (20°N, 156°W) or from Lauder (45°S, 170°E), at

southern mid-latitudes do show more conclusive evidence for a beginning recovery. Presently it is not understood, why the same is not seen above Central Europe.

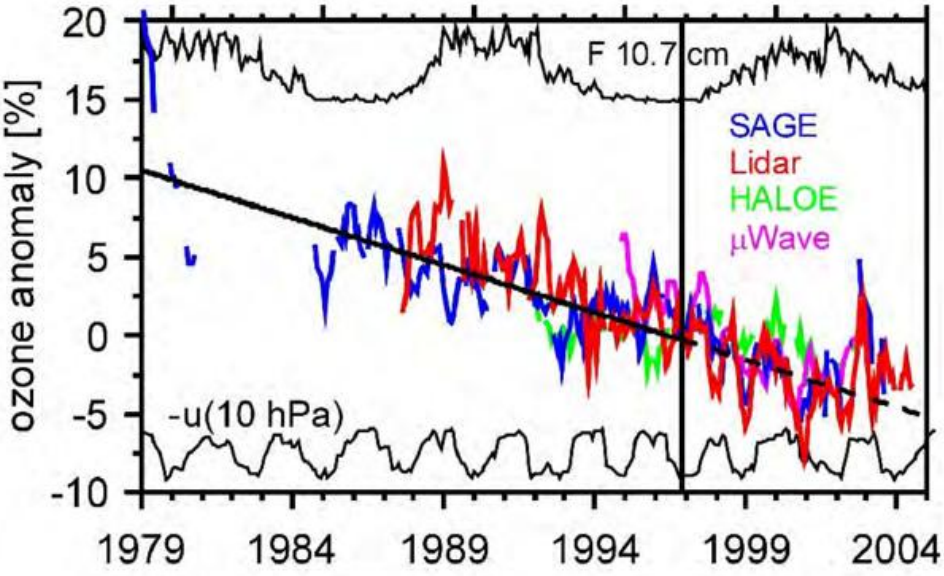

Figure 3: *Anomalies of upper stratospheric ozone between 35 and 45 km altitude, based on measurements by Lidar at Hohenpeissenberg (Germany), microwave radiometer at Berne (Switzerland), and zonal mean data from the SAGE and HALOE satellite instruments. Effects of the 11-year solar cycle (thin black line at top) and the quasi-biennial oscillation (QBO, thin black line at bottom) have been taken out.*

We may conclude that neither total ozone nor upper stratospheric ozone above Hohenpeissenberg and Central Europe show clear and unambiguous signs for a beginning recovery of the ozone layer. Chlorine levels are still near their maximum. Depending on other factors, among them climate change and the future evolution of stratospheric temperatures, periods with very low ozone levels have to be expected for many years.

Hydrometeorological Conditions During the Extremely Dry Year 2003 in the Long-Term and European Context

B. Rudolf and A. Meyer-Christoffer
Deutscher Wetterdienst, Global Precipitation Climatology Centre
gpcc@dwd.de

In 2003 Europe was affected by extremely high air temperature especially in the summer. According to an analysis of Luterbacher et al. (2004) it has even been the warmest summer in Central Europe since 500 years. The heat is the major cause of the European drought in this year. Figure 1 shows the high seasonal anomaly of air temperature up to 5K in the summer 2003 (June to August), and an area warmer than normal reached from western North Atlantic to the border of Russia and from North Africa to Arctic. A blocking high pressure area covered Europe in the summer and so the spatial distribution shows a typical omega structure.

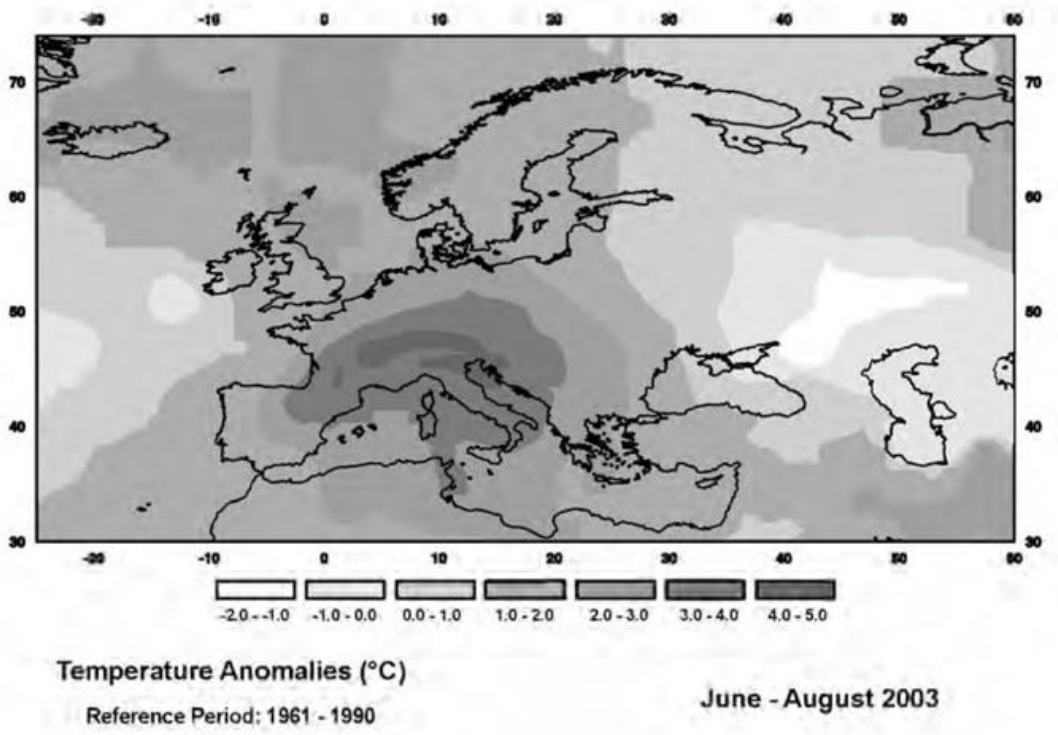

Figure 1: *Seasonal anomaly of air temperature (°C, June - August 2003)*

For complementation the spatial and temporal structures of precipitation anomaly have been evaluated based on gridded monthly precipitation analyses of the GPCC, which are based on meteorological data from SYNOP and CLIMAT reports received via GTS. The following analyses base on the global monthly grid data of the "monitoring product" of the Global Precipitation Climatology Centre (GPCC), available since 1986. This product contains monthly area mean precipitation with a grid area of 1° by 1° longitude and latitude from observed stations, which are calculated upon objective analyses (Rudolf et al.; 1992). So these results represent no selected points of conditions, but area means.

Figure 2 shows that the year 2003 was very dry over Central Europe not only from high temperature but also from low water supply by precipitation.

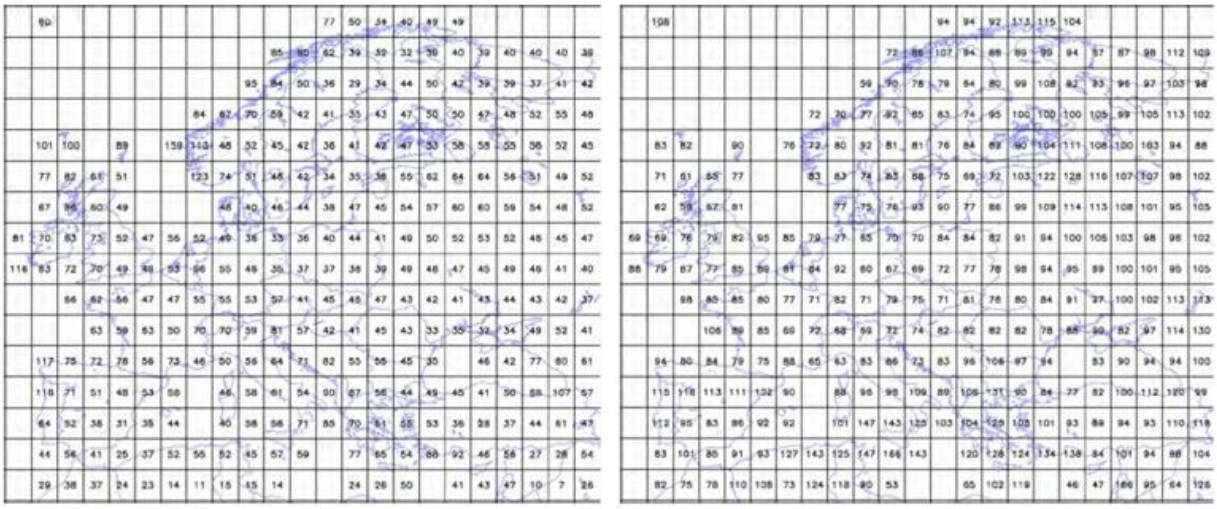

Figure 2: *Annual precipitation totals (mm/month, left) and percentage (%, right) for the period Dec. 2002 - Nov. 2003 (percentage related to normal 1961-1990, based on GPCC's monthly monitoring analyses).*

For seven selected areas of Europe the annual accumulation of monthly precipitation has been derived from the gridded data for each individual year of the period 1986-2003. The seven areas have been selected with respect to the annual precipitation anomaly (Fig. 2) and the spatial data coverage shown in Figure 3. The numbers in Figure 3 indicate the number of stations with data in the grid cell.

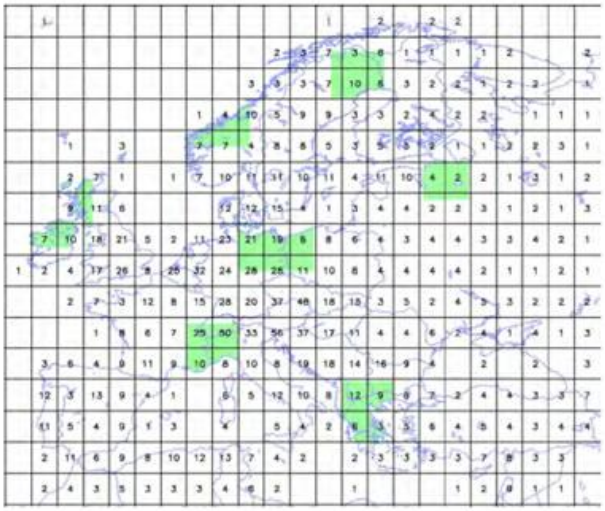

Figure 3: *Regions selected for analysis of time-series shown in Figure 4. Numbers indicate the number of stations for each grid box.*

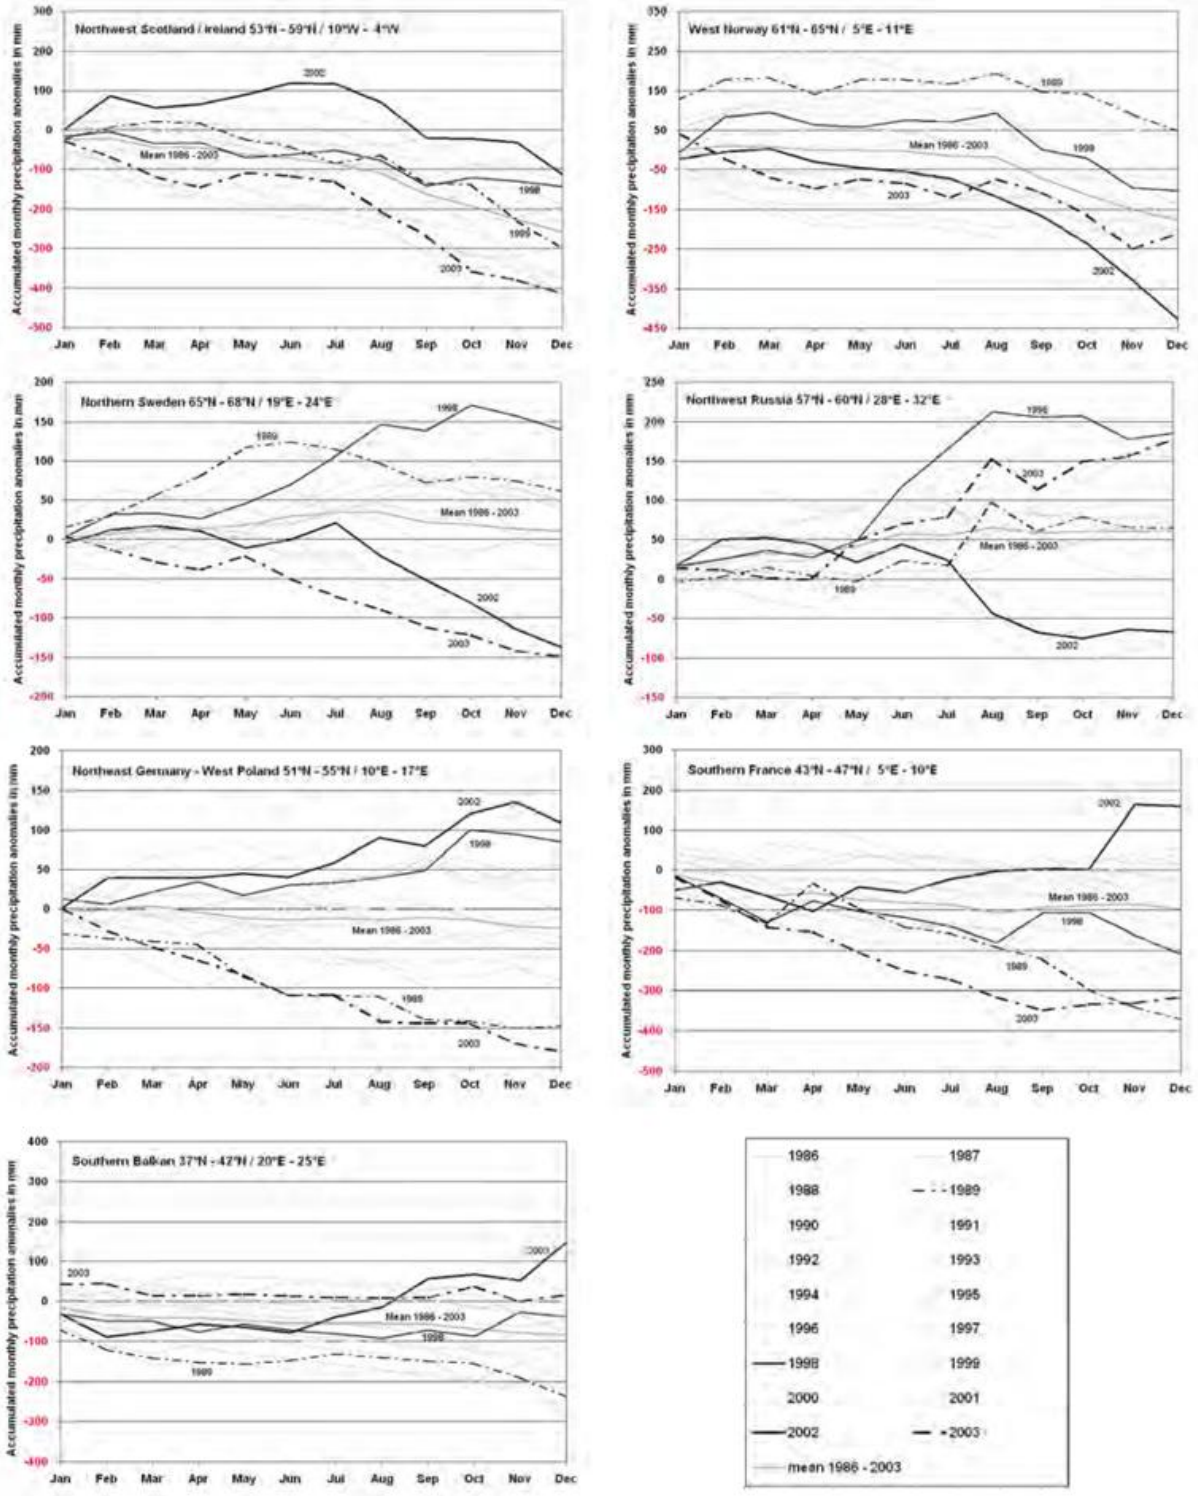

Figure 4: *Annual accumulation of monthly precipitation anomalies (mm) related to the period 1961–1990 for selected regions being marked in Figure 3.*

Comments on the diagrams of Figure 4:

Within the considered period 1986-2003 for the two regions Germany/Poland and Southern France both the recent years 2002 and 2003 are the most extreme years with 2002 being very wet and 2003 very dry. In France only 1989 had less precipitation than 2003. The yearly area mean precipitation for the period 1986-2003 in Germany/Poland is about 20mm, in Southern France nearly 100mm lower than for the period 1961-1990. Especially the precipitation

deficit in spring leads to less soil moisture in the upper layers of the soil. This decreases the evaporation in the summer and so intensifies the heat-wave.

On European scale, however, the behaviour is considerably different, especially for the annual evolution in the single years, caused by the large-scale circulation patterns:

- For Northern Sweden the year 2003 is the driest in the period 1986-2003, too, but 2002 is also dry and in Scotland/Ireland 2003 was nearly as dry as 1996 and 2002 rather humid.

- For the regions in Scotland/Ireland and West Norway near the Atlantic Ocean the precipitation above all in autumn decreases for the last 18 years. For West Norway the yearly area mean precipitation for the period 1986-2003 is more than 170 mm lower than in the normal period 1961-1990, in Scotland/Ireland even nearly 260mm lower than 1961-1990.

- The majority of the 18 years were more wet than normal above Northwest-Russia. The period 1986-2003 has about 60 mm more precipitation than the normal period 1961-1990. The extreme years 2003 and 2002 are contrary to Central Europe, 2003 is very wet, only in 1998 more precipitation has fallen, and 2002 is noticeable drier than normal.

- On the Southern Balkan in 2002 the high December precipitation is significant for the total precipitation in 2002, and 2003 is also rather humid, but 13 of the 18 analysed years were more arid than normal.

Table 1 summarises the annual precipitation results; dry and wet years are highlighted by different shades of grey (dark: wet, bright: dry), years with least and most precipitation in the period 1986-2003 are edged. So the table shows the dry and wet years and the course of the 18 years.

Over all, the period 1986-2003 has been drier than the normal period 1961-1990, apart from Northern Sweden and Northwest Russia. 2003 is drier than normal apart of Northwest Russia and Southern Balkan.

Period / Year	1961-1990	1986-2003	2003	2002	2001	2000	1999	1998	1997	1996	1995	1994	1993	1992	1991	1990	1989	1988	1987	1986

Table 1: Annual precipitation for the periods 1961-1990 and 1986-2003 and for the individual years.

Summary and concluding remarks

The character of the yearly atmospheric conditions in Europe first of all is influenced by the constellation of the meteorological conditions. This is shown by the analyses of the GPCC although not discussed here in detail.

During occurrence of extreme wet events within Europe, temporal and spatial differences are more distinct than under dry conditions. The scale differences between spacious droughts and local extreme flash floods can lead to such events at the same time as the extreme hot year 2003 has shown (Rudolf, 2004).

The appraisal of the frequency or the probability of occurrence and especially in dry periods the persistence of rare extreme events require an analysis of homogeneity controlled time series. Considered parameters are the trend of the precipitation depth, the variability of the precipitation, the trend of this variability, and the frequency distribution of precipitation classes. A statistical analysis accomplished at the University of Frankfurt documents a gradual increase of the frequency of extreme dry also as of humid months, and the variability of precipitation increased more strongly than the mean average (Grieser, Staeger, Schönwiese, 2000). The extreme events of the last both years match to these results, although causal connection with this trend is not proved. As single events they also could occur in the climatic range of the 20th century.

Further increase of mean air temperature as forecasted by climate modelling would lead to an increase and intensifying of extreme events in Europe, this means high air temperatures as in the summer 2003 and heavy rain as in the summer 2002 (Schär e tal., 2004).

This small study illustrates the potential of GPCC's gridded precipitation products for regional climate monitoring. This article is based on a poster presented at ECAC 2004 (Nice) and an article published earlier in German language.

Acknowledgement: The chart of the air temperature anomaly was kindly provided by Mrs. M. Seilkopf, Maritime Weather Office Hamburg, for this contribution. Thanks are given to Mr. P. Finger, Mr. J.N. Breidenbach and Mr. P. Stender for the compilation of the precipitation data and assistance at the analysis.

ACTIVITIES AND RESULTS OF EUROPEAN CLIMATE CENTRES 77

OZONE LAYER OVER CENTRAL EUROPE IN 2004 78

Foreword

This is now the 11th edition of the Annual Bulletin on the Climate in WMO Regional Association VI, providing information on the climate for the year 2004.

The National Meteorological and Hydrological Services of WMO Region VI provided once more valuable contributions to this issue, often illustrated by various maps, diagrams, tables and even photographs. For this reason the editors decided to present all the figures in colour again, like it was already done for the previous year. 40 out of 49 countries responded to the Call for Input which is sent every year in December. This has shown again that a high majority of the Member countries is interested in presenting their national results to the public in co-operation with their partners of the huge WMO RAVI community.

While 2004 was generally not such an outstanding year like 2003 with its unusual warm summer in Central Europe, there were some noteworthy events in 2004 too. It was again a warm year compared to the reference period 1961-1990. Especially in the Arctic regions the anomalies reached about +2°C. In Scandinavia, the months April and December were very mild. But also the precipitation anomalies were remarkable: Whilst Russia had its second wettest year according to the corresponding precipitation time series; it was a very dry year especially in Portugal and southern France. Other disastrous events were some heavy storms in the eastern Mediterranean in January and November, and some strong hailstorms and tornadoes in Central and Eastern Europe in June. Since the observation of tornadoes and other severe weather events have become more and more popular, they have to be included in any regular climate monitoring activity too.

Like in the editions before, this climate monitoring bulletin also reports on recent ECSN activities.

In order to present all this information in a reader-friendly way, the editors have slightly changed the layout of this issue compared to the previous one. The new single-column layout is probably easier to read, and highlighting the names of the countries in the text could help to find the contributions of the various Members more easily.

To all the contributors, I would like to express my warmest gratitude for this large amount of very interesting reports. I am especially thankful to the editors Mr. Peter Bissolli and Mr. Peer Hechler from Deutscher Wetterdienst (Department Climate Monitoring) for again taking over the whole task of coordination, editorial review, publishing and distribution of the Bulletin.

Daniel Keuerleber-Burk

President of WMO Regional Association VI

Outstanding Events and Anomalies in 2004

Temperature

- Very mild in the Arctic regions and in winter in Russia
- Record mild temperatures in Central Europe around February 4
- Very mild April in Norway and Sweden
- Very warm June in Portugal and Spain
- Very mild December in Scandinavia and the Baltic countries

Precipitation

- Very wet in most parts of Russia
- Very dry in Portugal and southern France
- High rainfall amounts with flooding in south-eastern countries in January
- Severe snowfall in the eastern Mediterranean area in February
- Abundant snowfall in the Alps on 23/24 March

Sunshine

- A very sunny September in Central Europe

Wind

- Heavy storms in the eastern Mediterranean in January and November
- Strong hail and tornadoes in Central and eastern Europe in June
- Heavy storm over Central Europe on December 17

Annual Survey

Temperature in 2004 was higher than the 1961-1990 average almost everywhere in the Region. In the Arctic (e.g. Svalbard, Jan Mayen), the annual mean temperature was about 2°C above normal. Northern European countries reported averages about 1°C above normal (e.g. Iceland +1.2 - +1.5°C, Norway +1.4°C, Sweden +1.1°C, Latvia and Lithuania +0.7°C), with higher anomalies in the West than in the East. In most of the other countries, the positive anomalies were between +0.5 and +1.0°C, in parts of south-eastern Europe also less than +0.5°C, in some areas of the East also between +1.0 and +2.0°C. Examples for monthly and annual means and/or anomalies are shown for Estonia (Fig. 0.1), Latvia (Fig. 0.2), Belgium (Fig. 0.3), Slovenia (Fig. 0.4), Romania (Fig. 0.5), Armenia (Fig. 0.6) and daily temperatures for Central England (Fig. 0.7).

The absolute mean temperature 2004 at Jan Mayen was above zero (0.8°C) and the second highest registered there since measurements started in 1921. In Denmark, although the year was warm like in other countries, the summer came very late. It happened the first time in Denmark since 1874 that the first summer day (maximum temperature >25°C) came as late as on 30 July.

Examples for spatial distributions of the annual mean temperature are shown for Norway (Fig. 0.8) and Hungary (Fig. 0.9).

In many countries, 2004 was one of the 10 warmest years since measurements started and the annual mean followed the general warming trend, e.g. in Russia (Fig. 0.10) and Denmark (Fig. 0.11).

Precipitation in 2004 was higher than normal in most parts of the northern European countries; typical anomalies were around 10% on country average. In Russia, 2004 was the second wettest year in the precipitation time series. Precipitation in Central Europe was close to normal. In the Southeast of the Region, most countries reported precipitation above normal. In contrast, it was a very dry year in Portugal, being the driest since 1931 and almost everywhere in the country below 60% of the 1961-1990 normal. In southern France it was also very dry (only 356mm or 52% of the normal in Toulon (Var) for the period October 2003 – September 2004), and furthermore, parts of western Switzerland were drier than normal.

Maps of annual precipitation are shown for Norway (Fig. 0.12), Finland (Fig. 0.13), south-eastern France (Fig. 0.14), Hungary (Fig. 0.15) and Portugal (0.16).

Fig. 0.16: *Annual precipitation 2004 in Mainland Portugal in % of normal 1961-1990*
From: Instituto de Meteorologia Portugal

Sunshine duration was higher than normal in some western European countries, e.g. Iceland, the Faroe Islands, Ireland (Fig. 0.17), Netherlands, Luxembourg (Fig. 0.18), Germany, Switzerland. The annual sunshine duration in Belgium (station Uccle) was slightly below normal. Among the more eastern countries, Finland reported a cloudy summer; in Lithuania the mean values were mostly near normal except at the seaside where it was sunnier. In most of the area of Slovenia the sunshine duration was below normal.

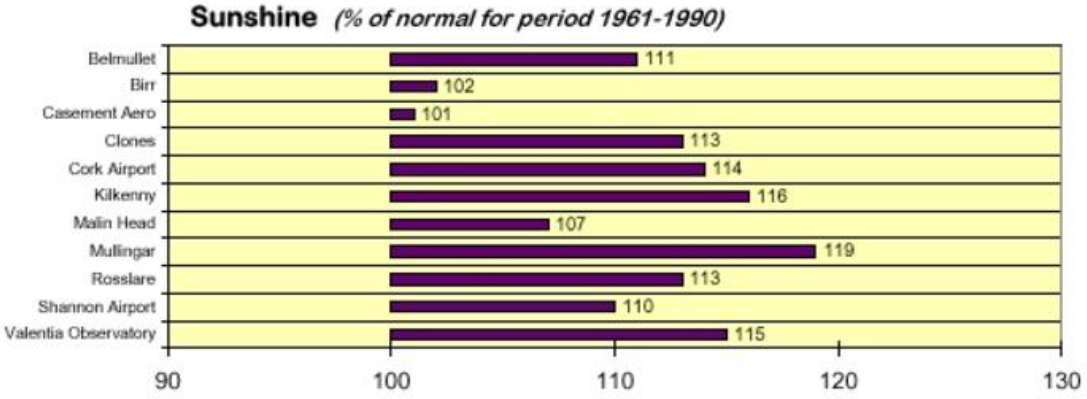

Fig. 0.17: *Anomalies of sunshine duration 2004 for some stations in Ireland*

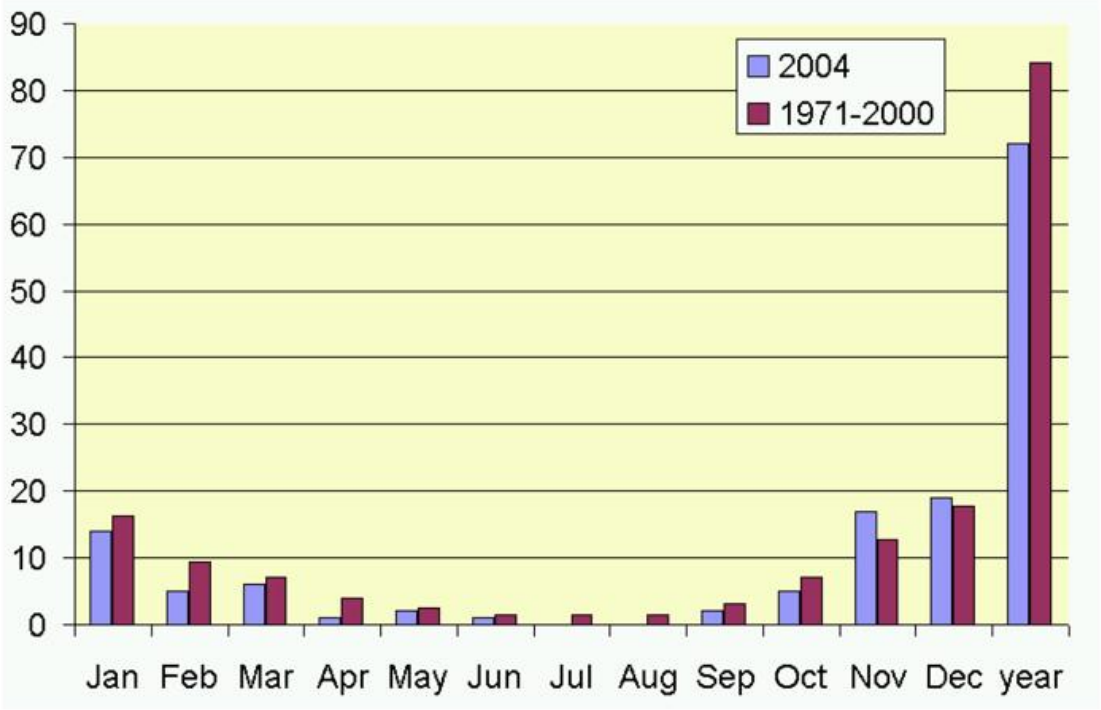

Fig. 0.18: *Monthly and annual number of days **without sunshine** 2004 compared to the 1971-2000 normal for Luxembourg Airport*
Data from: Service Météorologique, Administration de l'Aéroport, Luxembourg

Wind events were reported by some countries, e.g. storms, tornadoes, which are described within the monthly surveys. For the year as a whole, no exceptional storm frequencies were reported. Mean wind speeds of 17 - 20 km/h were reported for Ireland at most stations, 24 - 28 km/h at coastal stations of the North and Northwest.

Seasonal Survey

Winter 2003/04 was milder than the 1961-1990 normal in nearly the whole Region. Only a few areas had slight cold anomalies: parts of the Arctic region and along the northern Norwegian coast, but also in the Southeast around Greece, Turkey and the Black Sea. The highest positive anomalies (> +4°C) occurred over Russia, with lower values towards the West and the South, lowest in southern Central Europe and the Mediterranean, but again higher over parts of western and northern Europe.

Precipitation was higher than normal in most of the Region, especially over eastern areas of Europe, up to more than 150%. Dry areas can be found mainly over the Iberian Peninsula, some of the Mediterranean islands, the Caucasian area, and in the northern half of Europe in Ireland, Greenland, and eastern Sweden.

Spring 2004 also was warmer than normal in nearly the whole Region. Slight cold anomalies were found over parts of the western Mediterranean, the Aegean and the Black Sea. The highest positive temperature anomalies were found around the North Sea and parts of Scandinavia, there were some deviations >+1°C.

Spring was dry in almost the whole Region, especially in northern and Central Europe, Portugal and the eastern Mediterranean. Areas wetter than normal were concentrated on Greenland and Iceland, around the western Mediterranean and the Adriatic Sea, and Russia. Examples are illustrated by the spring precipitation distribution in Croatia (Fig. 0.19), Serbia and Montenegro (Fig. 0.20) and in Bosnia and Herzegovina (Fig. 0.21).

Summer 2004 was again warmer than normal in nearly the whole Region, although it was not such an extreme summer like the year before. Slight cold anomalies were observed over parts of the Atlantic and to the north of the Black Sea. Higher positive temperature deviations were continuing around the North Sea and parts of Scandinavia.

Most of the area had higher than normal precipitation in summer, especially in the eastern United Kingdom, northern Central Europe, parts of Scandinavia and Russia, and around the Black Sea. As an example, the distribution of summer precipitation for the Netherlands is shown in Fig. 0.22. In contrast, the Mediterranean region was mostly very dry, except southern Italy.

Autumn 2004 also had only warm anomalies nearly all over the Region. The highest positive deviations were recorded in central Scandinavia and Russia, but locally also in Central Europe and in the south-eastern countries, reaching >1°C. Lower anomalies and even small areas colder than normal were identified over the Atlantic, especially west of Ireland.

Autumn was mainly dry, in particular there were large dry areas over France and Spain, but also some parts of Scandinavia and around the Aegean Sea were very dry. Wet areas were found over Greenland and Iceland, but also in some other parts of Europe, in particular again in southern Italy and in the eastern areas of the Region.

Monthly Surveys

January 2004

- **Cold in most of the East and some areas in the North, mild in western Central Europe, Portugal and Spain**
- **Very wet in most of Central Europe, parts of Portugal and in the East, mainly dry in the Baltic countries and parts of the western Mediterranean, high spatial variability in northern Europe**
- **Some intense snowfall in southern Europe**
- **Severe storms with heavy rain and flooding in the eastern Mediterranean**

In Nuuk, **Greenland**, January was warmer than normal and fairly dry.

On the **Faroe Islands** at Tórshavn, the January temperature was about normal, sometimes with cold spells.

The temperature in **Iceland** in January was close to the 1961-1990 mean, there was substantial snow during a period in the northern part of the country, but elsewhere there was little snow.

There were great deviations from the normal both for temperature and precipitation in **Norway**. The monthly average in the eastern parts of the county of Finnmark was 2-3°C above normal, while in the county of Troms and higher parts in southern Norway the monthly mean was 1-2°C below normal. Sunndalsøra in the county of Møre og Romsdal measured the highest temperature with 11.2°C on January 24 while Karasjok measured -37.4°C as the lowest on January 6. Østlandet and Sørlandet received much more precipitation than normal and in some areas the month was among the wettest within the last 100 years while other areas in the counties Møre og Romsdal, Oppland, Sør-Trøndelag, Nordland and Troms received only 10-20%. At Sørlandet several stations registered new monthly and daily records for precipitation. The highest diurnal precipitation amount (77.0mm) was measured at the station Reine in the county of Nordland on January 23.

January was quite wintry in **Sweden** with some snowstorms, especially on 30-31 when about 20 000 households in south-west Sweden had a failure in the supply of electricity due to wet snow.

The year started a bit cold and wintry in **Denmark** with snow and frost. On January 5-6, considerable amounts of snow fell on the isle of Zealand, especially in the capital Copenhagen. At the end of the month the temperature was rather low with hard frost in the middle of Jutland.

In **Estonia** the month was colder than usual by 1°C and the precipitation achieved only half of the normal.

In **Latvia** this was the 9th driest January over the last 80 years.

January was the coldest month of the year in **Lithuania**. Its mean air temperature was -6.6°C (-1.5°C anomaly). The lowest temperature of the month was -24°C. The last decade was the coldest, when the daily mean temperature was -5°C below normal. Such a cold end of January had previously occurred in 1996. The monthly amount of precipitation was below normal in the western regions while exceeding it 1.2-2 times in the southern and eastern regions with a snow depth up to 30cm.

Kilkenny's (**Ireland**) lowest air and ground temperatures of -7.7°C and -15.6°C, respectively, on January 29 were the lowest such values at the station for around 20 years.

Within the **United Kingdom**, the Central England temperature exceeded the 1961-1990 normal by 1.4°C, the England-Wales precipitation by 32mm (=135% of the normal).

In **Belgium,** January was characterised by alternating maritime and continental flows. On the monthly average, the temperature was slightly above normal. Precipitation was very high, especially during the second decade with 102.4mm, a new record in the period since 1901.

January in **Luxembourg** was slightly warmer than normal (+0.3°C), but it rained very often (25 precipitation days), resulting in an anomaly of +32.8mm (145% of the normal).

Snow and freezing rain led to chaotic traffic on the streets in **Germany** on January 4-6, especially in the north. Two storms occurred with gusts up to 215 km/h in the Alps (Nebelhorn) on January 12-14. Trees broke down; fences and roof tiles flew in the air. 165mm precipitation in 24h fell on the mountain station Schauinsland (Black Forest). At the same time (January 13), a tornado untiled 7 houses north-west of Hamburg. Another traffic chaos due to snow and ice occurred on January 28-30. Some airports were temporarily closed. The monthly mean temperature for Germany was -0.1°C. This was 0.4°C above the value for the reference period 1961-90. However, January 2004 was extremely rich in precipitation (Fig. 1.1) and rather poor in sunshine duration. The average amount of precipitation was 109.4 mm, exceeding the normal by 48.6 mm or 80.0%. So this month became the 3rd wettest January in Germany since 1901. The average sunshine duration was only 34.0h, which is far below normal (anomaly -9.6h or -21.9%).

January was very cold in the entire area of **Poland**: monthly mean values ranged from -2°C in the North to -7°C in the Northeast. Monthly mean departures were between -2°C and -4°C. An extreme minimum temperature of -25.2°C was observed in the South of Poland on January 24. Precipitation in January was close to normal or slightly higher. The lowest values were observed in the North and South (below 70%); in the West precipitation exceeded 160%. A snow cover appeared at the beginning of the month and remained during the entire month, especially in the East. At the coast and over mountains strong winds (>70km/h) occurred together with snow storms.

In **Switzerland**, a westerly storm in the northern Alps with gusts up to 206km/h on the Jungfraujoch was observed on January 12-13. Precipitation of 60-100mm fell in the western part of the Swiss Alps. There were extremely mild temperatures, in some regions rain fell up to the altitude of 2300m. In the lowlands, in spite of continuous rain, 11-15°C were measured.

Up to 300% of normal precipitation fell in north-western parts of upper **Austria**. Very cold nights occurred in western and southern Austria during the last week of January. In St. Michael (province of Salzburg) –27.0°C on January 24 was the lowest temperature at this place since 1985.

An absolute minimum temperature of -21.8°C was measured at Szécsény in **Hungary** on January 23. The countrywide anomaly (compared to 1961-1990) of the monthly mean temperature was -0.5°C. As for precipitation, the monthly average was only slightly higher than normal (105%).

The mean air temperature was close to the 1961-1990 normal in **Slovenia**. The anomaly was mostly between -1 and +1°C; the largest anomaly was at Kredarica, where the temperature was 2.1°C below normal. Most of the precipitation was concentrated on the second third of January. The western part of Slovenia received less precipitation than normal; in Upper Soča valley even less than half of the normal precipitation amount was recorded. Elsewhere the normal was exceeded. The snow cover in the lowlands was up to 40cm; in Upper Sava valley 54cm were registered. At Kredarica on January 19 the snow depth reached 2.5m. There was much more sunny weather than on average, especially in Štajerska and Prekmurje. Only in the Northwest of Slovenia, in Notranjska and Koroška, the weather was less sunny than normal.

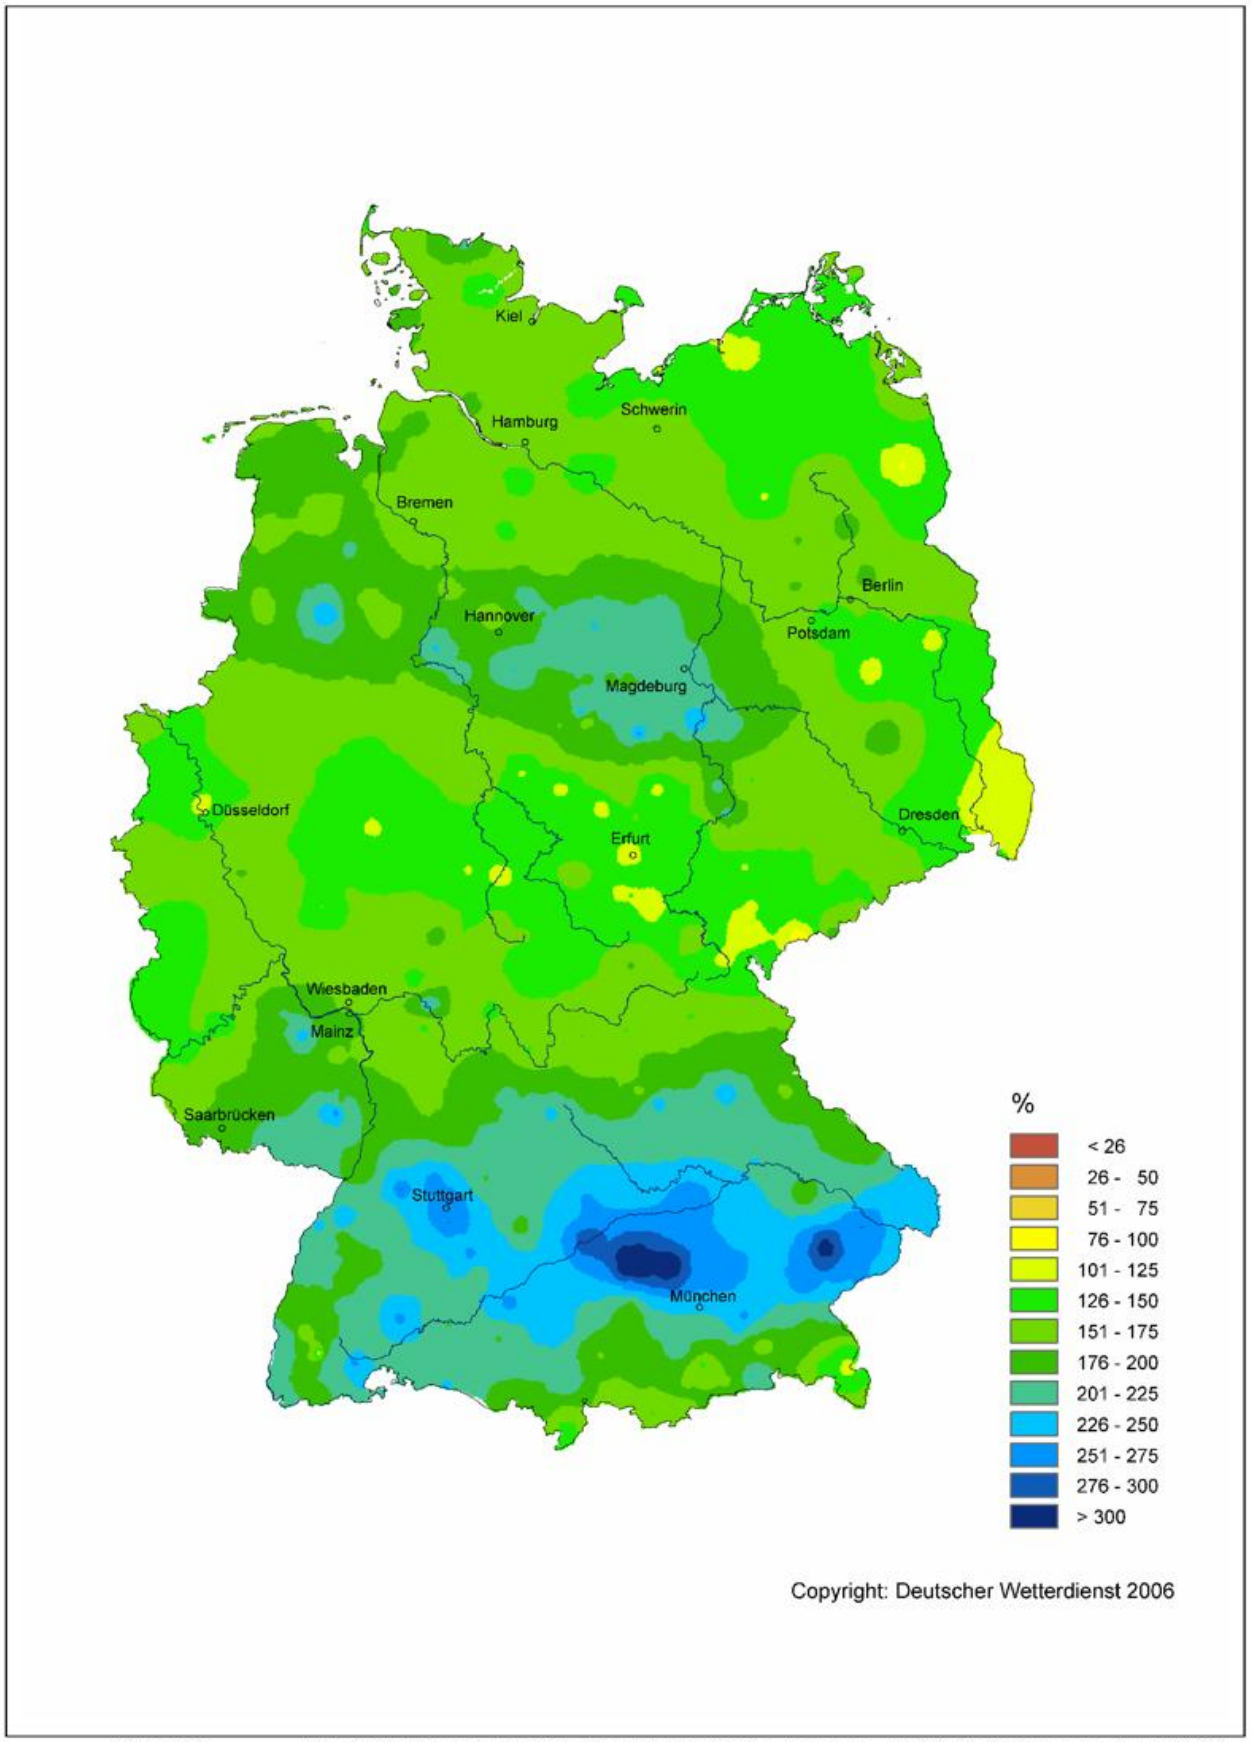

Fig. 1.1: *Precipitation anomalies for Germany in January 2004 (reference period 1961-1990)*
From: Deutscher Wetterdienst (DWD)

The monthly mean air temperature exceeded the 1961-1990 normal in almost the whole territory of **Portugal**. The precipitation amounts were below normal, except in the Lisbon region. In this region the daily maximum precipitation exceeded 101.2mm, the highest amount since 1901.

In **Spain** it was very warm in January, with average values lying generally in the upper quintile of the series. New records of January mean values were recorded at Tortosa (near the Ebro river mouth), at Murcia and at other observatories along the Mediterranean coast.

January was characterised by intense snowfalls in northern and central **Italy**.

In **Croatia**, temperature and precipitation were near normal in most parts of the country, only the South was cold (anomaly around –1°C compared to 1961-1990) and at some locations it was wet (150% of the normal or more).

The month was a little bit colder than normal in **Bosnia and Herzegovina** and wet. Many stations reported a monthly mean around –1°C, which is about 1°C less than normal (1971-2000). Monthly precipitation was around 100mm on station average; this was more than 40% above normal.

In **Romania**, January also was about 1°C colder than normal and the precipitation amount around one third higher than the average 1961-1990.

A high monthly precipitation amount of 394mm was registered in the north-eastern part of **Albania** this month. It also was the maximum of the whole year (usually the maximum is in November, Fig. 1.2) and it was far above the normal (more than 150%).

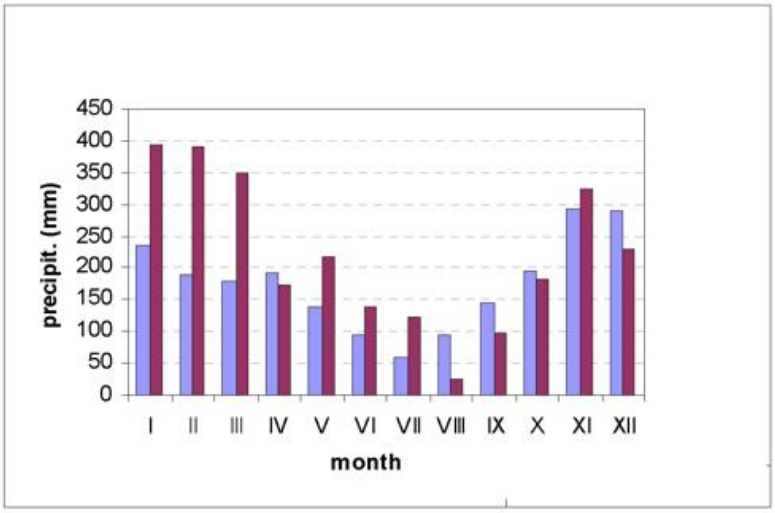

Fig. 1.2: *Annual course of the monthly precipitation sum in Puke in the north-eastern part of Albania (blue: average 1961-1990, red: 2004)*
From: Hydrometeorological Institute Albania

In **Bulgaria**, January 2004 can be identified as a cold month. The temperatures were about 1 - 1.5°C below normal. In terms of precipitation the month was rather normal. Only the north-eastern part of the country encountered precipitation up to 200% of the normal.

Strong storms with gusts >100km/h prevailed on January 22 over the Aegean Sea in **Greece** and resulted in damage of houses and crops. Failures in electric power network occurred in several parts of the eastern Aegean Sea. January 2004 was a very wet month for the country, probably the wettest January in the second part of the 20th century for the eastern and southern part of Greece (Tab. 1.1). An unusual phenomenon occurred in this month: a very deep barometric low with a core pressure of 971hPa (the deepest over the past 30-40 years) crossed the southern island part of the country on January 21-22. The pressure dropped by 28hPa over 24 hours.

Station	Location (latitude °N, longitude °E)	Altitude (m)	Monthly rainfall for January 2004 (in mm)	Long-term average rainfall for January (in mm)	Reference Period
Arta	39 10, 21 00	11.5	193.5	117.9	1976-1997
Mykonos	37 26, 25 25	121.0	243.2	81.8	1989-1997
Sitia	35 12, 26 06	114.5	240.8	90.5	1960-1997
Limnos	39 55, 25 14	3.0	242.4	65.9	1974-1997
Samos	37 42, 26 55	2.3	352.6	133.1	1978-1997
Rodos	36 24, 28 07	34.7	316.1	149.6	1955-1977
Kos	36 48, 27 06	127.1	278.0	94.0	1981-1997
Paros	37 05, 25 09	1.0	199.3	83.0	1975-1995
Argostoli	38 11, 20 29	21.2	178.9	109.7	1977-1997
Skiathos	39 10, 23 30	7.5	221.8	97.6	1986-1997

Tab. 1.1: *Monthly rainfall heights in Greece for January 2004 and long-term mean values From: Hellenic National Meteorological Service*

Houses and roads at Finike and Antalya in **Turkey** were affected by a storm with rain and flooding on January 10-11. Four ships sank in the seaport of Antalya. Another storm with heavy rain was observed there on January 21-23. Greenhouses and orange gardens were damaged, power lines broke off. Other locations, e.g. Istanbul, had snow causing severe problems for traffic roads, but also for sheep and goats.

January was rather warm in **Armenia**; the mean monthly temperature was above normal by 2°C.

The month was the wettest January (281.8mm) in **Cyprus** since 1902. On January 7, heavy snowfall occurred at Troodos, roads to the mountain villages were closed. Snowfall was also registered at Pentadaktylos and snowflakes were observed in southern areas of Lefkosia. On January 10-12 showers, thunderstorms and very strong winds occurred in various areas. The towns Lemesos and Larnaka and also some more south-eastern parts of the island were affected by flooding. On January 22 heavy showers, thunderstorms and very strong winds caused damage in various areas of the country.

January was very rainy in **Israel,** especially in the northern parts of the country, where rainfall amounts were 200-250% of the normal (average of 1961-1990). At many stations in the North this was one of the rainiest winter months since the beginning of measurements. Higher monthly rainfall amounts were measured before only in December 1951 and in January 1969. These large rainfall amounts in the North of Israel caused flooding and road closures. Significant daily amounts were recorded on January 23 with 130-170mm at some stations in the North. Rainfall amounts were larger than normal in the central and southern parts of the country, but not as extreme as in the North. Flooding in Tel Aviv and surrounding areas occurred on January 26 after 30mm of rain fell within 3-4 hours. Temperatures in January were close to normal.

February 2004

- **Generally very mild in most of northern and Central Europe, especially around February 4**
- **Some cold spells with snowfall in the south-eastern Mediterranean region**
- **Very dry in most of western Europe and the Mediterranean, wet in the North and East**

February was rather warm in **Iceland**, but windy, and there was much snow on places in the Northwest, North and East during the first half of the month. A heavy snowstorm passed over the island on February 6 and 7.

On the **Faroe Islands** in Tórshavn, February was warmer than normal, but some cold spells occurred.

The lowest minimum temperature in **Norway** was measured at Sihcajavri with -37.5°C and at Sveagruva (Arctic) with -34.7°C on February 10, the highest temperature at Tafjord with 14.5°C on February 4. With exception of Finnmark, the monthly average for February was above normal, in the inner and higher parts of south-eastern Norway, the anomaly reached between +4 and +5°C. Precipitation was below normal in the south-eastern parts of the country and above in the rest. In parts of the counties Møre og Romsdal, Oppland and Sør Trøndelag the monthly precipitation sum was more than 200% of the normal. The highest diurnal precipitation amount (74.2mm) was measured at the station Ålfoten in the county of Sogn og Fjordane on February 25.

February was considerably mild for the season in **Denmark**.

In **Estonia** the month was wet and warm, 2°C above the normal monthly mean. Snowmelt was observed, precipitation was falling as rain.

New records of maximum temperature were measured in **Latvia** on February 4. In south-east Latvia the air temperature fell from 0 to -27°C on February 18-20 within 40 hours, and then rose again to 0°C in the next 34 hours.

February was wintry in **Lithuania**, but not too cold. The weather was frequently determined by Atlantic cyclones. The mean air temperature was -2.2°C (+2.4°C anomaly). Highest maximum temperature values reached between 4 and 8°C, lowest minima were between -14 and -19°C, in south-eastern regions even between -22 and -25°C. A snow cover vanished in some parts of the country and reappeared 10 - 25cm deep in south-eastern regions. Precipitation in February was abundant and amounted to 240 - 280% of the normal at some places.

February was exceptionally sunny in **Ireland**. Belmullet recorded the highest gust of the year, 135km/h on February 3.

In the **United Kingdom,** on February 4 the highest February daily minimum Central England temperature (CET) and the highest February daily mean CET were recorded at 10.8°C and 12.8°C respectively.

The month of February started with record-high temperatures in the **Netherlands** on February 3 and 4. Eindhoven (southern part of the country) recorded a maximum temperature of 18.0°C on February 4.

In **Belgium,** February was influenced by maritime, sometimes tropical, sometimes polar air. The mild weather at the beginning of the month was compensated by a cold last decade, clearly below normal.

At Gardelegen (about 150km to the west of Berlin), **Germany,** the mildest February night with 14.2°C on February 4-5 exceeded the previous German record of 13.2°C on 16 February 1958 in Freiburg. Snowfall on February 8-11 and again on February 23 caused a lot of traffic accidents in the South and East of the country. For the areal mean of Germany, February 2004 was mild and near average in precipitation and sunshine. But there were large regional differences. While the North was considerably wet, a significant precipitation deficit was observed in the South. The mean temperature for Germany was 2.4°C (+2.0°C above the values for the reference period 1961-90). The average amount of precipitation was 51.3mm, which was 1.9mm or 3.9% higher than the mean of the reference period. The spatial mean of sunshine duration was 66.3 hours; this value was 6.3h or 8.7% below normal.

February was warm in **Poland** – positive mean monthly deviations reached +2.4°C in the West. The highest maximum temperature (+16°C) was observed in the South, the lowest minimum temperature (-20°C) occurred in the Northeast. Precipitation was higher than normal, especially in the Southeast (260%) and locally in the North (240%). A snow cover appeared occasionally with a few centimetres in the West up to 30-40cm in the East and 150 cm on mountains.

Extremely high temperatures in higher mountainous areas of **Switzerland** were observed on February 3-6, with freezing level up to 3600m.

Unusual high temperatures were measured during the first ten days in eastern **Austria**. On February 5, maximum temperatures went up to 22°C in the provinces of Lower Austria and Burgenland, causing new temperature records in some towns, e.g. Wiener Neustadt or Eisenstadt. Up to 310% of the normal precipitation fell in the eastern parts of Austria. A cold front passage on February 8 and 9 caused a lot of storm damage, especially in the counties Vorarlberg and Upper Austria. Along the river Rhine and within the forests east of Bregenz numerous trees were uprooted and roofs were partly damaged. Highest wind speeds, up to 130km/h, were recorded in Upper Austria. In the surroundings of Linz, road traffic was blocked by broken trees.

The mean air temperature in **Slovenia** in February was close to the 1961-1990 normal. The anomaly was mostly between -1 and +1°C; the largest anomaly was observed at Kredarica, where the temperature was 1.7°C above normal. Most of the precipitation fell in the last third of February. Precipitation was most abundant in the Upper Soča valley and in parts of the Julian Alps. The north-eastern part of Slovenia received less precipitation compared to the reference values. Elsewhere the normal was exceeded. The snow depth in the Upper Sava valley was up to 125cm, at Kočevje 68cm. Elsewhere in the lowlands up to 60cm were registered. At Kredarica on February 29, the snow depth was 4m. At the coast and in the Goriška region the average sunshine duration was below normal. The last decade was mostly cloudy everywhere.

February mean monthly temperatures in **Serbia and Montenegro** were near to normal. At the same time, precipitation quantities were higher than average at most places.

Torrential rain occurred at La Palma and Hierro (Canary Island, **Spain**). The highest total in 24h was recorded at La Palma on February 19.

February was characterised by intense snowfalls in northern and central **Italy**. In particular, the snow in late February caused many traffic problems both on railways and highways.

February was relatively warm and dry in **Bulgaria**. In the North and West of the country the temperatures were 1-2°C above normal. In terms of precipitation the northern part of the country reached only 50-70% of the normal and the South only 30-40%. Around February 27 an intense cold front passed the country from the Northwest to the East. It crossed the Danube plane in the North of the country within 3 hours. Thunderstorms were observed with strong winds (up to 70-90km/h). They caused significant damage to buildings and trees in the northern regions of Bulgaria.

The monthly mean air temperature in **Portugal** was equal or above normal in almost the whole territory. The precipitation amounts were below normal, except in the Algarve (southern region).

Severe snowfall occurred in **Greece** during the period February 12-13, affecting mainly the eastern and southern parts of Greece. For the periphery of Attiki (larger area of Athens) it was an unusual extreme phenomenon, particularly the great snow depth, which reached 40cm in the northern suburbs of Athens and 50-100cm in most northern parts of Attiki. Due to these severe snowfalls, the national road Athens - Lamia was closed for several hours causing serious traffic problems in domestic and rural areas. There were also failures in the electric power network and significant damage in agriculture. Unusual low daily minimum temperatures were observed in the middle of the month at some stations (Tab. 2.1). Most of these locations recorded new absolute minimum temperatures.

Station	Location (latitude °N, longitude °E)	Altitude (m)	Minimum daily temperature	Date	Long-term average monthly minimum temperature	Reference period
Arta	39 10, 21 00	11.5	-8.2	14/2/04	4.0	1976-1997
Hellinikon	37 54, 23 45	10.0	-3.8	14/2/04	7.1	1955-1997
N. Filadelfia (Athens)	38 03, 23 40	136.1	-6.0	14/2/04	5.4	1955-1997
Tanagra	38 19, 23 33	139.0	-11.2	14/2/04	3.4	1957-1997
Pyrgos	37 40, 21 26	12.0	-6.0	14/2/04	5.1	1975-1997
Zakynthos	37 45, 20 54	1.5	-2.0	14/2/04	6.2	1982-1997
Tympaki	35 00, 24 46	5.0	-0.5	15/2/04	7.3	1959-1997
Kasteli	35 12, 25 20	332.6	-7.0	15/2/04	5.5	1976-1997
Samos	37 42, 26 55	2.3	-2.8	15/2/04	6.5	1978-1997

Tab. 2.1: *Low minimum daily temperatures (in ^{0}C) in February 2004 and long-term averages*
From: Hellenic National Meteorological Service

A tornado passed Gazipasa and Antalya in **Turkey** on February 12. Greenhouses, farm areas and houses were damaged. Three days later, frost caused damage to citrus fruits, bananas and greenhouses. At Hatay, rain and floods affected farm areas and dwellings on February 21, followed by a storm on the next day, when trees were broken and mosque minarets were destroyed.

February was rather warm in **Armenia**; the mean monthly temperature was 2°C above normal.

Snowfall occurred on February 14 in the area of Troodos as well as in areas of low elevation in **Cyprus**. Slight snowfall was observed in Lefkosia town. On February 22, very strong winds caused damage to greenhouses and to the roofs of houses in the south-eastern parts of the island.

February was rainy in the northern parts of **Israel** and drier than normal in the central and southern parts of the country. Rainfall amounts were 110-130% of the normal in the North and 50-80% in other parts of the country. The most significant rain period occurred on February 13-16 with 100-150mm in the northern parts and heavy snowfall in the mountains, causing many road closures. In Jerusalem, 8-10cm of snow were recorded on February 14, but it melted within 24-36 hours. The last rainfall period was on February 18-21, and no further significant amounts were recorded until the end of the rainy season. The temperatures were slightly above normal with significant changes in the second part of the month. In the mountains, temperatures on February 14-15 were -1 to -2°C. On February 22, low temperatures were recorded once more (-1 to -2°C in the mountains), yet there was a significant warming during the following days. On February 29, 32-33°C were measured in the coastal plain.

March 2004

- **Warmer than normal in most countries except Greenland and some parts of southern Central and south-eastern Europe**
- **Most of the Region dry, but wet in Greenland, Ireland and some parts of the East and the Mediterranean**
- **Storms in Central Europe around March 20**
- **Abundant snowfall in the Alps on March 23-24**

In **Greenland,** March was colder and wetter than normal. The lowest temperature registered in 2004 in Nuuk was recorded on March 8 (-16.5°C). On March 25 a strong storm "hit" the west coast of Greenland, in Nuuk with gusts exceeding 140km/h. It moved through the Davis Strait in a north-easterly direction. The next day frost and rather large amounts of snowfall occurred.

March was very warm in **Iceland**, but windy; there was some local flooding in the first part of the month due to precipitation and snowmelt. It was the 6th warmest March in Reykjavik and the 3rd warmest in Akureyri.

The monthly mean in **Norway** was above normal for the whole country, 4-5°C above normal in the eastern and inner parts of Finnmark. The highest mean temperatures were to be found along the coast of Møre og Romsdal where the coastal station at Svinøy Fyr recorded 5.1°C (1.9°C above normal). The lowest monthly mean was reported from Finnmarksvidda and the mountainous parts of southern Norway. Sihcajavri (Finnmark) had the lowest value with -8.2°C (3.1°C above normal). The highest maximum temperature (16.1°C) was measured at Gvarv (southern Norway) on March 30 while the lowest minimum of the month (-31.0°C) was measured at Røros (Mid Norway) on March 5. The larger part of the country received less precipitation than normal. In some areas the month was among the 4-6 driest March months of the last 50 years. In parts of Troms, Oppland, and Møre og Romsdal the precipitation was 20-30% of the normal. Parts of Nordland and Trøndelag received precipitation above normal (150-175%). Among the synoptical stations, Modalen (western Norway) received most precipitation (229mm, 99% of the normal) while Saltdal (northern Norway) received least (3mm, 20% of the normal). At Lurøy in the county of Nordland 86.6mm were measured on March 18, which was the highest diurnal value of this month.

In **Finland** the 10-minute mean wind speed reached 76km/h in March which is regarded nationally as a level of gale warning in weather forecasts. The highest wind speed values of 104km/h were measured in the beginning of March.

The month was very warm in **Estonia** with mean temperatures up to 2°C above normal.

In **Latvia,** March 2004 was the 7th wettest March over the last 80 years.

The first half of March was dryer and colder than normal in **Lithuania**, while the second half was more humid and warmer. The monthly mean air temperature was 1.2°C (+1.9°C anomaly). In the beginning of the month there was some snowfall, changing to rainfall at the end of it. The monthly amount of precipitation was close to normal at most places, but exceeding the average up to 1.5 times at some localities. In the third decade of March, snowmelt and soil freeze ceased. The month was marked by fogs observed in eastern Lithuania on 4 to 7 days while persisting in western regions for 8 to 12 days in total. Sometimes the visibility went down to 100 metres, affecting air- and seaport operations and impeding road transport.

March was very wet and exceptionally sunny in **Ireland**, especially in the South. The strongest winds of the year at many stations were measured on March 20.

Mild and dry airflows influenced the weather in March in **Belgium** and caused a precipitation deficit. The temperature in Uccle was 1.1°C above normal and the precipitation was less than 50% there.

The monthly mean temperature in **Luxembourg** was slightly higher (+0.2°C) than the 1971-2000 normal. On March 17, a maximum of 20°C was reached, whereas the minimum was -4.6°C on March 1. Only 32.9mm precipitation fell this month, less than 50% of the normal.

March 2004 brought very mild weather to **Germany** (around the middle and at the end of the month), but also still contained wintry episodes (at the beginning and around March 25). The mean temperature for Germany was 4.1°C (+0.6°C above the 1961-90 normal). At two stations in the western part of the country, a new March 17 record temperature of 24.3°C was measured, exceeding the previous record of 23.7°C on 17 March 1961. The average monthly amount of precipitation was 37.6 mm, which was 19.0mm or 33.6% less than normal. The spatial mean of sunshine duration was 129.2 hours, exceeding the normal by 18.6 h or 16.8%. Stormy winds occurred on March 20-21 on the mountains Brocken (165km/h), Fichtelberg (148km/h) and Kahler Asten (130km/h). On March 23-24, record snowfall fell on the highest mountain Zugspitze (150cm in 24 hours).

The monthly mean temperature in March in **Poland** was again higher than normal with the highest values in the Northeast (deviation from normal +1.2°C). Extreme temperatures were -20.6°C and +22.3°C. Precipitation was higher than the 1971-2000 mean reaching 150% of the normal in the South. Only the West was drier with 75% of the normal precipitation.

Abundant snowfalls on the northern edge of the Alps in **Switzerland** were observed on March 23 and 24. A new record for fresh snow (75cm) since measurements started in 1938 was reported from St. Gall.

Austria was very wet with 250 to 300% of the normal precipitation in Vienna and in north-eastern parts of Lower Austria.

March in **Hungary** was a wet month with 158% of the 1961-1990 normal. Monthly temperature and sunshine duration were slightly lower than normal.

In March the mean air temperature in **Slovenia** was close to the 1961–1990 normal and well within the limits of the normal variability. The anomaly ranged mostly between -1 and +1°C. The largest anomaly was recorded from Kočevje, where the temperature was 1.9°C below normal. The first decade of March was colder and the second one was significantly warmer than normal. Maximum air temperatures in the lowlands exceeded 20°C. In the last decade the temperature dropped below normal again. Precipitation in the eastern half of Slovenia exceeded the normal values. About 60% more precipitation than usual fell in the Northeast of Slovenia. In Goriška valley only 38mm fell (37% of the normal). There was no precipitation in the second decade; most of the precipitation was concentrated in the last third of March. The snow depth in the Upper Sava valley was up to 115cm, in Kočevje 57cm, in Ljubljana 41cm. 430cm snow were measured at Kredarica on March 8. No snow cover was observed at the coast, Karst and in the Goriška region. In the western half of Slovenia and Prekmurje the sunshine duration was longer than on the average of the reference period. Especially in the second third of March the sunshine duration was longer than usual, while during the last decade much less sunshine was registered than in the reference period, except in the Goriška region.

The month was characterised as dry to very dry in the whole territory of **Portugal**, except in the northern region and the Algarve, where it was normal. The monthly average mean air temperature and the precipitation amounts were equal or below normal.

March was characterised by intense snowfalls in northern and central **Italy**.

In **Croatia**, the monthly mean temperatures were around normal or slightly below. Precipitation averages were also around normal or locally higher, except the most western region which was very dry. The station Poreč received only 28% of the normal.

Mean temperatures in **Bosnia and Herzegovina** were –0.5°C lower than normal, precipitation was about 120% of the normal on spatial station average.

In **Bulgaria,** March was warm and rather dry. The temperatures were 1 – 2°C above normal. Precipitation was up to 80% of the normal.

Unusual high daily maximum temperatures were measured in **Greece**. Daily maxima above normal were reported over several areas of the country (especially over the mainland) during the end of the second decade of March 2004 (Tab. 3.1).

Station	Location (latitude °N, longitude °E)	Altitude (m)	Maximum temperature on 18 March 2004	Long-term mean monthly maximum temperature	Reference Period
Agrinio	38 37, 21 23	24.0	23	16.9	1956-1997
Arta	39 10, 21 00	11.5	23	16.8	1976-1997
N. Filadelfia (Athens)	38 03, 23 40	136.1	22	15.7	1955-1997

Tab. 3.1: *Maximum daily temperatures (in °C) on 18 March 2004 and mean monthly maximum values*
From: Hellenic National Meteorological Service

Avalanches, floods and severe cold spells were reported on March 5-6 in **Turkey**, e.g. in Erzurum in the eastern part of the country. At the end of the month (March 31) frost returned to Malatya in the central part of Turkey, affecting blossoms of trees.

March was rather warm in **Armenia**; the mean monthly temperature was 2°C above normal. Very high temperatures were measured on March 1-6 and 21-28, when the maxima reached 30-31°C in Syunik valley, 23-28°C in Ararat Valley and Tavush, and 22°C in Yerevan. On March 5-6 stormy wind hit the Northeast of Armenia and the basin of Lake Sevan. The wind speed reached 125-160 km/h. Such strong winds in this region had not been reported during the whole observation period. Roofs of some buildings were blown off; the supply of electricity to some villages was disrupted. The total loss was about 2.5 million €.

The month was the driest March since 1902 in **Cyprus** and the areal average precipitation amounted to 0.8 mm or 1% of the normal. The mean temperature was 2.1°C above the normal value. On March 4-5 suspended dust affected the visibility.

March was warm and very dry in **Israel**. Rainfall amounts were 30-70% of the normal in the central and southern parts of the country. In the North, rainfall amounts reached only 5-20% of the normal, making it one of the driest March months ever recorded – since the beginning of measurements similar or smaller amounts in March were recorded only in 1925 and in 1962. The month was characterised by warm spells especially during its first part. On March 3-4, 34-36°C were measured in the coastal plain and 28-29°C were measured in the mountains. These were the highest temperatures for the first decade of March since 1960.

The lowest minimum temperature in 2004 recorded in **Jordan** was -6.6°C in Shoubak on March 6.

April 2004

- **Extremely warm, especially in northern Europe**
- **Dry in most of Central Europe, Portugal, the north-eastern and eastern parts of the Region, wet in the Northwest and parts of central eastern Europe**

The month was warmer than normal, but wet in **Greenland**.

April was a very favourable month in **Iceland**, amongst the warmest on record. Precipitation in the South was above the average.

The monthly average of the temperature in **Norway** in April was the highest since the Norwegian Meteorological Institute started this time series in 1867. A larger part of the observation stations including Svalbard noted a new record for April. The monthly mean sea surface temperature of the North Sea and the Norwegian Sea was very high too. The weather ship Polarfront, manning station "M" in the Norwegian Sea, noted new April records both for monthly air and sea temperature since 1949. The highest temperature (19.6°C) was measured at Kristiansund airport on April 19 and the lowest (-21.5°C) at Sichajavri on April 1. Precipitation for Norway as a whole was above normal, but there were large regional variations. The highest diurnal precipitation amount (94.4mm) was registered at the station Hovlandsdal in the county of Hordaland on April 14.

In **Sweden** it was especially mild in April when e.g. Östersund in the middle of Sweden set a new mean monthly record with 4.8°C in a series that started 1860.

Monthly precipitation in **Finland** was lower than normal in April 2004. It was the only dry month of that year.

April was warm and sunny in **Estonia**. Sunshine duration set a record in the time series of Tartu with 265 hours. The month was also extremely dry with a mean precipitation of only 10mm. The drought caused several forest fires.

In **Latvia**, April 2004 was the 4th driest April over the last 80 years. Precipitation in parts of the country was about 10 - 20% of the normal, resulting in poor growing conditions after resurgence of vegetation.

April weather was changeable in **Lithuania**: from cool and moist to warm and dry, and vice versa. The monthly mean air temperature of April was 7.1°C (+1.7°C anomaly). April was the sunniest month of the year with a total sunshine duration accumulating to 234 - 294 hours (85 - 110h above normal). Consequently, the monthly precipitation rate was only 57% of the normal, with some stations recording as little as 10%.

As spring was considerably warm in **Denmark**, the beech came into leaf in the last week of April.

April was particularly warm relative to normal in **Ireland**.

Mild airflows during the last two thirds of April caused monthly mean, maximum and minimum temperatures higher than normal in **Belgium**. Sunshine duration, precipitation and mean wind speed were near normal.

April was very warm in the **Netherlands** (10.4°C, normal 8.3°C). Only 5mm of precipitation averaged over the country fell in the period April 11 - 27.

This month was mild, dry and rich of sunshine in **Germany**. The areal mean temperature of the country was 9.3°C (+2.0°C deviation from the 1961-90 normal). For precipitation, the average amount was 40.1mm (-18.2mm or -31.1%). The spatial mean of sunshine duration

was 186.5 hours (+34.2h or +22.5%). A strong thunderstorm on April 22-23 around Cologne caused an interruption of power supply.

April was another warm month in **Poland**. Monthly mean deviations from normal achieved up to +1.6°C in the West. The extreme temperatures ranged from -7.1°C in the Northeast up to +22.4°C in the Southwest. Numerous ground frosts were observed during the entire month. Precipitation varied from less than 50% of the normal in the West up to 260% in central Poland. At the beginning of the month, intensive rainfall, above 30 - 40mm a day, caused high water levels in some rivers.

In April, the mean air temperature in **Slovenia** was slightly above the 1961-1990 normal and well within the limits of the normal variability. The anomaly was mostly less than +1°C; the largest anomaly was less than +1.5°C. In high mountains, at Kredarica, April was 0.8°C warmer than on the average in the reference period. It was mostly the last third of the month which determined the positive temperature anomaly of April. In Črnomelj, Bizeljsko and upper Vipava valley the temperature on April 8 slightly exceeded 25°C. The sunshine duration was lower than on the average in the reference period. Already during the first third of April there was notably less sunny weather than on the average, the second third of April was mostly cloudy, only between 20 and 50% of the usual sunshine duration occurred. In the West and most of the northern part of Slovenia there was less precipitation compared to the normal. In Zgornjesavska valley only 60% of the normal were reached, about 70% of the normal fell in the Goriška region, in Koroška 80% of the normal were reached. In central Slovenia and Bela krajina 50% more precipitation fell than on the average of the reference period. On April 6 and 7 it was snowing even in the lowlands. At Kredarica the snow depth was 465cm on April 7.

In **Croatia**, April was very wet in most parts of the country. Some areas were even extremely wet (Fig. 4.1).

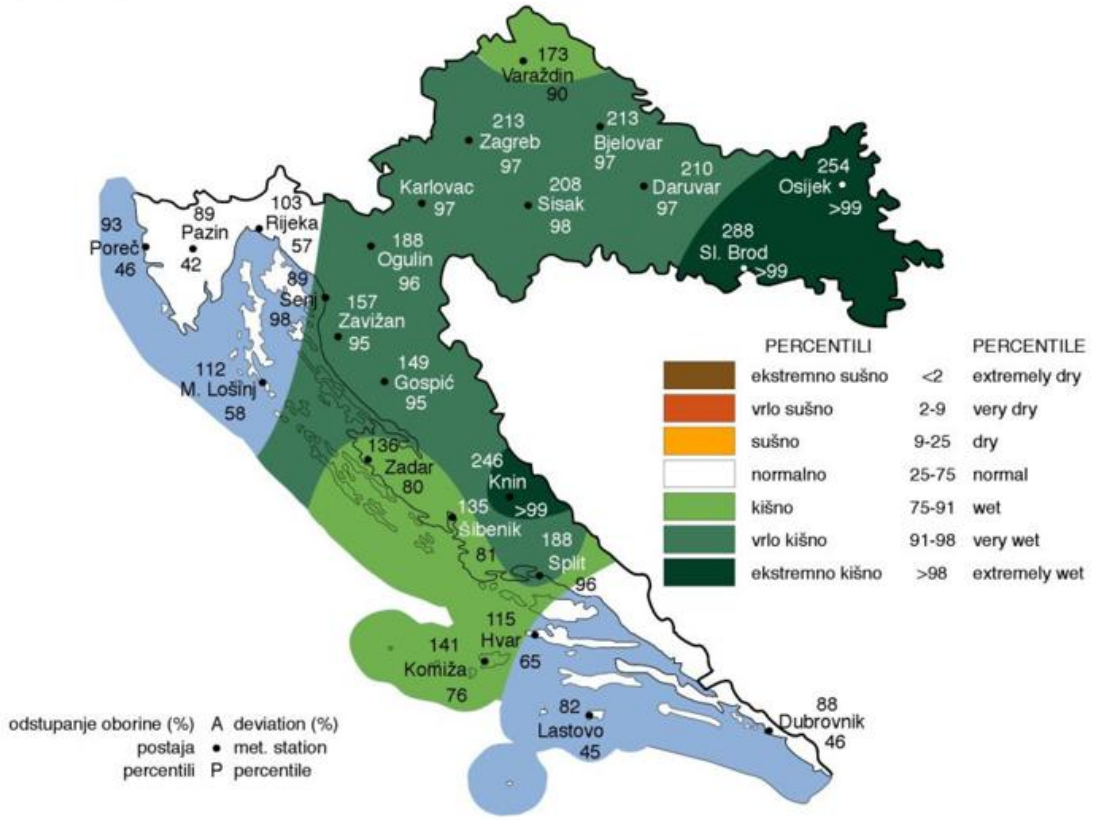

Fig. 4.1: *Monthly precipitation amounts of Croatia in April 2004, expressed as percentage of normal 1961 – 1990 (upper numbers) and percentiles (lower numbers). Blue areas are water areas with precipitation around normal.*
From: Meteorological and Hydrological Service Croatia

In **Bosnia and Herzegovina**, April was warmer than normal with 10.1°C on station average (+1.3°C anomaly with respect to 1971-2000). The precipitation sums were high (158.6mm or 176% of the normal on average), thus, April was the wettest month of the year this time.

The mean temperature of **Romania** was around 10°C on average, slightly higher than the 1961-1990 normal. April was also the beginning of a dry period; the monthly amount was a few mm lower than on long-term average.

April was rather warm and dry in **Bulgaria**. The temperatures were up to 1°C above normal but precipitation was as low as 50% of the normal.

The month was classified as being a dry to extremely dry month in the whole territory of **Portugal**. The monthly mean air temperature was equal or above the 1961-90 normal.

Unusual high daily maximum temperatures were reported over most areas of **Greece** (especially over the mainland) on April 11 (Tab. 4.1).

Station	Location (latitude °N, longitude °E)	Altitude (m)	Maximum daily temperature	Long-term mean monthly maximum temperature	Reference period
Arta	39 10, 21 00	11.5	27	19.7	1976-1997
Adravida	37 55, 21 17	11.1	27	19.2	1959-1997
Pyrgos	37 40, 21 26	12.0	27	19.8	1975-1997
Kastoria	40 27, 21 17	660.0	26	16.6	1980-1997
Naxos	37 06, 25 23	9.0	26	18.6	1955-1997
Spata	37 58, 23 55	67.0	26	18.5	1974-1997
Iraklio	35 20, 25 11	37.0	28	20.0	1955-1997
Mytilini	39 04, 26 36	4.2	28	19.0	1955-1997

Tab. 4.1: *Maximum daily temperatures (in ^{0}C) on 11 April 2004 and long-term mean values*
From: Hellenic National Meteorological Service

Frost and snow occurred in **Turkey** during April 3-5 including Izmir in the western lowlands of the country, damaging vineyards, flowers and trees. On April 21-22 torrential rain and hail was reported from Elazig and Sivas, respectively. However, on monthly average over the whole country, the precipitation amount was with 91% below the 1961-1990 normal.

On April 4-7 an unusual cold wave was observed in **Armenia**, the minimum temperature reached -10°C. A frost duration of 10 -13 hours was reported. As a result of the cold weather and continuous frosts near the surface all fruit trees were damaged in Ararat Valley.

On April 27 suspended dust affected the visibility in **Cyprus**. The month was dry (11.4mm or 38% of the 1961-1990 normal), the temperature mean only slightly above normal (+0.1°C anomaly).

April was dry in **Israel** with temperatures close to normal. There were some Sharav events but temperatures were not extreme.

Heat waves passed over **Jordan** in April 2004 (12, 13, 14 and 26, 27, 28) where the maximum temperature was 5°C above normal.

May 2004

- **Warm in the North and West, especially at the beginning of the month, cold in most of the East and the Mediterranean**
- **Snow in Scandinavia in late May**
- **Mostly wet, but dry in western Europe and in the Baltic countries**
- **Two extreme Sharav events in Israel**

In **Greenland,** May was fairly dry and mostly warmer than normal.

The first half of May was rather cold in **Iceland**, but the second half was warm and favourable.

The mean temperature of the month in **Norway** was above normal in most parts of the country, but the month was characterised by great variations in temperature. In the first week very high temperatures occurred, leading to flooding in rivers in southern Norway. Thereafter very low temperatures prevailed. Record low minimum temperatures for May occurred in the county of Vestfold. Parts of the counties of Oppland, Møre og Romsdal, Sogn og Fjordane and Sør-Trøndelag experienced one of the wettest May months ever with 250 - 400% of the normal for the month. The station Tafjord in Møre og Romsdal registered a new record maximum for May. Orkdal - Øyum measured the highest temperature this month with 26.6°C on May 6 and Sognefjellhytta the lowest with -13.2°C on May 23. Some stations in southern Norway received 20-25cm snow on May 21 and 22 which are quite unusual so late in May. The highest diurnal precipitation amount (123.1mm) was measured at the station Øvstedal in the county of Hordaland on May 19.

In **Sweden,** the latter half of May was chilly and wet.

In early May an exceptionally warm period lasted for about one week in **Finland**. The number of sunshine hours was generally lower than normal.

A relatively warm beginning of the month came to an end on May 13 when it snowed in **Estonia**.

The first decade of May in **Latvia** was the 3rd warmest of all first May decades in the last 80 years. New maximum temperature records for individual days were set this year on May 5 and 8; new minimum individual day records were set on May 13, 14, 17, 18 and 22. The very warm first decade of May gave poor growing conditions after resurgence of vegetation. Further serious problems were experienced with crops due to widespread strong air and ground frosts in the second decade. These weather conditions caused devastation of about 22 300 hectares of grain, rape, grass, potatoes and vegetables.

The beginning of May in **Lithuania** was influenced by southern airflows causing warm weather with a rise of air temperature to maximum values of 22 – 28°C, but later an eastward motion of Atlantic cyclones cooled the air down. As many as 18 nights of the month ended with morning frosts, resulting in a decrease of the minimum air temperature down to between -1 and -4°C and to between -7 and –9°C on the soil surface. The monthly mean air temperature anomaly was -1.3°C. Morning frosts damaged fruit trees and shrubs as well as gardens and crops. The May weather was predominantly overcast with little precipitation. The mean monthly precipitation accumulated to 44mm, these were 85% of the normal with even lower values at some locations.

In **Denmark,** there was occasionally cold weather; on May 22 snow and sleet fell locally.

May was particularly warm and one of the driest months of the year in **Ireland** relative to normal.

In the **Netherlands,** only 4mm precipitation fell from May 8 to 29, the mean temperature was below normal.

In **Belgium**, alternating mild and polar flows led to a temperature average near normal. The monthly precipitation amount in Uccle was 40.8mm (66% of the normal). Also the mean wind speed had an outstanding deficit.

A small negative mean temperature anomaly (-0.2°C) was noted in **Luxembourg**, but no frost was observed this May. The monthly precipitation was 86% of the normal.

The month was slightly cooler than in the reference period 1961-90 in **Germany**, precipitation reached nearly exactly the normal values, and small sunshine deficits resulted. However, there were rather large regional differences especially in precipitation. While the Northwest was very dry, large precipitation surpluses resulted in parts of eastern Germany. Due to a thunderstorm with strong gusts on May 10, houses in the region of Saxony were untiled. The mean temperature for Germany was 11.6°C. This was 0.5°C below the values for the reference period 1961-90. The average amount of precipitation was 72.3mm (1.2mm or 1.8% more than in the reference period). The spatial mean of sunshine duration was 180.0 hours (15.7 h or 8.0% below the normal).

May 2004 was one of the coldest months in **Poland** for the last 38 years and much wetter than the corresponding 1971-2000 normal. The mean monthly departures from normal were -1 to -2°C. The second and third decades were very cold with frequent ground frosts leading to crop damage. Precipitation was very intensive, especially in the first half of May, with downpours exceeding 40mm a day.

Heavy snowfall on May 5-6 on the northern comb of the Alps was observed in **Switzerland**, resulting in a fresh snow depth of 100 - 150cm at higher altitudes and partly causing severe avalanches.

It was a cold month in **Hungary** (-1.4°C anomaly). The monthly precipitation amount reached 84% of the normal.

In **Slovenia,** the mean air temperature in May was slightly below the 1961-1990 normal. Only in Bela Krajina the anomaly was slightly positive. In high mountains, at Kredarica, May was 1.1°C colder than normal. It was during the first third of May that mostly cloudy weather prevailed; the rest of the month was sunnier than on long-term average. Precipitation was abundant in Upper Soča valley; regions with modest precipitation were Prekmurje and Štajerska. At Kredarica on May 8 the snow depth was 435cm.

Most parts of **Croatia** were 1-2°C colder than normal (1961-1990) on monthly average. The precipitation anomaly distribution was very variable this month from 26% of the normal in the North up to 197% in the Southeast (Dubrovnik).

The monthly mean temperature for an average of 12 stations in **Bosnia and Herzegovina** was 13.1°C, which is 0.8°C colder than the long-term mean 1971-2000. The precipitation amount was slightly higher than normal (108% of the normal or 92.5mm).

May was also colder than average in **Serbia and Montenegro,** by 1.3 to 2.4°C (Fig. 5.1). In mountainous areas, frost was recorded, e.g. 9 frost days at Kopaonik (average: 5).

Widespread strong thunderstorms with heavy rain showers and strong wind gusts occurred in **Bulgaria** on May 10. Hailstorms with a reported hail size up to 3cm caused heavy damage on crops (up to 60-70%). On average, May was relatively cold and wet. The temperatures were 1 – 2°C below normal. The north-east region was the wettest with precipitation up to 250% of the normal while the Southwest was rather dry with only 50% of the normal.

May was characterised by a mean maximum temperature up to 2.5°C below normal in **Albania**. The mean minimum temperature in general had a negative deviation in May (-2.3°C); in the north-eastern and eastern part of the country -5.1°C were recorded.

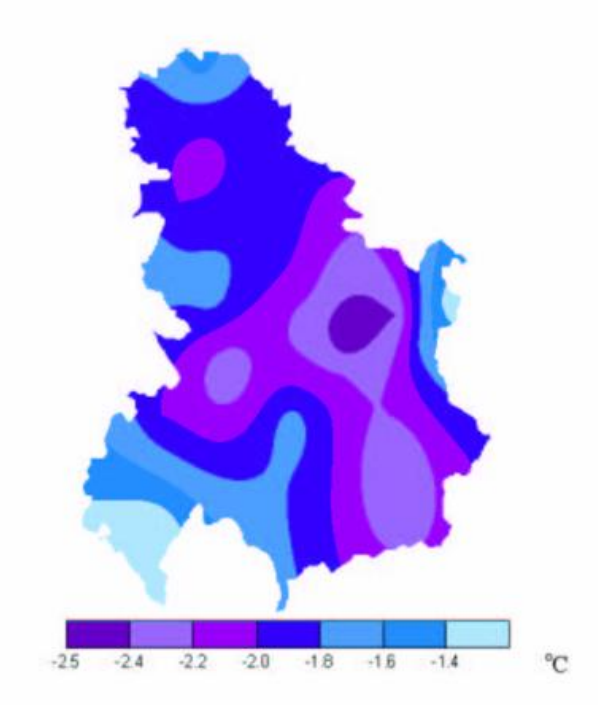

Fig. 5.1:
Deviation of mean temperatures in May 2004 against the normal 1961-1990 in Serbia and Montenegro
From: Republic Hydrometeorological Service of Serbia

The monthly mean temperature of May for Shtip, **Republic of Macedonia** was -2°C below normal representing the sixth lowest value in the time series starting 1926. Similar anomalies were reported in other parts of the territory of the Republic of Macedonia.

In **Portugal,** temperature in May was equal or above normal. The precipitation amounts were below normal in almost every coastal region and equal or above the average in the other regions.

Hail was reported in **Turkey** in the beginning of the month (May 2-3 in Beysehir, Konya, and Karaman) and at the end (May 29 in Kutahya). Rain and floods affecting crops were observed in Merzifon and Amasya. The monthly averages of precipitation and temperature were near normal. On May 20, late frosts with damage on vegetables occurred in Urgup and Nevsehir.

In May the mean monthly temperature was about normal in **Armenia,** in some regions it was above normal by 1°C.

On May 10 - 11 suspended dust affected the visibility in **Cyprus**. Only 3.9mm precipitation fell this month, these were 20% of the 1961-1990 average. The mean temperature was near normal (-0.1°C).

May was slightly cooler than normal in **Israel**, yet two extreme Sharav events occurred. On May 6, 38 - 39°C were recorded in the coastal plain and in the Negev. A Sharav occurred also on May 9 with an interesting phenomenon during the night (May 9 - 10). Towards midnight there was a severe warming with temperatures rising more than 10°C within 30 minutes, reaching 34 - 36°C in the central coastal plain at 00:00 - 03:00 a.m. In the last 40 years there were only two occasions with similar temperatures at night. Temperatures dropped later but rose again during the morning, reaching a maximum of 40 - 42°C in the coastal plain and in the Negev, and 43 - 45°C in the Jordan Valley.

June 2004

- **Warm in Iceland, France, Slovenia and the Iberian peninsula, cold in most of Scandinavia, the Northeast and parts of the East of the Region**
- **Dry in most parts of western Europe, wet in most of the North, the Alps and some countries of the East**
- **Strong hail and tornadoes in Central and eastern Europe**

In **Greenland,** June was mostly warmer than normal.

June was warm and favourable in **Iceland**.

The monthly mean temperature was below normal in most parts of **Norway**. Only the eastern and northern part of Finnmark and Svalbard had temperatures above normal. The maximum temperature of the month (25.5°C) was measured at Lærdal - Moldo on June 2 while Sognefjellhytta in the same county (Sogn og Fjordane) registered the lowest temperature (-4.2°C) on June 16. Some locations in southern Norway and in the county of Nordland received more precipitation than usual. Parts of the county of Møre og Romsdal experienced one of the wettest Junes with 200-250% of the normal. Sundsfjord in the county of Nordland measured 113.5mm as the highest diurnal precipitation amount on June 15.

In **Sweden,** the chilly and wet weather continued in June.

The number of sunshine hours in **Finland** was generally lower than normal.

June in **Estonia** was the wettest since 1998. Two tornadoes were reported in the central part of Estonia.

In **Latvia** it was the 10th wettest June for the last 80 years.

June weather in **Lithuania** was comparatively cool while being predominantly dry in the first half of the month and rainy in the second one. It was the coldest month of the summer, with a mean air temperature of 13.9°C (-1.5°C anomaly). Morning frosts persisted as long as until June 18. In total, morning frosts in June caused damage to agriculture (horticulture) amounting to some 5.5 million €. Due to persistently dry weather, the forests in the north-eastern regions encountered increasing fire danger until June 11, when it started raining almost daily. The total amount of precipitation was very uneven and varied from 44 to 182mm (70 to 180% of the monthly normal).

Cork Airport in **Ireland** measured 16 hours of sunshine on June 15, the highest daily value of the year and the highest value at the station since it opened in 1962.

The highest temperature in 2004 in the **United Kingdom** was 31.5°C at Cambridge on June 8.

The summer started a bit chilly in June in **Denmark** with a few days with clear sky and sunshine, but from June 18 the weather was constantly unstable for 5 weeks and rather chilly for the season.

June was warmer than normal in Uccle, **Belgium**, by 0.8°C. It was the first in a series of wet summer months; the monthly precipitation amount of this station was 78.4 mm, which was about normal.

The temperature anomaly for **Luxembourg** (1971-2000 normal) was 0.6°C. A maximum of 30.1°C was reached on June 9 which also marked the only hot day (maximum >30°C) this month. Only little precipitation fell: 43.1mm or 54% of the normal.

In **France** the monthly mean temperature was approximately 1.5°C above normal, designating June as the month with the largest anomaly of the year.

It was a bit too dry in **Germany** and sunshine duration was slightly less than normal. The mean temperature for Germany was 15.3°C, only 0.1°C below the values for the reference period 1961-90. The average amount of precipitation was 72.6mm which was 12.0mm or 14% below normal. On June 9 and 10 there were strong thunderstorms in northern and western Germany with hail and local daily precipitation of more than 30mm. A storm on June 23-24 with gusts up to 110km/h occurred in the mountains. 3 tornadoes were observed on June 23, all in northern Germany. The spatial mean of sunshine duration was 187.4h. This was 10.8 h or 5.4% less than in the reference period.

The mean temperature in June in **Poland** was lower than the 1971-2000 normal by about 1°C. Only the south-western region was slightly warmer. Ground frosts were still observed in the North. The minimum temperature fell to +1.1°C in north-eastern Poland. It was also a rainy month: 23 days with precipitation occurred on country average (120-130% of the normal). The most intensive rains, above 40mm a day, with storms, were observed in the South.

A tornado of F3 intensity according to the Fujita scale occurred on June 9 in Litovel, in the northern part of the **Czech Republic**. It was connected with a mesoscale convective system that was moving from northern Germany across the north-eastern part of the Czech Republic to Slovakia. This tornado caused extraordinary damage on parts of Litovel town, destroyed tens of houses and rooted up many trees. Many electricity lines were broken off, one man was killed. The cost of this damage was about 3.5 million€.

Large damage was caused by an extremely well developed supercell with strong wind and hail on June 9 in the south-western part of **Slovakia**.

Heavy rain occurred in the catchment-basin of the river Aare in **Switzerland** on the northern slope of the Alps from June 1 to 5; the village of Marbach (canton of Lucerne) received 103.5mm during the period beginning in the morning of June 1 and ending in the morning of June 2. This caused local inundations. At certain locations the highest precipitation quantities since 1901 were measured over 2, 3 and 5 days respectively. Only very few thunderstorms occurred in June in the South of Switzerland (region of Sottoceneri in the Canton of Ticino). It was the driest month of June in this region since records started in 1864.

In **Austria** the month was wet with 150 to 250 percent of the normal precipitation in the South and East. In the morning of June 11 thunderstorms with heavy precipitation caused damage in Upper Austria. Within the district of Braunau the communities Esternberg and St. Veit suffered from flooding. In the towns Linz and Wels a lot of cellars and underpasses were flooded, too. Later, in the evening, precipitation events caused floods in the most eastern regions of Austria. In the county Burgenland several communities of the southern districts Oberwart and Güssing were affected by floods. At the same time hailstones with the size of hens' eggs caused enormous damage to crops in the district Deutschlandsberg, south of Styria. On June 20 another heavy hailstorm occurred in Styria, causing total crop losses on the agricultural areas in the districts Weiz and Fürstenfeld. Simultaneously heavy precipitation resulted in several landslides in Carinthia. Streets were spilled in the valley of the river Lavant; districts of the capital Klagenfurt were flooded. Thunderstorms and heavy precipitation events on June 28 again caused enormous damage in Styria. Hailstones completely destroyed agricultural areas southwest of the capital Graz.

On June 9 a heavy storm rushed through **Hungary** causing one death in Budapest. Several villages suffered from the lack of electricity; trees, traffic sign boards, roofs were torn up by the strong winds (max. wind speed: 116km/h, Budapest). In Miskolc heavy hail contained egg-sized pieces. Averaged over the country, 127% of the normal precipitation fell. The monthly mean temperature was near normal (-0.1°C).

In **Slovenia,** the monthly mean air temperature was slightly above the 1961–1990 normal. In high mountains, at Kredarica, June was 0.9°C warmer than normal. The Primorska region

got about 10% more sunshine than normal, elsewhere the sunshine duration was below normal. At the coast not even one half of the average precipitation fell, but in Koroška, Goriško and Maribor the usual precipitation amount was almost doubled. In the Štajerska region thunderstorms were quite frequent; 12 days with thunderstorm or thunder were registered. At Kredarica the snow depth was 290cm on June 1.

In **Portugal,** the year 2004 was characterised by a very warm June, with air temperature values well above the 1961-90 normal (Fig. 6.1). Values of maximum, minimum and mean air temperatures were the highest since 1931. It was dry to extremely dry in the whole territory.

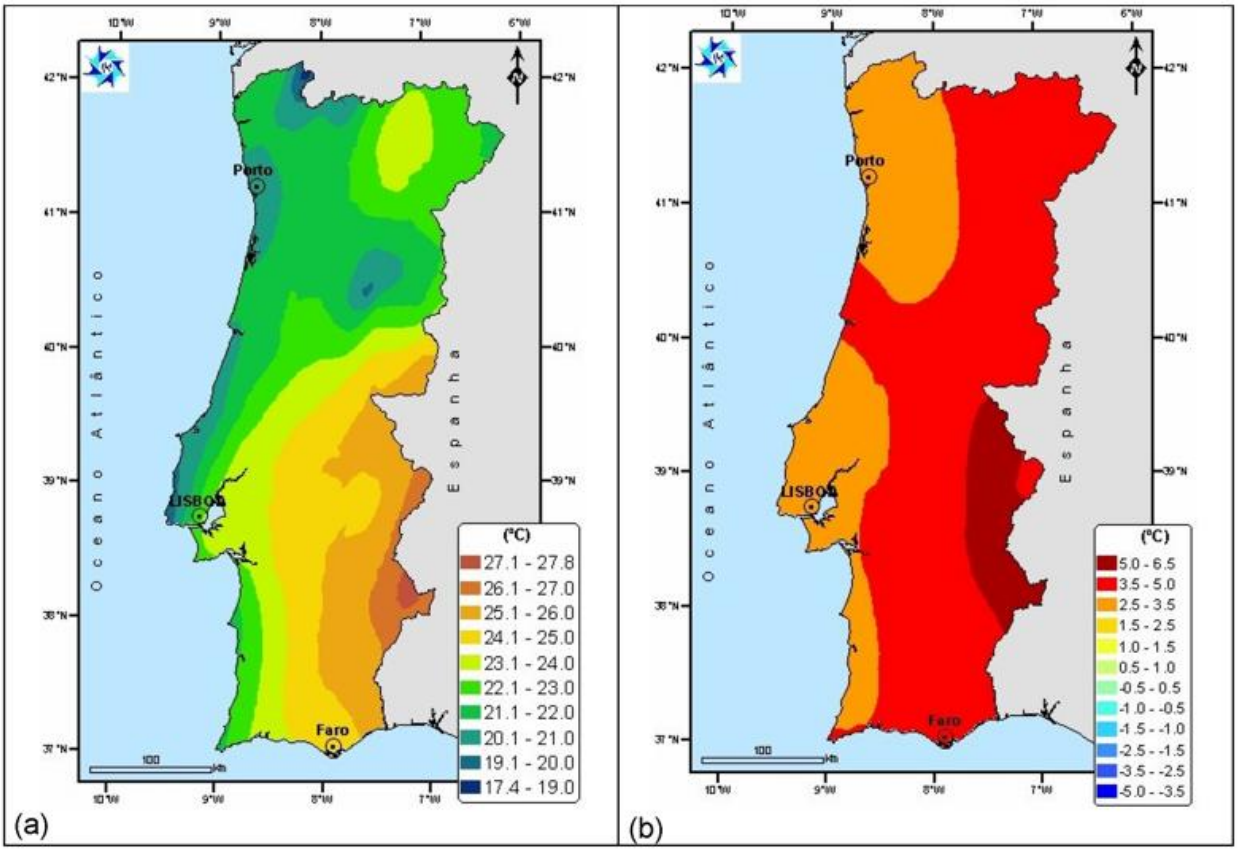

Fig. 6.1: *Spatial variability of mean air temperature in Mainland Portugal in June 2004 (a) and anomalies with respect to the 1961 – 1990 normal (b)*
From: Instituto de Meteorologia Portugal

June was very warm all over continental **Spain** and some of the Canary Islands. However, in most cases it was not so extreme like the June of 2003, especially regarding the persistence of the heat. Nonetheless new records in mean values were set in Galicia, Extremadura and Western Andalucía at around 20% of the observing stations. As an outstanding example at Badajoz the mean value was 1.5°C higher than the previous one for that station. As for mean and minimum mean temperatures the percentage of stations reporting new records was around 15%. The warmest days were concentrated in the period between June 23 and 29, giving new records of absolute maximum temperature for the month at several stations (for example at Madrid – Retiro: 38.4°C on June 29 which is 0.3°C above the previous record).

It was warm in the coastal region of **Croatia** (anomaly between +0.5 and +1.0° compared to 1961-1990), whereas upcountry the mean temperature was near normal.

In **Bosnia and Herzegovina**, the monthly mean temperature was 0.6°C above the 1971-2000 normal. Also the precipitation amount of 96mm on station average was slightly above normal (103%).

Heavy rain caused flash floods during the night of June 5 in **Republic of Macedonia**. Disasters were caused by a south-western outbreak of cold air over the southern and a small north-western part of the country. The floods affected particularly the southern region (Gevgelija, Strumica, Valandovo, Dojran and all the villages). Heavy precipitation was registered from 07.00 until 19.00 h on June 4 and from 01.00 until 07.0 0h on June 5. The daily amount of precipitation in Gevgelija was 201mm on June 5 which corresponds to 350% of the normal 1961/90 for June. The adverse weather caused flooding of all rivers in this region, it damaged more then 20 bridges and dams, railroad tracks and roads, flooded agricultural land and many houses, interrupted the electric power lines, water pipes and phone connections.

On June 21-22, thunderstorm and hailstorm activity was observed in most of **Bulgaria** with heavy rain showers and hail with the size of eggs or even baseballs. The most severe damage was registered in northern Bulgaria. Floods occurred in dense populated urban areas like the cities of Sofia and Varna. On June 29, another severe thunderstorm hit the capital city of Sofia with a heavy rain shower (22mm) and strong wind gusts up to 65km/h. The rain caused floods on the streets in the city centre and in the suburbs as well as in the building of the National Assembly. Trees were uprooted and the public transport system was affected. The thunderstorm caused delays at the Sofia airport. On monthly average, June was normal in terms of temperatures and rather wet. The south-western region was the wettest with up to 280% of the normal.

Unusual heavy rain and thunderstorms occurred on June 5 over the east-central mainland of **Greece**. These thunderstorms resulted in floods in the area of eastern Thessalia, particularly in Volos city, with destructive results on roads, shops and houses, and on agriculture. June 2004 (particularly the first decade) was in general a month with increased thunderstorm activity over the North and central mainland part of Greece. The June 2004 rainfall and the corresponding mean values are shown in Tab. 6.1.

Station	Location (latitude °N, longitude °E)	Altitude (m)	Monthly rainfall for June 2004 (in mm)	Monthly long-term mean rainfall for June (in mm)	Reference period
Serres	41 05, 23 34	34.0	42.9	40.7	1971-1997
Trikala Imathias	40 36, 22 33	0.8	36.0	29.7	1980-1997

Tab. 6.1: *Monthly rainfall heights for June 2004 and long-term mean values*
From: Hellenic National Meteorological Service

Hail damage was reported in **Turkey** on June 5 (Kastamonu), 6 (Merzifon/Amasya), and 16 (Malatya). In addition, strong rain and floods were observed on June 11 (Trabzon), 19 (Kocaeli), and 23 (Goztepe/Istanbul). Late frost occurred at Devrekani/Kastamonu on June 11.

In June the mean monthly temperature in **Armenia** was in general normal; in some regions it was higher than normal by 1°C. One fatality, three injuries due to lightning were reported.

June was cooler than normal in **Israel**, and in the coastal plain it was the coldest June in the last 8 - 10 years.

July 2004

- **Mostly warm, cold in Greenland, Ireland and parts of northern, central and eastern Europe**
- **Dry in most parts of the Mediterranean and Portugal, wet in some parts of central and northern Europe and in the East, occasionally with flooding and hail**

In the **Arctic**, the highest maximum temperature was measured at Bjørnøya with 22.8°C on July 27. This is a new record for July at Bjørnøya. The earlier maximum for July was 22.4°C in 1972.

The highest temperature in 2004 in Nuuk, **Greenland,** was 18.2°C, registered on July 23 during a foehn situation.

In **Iceland**, the July was warm and favourable.

The monthly average of mean temperature was below normal in the southern part of **Norway**, near the normal in the counties of Møre og Romsdal and Trøndelag, and above normal in the county of Nordland and northwards. In the eastern parts of Finnmark the monthly average was 4-5°C above normal. Rustefjelbma and Alta Airport had the highest values both with 17.1°C (4.8°C and 3.7°C above normal). For the larger part of Finnmark and Troms this was the fourth warmest July since 1900. The lowest monthly temperature average was recorded at mountain stations in southern Norway. Sognefjellhytta was coldest with 6°C (0.3°C above normal). The highest maximum temperature (28.8°C) was measured at Nordreisa - Øyeng on July 25 while the lowest minimum temperature (-3.6°C) was registered at Hovden – Lundane on July 8. This was the lowest minimum for July for the county of Aust-Agder. In most parts of the county Troms and some areas in Oppland and Nordland the precipitation was markedly above normal. In the rest of the country the precipitation was below normal. The highest diurnal amount of precipitation (57.8mm) was measured at the station Grunnfarnes in the county of Nordland on July 21.

The chilly and wet weather in **Sweden** continued into July. During the four days July 9-12 about 180mm fell in parts of central Småland with widespread flooding as a result. Hundreds of roads had to be closed for traffic. In some rivers the discharge rose to levels that were estimated to have return periods of some hundreds of years. A canoe tourist drowned in one of the swollen streams. Also the northernmost part of the country and more precisely the Kebnekaise area got very heavy rain on July 20-21 and a landslide disrupted the northernmost road to Norway.

Large areas in southern and central **Finland** experienced very heavy rainfall, particularly in the last week of July. The largest daily precipitation of 122mm was measured in eastern Finland on July 28. Due to the heavy rainfall the water level in many lakes and rivers was high; this caused flooding of some southern Finland rivers and thus economical losses in many buildings and households. The monthly precipitation in July amounted to 200-246mm at some locations and the return period of these high values is longer than 100 years. High precipitation resulted in big problems for agriculture as the harvesting was difficult due to wet fields. The number of sunshine hours in July was generally lower than normal. In Lapland, July was exceptionally warm.

July was outstanding because of torrential rain in Tallinn, capital of **Estonia** (145mm in three days, monthly mean - 79mm). There were also many thunderstorms, and a tornado was reported.

The month was cool and rainy in **Lithuania**. The monthly mean air temperature was 0.2°C below normal. The month had only 6 days without rain. Precipitation was not abundant except isolated heavy rainfall. On July 22, one such downpour in Biržai amounted to 56mm

in 3 hours. The water flooded lowlands and streets; crops were damaged. On July 11, some locations encountered severe hail with 20mm large hailstones smashing about 50 hectares of crops. The monthly amount of precipitation was close to normal at many places, while reaching 50 – 70% of the normal in some western and eastern regions. Thunderstorms, occasionally related with squall lines, were reported on 13 days of the month. The sunshine duration was 25 – 40 hours below normal.

July 2004 was one of the only two months in 2004 which was colder than normal in **Ireland**.

Wittering, Cambridgeshire, **United Kingdom**, recorded 107.4mm of rainfall in 19 hours on July 7-8, with a return period of about 150 years.

In **Denmark**, the chilly and unstable weather continued at first, but at the end of July three weeks of warm, dry and sunny weather began.

In the **Netherlands**, 50mm of precipitation or more were registered on two days in July.

No high temperature deviations from normal were to be found in **Belgium**. The mean temperature at Uccle (17.4°C) was 0.2°C higher than normal. The precipitation amount, however, reached 112.4 mm, which were 151% of the long-term mean.

July was 0.3°C colder than the 1971-2000 normal in **Luxembourg**. The temperature maxima did not exceed 30°C. For precipitation, the monthly sum (68.9mm) was slightly below normal (96%).

The areal precipitation average of **Germany** in July reached 104.0 mm, exceeding the 1961-90 normal considerably (+26.4 mm or +34.0%). This was due to some exceptional thunderstorms: On July 7-8 there was a first thunderstorm with strong precipitation, partly with hail in south-western and central Germany. Around Freiburg/Breisgau and near the lake Bodensee, pigeon egg sized hail grains were observed for 15 minutes. One day later a second thunderstorm with strong rain occurred in the North and East of Germany; 75mm were measured at the station Zinnwald-Georgenfeld, 67mm of this amount fell during one hour. A third violent thunderstorm came on July 18-19, accompanied by a tornado near Duisburg in western Germany. The mean temperature (16.7°C) was near normal, only 0.2°C below. Also the spatial monthly mean of sunshine duration was below normal (196.5h, -12.3h or -5.9%).

July was a further cool month in 2004 in **Poland**. The mean temperature was generally 1°C lower than normal, only in the Southeast it was warmer (0.6°C above normal). The weather in July was very variable throughout the month and within the country. The maximum temperature measured was +33.9°C, the minimum only +7.2°C. Precipitation reached 170%, but the central part of the country was rather dry – only 50% of the normal precipitation occurred in that region. Mixed rain and snow were observed in mid-July in the Tatry Mountains which is a rather rare phenomenon in this month. The southeast region was partially flooded. In July storms with torrential rain and gusts occurred numerous times in various regions of Poland causing damage to buildings and forests.

A significant regional flood occurred after long-lasting abundant precipitation from July 26 to 30 in the eastern part of **Slovakia**. In the most affected areas the 5-day sum of precipitation exceeded 200mm (maximum of the last 54-year period). The water levels of Ondava, Topľa, Hornád and Torysa rivers in the middle parts of their catchments were near to historical records. The costs of damage by floods on property of citizens, municipalities and government were estimated to more than 5 million €.

A severe hail storm north of the Alps in **Switzerland** occurred on July 8. A 40km wide hail zone extended to the whole lowlands from the Lake of Geneva in the Southwest to the Lake of Constance in the Northeast. The sum of insured damage amounted to around 100 million Euro.

Thunderstorms with hail were observed on July 6 in Styria, **Austria**. There were devastations in the district of Radkersburg (along the border to Slovenia). Heavy precipitation events on July 19 and 22 caused destruction in Carinthia, twice within the same area, Metnitztal, in the

district St. Veit an der Glan. Fields, meadows and streets were spilled with rocks, earth masses and water; one bridge and five kilometres of the roadway were destroyed.

In July, the mean air temperature in **Slovenia** was slightly above the 1961–1990 normal. In the high mountains at Kredarica July was 0.5°C warmer than on average in the reference period. The sunshine duration in the Primorska region was about 10% higher than normal; in Prekmurje only 90% of the normal were reached. Precipitation was most abundant in the Julian Alps and Kamniško-Savinjske Alpe, while in Prekmurje, Karst and Vipava valley precipitation was modest. Also some severe thunderstorms with hail occurred in July causing locally significant damage. At Kredarica on July 1 the snow depth was 30cm.

In **Hungary**, an absolute maximum of 37.2°C was registered at Körösszakál on July 9. Between July 26 and 28, 60-110mm precipitation poured into the eastern part of Hungary, which is to be regarded as exceptional. On monthly average, however, the precipitation amount was only slightly above normal (105%), the mean temperature as well (+0.4°C).

Especially the coastal region of **Croatia** was very warm this month (departure from 1961-1990 mean around +1.5°C). Up to the Northeast, the anomalies were smaller, but also mostly positive. Some areas of the country were quite dry. At Split, only 4% of the normal precipitation fell this month.

Many stations in **Bosnia and Herzegovina** had a monthly mean temperature around 20°C which was 0.9°C warmer than the 1971-2000 normal. Also the average precipitation amount (86mm) exceeded the normal by a factor of 109%.

Mean monthly temperatures in **Serbia and Montenegro** were close to normal, but there were some remarkable characteristics this month: high temperatures in the first third of the month, then a sudden drop of temperature on July 10 (maximum and minimum temperature decreased by 10°C within two days), then again high temperatures until July 25, and around the end of the month a breakthrough of considerably colder air and a drop of maximum temperatures by 15°C within two days. Although the maximum temperature often exceeded 30°C, absolute record maxima were not reached. Considerable quantities of precipitation were measured around the end of the month (starting on July 26). Rain fell almost every day. Total monthly precipitation quantities higher than normal were registered in the far north of the country, in western and south-western parts and also in the area of Beograd, Leskovac and Smederevska Palanka. In the area of Negotin and Crni Vrh as well as in the coastal part of Montenegro, precipitation quantities were lower than average.

The highest maximum temperature of the year in **Romania** was 40.0°C, recorded in southern Romania, at Turnu Magurele, on July 10.

On July 11, there were widespread hailstorms in **Bulgaria** with hail as big as eggs. Damage was reported in 8 of 28 administrative regions in the country. The highest precipitation amount registered in an urban area for this stormy day was in Sliven (50mm). On July 24, there was thunderstorm and hailstorm activity mainly in the eastern half of the country with heavy downpours and strong wind gusts. Reported damage concerned, for example, smashed cars by uprooted trees, street floods and inundated houses in the urban areas of Varna and Dobrich. The harbour of Varna was closed and ships were in emergency in the bay of Varna. The monthly mean temperature anomaly of July was between -0.5°C and +0.5°C, the spatial average of precipitation was about normal. However, the precipitation had a very irregular pattern – from 20% to 330% of the normal all around the country.

For July, usually one of the driest months in **Albania**, precipitation values several times higher than the long-term average were registered.

The period July 23 - 27 was extremely hot in **Portugal**, especially in the southern regions with temperatures reaching 40°C. Record values of both maximum and minimum temperatures were exceeded in this period at some stations in the South. The mean air temperature was in general above normal. The Algarve was one of the most affected regions. For example in Faro, on July 25 and 26 the maximum temperature was 44.3°C and 41.7°C, respectively, exceeding the previous maximum of 39.8°C (August 2003). At this

station, the maximum temperature never was higher than 40°C since 1921. In Faro the minimum temperature of 32.0°C on July 26 was the highest minimum temperature ever recorded in Mainland Portugal, it also exceeded the previous maximum of 30.7°C (August 2003, at another station). July was also characterised by precipitation sums below the 1961-1990 normal in the whole country.

The only summer heat wave episode in **Greece** was recorded on July 10-12 over several areas of the country, especially over the mainland. The maximum daily temperature reached 38-41°C. The recorded maximum temperatures and the corresponding mean values are listed in Tab. 7.1.

Station	Location (latitude °N, longitude °E)	Altitude (m)	Daily maximum temperature	Date	Mean monthly maximum temperature	Reference period

Tab. 7.1: *Maximum temperatures (in °C) on 10-12 July 2004 compared with mean maxima of reference periods*
From: Hellenic National Meteorological Service

In **Turkey,** hail events occurred on July 16 (Urgup, Nevsehir) and 18 (Ardahan), causing damage to vegetable gardens and crops.

July in **Israel** was warmer than normal, which makes it the tenth July in succession that is warmer than normal. However, July 2004 was not as extreme as July 2000 and July 2002. The hottest period was during the first part of the month with temperatures reaching 39-41°C in the Negev and 43-45°C in the Jordan Valley.

In **Jordan,** the highest maximum temperature recorded at Amman was 39.6°C on July 6 and 44.1°C at Aqaba on July15.

August 2004

- **Warm in nearly the whole Region**
- **Mostly wet, but dry in the Mediterranean**

Bjørnøya in the **Arctic** measured the highest diurnal precipitation of the Norwegian arctic stations with 39.4mm on August 21. This was the highest diurnal precipitation registered at this site in August since measurements started in 1920.

August was warm and favourable in **Iceland**. There was a memorable and unusual heat wave in the second week of August. The heat was especially prominent in the southern and western districts, but also in the interior of the country. Maximum temperature records were broken at many stations, e.g. in Reykjavík, where the temperature reached 24.8°C on August 11, which was the highest-ever registered maximum there. The heat wave lasted for many days and the temperature in Reykjavik rose above 20°C on four consecutive days. This did not happen before since the start of continuous observations in 1870. The highest temperature in the whole country was measured at Egilsstaðir in the eastern inland on August 11, 29.2°C, setting a new record for the country in August which was only slightly lower than the absolute record for Iceland (30.5°C). August 2004 on monthly average was the second warmest on record (only August 2003 had been warmer) and almost 1°C warmer than July 2004, which was highly unusual. Heavy precipitation preceded the heat wave in the south-eastern part of the country, with some local flooding. Elsewhere the month was sunny, generally the sunniest August since 1960. In Akureyri, August 2004 was the sunniest on record.

The highest temperature registered in 2004 in Tórshavn on the **Faroe Islands** was 20°C (August 10). August as a whole was very dry with a surplus of sunshine.

The monthly mean temperature in **Norway** was well above normal for the whole country. In parts of western Norway the mean temperature was 3°C or more above normal. The highest monthly mean was registered around the Oslofjord. Færder Fyr was the warmest station with 18.2°C (2°C above normal). The lowest monthly temperature was registered in the mountains in southern Norway and in the coastal areas of the county of Finnmark. Sognefjellhytta was coldest with 8.7°C (3.3°C above normal), followed by Finsevatn 9.6°C (+2.8°C) and Slettnes Lighthouse 10.5°C (+1.3°C). The highest country-wide maximum (32.4°C) was measured at Vossevangen (western Norway) on August 11. The lowest temperature (-3.2°C) was observed at Hovden – Lundane on August 24. The monthly precipitation for Norway as a whole was 111% of the normal, in some parts of southern Norway even 200-250%. The station Konsmo – Høyland in this area received 348mm which is the second highest monthly amount for August at this station since 1951. In contrast, the county of Nord-Trøndelag registered only 20-70% of the normal. The station Saltdal in the county of Nordland had only 12mm (40% of the normal). Some stations of the county Aust-Agder and Bear Island received the highest diurnal precipitation amount ever measured in August. The highest diurnal precipitation (95.0mm) was recorded at the station Hundseid i Vikedal in the county of Rogaland on August 20.

In **Sweden**, on August 4 exceptional heavy thunderstorms caused flooding and landslides close to Hagfors in the province of Värmland. Some villages were isolated for 2-3 days and a car fell into a new, deep ravine but nobody was seriously hurt. The second largest daily rainfall at an official meteorological station in Sweden with 189mm was measured in Råda close to Hagfors also on August 4. Private measurements registered around 210mm slightly south of Råda. The estimated costs for road authorities were at least 15 million Swedish crowns (1.6 million €) both in Småland and Värmland, and the loss for agriculture was above 100 million crowns (11 million €) in Småland.

The most severe damage in **Finland** was caused by a tornado that hit Kontiolahti in eastern Finland on August 20.

New maximum temperature records in **Latvia** for individual days were set this year on August 3 and 5.

August was warm and rainy in **Lithuania**. It was the warmest month of the summer. Its mean air temperature anomaly was +1.8°C. The highest temperatures of the month reached 27–31°C. Quite often, night-time temperatures remained above 17°C in Nida. The sunshine duration was close to normal except for coastal regions receiving 40 hours above normal. There were many days with rain, but with varying intensity. On August 14, in Biržtonas the rain amounted to 82mm in 9 hours and in Vilnius to 52mm in 10 hours. On August 3, some north-eastern regions were affected by 30 – 40mm large hailstones accompanied by squall winds reaching 110km/h. The hailstones damaged crops and left many trees and gardens leafless. They also shattered greenhouses and some window panes. Wind gusts tore away 20 house roofs and broke many trees. Precipitation amounted to 200% of the normal in some parts of eastern Lithuania while reaching merely 50% at the Lithuanian seaside.

At the majority of stations in **Ireland**, the highest temperatures of the year coincided with the August bank holiday on 1st/2nd, when maxima rose above 25°C in many places and over 27°C at Birr.

The highest temperature in 2004 in the **United Kingdom** was 31.5°C at London Weather Centre on August 7. However, August was the 5th wettest August in the 239-year EWP (England-Wales precipitation) record (1766-2004); the monthly total was 157mm (Fig. 8.1). The heaviest 24-hour total rainfall recorded in the United Kingdom in 2004 was 200.4mm at Otterham, Devon, on August 16, with a return period well in excess of 200 years. Nearly all this rain fell during a 4-hour period and resulted in devastation – though without loss of life – in the coastal village of Boscastle when two rivers burst their banks.

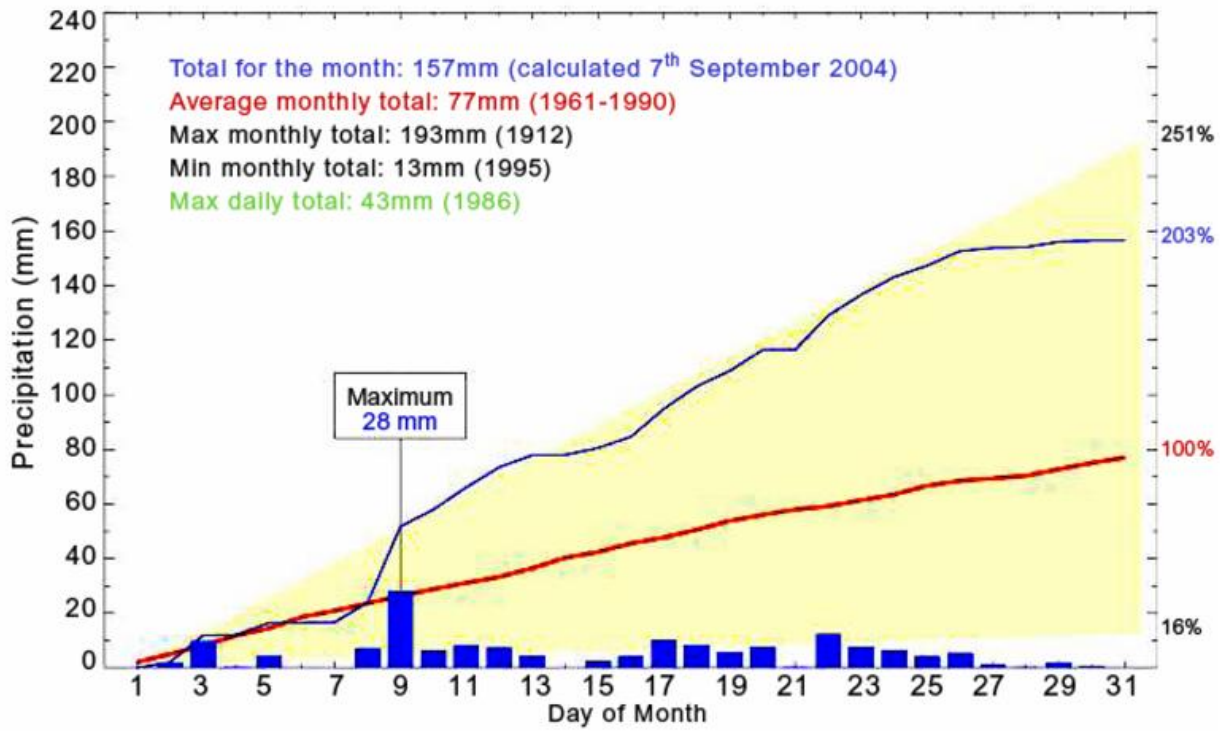

Fig. 8.1: *Daily and cumulative England and Wales rainfall for August 2004. The records of monthly maximum and minimum totals (borders of yellow shaded area) are since 1766 and the daily maximum totals are since 1931*
From: Met Office United Kingdom

August in the **Netherlands** was very warm (18.8°C, normal 17.2°C). The period August 2–11 was marked by a heat wave with temperatures in De Bilt reaching 25.0°C or more and three days with maximum temperatures of 30.0°C or higher. The highest temperature of the year was recorded during this heat wave: 33.6°C on August 9 in Soesterberg (near De Bilt, central part of the country). New record high minima were set on a number of stations during that day with temperatures not lower than 21°C locally. The first decade in August was at many stations one of the warmest for at least 50 years. Station Eelde recorded six "tropical" days (maximum temperatures of at least 30.0°C) on row. The most striking phenomenon was the abundant rainfall in parts of the country during August. At a number of stations more than 200mm fell. In Maasland (south-western part of the country) 325mm were registered. This was a new national record. The old record was 321 mm in Zantvoort (October 1932). On 10 days in August at least 50mm fell at one or more of the Dutch precipitation stations. Extreme amounts fell in particular on August 12 and 13 in the northern part of the country: more than 80mm in approx. 30 hours. Also in Maasland 97mm were recorded in approx. 36 hours and in Purmerend 90mm fell in 36 hours. The return period of these events is once in every 125 years.

In **Belgium**, during the first decade of August the weather was determined by meridional warm air currents, so there was an exceptional high mean of the minimum temperature. At Uccle, the monthly mean minimum (15.4°C) was 2.4°C higher than normal, the mean temperature 2.1°C. Precipitation also had a large amount (159% of the normal at Uccle), relative humidity and mean surface pressure as well. A remarkable number of 23 thunderstorm days was registered, compared to the normal of 11.1 days. This was a new record for the country; the previous one was 17 days in 1939.

In 2004, August was not as hot as in the year before in **Germany**, nevertheless the month was too warm all over the country. The areal mean temperature reached 18.5°C. This value was 2.0° above normal for the reference period 1961-90. Like in the three years before, August was once again the warmest month of the summer. There was quite a lot of rain, but there were significant regional differences. On average, the precipitation amount of August 2004 was 89.2mm, exceeding the normal by 12.0mm or 15.6%. Strong thunderstorms occurred on August 7-8 in the Southwest (49mm rain within 1-2h, hail cover of up to 90 cm), on August 12-13 in the West and South (55mm daily precipitation, in Munich gusts up to 120 km/h), and on August 18-19 in the Southwest and West (34mm daily precipitation, gusts up to 100km/h). Sunshine duration was near to normal (spatial mean 211.3 hours, +14.5h or +7.4%).

August was warmer than normal in **Poland** after a cool three-month period. Mean monthly temperature deviations varied from +1°C to +2°C. The highest measured temperature was +34.8°C (August 19), the lowest +3.8°C in mountain valleys. Precipitation was close to normal except for the eastern and northern regions where 200% of the normal were reached. In mid-August the meteorological conditions changed resulting in a significant decrease of temperature, storms with torrential rain and gusty winds causing damage in northern Poland.

In **Switzerland,** two tornadoes (F2 and F1) at Massonnens (western pre-alpine area) were observed on August 10. It was an extremely wet month in western Switzerland. The highest precipitation amount at Adelboden was reported since records started in 1901. In Geneva this was – after 1927 and 1878 – the third wettest August since measurements began in 1864.

In **Slovenia,** the August mean air temperature was above the 1961–1990 normal values and at some sites it exceeded the limits of the normal variability. In the mountains, at Kredarica, August was 1.2°C warmer than on average in the reference period. The sunshine duration was above normal, in the Julian Alps only by 7%, in Celje by 21%. Precipitation was most abundant in the Julian Alps, while on the coast only 41 mm fell (35% of the normal precipitation in August). There were severe thunderstorms, the strongest ones in Štajerska, some of them with hail and strong gusty winds. At Kredarica on August 27 the snow depth was 7cm.

The maximum daily amount of rainfall in **Hungary** was 128mm (Újszentmargita, August 26), but the monthly mean precipitation amount was near normal (99%). The average temperature was 0.8°C higher than the long-term mean.

In **Croatia**, the month was warm, particularly in the western half of the country where anomalies between 1 and 2°C were recorded. The precipitation amounts were generally low, especially in the West. As an outstanding example, the station Poreč received only 13% of the normal.

August was 0.5°C warmer than normal on average in **Bosnia and Herzegovina**. 91% of the 1971-2000 normal precipitation fell during the month.

In **Serbia and Montenegro**, mean monthly temperatures were in the normal range. Maximum temperatures often did not exceed 30°C, so the number of tropical days was less than average.

On August 28, exceptional precipitation amounts were reported from south-eastern **Romania**. In southern Dobrudja the precipitation summed up to 312mm (at Pantelimon), 281mm (at Agigea), 200mm (at Mamaia), and 195mm (at Constanta).

In **Moldova,** 235mm of precipitation fell during 21 hours at the meteorological station Soroca on August 22 – 23, due to a strong cold front with waves. Such a phenomenon was never recorded before on the territory of the Republic since the meteorological observations were carried out. A record breaking amount of hourly precipitation of 149mm was measured, which was three times as much as the monthly normal. The monthly precipitation sum for this station was 352mm, also this was a record. On August 28 another exceptional precipitation sum was registered: 166mm of precipitation during 9 hours (325% of the normal) at the meteorological station Leovo; again this was a result of a moving cold front with waves and it also was a new record for the South of the Republic. Due to heavy showers that occurred during the third decade of this month, houses, roads and crops were flooded and damaged. In Leovo, two persons died when a dam broke. The total amount of material losses was estimated to about 16 million €.

There were widespread thunderstorms in **Bulgaria** on August 14, 22-23 and 27-28 with heavy rain downpours and strong wind gusts as well as hailstorms. Hailstones as big as walnuts and eggs were seen. Floods were reported from the cities of Veliko Turnovo, Shumen, Dobrich and Varna; daily amounts of precipitation up to 40-50mm were registered. Ball lightnings were observed during thunderstorms on August 3 and 27. 130 villages were without electricity in the administrative region of Dobrich. The monthly average of August was normal in terms of temperature but wet. Precipitation was 100 to 400% of the normal.

Very low values of precipitation (about 30% below the long-term average) were registered over the country of **Albania** this month.

In **Portugal,** August was characterised by significant rainfall. High precipitation amounts were recorded at some stations and, in the northern and central regions, such a rainy August had not occurred since 1999. The maximum mean air temperature was well below the 1961-90 normal (especially on August 9 and 10, with some stations recording anomalies down to -11°C) while the minimum mean air temperature was above normal. The number of days with air temperature equal or above 35°C was significantly below normal, mainly in the northern and central regions. No maximum air temperatures equal or above 40°C were recorded at any of the stations of the territory.

Rain and floods occurred very frequently this month in **Turkey.** A tornado was observed on August 11 at Zonguldak.

In August the temperature in **Armenia** was above normal by +1 to +2°C. The precipitation amounts were low on average. Yerevan reported only 1mm for the whole month.

August was slightly cooler than normal in **Israel.**

September 2004

- **Mostly warm**
- **Mostly dry, except in the North**
- **Very sunny in some countries of Central Europe**

In **Greenland,** September was warmer than normal.

The month was rather warm in **Iceland**, but dull.

September was very wet on the **Faroe Islands,** but also with a surplus of sunshine. A large part of the rain in September was registered on September 13–14, about 50mm.

The monthly temperature was well above normal in **Norway**. For the country as a whole, it was 1.3°C higher than normal, in parts of southern Norway even 2°C. The highest monthly mean temperatures were recorded around the Oslofjord and along the coast until Lindesnes. Færder Fyr was warmest with 14.3°C (1.4°C above normal). The lowest mean temperatures were reported from the mountain areas in southern Norway and Finnmarksvidda. Sognefjellhytta was coldest with 2.7°C (1.5°C above normal). The highest maximum temperature (25.3°C) was measured at Nesbyen-Todokk on September 5 while Rustefjelbma in the county of Finnmark measured the lowest (-8.0°C) on September 19. Precipitation was very plentiful this month in large parts of the county of Trøndelag; the monthly mean was 200-300% of the normal. In some areas of Sør-Trøndelag this was the precipitation record for September for the last 100 years. In contrast, some parts of south-eastern Norway were drier than normal (50-60%). Based on the observations of all the synoptical stations the monthly mean precipitation in Norway was 130% of the normal. The highest value within the country was reported from Kvamskogen in western Norway with 497mm (127% of the normal), the lowest at Saltdal in the county of Nordland (25mm or 78%). Haukeland in western Norway had 99.8mm on September 27 as the highest daily value of the month.

On September 9 – 10 early in the morning, rime was observed on the grass in western Jutland in **Denmark.**

In **Estonia,** the monthly mean temperature of September was 2°C above normal. There were many thunderstorms with hail.

The month was warm in **Lithuania**. Its mean air temperature anomaly was +1°C. The mean daily air temperature decreased below 15°C ten days later than usually. Concerning precipitation, the first and second decade were dry and the third one was rainy. Heavy rain occurred in the south-western regions on September 22 – 24. The three-day precipitation sum amounted to 95 – 147mm, exceeding 4 – 4.5 times the normal of the last decade and 1.5 times the monthly normal. Small rivers flooded about 3 000 hectares of land. The monthly precipitation amount was very inhomogeneous within the country and varied from 29 to 196mm. At the end of the month a second blooming of apple-trees was observed at the seaside, but also 6 days with thunderstorms were recorded there.

September was very sunny in the **Netherlands**. The first decade of this month was the sunniest for at least 50 years at some stations. In De Bilt 99 hours of sunshine were recorded in the first decade. Since 1901, only the first decade in 1959 was sunnier with 109 hours.

Also in **Belgium** it was mostly sunny this month. At Uccle, the sun was shining for 173 hours; these were 113% of the normal. However, a significant deficit of sunshine duration was noted for the third decade: With 14.6 hours this was the lowest registered value since 1951 (the preceding lowest value for the third decade of September was 21.8 hours in 1964). The monthly mean temperature was 1.2°C above normal, the precipitation sum 119% of the normal.

Nearly all over **Germany** the month was warmer and much sunnier than in the reference period 1961-90. The mean temperature for Germany (14.2°C) was 0.9°C above normal. The spatial mean anomaly of sunshine duration (187.3 hours) was +37.9 hours or +25.4% (spatial distribution see Fig. 9.1), and so the month became the 5th in the line of Septembers rich in sunshine in Germany since 1951. On the other hand, the areal mean of precipitation (64.3 mm) was near to normal (+3.2 mm or +5.1%), but there were large regional differences. On September 21, due to a storm, wind gusts of more than 120 km/h were measured on mountains (Brocken, Fichtelberg) in north-east Germany and on the island Helgoland in the North Sea, also with flooding at the North Sea coast.

September was another warm month in **Poland**. Mean temperatures exceeded the average value by 0.5-1.0°C. The difference between the lowest (-0.8°C) and the highest observed temperature within this month (+28°C) was considerable. Precipitation sums in September were generally lower than normal except in the North of Poland. In the South less than 50% of the long-term average rain fell. Rainless weather at many locations caused progressive soil dehydration.

In **Slovenia,** September mean air temperatures were close to the 1961-1990 normal values. The largest anomaly occurred in the Primorska region. With exception of Kočevje, Dolenjska and Bela krajina, the sunshine duration exceeded the 1961-1990 normal. Especially the Gori ška region was very sunny with 20% above normal. Precipitation was most abundant in the Julian Alps, while in Upper Vipava valley and in Goričko less than 60% of the average precipitation fell. At Kredarica the snow depth was 15cm on September 8.

The monthly average temperature in **Portugal** was equal or above normal (1961-90) in almost the whole territory. The precipitation amounts were below normal.

In **Italy**, a flood affected the province of Viterbo, north of Rome. The costs of damage to walls and streets, electrical equipment (due to thunderbolts) and, mostly, to the production of hazelnuts, were estimated to 2 million Euro.

The temperature anomalies in **Croatia** varied between –1°C in the East to +1°C in the West. The variability of the precipitation anomalies was high, from 18% at Split to 284% at Lastovo in the outermost South of the country.

In **Bosnia and Herzegovina**, the monthly mean temperature was exactly normal (1971-2000) on average (14.8°C), but the precipitation amount was less than the long-term mean (67mm or 73%).

Monthly means of temperature and precipitation in **Bulgaria** were around normal except the southern part of the country which received around 150% of the normal precipitation. But September was also a month with some severe weather events. There were violent thunderstorms in the East of the country on September 27. Varna, the major Bulgarian city at the Black Sea coast, encountered a severe hail storm with hailstones as big as eggs. Heavy rain showers and wind gusts were reported to have caused damage in 4 local administrative regions for as much as 2.3 million EUR, in particular in the city of Varna the reported damage was 1.8 million EUR. At this location the wind gusts reached 90km/h causing interruption of the harbour service. There was even a tornado reported in the Rodopi Mountains in the South of the country which caused damage at least to 37 houses.

Heavy rain and floods occurred in **Turkey** at Giresun on September 4 and at Bodrum and Mugla on September 25 with injuries of people and damage on houses and traffic. In contrast, it was very dry on September 9 at Urgup and Nevsehir and on September 30 at Sivrihisar, Eskisehir, Avanos and Nevsehir. Frost with damage on vegetable gardens appeared at Urgup and Nevsehir on September 11.

September was slightly warmer than normal in **Israel**.

Heat waves passed **Jordan** on September 27-29. The maximum temperatures during these days were 5°C above normal.

Fig. 9.1: *Percent of normal 1961-1990 of sunshine duration for Germany in September 2004*
From: Deutscher Wetterdienst (DWD)

October 2004

- **Mostly warm**
- **Dry in the North and around the Mediterranean, wet especially in Ireland, in some parts of Central Europe and in the East**

This month was warmer than normal at Nuuk in **Greenland** and at Tórshavn on the **Faroe Islands**.

In **Iceland**, October broke a run of 30 consecutive months with above-average temperatures in Reykjavík. There were two intense northerly storms with wind gusts above 215km/h in October.

The monthly mean temperature in **Norway** was close to normal for most of the country. At some stations of Finnmark it was 1.5°C above the long-term average. Precipitation was very sparse in parts of the counties of Trøndelag, Oppland and Møre og Romsdal. At some locations that month was among the two to three driest Octobers during the last 50 years. The highest maximum temperature (18.9°C) was measured at the station Hjelvik– Myrbø on October 4 while Kautokeino registered the lowest minimum (-18.5°C) on October 30. The station Laupstad in the county of Nordland measured 123.2mm of precipitation on October 31 as the highest daily value for this month.

October was a further mild autumn month in **Sweden** with no serious storms.

In **Denmark** on October 9, the first frost was registered near Kolding in Jutland. However, the monthly mean temperature was above normal.

The month was warm on average in **Estonia**. 6.9°C was recorded as the mean temperature of the country; this was 0.4°C above the 1961-1990 normal. The maximum temperature was 18.1°C, whereas the minimum was not lower than –4.7°C. The precipitation was slightly higher than the long-term mean (67.2mm or 102% of the normal).

New maximum temperature records in **Latvia** for individual days were set on October 6 and 26. The monthly mean temperature was only slightly above normal, but the month was rainy with around 140% of the 1961-1990 average.

October weather was rather warm and humid in **Lithuania**, though changeable. The mean monthly air temperature was 8.2°C (+1°C anomaly). Especially the first and the third decade were warm. Maximum temperatures reached 18 – 20°C at southern stations on October 25-26. The coldest days were from October 10-15 with a night-time temperature falling to -4 to -7°C. The monthly amount of precipitation was close to normal in the southern part of the country and up to 220% of the normal in the northern borderland. Moist soils hampered agricultural fieldwork. In western Lithuania, water in rivers rose to 170 - 230cm and exceeded its normal level by almost 50cm.

October was very wet in **Ireland**, especially in the South. The heaviest rainfalls of the year occurred during the second half of October, leading to significant flooding in parts of the South and Southeast. Rainfalls of up to 150mm were measured in this area in the 48-hour period of October 27-28 (Fig. 10.1), while at the same time, a combination of exceptionally high tides and gales, caused by a depression with a core pressure of 953hPa in the South of Ireland, brought flooding along the southern coast. The highest daily rainfall amounted to 44.7mm at Rosslare on October 22.

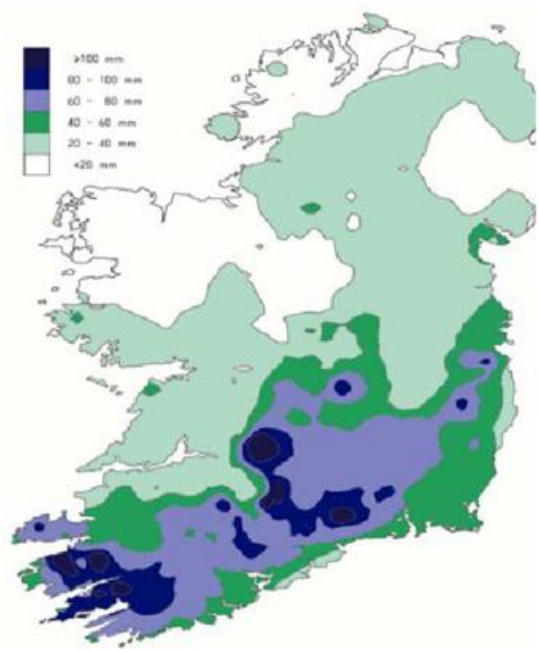

Fig. 10.1: *48-hour sum of rainfall in Ireland during October 27-28*
From: Irish Meteorological Service

For the **United Kingdom**, the Central England temperature was about normal this month, but the England and Wales precipitation was 155m or 178% of the 1961-1990 normal.

The month was warm and precipitation quite normal in **Belgium.** At Uccle, the monthly mean temperature was 11.7°C (anomaly +1.2°C), the precipitation amount 67.6mm (95% of the normal). There were remarkable anomalies of the surface pressure which was lower than normal on monthly average (-4.8 hPa at Uccle), and of the lowest temperature of the month, which was higher than normal (+1.4°C).

In **Luxembourg**, it was also quite warm with a monthly temperature mean of 10.1°C and an anomaly of 1.2°C above the 1971-2000 normal. A maximum temperature of 23.1°C was measured on October 4, a minimum of 2.8°C on October 19, two frost days were observed (the normal is 5.9 days). The precipitation amount was slightly below normal (75.3mm or 92% of the normal).

October 2004 was also rather mild in **Germany**. The areal mean temperature was 10.2°C (1.2°C above the long-term average). With an average precipitation amount of 53.2mm, this month was 2.6mm or 4.6% drier than normal. A spatial monthly mean of 114.2 hours of sunshine duration was reported, this sum was 5.7% or 5.2 hours above normal. However, there were large regional differences, as the Southwest was very wet and relatively poor in sunshine, while it was partly too dry and sunny in the East. On October 5 in western Germany (Minden-Porta Westfalica-Rinteln) heavy rain (up to 22mm), lightning strokes and a tornado were reported. On the same day in southeast Germany, 28.2°C were measured at Munich; this was the highest temperature ever measured there on an October 5 since 1879.

October was warm in **Poland** – deviations of mean monthly temperature from the long-term average reached +2.5°C in the South. Only the second decade was cold, but the mean temperature of the last third of the month exceeded +10°C and the maximum temperature +20°C. Even on October 30 the maximum temperature was +22.8°C in the South. Precipitation was higher than normal exceeding 150% of the normal in the North. Dry conditions were observed in the East with only 50% of the normal precipitation. Mid-October daily rainfall sums were above 50mm in high mountains.

The monthly average temperature was near the mean value in **Portugal**. The month was rainy to extremely rainy in the northern and central regions and dry in the southern regions. Percentages of precipitation totals (with respect to the 1961-90 normal) were between 56% (South) and 300% (Fig. 10.2).

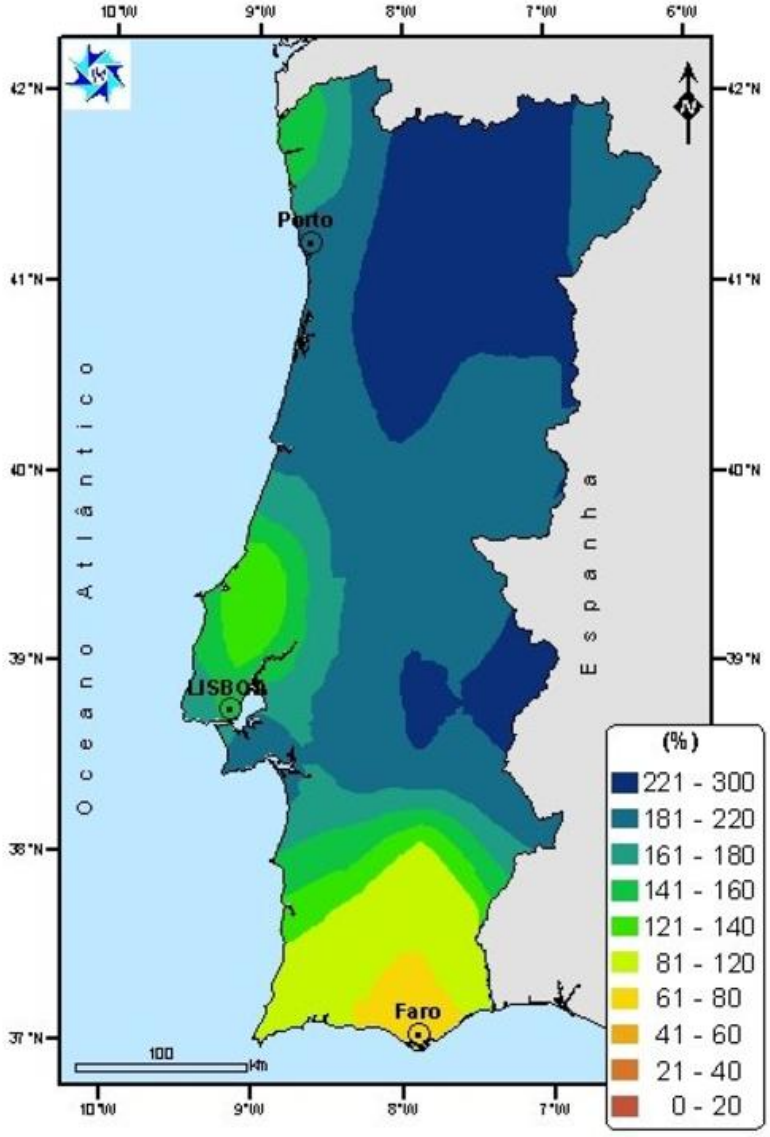

Fig. 10.2: *Percentages of precipitation totals (with respect to the 1961–1990 normal) in October 2004*
From: Instituto de Meteorologia, Portugal

In **Switzerland,** extremely high temperatures in and north of the Alps were measured on October 5, locally attaining 28.4°C. Some values represented the second to fourth highest October values. In the Northwest and the south-eastern neighbouring lowlands, it was partly the wettest October since 1939.

The month was warm in **Austria** with temperatures from 1.5 to 3.5°C above normal, but dry with precipitation around or below normal (50-70% of the normal). A wet period on October 29 – 31 occurred with up to 280% of the normal precipitation in Carinthia. In the South of Carinthia large floods along the rivers Gail, Lesach and Drau affected meadows, fields and cellars. Roads were blocked by landslides. The station Reisach im Drautal recorded a three-day precipitation amount of 167mm, near to the normal monthly precipitation amount.

It was also warm in **Hungary**, 1.3°C above normal on average. On the other hand, it was wet; the precipitation total was 145% of the normal.

In **Romania**, the monthly mean temperature was only slightly higher than normal; precipitation amounts were lower than the long-term mean.

In **Slovenia,** in spite of significant advection of cold air at the beginning of the second third of October, the month as a whole turned out to be warmer than on average. The mean air temperature was at least 1°C above the 1961-1990 normal. At most places the temperature anomaly was statistically significant, at some stations it even reached up to 3°C. Precipitation also exceeded the 1961-1990 normal; it was most abundant in the Julian Alps. Sunshine duration was below the 1961-1990 normal, in Vipava valley and in Notranjska only 40% of the normal sunshine duration was registered. It was snowing in the lowland of Notranjska region during the early morning on October 17. At Kredarica the snow depth reached 85 cm on the same day.

It was very warm over large parts of **Croatia,** partly extremely warm (Fig. 10.3). Precipitation values were very high in the northern part of the country (e.g. in Zagreb 270% of normal), but mostly drier than normal in the South.

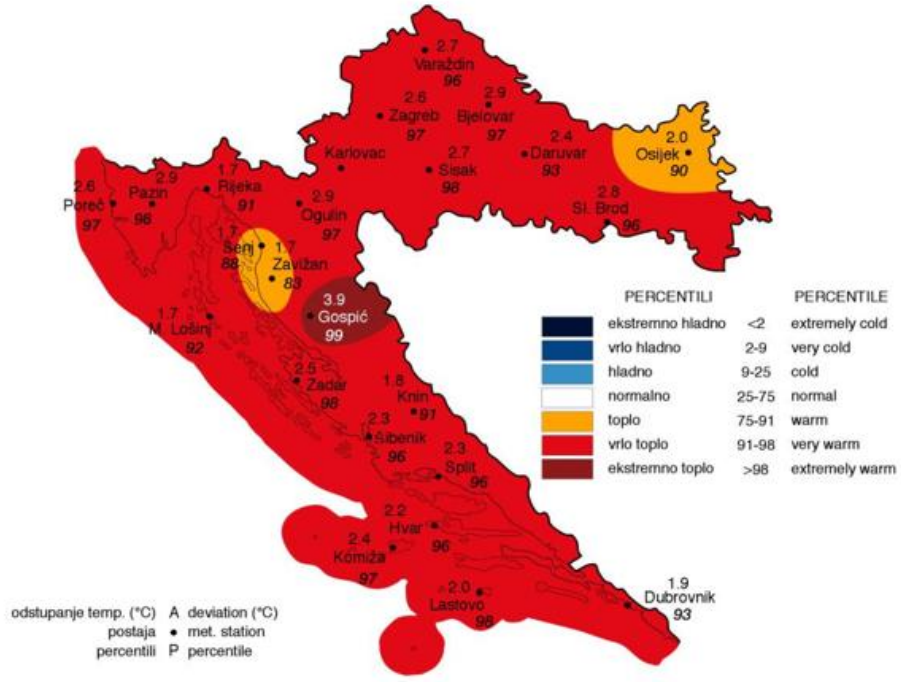

Fig. 10.3: *Monthly air temperature anomalies from normal 1961 – 1990 in °C (upper numbers) and percentiles (lower numbers) in Croatia in October 2004*
From: Meteorological and Hydrological Service Croatia

In **Bosnia and Herzegovina**, it was also very warm. The average monthly mean temperature (13.3°C) was 3.2°C above the 1971-2000 normal. The precipitation amount was notably below normal (82% of the normal 1971-2000).

Again, October was very warm in **Serbia and Montenegro** with mean maximum and minimum daily temperatures of 2 - 3°C above average. Especially the last decade of the month was outstanding warm (Fig. 10.4). Maximum temperatures at all the stations (except those on the mountains) were above 20°C during the first ten days. After October 17 the temperature even exceeded 25°C on some days.

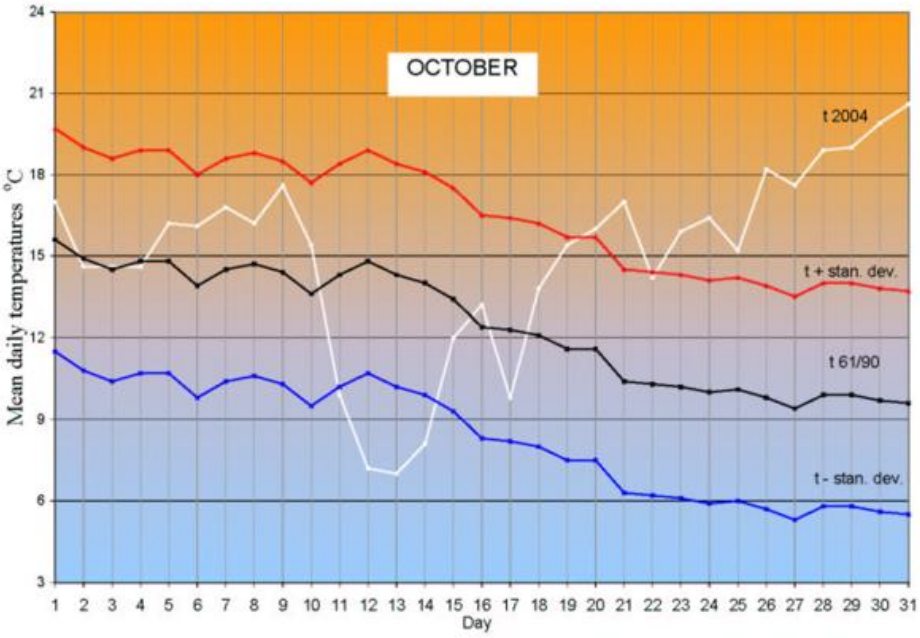

Fig. 10.4: *Mean daily air temperatures in Belgrade in October 2004 compared with 1961 – 1990 normal values and standard deviations*
From: Republic Hydrometeorological Service of Serbia

In **Albania**, the mean maximum temperature of October 2004 was the fourth highest within the available time series. At Elbasan (central part of the country), 2004 had the highest value since 1951 (Fig. 10.5). For the mean minimum temperature mostly a positive deviation was registered (up to 3°C), but a negative one in the north-eastern and eastern parts of the country (-2.9°C).

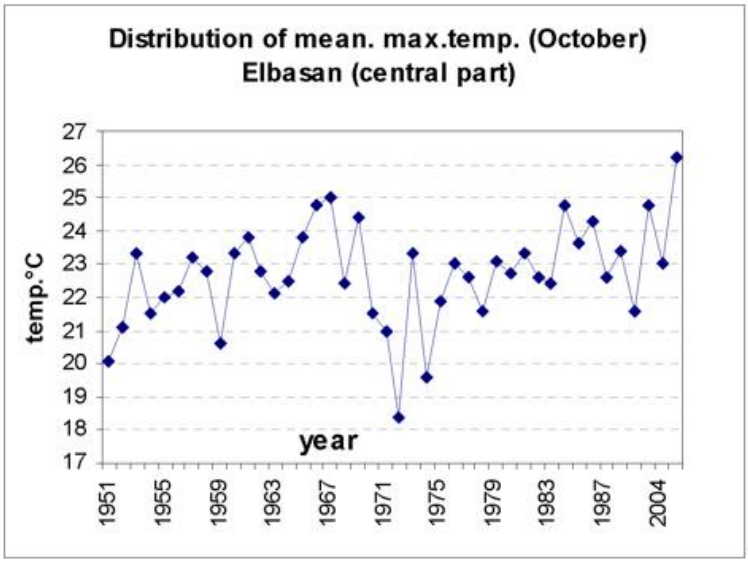

Fig. 10.5: *Mean maximum temperature in October at Elbasan (central part of Albania) 1951-2004.*
From: Hydrometeorological Institute of Albania

October was warm in **Bulgaria** with temperatures from 1.5 – 3.5°C above normal and dry with precipitation amounts around or below normal (50-70%of the normal).

Unusual high daily maximum temperatures between 27 and 33°C in **Greece** were reported for several areas of the country during the period October 17-19. The corresponding monthly long-term averages are 22-25°C (Tab. 10.1).

Station	Location (latitude °N, longitude °E)	Altitude (m)	Highest maximum temperatures during October 17-19	Date	Long-term mean monthly maximum temperature	Reference period
N. Filadelfia (Athens)	38 03, 23 40	136.1	27	17/10/04	23.3	1955-1997

Tab. 10.1: *Unusual maximum daily temperatures (in ^{0}C) in October 2004 and mean monthly maximum values*
From: Hellenic National Meteorological Service

In **Turkey**, heavy rain and flooding occurred in Istanbul on October 8 injuring people, damaging houses and traffic. A storm was observed on October 12 in Amasra, Bartin, Bandirma and Balikesir; the seaway was closed. A dry period started on October 25 in Seydisehir and Konya, consequently, germination of seeds did not proceed. The month as a whole was also dry, only about half of the normal precipitation fell on average, and it was warmer than normal.

The month was very dry in **Cyprus**. The monthly precipitation amount was only 8.5 mm, which was 26% of the normal value. Furthermore, it was very warm; the mean temperature of the month was 2.3°C above normal. On October 13 heavy showers caused floods in the Lefkosia region. In the same area, a hailstorm occurred on October 29 and on the same day another hailstorm, very strong winds and a tornado caused damage in the south-eastern parts of the island.

In **Armenia**, this month was warm and dry. At the station Yerevan, a monthly temperature mean of 14.9°C (2.1°C warmer than normal) and a precipitation sum of 9mm (28% of the normal) were recorded.

October was warmer than normal in **Israel** with a significant rain event at the end of the month. On October 29 large amounts of rain were recorded within a short time in the southern and eastern parts of the country. In Neve Ur (northern part of the Jordan Valley) 100 mm fell within two and a half hours. This was the largest daily amount ever recorded in that area as well as the strongest rainfall intensity. In Sedom (southern part of the Dead Sea) 74 mm of rain were recorded on October 29, most of it within two and a half to three hours– a record breaking event for this area. Large amounts (40-65 mm) also were recorded at other stations in the Jordan Valley and the Negev. The rains caused severe structural damage which was estimated to more than 50 million IS (10 million Euro)– roads and bridges in the eastern Negev and near the southern Dead Sea were damaged, some were totally ruined. Strong hail in areas near Jerusalem caused damage to cars and to private homes.

November 2004

- **Mostly warmer than normal, colder in the Northeast and Southwest**
- **Dry in western Central Europe and on the Iberian Peninsula, wet in western Norway, eastern Central Europe and in the Southeast**
- **Strong winds in eastern parts of Central Europe around November 18**

In **Iceland**, large temperature anomalies were observed in November. In Reykjavík the minimum temperature went down to -15.1°C, the lowest in November since 1893.

The monthly mean temperature in **Norway** was near normal for the larger part of the country. The highest maximum temperature (15.5°C) was measured at Nelaug in the county of Aust-Agder on November 15 while Kautokeino in the county of Finnmark registered the lowest minimum temperature, -34.3°C on November 21. In the inner parts of Finnmarksvidda the mean temperature was 1.5 - 2.0°C below the long-term average. The monthly sums of precipitation were the highest or second highest for the last 100 years in parts of the counties Oppland, Trøndelag and Møre og Romsdal. The precipitation station Opstveit in the county of Hordaland received 195.0mm on November 15. This was the highest diurnal precipitation value registered in Norway in 2004 and the highest diurnal value registered at Opstveit since the measurements started there in 1968. This was also the fourth highest diurnal precipitation ever measured in Norway.

In **Sweden,** at Visby on the island of Gotland, a record breaking snow depth for November was registered with 23cm of snow, and locally 30-40 cm of snow were measured in southern Sweden. Just 200m east of Gotland a towboat turned over during the snow storm on November 23 and one person drowned. About 15 000 households in south-eastern Sweden had a failure in the supply of electricity due to snow and strong winds on that day.

Frequent storms occurred at the western coast of **Estonia** in November 2004.

In **Latvia,** the air pressure at sea level fell by 43hPa in 38 hours at the Baltic Sea coast on November 23 - 24.

The first half of November was warm in **Lithuania**. During this period, the maximum temperature rose up to 9 – 12°C, but afterwards, starting on November 17, it fell down below zero. The monthly mean air temperature anomaly was -0.6°C. Frequent rainfall appeared during the first half of the month, changing to snowfall in the second half. Most precipitation fell at the seaside, elsewhere it was less, being 86% of the normal. A snow cover formed gradually and reached 4-12cm by the end of the month. The Lithuanian seaside encountered high wind speeds up to 72 – 86km/h for 8 days in total. Fogs were quite frequent, sometimes followed by freezing rain hampering transport operations.

In the **United Kingdom**, November 2004 was the 22nd driest November in EWP (England - Wales precipitation) with 49mm.

Belgium had a persistent flow of maritime air masses, sometimes of polar origin. On average, the month was quite normal. The only remarkable values were an exceptional low mean wind speed and an outstanding anomaly of high surface pressure.

On average over **Germany,** November 2004 did not show any larger deviations from the values of the reference period 1961-90. However, there appeared significant regional differences, especially in precipitation. While it was too wet in large parts of northern and eastern Germany, it remained rather dry in the Southwest. Spatially averaged over the whole country, the precipitation amount was 72.8mm in November 2004, 6.4mm or 9.7% more than in the reference period. On November 9-10, heavy snowfall affected the traffic in central Germany. Up to 30cm fresh snow fell in the mountains. In terms of temperature, the monthly mean for

Germany was 4.2°C, slightly warmer (+0.2°) than normal. The spatial mean of sunshine duration (48.2 hours) was 10.0% or 5.4 hours below normal. Stormy winds were registered on November 17-18 in northern Germany (island Hiddensee in the Baltic Sea 169km/h, mountain station Brocken 158 km/h) and on November 19 over the southern mountains (Zugspitze 169km/h, Feldberg/Black Forest 140km/h).

November was warm and pretty wet in **Poland**. Monthly mean temperature deviations reached 0.5 – 1.0°C. At the beginning of November, maximum temperatures still exceeded 10°C, and even 20°C in the South. The warm weather favoured agricultural activities and winter crops growth. Only the third decade of the month was chilly with minimum temperatures below 0°C. Monthly precipitation sums were generally higher than normal with 200% of the normal at most locations in the South. November was also a very windy month – almost every day wind gusts exceeding 50km/h were observed. The strongest winds (>90 km/h) were measured on November 17-18, resulting in 7 casualties and 10 people injured, much material losses were estimated (damage in energy transmitting lines, buildings, cars). The highest noted wind gust was measured at mount Kasprowy Wierch (137km/h) on November 19.

In **Slovakia**, a strong downslope wind in the High Tatras area reached gusts of 160 - 194km/h on November 19. This event had extensive influence on forest vegetation and caused huge damage (12 500ha of forest were devastated, Fig. 11.1), the volume of windfall wood was estimated to 2.5 million m³. It was the most violent storm in this region for the last 100 years. A previous similar event occurred in the year 1941, with damage not exceeding 20% of the 2004 event.

Fig. 11.1: *Damaged forest vegetation in the High Tatras after the storm on 19 November 2004, photo: Pavel Kapusta*
From: Slovak Hydrometeorological Institute

November was warm and dry in **Austria** with temperatures 0.5 – 2°C above normal and precipitation of 50 - 90% of the normal. A storm situation north of the main ridge of the Alps persisting for five days (Nov. 18 – 23) caused severe damage. Wind speeds up to 119 km/h (recorded at the station Vienna, Hohe Warte, Nov. 18) caused damage to a lot of houses and roofs in Vienna; in the surroundings of Vienna rail and road traffic were blocked by broken trees.

On November 19 a gale (accompanied by 120km/h blasts) caused traffic accidents in **Hungary**, ruined trees and buildings. The month was mild with a temperature anomaly of +0.9°C on average, precipitation amounts were about normal (102%).

In **Romania,** the largest precipitation amounts of 2004 nation-wide fell in November (Fig. 11.2), the monthly sum amounted to 179.3% of the 1961-1990 normal. Torrential rainfalls, generating flooding in the Southwest of the country, caused high damage: 18 people were killed, 14 325 houses were affected, 111 371ha of agricultural land were flooded. The monthly mean temperature was only slightly above normal.

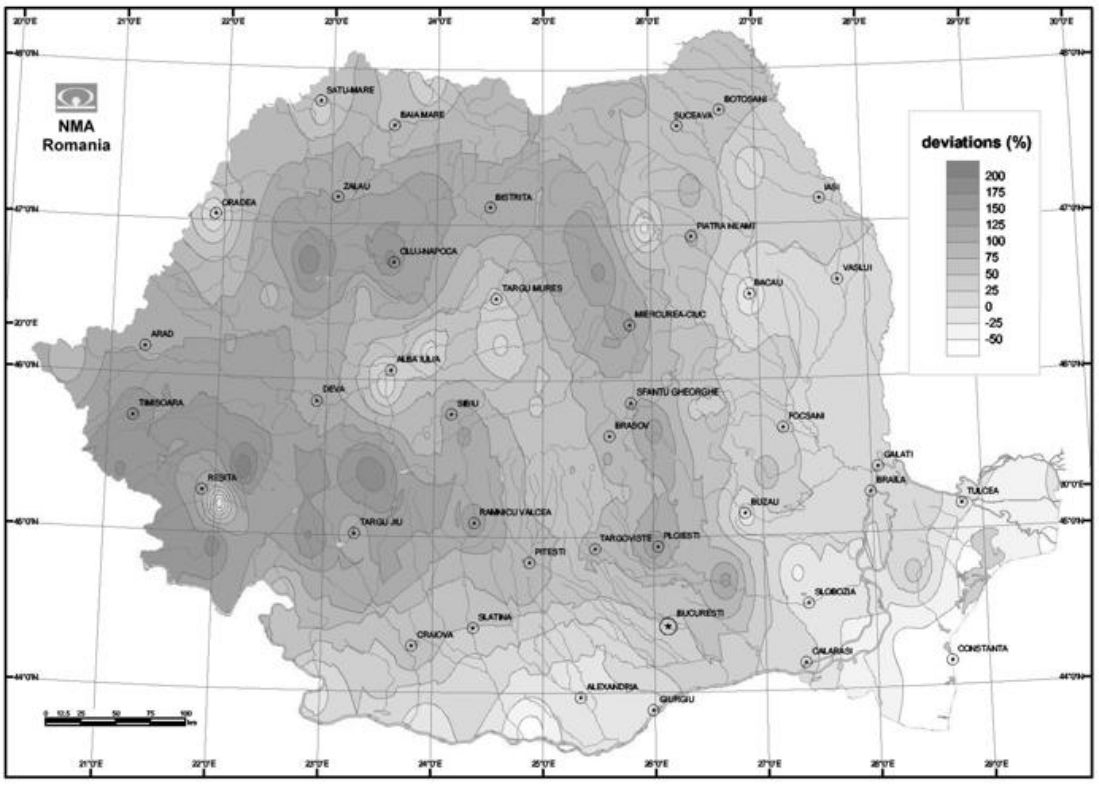

Fig. 11.2: *Deviation of the precipitation amount in November 2004 from the normal 1961–1990 in Romania*
From: National Institute of Meteorology & Hydrology Romania

Air temperature was near the 1961-90 normal in **Portugal,** except in Lisbon and north-eastern regions, where it was below the long-term average. November was extremely dry in the whole territory with precipitation amounts significantly below the mean values. Percentages of precipitation totals (with respect to the 1961-90 normal) were between 11 and 27%.

In November, rainfall was intense in **Spain** on November 8, with more than 150mm at 2 locations.

In **Italy**, the most striking weather phenomena in November concerned Calabria and Sicily regions. Floods in the provinces of Catanzaro, Cosenza and Reggio Calabria occurred together with a sea storm at Crotone and funnel clouds in Catanzaro and south of Sicily;

streets, buildings and agriculture suffered a lot of damage. Related to this event, the weather station of Monte Scuro (Calabria) measured 100.4mm, which is a record value of daily precipitation since 1951. Other stations in the area also registered very heavy precipitation (Fig. 11.3).

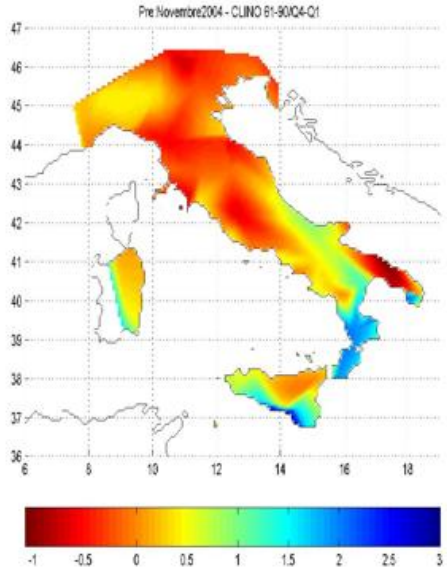

Fig. 11.3: *Precipitation anomaly of November, cumulated values versus 1961–90, divided by the fourth minus the first interquintile range*
From: Ufficio Generale per la Meteorologia, Italy

In **Slovenia,** November began with exceptional warm weather in the Gorška and coastal region. The maximum daily temperature in Bilje was 25.0°C on November 2 and in Portorož 24.4°C was the highest temperature ever recorded in November. The mean air temperature of the month was above normal (1961–1990) almost all over the country. Only on high mountains the mean air temperature was slightly below normal. Precipitation remained below the 1961–1990 average, in the West and at some places in the East of Slovenia not even one half of the usual precipitation fell. The sunshine duration was below normal in the northern part of Slovenia, but in the Notranjska region and Ljubljana's basin, sunny weather appeared more frequently than usual. The most significant weather event was an exceptionally strong wind on November 14, a few days later, on November 19, another episode of a very strong wind occurred, especially in the eastern part of Slovenia and on the high mountains. In both cases the wind caused some damage to buildings, particularly roofs and trees.

On November 2, the highest maximum temperature of the last 56 Novembers (since 1948) was observed in Split Marjan, **Croatia** (Tab. 11.1). But this was also the end of an extremely warm period persisting from the last two weeks of October until the beginning of November. The monthly mean temperatures were generally higher than normal, at Zagreb the anomaly was +1.7°C. For precipitation, it was drier than normal in the North of the country, but wetter in the Northeast and Southeast.

Year	2004	1992	1972	1990	2003	1999	2001	1948	1969	1998
T in °C	25.8	22.0	21.7	21.5	21.4	21.3	20.7	20.6	20.5	20.5

Tab. 11.1: *The ten years with the highest maximum temperatures in November in Split Marjan, period 1948-2004*
From: Meteorological and Hydrological Service Croatia

The monthly mean temperatures were around normal in **Bosnia and Herzegovina**, and also the average monthly precipitation amount exceeded the 1971-2000 normal only slightly (107%).

Large fluctuations of air temperatures during the month were characteristic for November in **Serbia and Montenegro**, especially in mountainous areas. The highest temperature of 27.3°C in the area of Serbia was measured in Sjenica on November 2 (altitude 1038m), exceeding the former absolute maximum of that station since measurements existed. Some more records of absolute maximum temperatures were broken at other mountainous stations: Crni Vrh, Zlatibor, and Kopaonik. In the second half of the month it was cold especially in mountainous areas and in southern Serbia, some stations reported freezing days. The lowest minimum temperature was -18.4°C in Sjenica. Precipitation occurred during the whole month, mostly during the second and third decade. In many parts of the country, precipitation quantities were extremely higher than average (Fig. 11.4). At some stations (Veliko Gradiste, Zrenjanin, Novi Sad, Beograd) new record values of monthly precipitation sums were achieved.

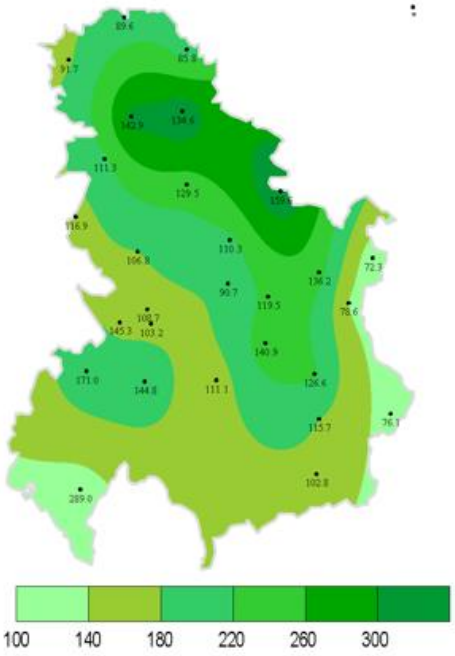

Fig. 11.4: *Precipitation totals in November 2004 in mm (values at stations) and in % of the normal 1961-1990 (isolines) in Serbia & Montenegro*
From: Republic Hydrometeorological Service of Serbia

The second highest monthly precipitation amount of 2004 in **Albania** was registered at Lezhe in the western part of the country with 284mm, which is about one third more than normal.

In **Bulgaria**, 24-hour precipitation amounts of more than 130mm were reported on November 14 (Fig. 11.5). The water level of river Vacha (Zabral Bridge) increased from about 100cm up to more than 350cm during the night of November 14-15. This caused a lot of damage in the villages around.

Heavy thunderstorms affected the island of Crete in **Greece** on November 5 and the periphery of Attiki on November 8. These storms caused floods in the western parts of Crete (Souda) and Attiki, with damage on roads, houses and agriculture. Extreme maximum 24-hour precipitation amounts of 120mm at Souda and 83mm at Attiki were recorded for these days.

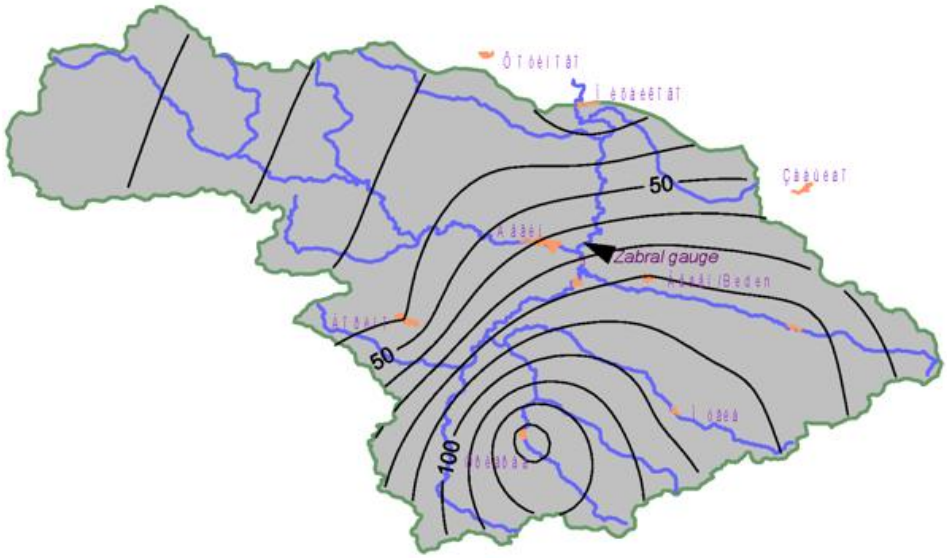

Fig. 11.5: *Distribution of 24-h precipitation totals recorded on November 15 at 08 a.m. local time in a region around river Vacha, Bulgaria*
From: National Institute of Meteorology and Hydrology, Bulgaria

In **Turkey,** a dry period started on November 2 in Urgup and Konya, seeds did not germinate. Frost came to Malatya on November 5 and to Odemis and Izmir on November 23, vegetable gardens were damaged. Heavy rain and flooding affected agricultural areas in Mugla on November 15 and again on November 20. Storms appeared on November 15 in Kocaeli, on November 19 in Kutahya and on November 25 in Cinarcik and Yalova (seaway was closed). Heavy snowfall was recorded in Sivas on November 22 and in Yozgat on November 25, traffic stopped on main roads. The monthly station averaged precipitation sum was high with 116mm or 162% of the normal.

In the Ararat valley and in some mountainous regions of **Armenia** a snowstorm occurred, the wind speed reached 90-100km/h. November was the wettest month of 2004 in the country, the monthly total precipitation was 137% of the normal.

On November 21 very strong winds occurred in various areas of **Cyprus** and a tornado caused damage to greenhouses in the southern part of the island. The first snowfall occurred around Troodos on the same day and later also in other parts of the country, in particular in areas with an elevation above 400 meters. The month as a whole was wet with 73.2mm or 137% of the normal on average. A mean temperature anomaly of +0.6°C was recorded.

November was rainy in **Israel**, with rainfall amounts reaching 150-200% of the normal in most parts of the country. Some parts received 200-300% of the normal. This was the first time that rainfall amounts in November were above normal since 1995. The first part of the month (November 1-15) was warm and dry with an average temperature of 28-30°C in the coastal plain and 23-25°C in the mountains. A rapid fall of temperature started on November 16, and the average temperature for the second part of the month (November 16-30) was 8-10°C less than in the first part of the month. This was the largest difference between the two parts of November for the last 40 years.

In **Jordan** it was very mild on November 4-7 with a maximum temperature 5°C above normal. The highest rainfall amount in 24 hours was 76.4 mm recorded on November 17 in Ras-Muneef.

December 2004

- **Very mild, especially in Scandinavia and in the Baltic countries, colder than normal in some parts of the Southwest ("white Christmas" in northern Spain) and in the Southeast**
- **Mostly very dry, but wet in some parts of the North and the Mediterranean**
- **Heavy storm in Central Europe on December 17**

December was very cold in some parts of **Greenland**, despite a warm start in the first week.

Mean values of December 2004 were close to normal in **Iceland**, but the weather was very unsteady with large temperature fluctuations, leading to difficult traffic conditions in large parts of the country. Only one hour of bright sunshine was measured in Reykjavík (the December average is 12).

December 23 was the day with the lowest temperature of 2004 on the **Faroe Islands** (-4.9°C).

The monthly mean temperature of **Norway** as a whole was 3.6°C above normal. In parts of the county of Finnmark it was 6-8°C above which was the third highest anomaly registered in December during the last 50 years. The highest daily maximum temperature was measured in Tafjord with 15.0°C on December 14, the lowest minimum temperature at Røros Lufthavn with -33.9°C on December 27. As for precipitation, the country average in this month was 135% of the normal. Parts of the county of Hordaland experienced the wettest December for the last 100 years. The station Bergen–Florida received a monthly sum of 568mm which was a new December record for the central parts of the county of Bergen since 1861. Takle in the county Sogn og Fjordane registered 774mm. The highest diurnal value was measured at the station Lavik in the county of Sogn og Fjordane with 161.0mm on December 5. Of the synoptical stations, Takle reported the highest diurnal sum with 114.3mm on this day. In contrast, the eastern part of Norway received less precipitation than normal. For some areas of the counties of Hedmark and Oppland December 2004 was the driest for the last 50 years.

December 2004 was very mild in **Sweden** with no significant weather events.

The end of the year was very mild in **Finland**; the December mean temperature anomaly was about +3°C, in some locations even +6°C compared to the normal. The largest storm in terms of spatial extension and also in terms of damage happened just before Christmas on December 23.

The month was 4°C warmer than normal in **Estonia**. The first ten days were especially warm and were among the warmest for the last half century.

December 2004 was the 7th warmest December in **Latvia**.

In **Lithuania,** December was warm and humid. For the most parts of the month, its mean daily temperature was positive and the monthly thermal anomaly amounted to +3.7°C. Over the past 100 years, a higher mean air temperature was recorded in December 1960 and similar mean values were recorded in the Decembers of 2000 and 2003. Only five days of the month were without precipitation. Mostly precipitation was of mixed nature, including snowfall and sleet. A snow cover was forming and melting alternately. The monthly amount of precipitation was close to normal. There was no soil freeze until the end of the month. December's warm weather was unfavourable for winter crops. Due to a prevailing influence of Atlantic cyclones, the Lithuanian seaside regions encountered strong winds for as many as 10 days, and fogs were very frequent too.

The lowest temperature in 2004 in the **United Kingdom** was -15.2°C at Kinbrace in northern Scotland on December 18-19. December 2004 was dry across England & Wales.

In **Denmark**, December was very mild with occasional frost and snow a couple of times in the last half of the month. On several places in the northern parts of Jutland and Zealand there was a rather deep snow cover on Christmas Eve ("white Christmas").

December was very sunny in the southern part of the **Netherlands**. The month was the 5th sunniest December month in Vlissingen (south-western part of the country) since 1907 and in Maastricht the 7th sunniest since 1906, both with 69 hours of sunshine.

December 2004 in **Belgium** was characterised by an exceptional high mean wind speed. Precipitation, mean temperature and sunshine duration were near normal. The anomalies for Uccle were –0.4°C for the mean temperature, 95% of the normal for precipitation and 121% for the sunshine duration.

The month was cold in **Luxembourg**. A monthly mean temperature of 0.1°C was recorded which corresponds to an anomaly of –1.7°C compared to the 1971-2000 normal. December was the coldest month of the year this time. It also had the lowest maximum (8.2°C on December 24) and the lowest minimum (-8.7°C on December 21) of the year. Nearly on all days of this month (28 out of 31), a frozen soil was reported (the normal is 20.7 days). A monthly precipitation amount of 43.3mm was registered which was only 51% of the normal. The highest wind speed of this month was 84km/h on December 17, when a storm passed over Central Europe.

The most outstanding weather event in **France** of the whole year 2004 also was in fact the storm that occurred on December 17 which swept along the North of the country. Violent gusts occurred from the northern coast of Brittany to the Picardie and as far as the North of Lorraine. In the coastal areas the strongest wind gusts up to 155 km/h were measured at Cap-de-la-Hève (Seine-Maritime). Inland, the strongest winds occurred in Oise, Somme and Aisne with gusts reaching 120 to 140 km/h. This storm caused a lot of damage and the death of six people.

December 2004 was very rich in sunshine and rather dry in **Germany**. The average sunshine duration in Germany in December 2004 amounted to 48.6h, which was 10.1 h or 26.2% above normal. The average precipitation sum in December 2004 was only 45.1mm, this value was considerably lower (25.1mm or 35.8%) than in the reference period 1961-1990. There were some days with freezing rain and/or heavy snowfall on December 16-17 (especially southern and eastern Germany), December 17-18 and December 22-23, causing severe traffic problems on the roads. On December 17-18 a heavy storm passed over south-western Germany. The mean temperature for Germany (1.1°C) was not far from normal (+0.3°C), but there were significant regional differences.

The month was unusually warm in **Poland**. Departures of monthly mean values from the normal in the eastern part of the country reached +2.9°C. The maximum daily temperature of the country exceeded +10°C; the minimum locally fell below -11°C. Precipitation was lower than usual with 72% of the 1971-2000 normal on average. Higher precipitation was noted only in the North (>120%). In the remaining regions, precipitation was scarce, lower than 40% at some sites. The number of days with snow cover ranged from 0 in the West up to 9 in the north-eastern region, but the snow depth was small (<10cm).

The weather was very mild and sunny in **Switzerland** in the Alps during the first half of December with a freezing level at 2500-2800m from December 4 to 13. Consequently, there was an extraordinarily poor snow cover in the Alps until December 16, afterwards the conditions for winter tourism improved only partially.

The monthly average temperature was normal in **Portugal** with respect to the 1961-90 period, except in the Minho region and at some places of the central region. The precipitation amounts were below the 1961-1990 normal in almost the whole territory, and the month was classified as being dry to extremely dry. Percentages of precipitation totals were between 19 and 60% of the normal. At the end of this month, a drought was well established in Mainland Portugal with a moderate to extreme intensity according to the Palmer drought index (Fig. 12.1).

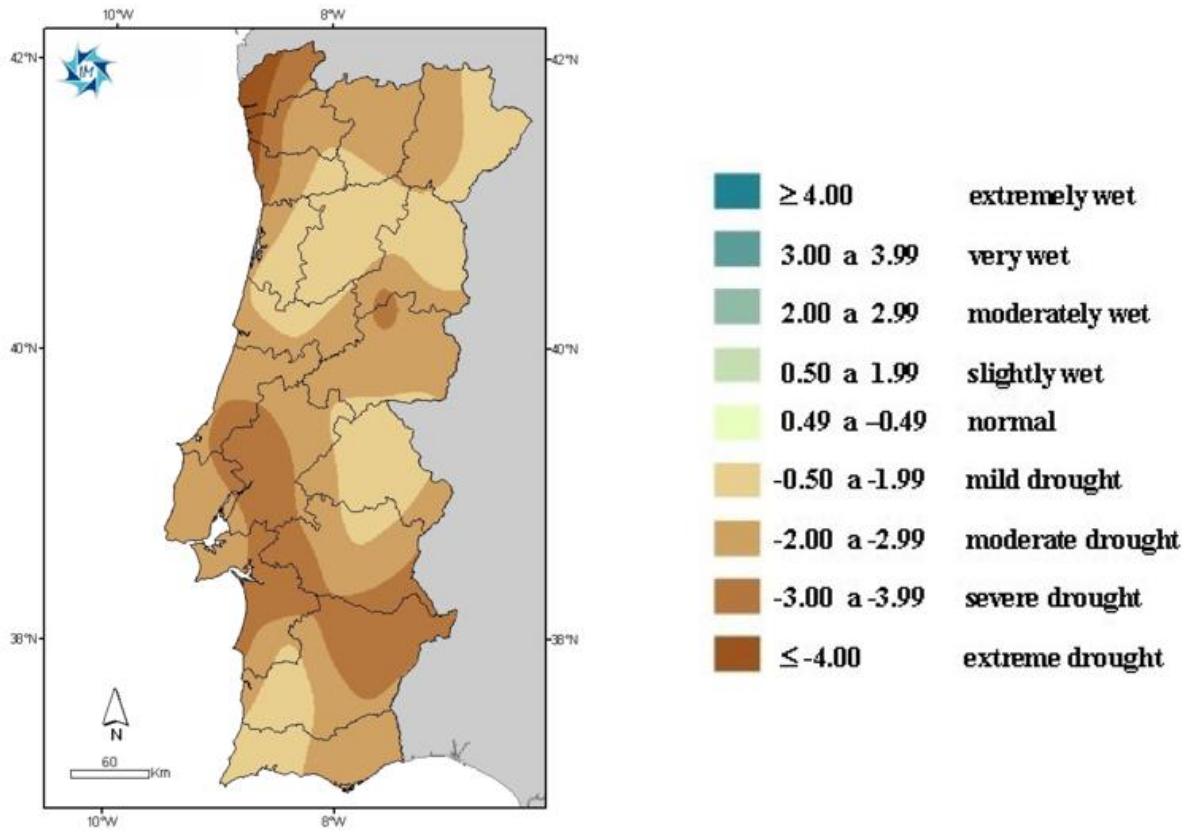

Fig. 12.1: *Palmer drought index (PDSI) in December 2004 in Mainland Portugal*
From: Instituto de Meteorologia Portugal

Abundant snow at Christmas was observed in higher elevations (upper third) of **Spain**. The cities in this region, especially on the Castilian Plateau, were snow-covered on December 26-27, a beautiful spectacle that had not been seen at some places for about 30 years. But not everything was enjoyment; it also caused severe traffic problems on the roads and in the cities.

In **Italy**, some funnel clouds struck again at Sicily, and the minor islands were isolated due to very adverse sea conditions, but the worst was a flood in Sardinia (Fig. 12.2) which caused the death of 3 persons.

Fig. 12.2: *An image of the Sardinia flooding in December 2004*
From: Ufficio Generale per la Meteorologia, Italy

The mean air temperature in December in **Slovenia** was above normal (1961–1990), but only on the high mountains and in the Primorska region the temperature anomaly was significant. There were quite a number of days with a strong temperature inversion and low cloudiness in most parts of the lowland during the first and second third of December. The majority of the precipitation fell during the last third of December, while the second third of the month was almost dry with the exception of the Primorska region. Monthly precipitation was below normal in the Northeast of Slovenia, in the Prekmurje region only about 60% of the usual precipitation fell. In contrast, more than 50% above normal precipitation fell in the coastal region. The sunshine duration was below normal in Bela krajina and Novo mesto, while more than 150% of the sunshine duration normal was registered in the Ljubljana basin and Celje. In most parts of the lowland the first third of December was grey, sunny weather was rare, but the last third of December was unusually sunny everywhere. In Upper Sava valley a snow cover persisted throughout the month, whereas in most of the lowland no snow cover was observed. At Kredarica the maximum snow cover on December 28 reached 125cm.

In **Hungary**, December was 0.6°C warmer than normal, but with 80% of the normal precipitation it was one of the dry months.

The month was warm at the Adriatic coast area of **Croatia**, in some parts even very warm or extremely warm (Fig. 12.3). Some areas of that region were also wet this month. The station Šibenik registered an extremely high monthly amount of 320% of the normal which corresponds to the 99% percentile.

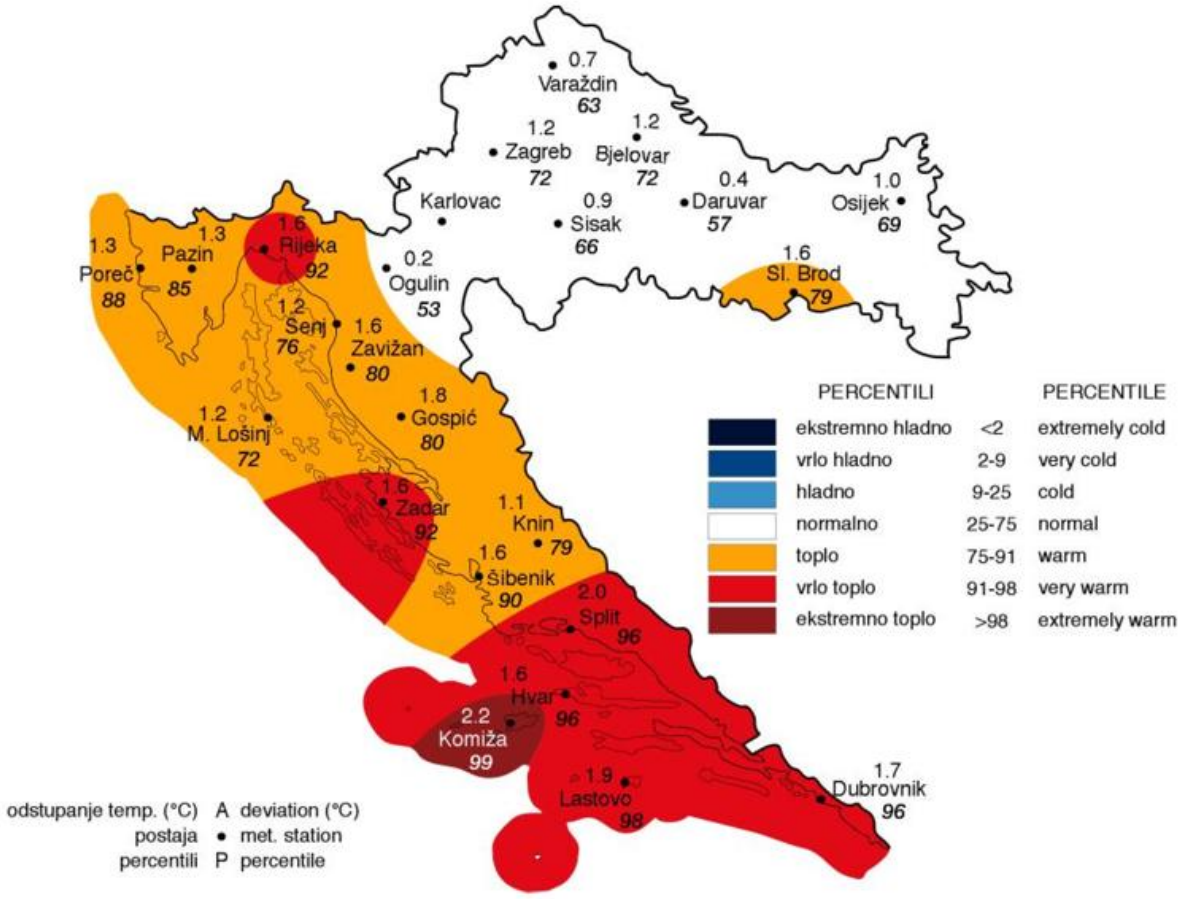

Fig. 12.3: *Monthly air temperature deviations from normal 1961–1990 (upper numbers) and percentiles (lower numbers) in Croatia for December 2004*
From: Meteorological and Hydrological Service Croatia

In **Bosnia and Herzegovina**, December was 1.3°C milder than normal on average. The month was in general wet compared to the 1971-2000 normal (145% of the normal on average). At the station Ivan Sedlo a monthly sum of 288mm (222% of the normal) was recorded, by far the highest value of the whole year at this station. Other stations (Livno, Mostar) also received more than 250mm of precipitation.

December was warmer than average in the whole country of **Serbia and Montenegro**. Especially the minimum temperatures were high. The deviation of mean minimum temperatures from normal ranged from +1.5 to +3.1°C. Precipitation quantities were lower than average in almost the whole country.

The monthly temperature mean was slightly higher than normal in **Romania**. Precipitation amounts were on average 75% of the 1961-1990 normal.

In **Albania**, a positive deviation of mean minimum temperatures from normal was recorded for December (up to 3.0°C). Precipitation amounts were lower than normal.

The mean temperature anomaly of **Republic of Macedonia** was almost +2°C in the whole territory of the country.

December was warm as well in **Bulgaria**. In terms of precipitation the amount was 110% to 230% of the normal in most of the country although it was drier in the far north-western and south-eastern regions with only 60 to 70% of the normal.

An avalanche was observed on December 14 at Artvin, **Turkey**. Heavy rain and flooding occurred on December 18 at Kas and Antalya, affecting agricultural areas, and on December 29 at Edirne. On the latter day, there was also a storm at Seferihisar, Izmir, Uluborlu and Isparata. Greenhouses were damaged, trees were broken. The month as a whole was dry with only 52mm precipitation on average (53% of the normal).

In December, the weather was quite cold and dry in **Armenia**. The monthly mean air temperature was below normal by 3-5°C. Minimum temperatures at Ashotsk reached -30°C, at Yerevan the minima were between –13 and -15 °C. The averaged precipitation amount was only 21% (8mm) of the normal. At Yerevan, not more than 2mm precipitation fell during the whole month.

On December 7 heavy showers occurred in the Pafos area of **Cyprus**. The averaged monthly precipitation amount of 75.9mm, however, was considerably lower than the long-term mean (72% of the normal). For the monthly mean temperature, the anomaly was -0.3°C.

December was colder than normal and dry in **Israel**. The northern parts of the country received only 30-35% of the rainfall average, other parts 50-80%. A significant cold period occurred on December 16-18. In many areas temperatures at night dropped below 0°C. In Yizre'el Valley (northern Israel) the minima were -3 to -4°C, the lowest since 1973.

In **Jordan**, the lowest minimum temperature recorded at Amman in 2004 was -2°C on December 17 (Fig. 12.4).

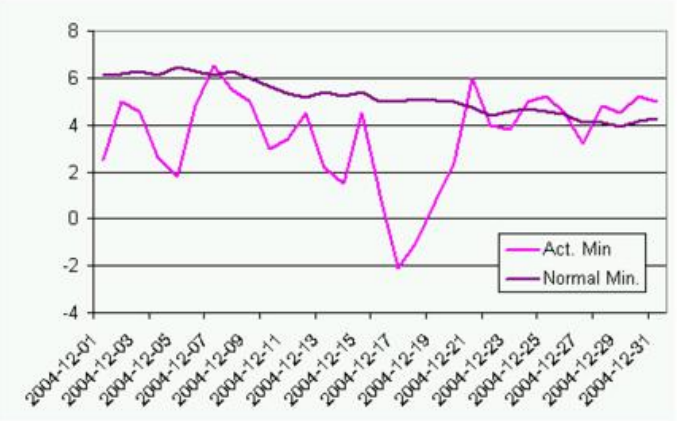

Fig. 12.4:

Daily minimum temperature in °C (Act. Min.) of December 2004 at Amman (Jordan) and corresponding normal values

Activities and Results of European Climate Centres

Report on ECSN activities 2004
by: Walter Kirchhofer, MeteoSwiss

- **General remarks**

The EUMETNET Council decided to continue the ECSN Programme for a third phase of three years, starting on 1 January 2004 with MeteoSwiss as Responsible Member.

The 9th ECSN Advisory Committee (EAC) Meeting took place in Dublin, Ireland, 8 - 10 September 2004. It was an interesting and fruitful meeting, also with regard to new activities, and well organised by Met Éireann.

The EUMETNET Council decided that the European Meteorological Society (EMS), in partnership with ECSN, organises the European Conference on Applied Climatology (ECAC). The first combined Conference "EMS/ECAC" took place in Nice, 26-30 September 2004. The scientific part of ECAC-2004 was managed by the ECAC Advisory Board (EAB) and the Conveners. EAB organised three Planning Meetings, in Berlin, in Toulouse and in Nice. About 250 papers had been submitted and selected by the conveners. Thanks to the efficient work done by the conveners and by the EMS Secretariat, ECAC-2004 was, with respect to climatology and its application, a success.

- **European Climate Assessment & Dataset (KNMI)**

After the successful termination of the two projects „European Climate Assessment" (ECA) and „ECSN Climate Dataset" (ECD), the follow-up project „European Climate Assessment & Dataset" (ECA&D), conducted by KNMI, is well on the way. The new website http://www.eca.knmi.nl was formally launched and presented at the ECAC conference in Nice.

- **Generate Climate Monitoring Products (DWD)**

The project "Generate Climate Monitoring Products" (GCMP) was terminated by a Final Report. European and national climate monitoring products are now available to the Members and to the public via the GCMP Internet platform http://www.gcmp.dwd.de. In order to enhance the number of participating Members, it was decided to keep the GCMP platform in a quasi operational mode. A follow-up project "EuroCLIS" is planned to be launched soon by DWD.

- **Climate Atlas of Europe (Météo-France)**

The project „Climate Atlas of Europe", based on climatological normal values for the period 1971-2000, is completed. A CD-ROM in a French and in an English version of the software has been prepared, containing the dataset from nearly 700 European weather stations, and sent to all the participating countries to make further use of this important climatological information.

- **ENSEMBLES (KNMI, MeteoSwiss)**

Within the European Integrated Project "ENSEMBLES", the project "Development of daily high-resolution gridded observational datasets for Europe" started on 1 September 2004.

- **New project activities**

The projects EuroCLIS and EuroGRID have been initiated. Based on the existing GCMP prototype a new system will be developed to provide climate monitoring products on a routine basis. The idea of a EuroGRID project is to create and to promote a rational and a quality assured climatological production of gridded data in a high resolution, based on information from the European National Meteorological and Hydrological Services (NMHSs).

Ozone Layer over Central Europe in 2004

by Wolfgang Steinbrecht, Ulf Köhler, and Hans Claude, Deutscher Wetterdienst

Above Central Europe, the annual mean ozone column in 2004 was only about 6 DU (Dobson Units) or 2% below its long-term mean. This is exemplified in Fig. 13.1, which gives the annual mean ozone columns observed since 1968 at Hohenpeissenberg in southern Germany. The 2004 ozone column follows the general pattern of stabilised ozone levels since about 1999, after the large decline from 1980 to 1997. In part, this stabilisation reflects the levelling off expected from the evolution of stratospheric chlorine (red curve for ozone changes related to EESC in Fig. 13.1). However, ozone levels in recent years have also benefited from the past 1999 to 2003 solar maximum, whereas in 2004 the solar activity decreased (see blue curve in Fig. 13.1). Another important factor, not included in Fig. 13.1, are changes of the large scale circulation over the Atlantic in the past few years. These are represented e.g. by changes in the Arctic Oscillation or North Atlantic Oscillation indices in recent years, and have contributed several Dobson Units to the improved ozone columns in the past years.

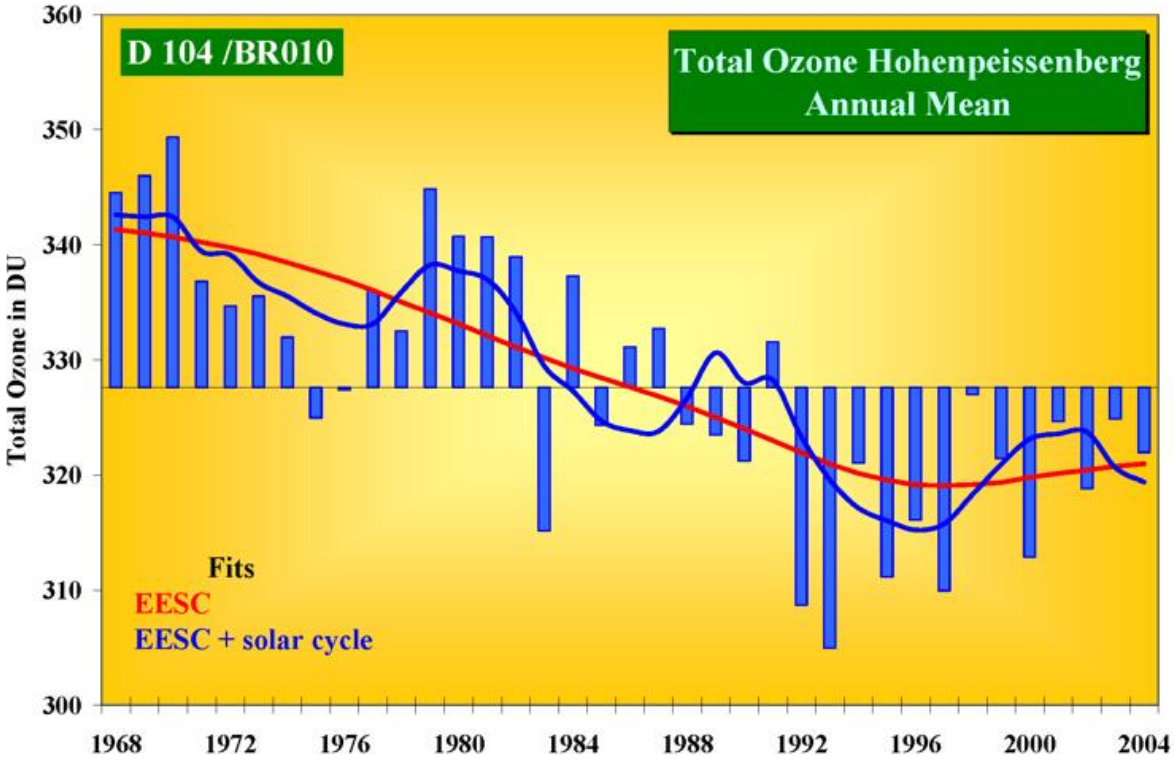

Fig. 13.1: *Annual means of total column ozone above Hohenpeissenberg since 1968. The red line shows the approximate ozone decline due to chlorine (equivalent effective stratospheric chlorine = EESC). The blue line additionally includes the approximate effect caused by the 11-year solar cycle.*

The time series of daily total ozone anomalies for 2004 is given in Fig. 13.2. Anomalies are defined by the relative deviation from the climatological long-term mean for a given day or month. Fig. 13.2 shows the typical sequence of positive and negative anomalies, alternating on a time scale of one or two weeks. Largely, these ozone variations are a consequence of tropospheric weather patterns. In late spring and early summer, substantial additional variation is introduced by air exported from the break-up of the polar winter vortex. Depending on vortex conditions during the preceding winter, this air may be ozone rich, or ozone may be chemically depleted. In 2004, polar ozone depletion in spring was quite small, compared to 2003 when depletion was large. In Fig. 13.2 this is reflected by the absence of large negative excursions in May and June, whereas total ozone levels were quite low in these two months in previous years. Still, the substantial negative anomalies observed in late April 2004 are in part caused by advection of ozone depleted air from the vortex (see also 20 km region in Fig. 13.3). Warm weather in the troposphere played an additional role. In 2004, generally low ozone columns were observed throughout much of summer, from late June to September. Low total ozone usually goes hand in hand with enhanced UV radiation. This can be particularly harmful to human health in spring and early summer, from April to June, when solar irradiation is already high, but the skin of people from Central and especially Northern Europe has not yet adjusted to enhanced UV radiation.

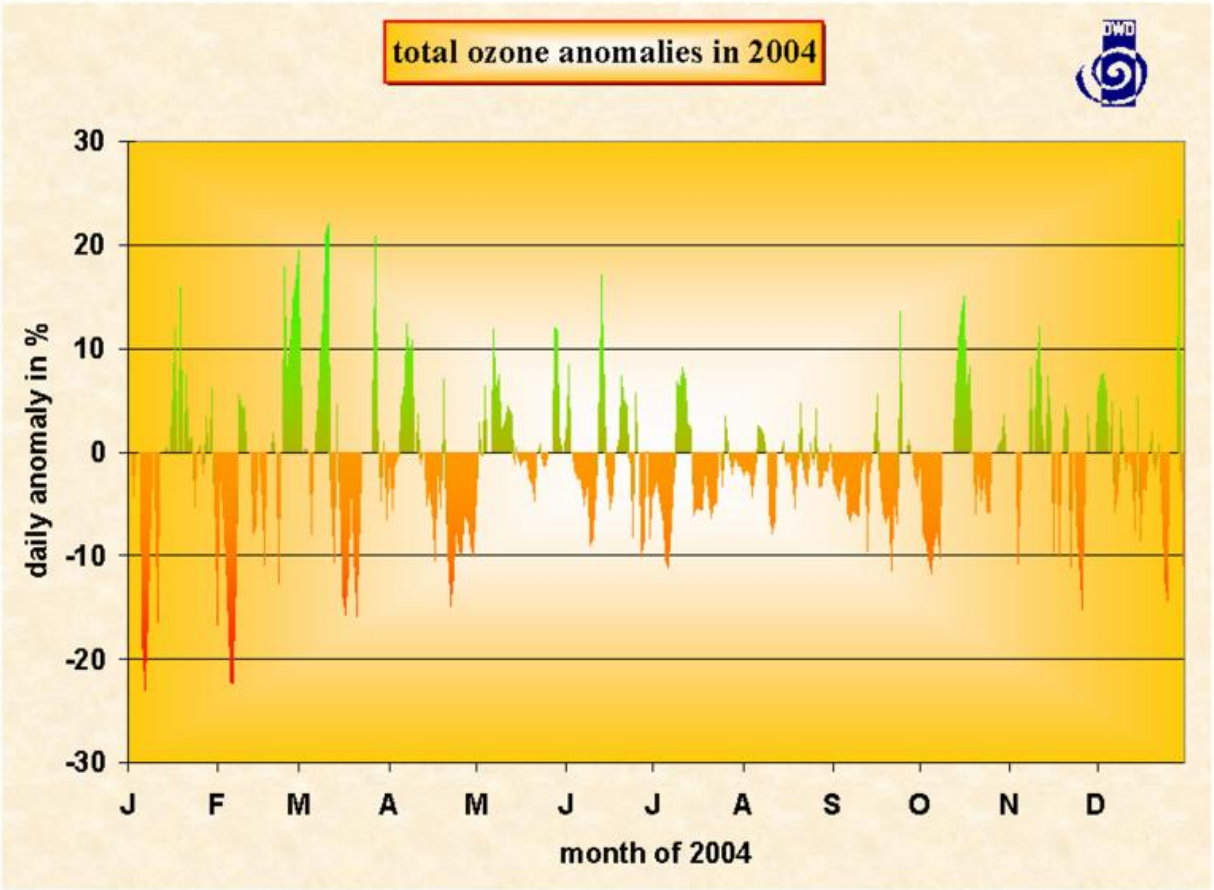

Fig. 13.2: *Relative deviation of total ozone daily means from the climatological long-term mean 1968-2004. Measurements are for the year 2004 at Hohenpeissenberg (47.8°N, 11.0°E).*

The vertical distribution of ozone anomalies in 2004 is given in Fig. 13.3. Above 20 km altitude, ozone was consistently below normal. As in previous years, the largest negative anomalies can be seen in the upper stratosphere, above 30 km. They are a consequence of chemical ozone depletion by man-made chlorine. It is expected that chlorine levels will decline over the next decades, and that ozone levels will begin to improve. Still, the very low levels observed above 30 km in November 2004 are among the lowest of the entire record since 1987.

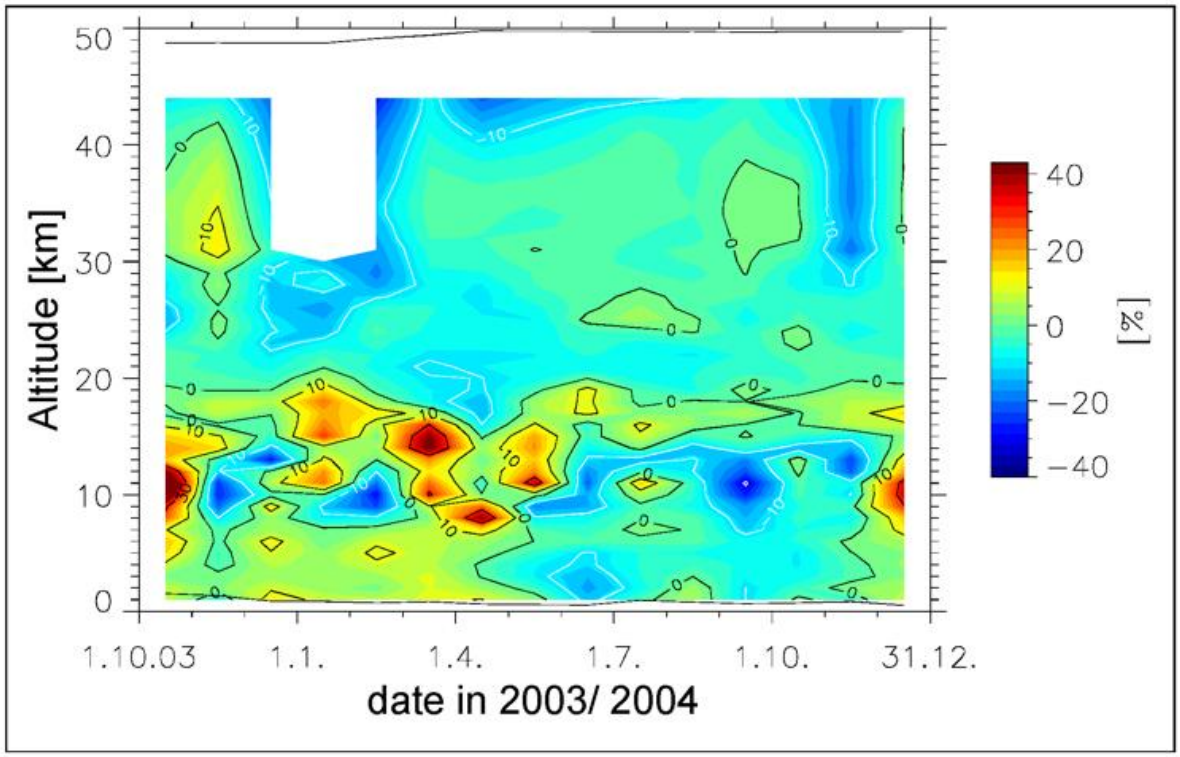

Fig. 13.3: *Relative deviation of ozone monthly means from the climatological long-term mean 1968-2004, as a function of time and altitude. Data are for the year 2003/2004 at Hohenpeissenberg (47.8°N, 11.0°E).*

Below 20 km, ozone is highly variable. The high total columns in March 2004 and the low columns from late June to September 2004 (Fig. 13.2) are associated with corresponding positive and negative anomalies in the 10 to 20 km region of the lower stratosphere (Fig. 13.3). As mentioned, ozone in this region is closely coupled to tropospheric weather and climate. A substantial contribution to the levelling out of the total column in Fig. 13.1 comes from this altitude region. It is not a sign of positive effects from chlorine reduction after the Montreal Protocol, but rather a consequence of complex coupling processes between climate and ozone changes.

To conclude, ozone levels in 2004 were within the range observed in recent years. No spectacular new developments were observed in 2004. As in previous years, neither total ozone nor upper stratospheric ozone above Hohenpeissenberg and Central Europe show clear and unambiguous signs for a beginning recovery of the ozone layer. However, 2004 was another year to show that the strong decline observed in the 1980s and 1990s has not continued in the new millennium.

The Bulletin is a summary of contributions provided by the National Meteorological Services. The author does not warrant, guarantee or make any representation regarding correctness, accuracy, reliability, or any other aspect regarding characteristics or use of the information presented.

Meteorological Aspects of the Extreme Flood in August 2005 in Southern Bavaria 92

Foreword

For the 12th time, a new issue of the Annual Bulletin on the Climate in WMO Regional Association VI is ready. It is based on valuable contributions from 37 National Meteorological and Hydrological Services of our Region.

This issue concerns 2005 which was a remarkable year for many reasons. First of all, according to the analyses of the Hadley Centre, it was the warmest year on record, averaged over the northern hemisphere, and also within our Region, it was warmer than normal nearly everywhere. The north was particularly affected. In the Arctic the anomalies of the annual mean temperature reached up to +4°C with even higher anomalies in the winter months. This is considerable and exceeded the positive anomalies of 2004. Another large area which was notable for an enormous warming was the Atlantic Ocean, where sea surface temperatures exceeded the 98th percentile. I think this is quite outstanding. Secondly, two exceptionally long lasting regional climate events affected parts of Europe very seriously: One was the extensive drought in southwestern Europe from the beginning of the year until October, and the other one, in a sharp contrast, the large precipitation amounts in southeastern Europe, especially in Romania and Bulgaria, during the summer. Thirdly, the high number of hurricanes and tropical storms in the Atlantic was another characteristic of that year. Among the 27 named tropical cyclones in the Atlantic, four of them reached our Region when they became extratropical. Out of these four, there was one which passed the south of the Iberian Peninsula and two which affected the west coast of Norway, all of them associated with considerable rainfall amounts. And last, but not least, this year was also a record year of damage reported to the insurance companies, caused by significant weather events. The list of such events this year does not only comprise those already mentioned, but also heavy storms in various parts of the Region, severe flooding in the Alpine region in August, etc.

All these significant anomalies and events were carefully documented by the contributing Members concerned and compiled reliably by the Deutscher Wetterdienst. Three special reports are included in the Bulletin too: on the annual activities of the ECSN, on the ozone trends until 2005 and a review of the August flooding in the Alpine area. The latter was prepared by the Global Precipitation Climatology Centre in Germany. Once more, all the co-ordination, the editorial review, the publishing and the distribution of the Bulletin was in the hands of our editors Dr. Peter Bissolli and Peer Hechler from the Deutscher Wetterdienst, Department Climate Monitoring. After the recent distribution of the previous Bulletin 2004, they went to enormous lengths to prepare this Bulletin 2005 within the same year of publication to reduce the delay between the end of the reporting year and distribution.

I wish to seize the opportunity to gratefully acknowledge the excellent work of the authors and thank them for their effort. I also wish to express my appreciation to the Deutscher Wetterdienst and its President who makes the resources available for this task every year. Last but not least I extend my gratitude to all those from the NMHSs of the WMO Regional Association VI who contributed to the 2005 edition of the Annual Bulletin on the Climate.

Daniel Keuerleber-Burk
President of WMO Regional Association VI

Outstanding Events and Anomalies in 2005

Temperature

- Anomalies of the annual temperature up to +4°C in the Arctic
- Warm North Atlantic in all seasons
- Cold winter in Portugal and Spain
- Warmest summer in Portugal since 1931
- Very warm autumn in northern, central and eastern Europe

Precipitation

- Extensive drought in Spain, Portugal and parts of western and southern France
- Very wet in northern Scandinavia
- Severe flooding May – August between the Adriatic coast and the Black Sea
- Severe flooding in the Alpine region in August

Sunshine

- 15-20% sunnier in many countries of northern and central Europe

Wind

- Heavy storm over northern Europe on January 7-9
- Severe winter storm in central Europe on November 25-27
- Severe storm in western France on December 1-2 (gusts up to 160 km/h)
- 2 storms over eastern Greece and the Aegean Sea with gusts >100 km/h
- 4 Atlantic tropical storms in the Region

Annual Survey

Temperature

The year 2005 was again warmer than normal nearly all over the Region. Especially in the northern countries the anomalies compared to the 1961-1990 mean were mostly higher than +1°C, locally exceeding +2°C, especially in winter. In the central and southern parts of the Region the deviations from normal were mostly less than +1°C; in and around the Mediterranean region some areas were even slightly colder than normal.

Anomalies for countries or large parts of countries (areal or station mean) also imply mainly a decrease from the north to the south and to some extent also from the west to the east (except for the coastal and marine areas): Norway +1.5°C, Sweden +1.6°C, Russia +1.6°C, Denmark +1.1°C, central England temperature +1.0°C, Ireland around +1°C, Netherlands and Luxembourg +0.9°C, France +0.5°C, Germany +0.7°C, Estonia +1.1°C, Latvia +0.6°C, Lithuania +0.9°C, Poland +0.3°C, Hungary –0.2°C, Romania –0.1°C, Cyprus +0.4°C, Portugal +0.6°C (for Luxembourg and Poland the 1971-2000 mean was taken).

In the north, 2005 was among the warmest years ever according to time series available. It was the 6th warmest year for Norway since the measurements began in 1867. The largest deviations from the mean were located in parts of Finnmarksvidda (northern Norway) and the inland parts of eastern Norway (mostly +2.0 to +2.5°C, Fig. 0.1). The annual means of the Arctic stations Svalbard airport (-3.0°C, anomaly +3.6°C) and Hopen (island 100 km southeast of Spitsbergen, -2.4°C, anomaly +4.0°C) were the highest ever registered there. The warmth affected the sea-ice cover considerably. Also in Sweden, 2005 was to be ranked among the warmest years for more than 140 years (since 1860), for Denmark it was the 6th warmest since 1874. Nuuk in Greenland was also rather mild on the yearly average with 0.3°C (5th warmest year on record) which corresponds to an anomaly of +1.7°C, and also the other stations in Greenland were all above normal; at Danmarkshavn in northeastern Greenland it was the warmest year since 1949 (Fig. 0.2). Also in the northern part of Finland unusually high annual mean temperatures of locally 1.5°C were measured which were 2.3°C above the 1971-2000 average. For the Netherlands this was the 5th warmest year since 1901, together with 1989, and the 9th consecutive year with an annual mean temperature of at least 10°C. In Belgium, the anomaly of +1.2°C in Uccle exceeded the 90% percentile.

Over large areas of the North Atlantic ocean, sea surface temperatures exceeded the 98th percentile for the year as a whole and some areas were the warmest for 156 years. Iceland, although located in the north, did not experience extremely high, but still above normal anomalies: +0.7 to +0.9°C in most areas, only +0.3 to +0.6°C in the southeast. For the Faroe Islands the temperature deviations also amounted to only +0.3°C, but even there 2005 could be placed among the 10 warmest years since 1873.

In Austria, Hungary, Slovakia, Bulgaria, Croatia, Serbia and Montenegro the mean temperature was more or less around normal or slightly below. In Belgrade, after seven warm years, the temperature dropped below normal in 2005 (Fig. 0.3). The coastal part of Montenegro was the only area of the country where it was warmer. Slovenia had a mean temperature mostly above normal, but the anomaly was less than 0.5°C, with the exception of Ljubljana where it was higher. Italy reported for 2005 a temperature decrease of about 0.5°C compared to 2004. In Portugal the maximum temperatures were exceptionally high (+1.4°C anomaly on average, 2nd highest since 1931), but the mean minima were slightly below normal for the first time in 18 years. The annual mean temperature in Portugal was above normal all over the country, especially high (>+1°C) in northern and southern inland regions (Fig. 0.4).

Among the eastern parts of the Region, the Ukraine reported an annual mean of 7.1 to 11.7°C, increasing from the north to the south, which was +0.6 to +1.4°C above normal. For Russia, 2005 was the second warmest year since 1936 (Fig. 0.5). The temperature in most parts of the Lebanon was also above normal.

Precipitation

It was a very dry year for Spain, Portugal and for western and southern France, but also for the eastern Mediterranean, in particular Cyprus and southern Turkey. Wetter than normal areas were to be detected in northern Scandinavia including most of Greenland, and partly in the south, especially in parts of Italy due to an extreme event in November and in some countries west of the Black Sea. In the rest of the Region the annual precipitation totals were mainly around normal, in northwestern central Europe mostly slightly lower, in southeastern central Europe somewhat higher.

In Portugal, the annual precipitation total was the lowest value recorded since 1931. In large parts of the country, precipitation amounts were below 60% with respect to the 1961-1990 mean and even below 50% in some northern and central regions of the country (Fig. 0.6). Also for

Spain, new records were set. At Madrid, the hydrological period November 2004 – September 2005 was the driest such period since 1859 (Fig. 0.7). For the whole of the year 2005, the annual total of 252 mm was the second lowest in Madrid after 1954. Numerous stations in the central and western parts of the Iberian Peninsula showed a similar behaviour. Severe forest fires were the consequence. This extremely extended drought persisted from the beginning of the year until October. In western France about 50% of the normal precipitation was registered (Fig. 0.8). Due to some exceptional rainfall events in northern France in July and in southern France in September, the annual amount was not so low in all parts of this country.

At Nuuk in Greenland, the annual accumulated precipitation of 1219 mm reached an extreme value of 162% of the normal. This was the wettest year there since 1958. For Norway, 2005 was the fourth wettest year since 1900. The stations Røst in the county of Nordland (northern central Norway) and Kautokeino in the county of Finnmark (northern Norway) registered new records for the annual precipitation total with 1090 mm and 534 mm, respectively, within a more than 100-year time series. The Bergen-Florida station recorded 3054 mm which was the third highest measured in the central parts of the county of Bergen since 1868. The highest reported value in Norway, however, came from the precipitation station Haukeland – Storevatn (southwestern coastal region) with 4634 mm (131% of the normal). This was not the only location with annual totals above 4500 mm (Fig. 0.9). From the Norwegian arctic stations, Jan Mayen had the highest value with 812 mm (119%).

Sweden was wet in the northern half, while in the southernmost part it was quite dry with anomalies up to 25% below average in some coastal areas. In the southeast of England the total annual precipitation was 572 mm. Thus, 2005 was the 7th driest year in the 133-year record and the driest since 1973.

Moving to the southeast of the Region, some areas with very high precipitation were to be encountered, causing severe floods and landslides. In the Balkan region, the duration of this period of high precipitation lasted from the end of March until August, first with snow, later on with rain. The yearly areal mean precipitation total of Slovakia (880 mm) was the highest since 1974. For the summer half of the year, several stations in eastern Slovakia reached extreme values (828 mm in Kokošovce was the highest total since 1931). In Hungary, the year was 20% wetter than usual. Romania was also very wet with 866.5 mm or 134% of the normal on areal average, causing widespread flooding events. Especially in the west of the country, it was the most severe flooding for 50 years. In Bulgaria, the percentages reached even higher values of 130-170% of the 1961-1990 mean, especially in the warm half of the year they were extremely high (Fig. 0.10). In contrast, some western and southern parts of the Ukraine reported only 75-85% of the normal annual precipitation. The lowest yearly amount measured there was 381mm.

Slovenia was drier than normal in the west, but wetter than normal in the east (Fig. 0.11). Parts of the Dolenjska region (western Slovenia) received about 120% of the normal. In northeastern Croatia the year was extremely wet; the station Osijek received 151% of the 1961-1990 mean. High precipitation amounts also characterised the year 2005 in almost the whole territory of Serbia (Fig. 0.12).

In the eastern Mediterranean, Cyprus reported 383 mm as annual total, which was quite low with 76% of the normal. Rainfall amounts in Israel during the 2004/05 rainy season (September 2004 – May 2005) were below average (70-90%) in the northern parts of the country, but above average (120-160%) in the southern parts.

Sunshine duration

2005 was unusually sunny in many countries; the duration was around 115-120% of the normal for northern and central European countries as far as reported. At Reykjavik (Iceland) this was the sunniest year since the record year of 1924, the number of sunshine hours being 1548 or 122% of the 1961-1990 mean. Denmark reported a high value of 1837 hours, corresponding to a similar percentage of 123%. For the Netherlands, 1820 hours of sunshine were registered which was 117% of the normal. Since 1901, only 6 years were sunnier than 2005. Luxembourg received even more sunshine (1905 hours, 116% of the 1971-2000 mean). Only 61 days were without sunshine, the normal value is 84.2 days. In France, the sunshine duration was also higher than normal over the whole country. In Germany, the areal mean was 1742 hours; this was 114% of the 1961-1990 mean. Thus, 2005 became the 5th in line of the sunniest years there since the middle of the 20th century. Austria reported durations in the range of 105-120% of the normal.

An exception was Ireland where the annual sunshine totals were generally close to normal or slightly lower (88-102%, Fig. 0.13). In Slovenia, the sunshine duration also was mostly close to normal, only in the Ljubljana basin and Celje was there significantly more sunny weather than on average of the reference period 1961-1990 (111 and 117%, respectively).

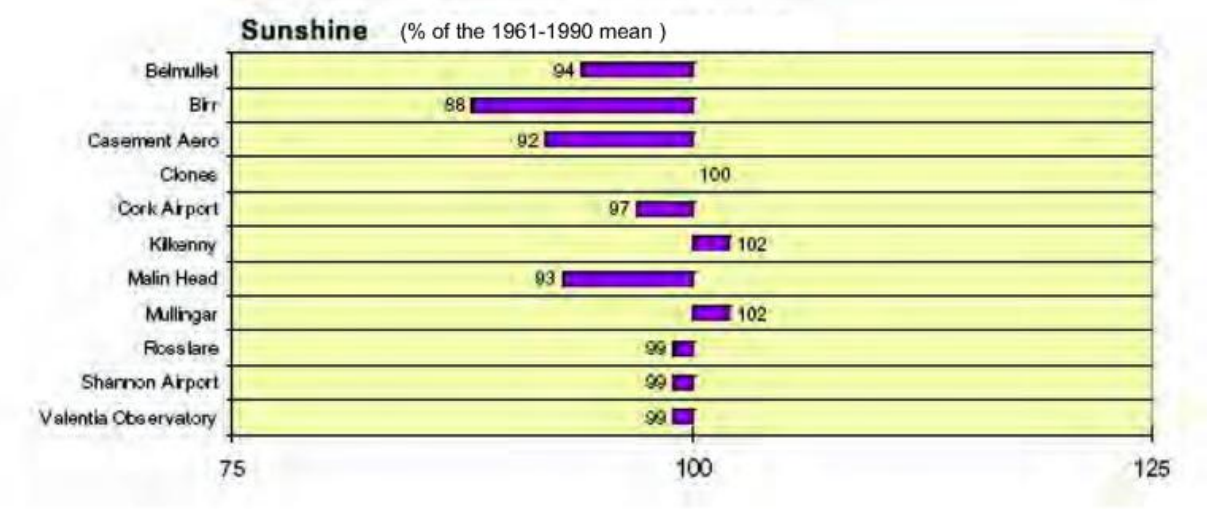

Fig. 0.13: *Sunshine duration 2005 as percentage of the 1961-1990 mean for some stations in the Republic of Ireland.*

Wind

From the beginning of the year until the middle of February, several storms passed over northern Europe and caused severe damage. The highest wind speed in 2005 in Norwegian waters was measured at the Ekofisk field (southern part of the North Sea) on January 8 with 105 km/h. This storm also passed over Sweden, Denmark, Germany and Finland. In Sweden, a mean wind speed of 119 km/h was reached on the same day at the coastal station Hanö in Blekinge; the highest gust was 151 km/h. Germany reported gusts of 156 km/h that day in Kiel in the north of the country. Finland experienced the heaviest storm at the end of October; the highest measured mean wind speed was 97 km/h over the southern coastal waters. The annual number of storm days with a 10-minute mean wind speed >72 km/h, however, was 25 in Finland which was a usual amount. In late summer, a large number of small tornadoes was observed in Finland, more than ever before. Other countries reported several tornadoes too (see monthly survey).

Some severe storms occurred in western and central Europe. Brittany in western France was hit by a severe storm on December 1-2. The gusts reached 120-160 km/h at the coasts of Finistère. On November 25-27, a strong winter storm caused a lot of damage in Germany. In particular, power lines were affected by freezing rain, snow and gusts. Some days later, on December 15-16, another storm passed over Germany with gusts up to 148 km/h on mountains in the east of the country. The maximum mean wind speed in Luxembourg amounted to 87 km/h on February 12.

For the south of the Region, Greece reported storms with gusts around 100 km/h or more on January 16-17 and February 15, both over eastern Greece and the Aegean Sea. In the Lebanon, a wind maximum of 119 km/h was registered in spring, 101 km/h in autumn.

The year 2005 was also notable for being the most active Atlantic hurricane season on record. Some hurricanes even encroached on the Atlantic part of the Region: Maria (September 11), Nate (September 12), Ophelia (September 21) and Vince (October 10).

Seasonal Survey

Temperature

In all seasons, it was mostly warmer than normal within the Region, areas slightly colder than normal appeared only temporarily.

Winter 2004/05 was particularly mild over northern and eastern Europe and the southern part of the North Atlantic (anomalies > +1°C). The greatest positive anomalies (> +3°C) were registered in northern Scandinavia. For Norway, the mean seasonal temperature anomaly was +3.5°C, in parts of eastern Norway the winter was 5.5-6.5°C above normal. Parts of Svalbard experienced the warmest winter ever registered there. In the east, the anomaly for Poland was

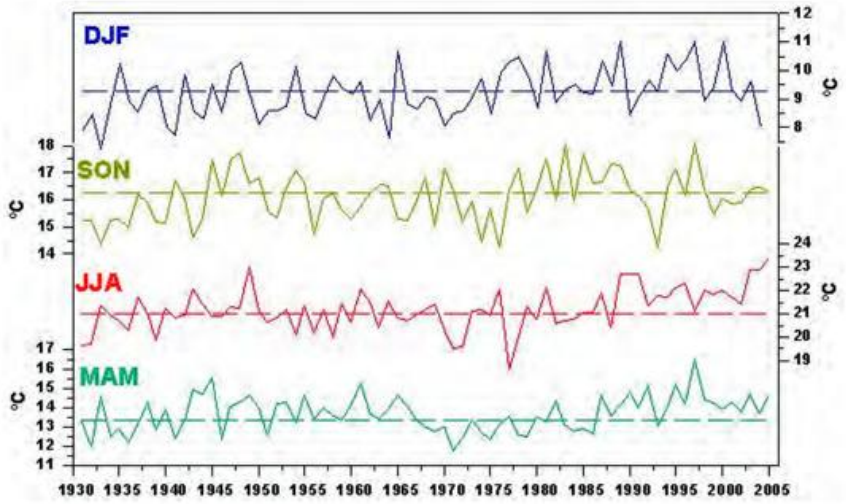

Fig. 0.14: *Mean seasonal temperatures in mainland Portugal 1931-2005*
Source: Instituto de Meteorologia, Portugal

+0.9°C. The temperatures in the remaining parts of the Region were mainly around normal or below. Germany reported a mean anomaly of +0.4°C. In France, the mean seasonal temperature was around normal in the northwest and southeast, but 1 to 2°C below normal in other regions. In Austria, regions with negative anomalies (down to -1°C) could be found in western and central parts of the country. In Portugal, this winter was the 8th coldest since 1931

(anomaly -1.1°C, Fig. 0.14). Such a cold winter had not occurred in Portugal since 1970. A similar case in southwestern Spain: in this region, the winter was the coldest for 34 years with an anomaly of -1.4°C from the long-term mean. This was clearly in contrast to the positive anomalies of the winters before (Fig. 0.15).

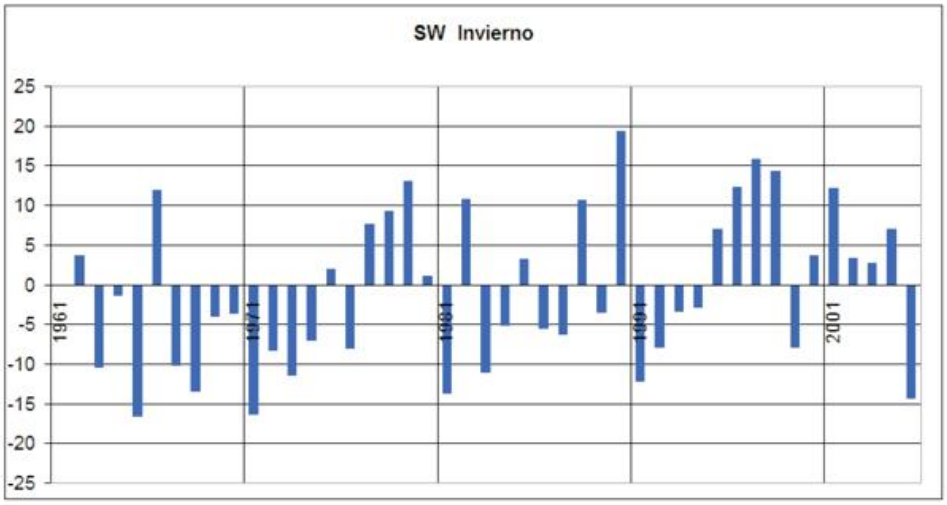

Fig. 0.15: *Mean temperature anomalies in winter in southwestern Spain in 1/10°C from the long-term mean 1961-2005*
Source: Instituto Nacional de Meteorologia, Spain

Spring 2005 was still warm over the North Atlantic and the warm air masses extended from the Atlantic to western central Europe. In France, anomalies of 1 to 2°C above normal were registered in some regions. Germany had an anomaly of +0.8°C. In the other parts of the Region the seasonal temperature was mainly around normal, in the east partly slightly below (e.g. Lithuania -0.6°C, Poland -0.4°C). Anomalies in Norway were not higher than +1.2°C.

Summer 2005 showed a continuation of large positive anomalies over the North Atlantic and significantly in western and southwestern Europe. For Portugal, this was the warmest summer since 1931 (anomaly +2.4°C, Fig. 0.14). In France, the summer temperatures were 1 to 2°C above normal except in the northeast. Scandinavia also had a warm summer, but not outstandingly. The mean anomaly for Norway was +0.5°C. In the more northern parts, the anomalies were higher; at the airport on Svalbard the anomaly was +2.0°C, the highest since 1912. For Russia, this summer was the 4th warmest since measurements began; the mean anomaly amounted to +1.1°C. In the southeast of the Region (eastern Mediterranean and east of it), positive anomalies exceeded the 90% percentile. For example, Israel had a warmer summer than normal; it was warmer than the summer of 2004, but less warm than the summers of 1998-2002. The other parts of the Region had temperatures slightly above normal (e.g. Germany +0.4°C, Poland +0.5°C).

Autumn 2005 had again large positive temperature anomalies especially over northern Scandinavia and Russia. The mean anomaly of Norway was +2.1°C. Russia reported anomalies up to +2.7°C; this was the warmest autumn for Russia since 1900 (Fig. 0.16). In Denmark, it was the second warmest autumn since 1874. The North Atlantic, the North Sea and western Europe remained very warm (anomalies > +1°C). In the Netherlands, this autumn was the warmest for at least three centuries (Fig. 0.17). In Germany, it was the 5th warmest autumn since 1901 (+1.3°C anomaly, spatial distribution Fig. 0.18). Eastern central Europe also registered positive anomalies of this magnitude (e.g. Lithuania +1.4°C, Poland +1.2°C). The southern parts of the Region had temperatures around normal.

Precipitation

Winter 2004/05 was dry in most parts of western and especially southwestern Europe, but also in Slovenia, in Turkey and east of the Mediterranean. For Portugal, this winter was the driest since 1931 (Fig. 0.19). In Slovenia, less than 50% of the normal fell in the Upper Soča valley and on the Trnovska plateau. Most parts of northern and eastern Europe were wetter than normal. The precipitation for Norway as a whole was 130% of the normal. Parts of western Norway received more than 200%, being the wettest ever registered; e.g. Bergen-Florida measured 208 mm (209% of the normal), the highest amount since 1867/68. Western Russia had a lot of snow. In most of central Europe the precipitation totals were around normal. In Austria, the winter was rather dry in the west and south (50-80% of the normal), but rather wet in the north and east (120-160%). Some areas near the central Mediterranean (e.g. Italy, Greece) were also very wet.

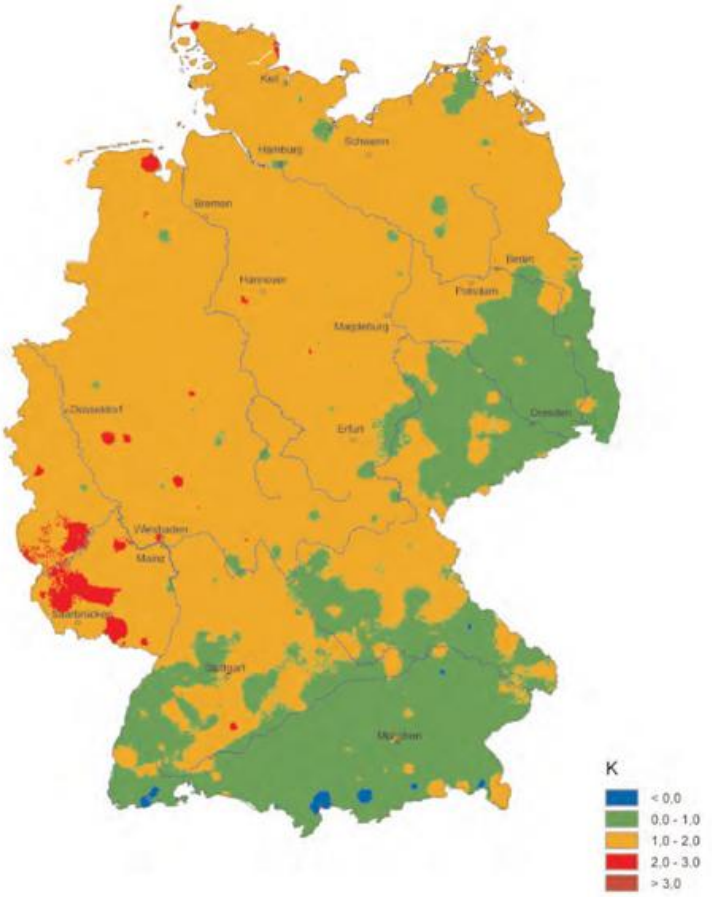

Fig. 0.18: *Mean autumn temperature anomalies 2005 from the 1961-1990 mean in Germany*
Source: Deutscher Wetterdienst

Spring 2005 was dry around the whole of the Mediterranean and most of western Europe. In Portugal, this was the 4th driest spring since 1931 (Fig. 0.19). In the north of the Region, Norway reported a seasonal total of 120% of the normal, in parts of the northern county of Finnmark 200-300%. The station Kautokeino in Finnmark measured 105mm (269% of the normal) which was the highest spring amount since 1895. Larger parts of eastern Norway received less precipitation than normal. Eastern Europe was mostly wetter than on the average. The seasonal mean for Lithuania was 120% of the normal. In central Europe the seasonal totals were mainly around normal. Austria was drier than normal in the south and west, but wetter (up to 180% of the normal) in the rest of the country. Most of the territory of Slovenia received less precipitation than normal.

Summer 2005 showed a continuation of the drought period which was severe especially over southwestern Europe. Forest fires were very frequent in Portugal and Spain. For Portugal, this was the 3rd driest summer since 1931 (Fig. 0.19). In the north of the Region, some northern counties of Norway were wet with a precipitation total of 150-175% of the normal, and also in Finland it rained more than usual. Lithuania reported 126% of the normal. Central and north-eastern Europe had mostly totals around normal, except in the Alpine region where it was wetter due to a severe flooding in August. In parts of western Austria, precipitation amounts reached up to 160% of the normal. In the east of Europe, some very dry areas were to be encountered, e.g. in the Bashkiria region of Russia there was a drought, which was the severest for about 30 years. In southeastern Europe, mainly between the Adriatic coast and the Black Sea, a larger area of wetter than normal precipitation was to be identified. In this area, also some severe

flooding occurred. About one half of the territory of Slovenia received at least 120% of the seasonal normal. In Hungary, this summer was one of the rainiest for about a century, the seasonal precipitation amount was 1.5 - 3 times more than normal (Fig. 0.20).

Autumn 2005 was dry in most of northern, eastern and central Europe. Germany reported an annual mean of 78% of the normal, Poland less than 60%. In large parts of Austria, 50-100% of the normal seasonal precipitation fell, only some regions in the west and south of the country were wet (up to 130% of the normal). In Latvia, this autumn was the 13th driest for the last 80 years (68% of the normal). From Russia, a seasonal total of 88 mm was reported for Moscow;

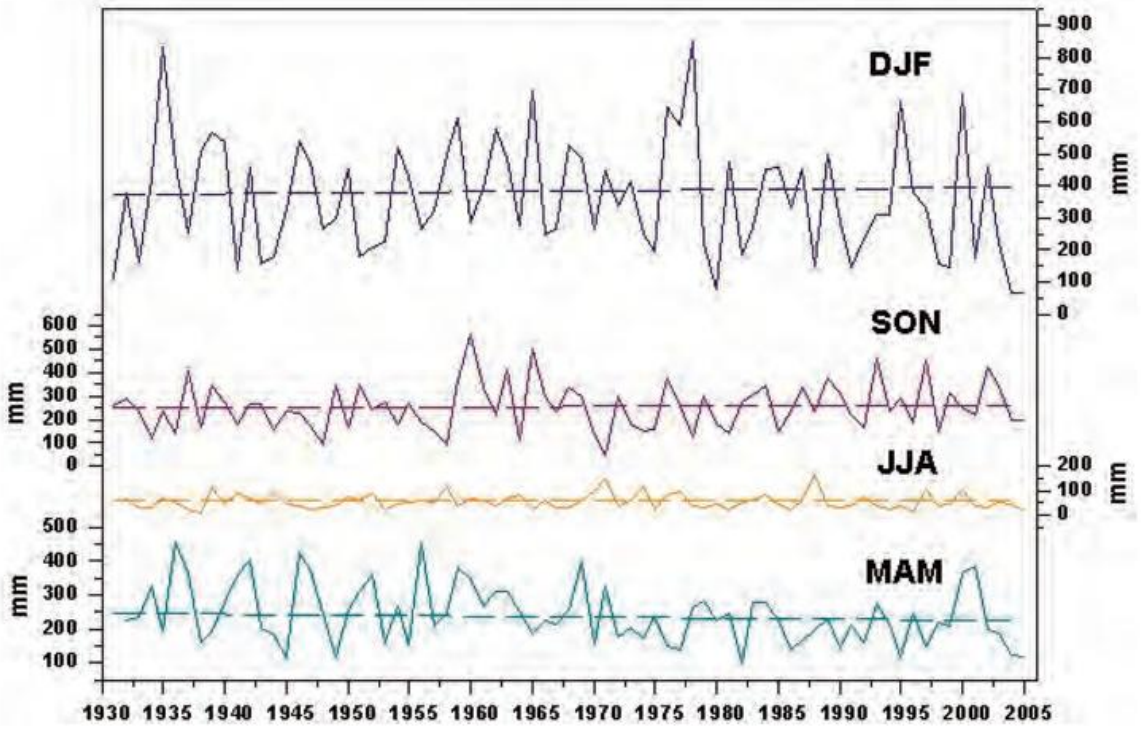

Fig. 0.19: *Seasonal precipitation totals in mainland Portugal 1931-2005*
Source: Instituto de Meteorologia, Portugal

this was the driest autumn since 1975. However, some parts of the northern Norwegian counties received 150-185% of the normal precipitation. In the south of the Region some wet areas were to be found north of the Mediterranean.

Monthly Surveys

January 2005

- **Very mild and wet in the north and east**
- **Storm with heavy precipitation over Scandinavia, northern central Europe and the Baltic countries on January 7-9**
- **Cold in the south**
- **Very dry in the southwest**
- **Wet in countries west of the Black Sea and in the central Mediterranean**

A strong meridional circulation structure prevailed over the Region this month. A high pressure zone with warm air masses was situated over the North Atlantic. The Azores high moved to a very northward position with its mean centre near the Biscay, indicating subsidence and further warming of the Atlantic there. North of this high pressure centre, mild and humid air masses moved over Ireland and the United Kingdom to Scandinavia and then further to northeastern and eastern Europe. Colder continental air masses from the east seldom reached northern and eastern Europe and then quite weakly. This resulted in a very mild, but wet January in the north and east of Europe.

In **Iceland**, the first part of January brought heavy snowstorms and wind, with avalanche conditions in the northwestern and northern districts. One residential house was demolished and a few other houses were damaged, but as the inhabitants had been evacuated, there were no injuries. During the last week of January, milder weather set in and the snow disappeared quickly.

Ireland had a particularly mild January with a monthly mean temperature anomaly of +2.2°C at the Casement Aerodrome in Dublin. It was also 18% wetter than normal there. The **United Kingdom** mean temperature was 2.3°C above average, making it the warmest January since 1990, and the 7th warmest in the series back to 1914. Rainfall and sunshine levels were both slightly above average, with 113 and 109%, respectively. A lot of precipitation fell in Scotland while the southern parts (England and Wales) were dry with only 60% of the normal precipitation.

The mean temperature was well above normal in the whole country of **Norway**. In parts of the county of Hedmark (southeastern Norway) it was 8 to 10°C above normal. The eastern parts of the country experienced the warmest January for the last 100 years. The monthly total precipitation in Finnmarksvidda, parts of the counties of Trøndelag and the western part of the country was the second highest registered since 1900. January was unusually mild and wet also in **Finland**. The monthly mean temperature was 4 to 6°C above the 1971-2000 mean in the whole country. Thus, precipitation was for the most part rain or sleet. In several places monthly precipitation exceeded 100 mm and it remained wet in January. The highest monthly amount (156 mm) was recorded in the southeast of Finland. Due to the high temperatures, a permanent snow cover did not appear in the southern parts of the country until the end of the month.

Estonia reported a mean temperature anomaly of +4.9°C, making this month outstanding compared to the rest of the year (Fig. 1.1). The mean monthly precipitation in this country was also high with 70 mm (186% of the normal). **Latvia** was mild, too (anomaly +4.7°C), but the precipitation was only slightly higher than normal (118% of the normal). **Lithuania** reported +4.9°C and 136% of the normal precipitation.

In the central parts of **Russia** it was the warmest January since the beginning of the time series in 1900. It was particularly mild in the northeast of the European part of Russia with anomalies of more than +8°C. For Moscow this was the third warmest January since measurements began. However, Moscow also registered the highest snow depth and a monthly precipitation total of 98 mm (233% of the normal). For the **Ukraine**, the temperature anomalies (+4.2 to 5.5°C, depending on the climate region) were also outstanding compared to the rest of the year (Fig. 1.2), the precipitation total was around 120% of the normal.

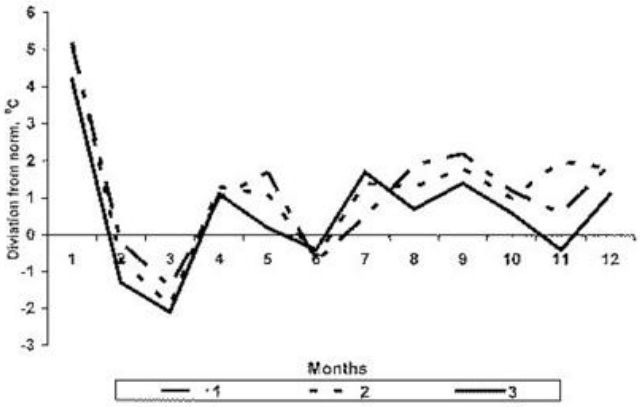

Fig. 1.2: *Ukrainian monthly temperature anomalies from the 1961-1990 mean for all months of 2005 and different climate zones: 1 – above normal humidity zone, 2 – normal humidity zone, 3 – low humidity zone.*
Source: Ukrainian Hydrometeorological Centre

On **January 7-9**, a severe winter **storm** with gusts of hurricane speed moved over Scotland and south Scandinavia to Russia. High rainfall amounts were measured in the northern half of the **United Kingdom**: 143 mm of rain fell in the 24-hour period ending 09 UTC on January 7 at Kinlochewe (Scottish Highlands) and 225 mm fell at Shap (Cumbria, northwest England) in a 72-hour period ending 09 UTC on January 8. This period of prolonged rainfall resulted in severe flooding in Carlisle that was considered to be the worst to affect this town since 1822. The lowest pressure was registered on January 8 around 18 UTC close to the Norwegian-Swedish

border with about 960 hPa reduced to mean sea level. In **Norway** it was the severest storm for more than 10 years. Gusts of up to 105 km/h were reported from the southern part of the Norwegian North Sea (Ekofisk Field station). This high wind speed resulted in significant wave heights of more than 10 m. At the Norwegian station Opstveit in Hordaland (southwest Norway) a diurnal precipitation amount of 146 mm was measured during the storm passage on January 7. **Denmark** was affected by the storm on January 8; it was the severest since December 1999. **Sweden** was hit by the storm on January 8-9 with a maximum gust of 151 km/h measured at the coastal station Hanö in Blekinge (south Sweden, Baltic Sea) and 119 km/h inland in southern Sweden. There it was the worst tree-felling storm since around 1930. Approximately 75 million m³ of trees fell in Sweden. This corresponds to about 250 million mature trees or a normal annual cutting for the whole country. About 85% of the fallen trees were spruces (Picea abies, Fig. 1.3). The total economic loss for Sweden was estimated at around 25 billion crowns (2.7 billion €). For the insurance industry this was the 5th most expensive storm within 50 years. Nine people lost their lives directly during the storm and around 20 during the dangerous clearing up work afterwards. Over 400 000 households were without electric supply, about 10 000 for more than four weeks. The situation was very difficult in the countryside where many elderly people had to be evacuated. The train connection Stockholm-Malmö was interrupted for more than a week. Along large stretches of the west Swedish coast, sea water rose to unprecedented levels, e.g. 164 cm above normal close to Varberg. A high sea water level was also observed in the Gulf of **Finland** on January 8-9. This led to exceptional flooding of sea water into houses on the southern coast of Finland. Huge floods were also reported from Pärnu in **Estonia**. The water level was 275 cm above average. Wind speeds in gusts exceeded 125 km/h. **Latvia** reported strong gusts of hurricane force (up to 144 km/h, Fig. 1.4); in some locations these were new records. As a consequence, electric power lines fell down in many areas of Latvia, causing widespread power interruptions. Trees were destroyed, many houses lost their roofs, and there was damage to agriculture and loss of livestock. The event caused a sea level rise in the southern part of the Gulf of Riga and thus also a rise in the water level in the city of Riga and its port area (up to 213 cm above average on January 9). This level had not been reached since 1969. Several houses and roads were flooded in Riga and in coastal regions. The total cost in storm damage for Latvia was more than 190 million €. In **Lithuania**, widespread gusts of 85-105 km/h were measured, at the coast up to 130 km/h.

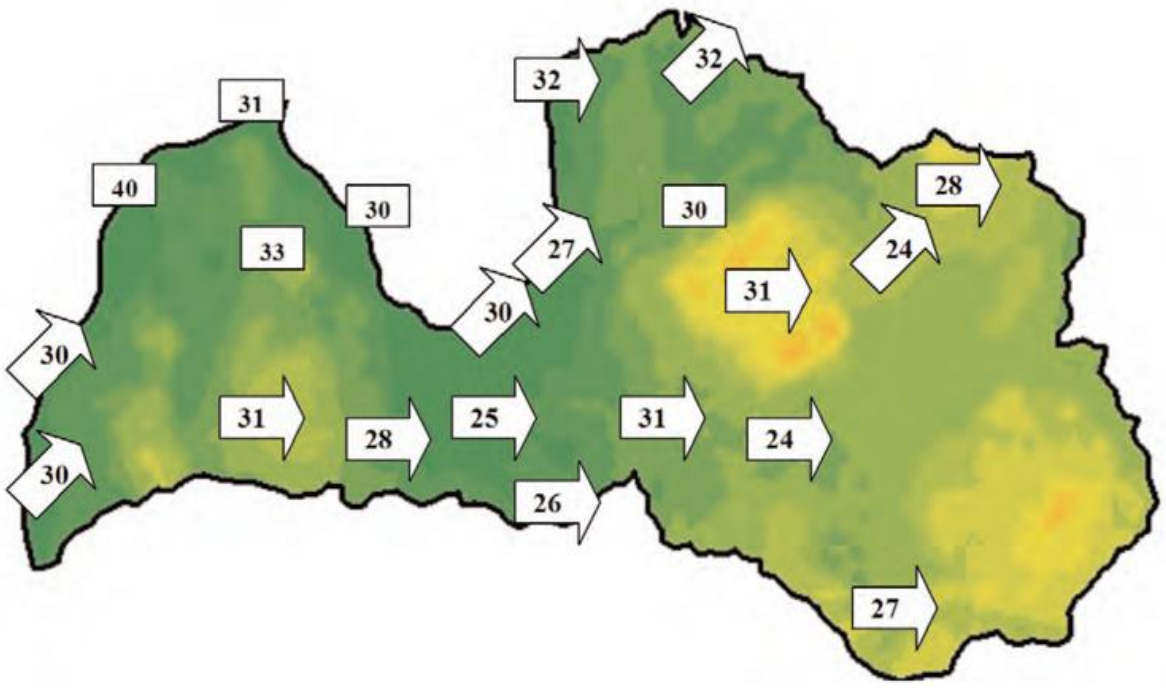

Fig. 1.4: *Maximum wind gusts (in m/sec) and mean wind directions in Latvia on January 8-9. The maximum of 40 m/sec corresponds to 144 km/h.*
Source: Latvian Environmental, Geological and Meteorological Agency

This storm also brought extremely warm air masses to northern Europe. A record-breaking temperature of 12.4°C was measured on January 10 in **Denmark** near the border to Germany. In **Latvia**, new local records of the maximum temperature for 80 years were set during the period January 6-9. **Lithuania** reported a mean diurnal temperature above 5°C during the period January 8-12; the highest daytime temperatures reached 7 to 10°C. Soils were frost-free and the warm weather prompted the germination of snowdrops and tulips, flowering of violets, and in southern forests people were looking for mushrooms. In **Russia**, 5.2°C were measured in Moscow on January 9.

In central Europe, the storm passage was also recorded in **Belgium** on January 8. In northern **Germany**, gusts up to 181 km/h in List (Sylt) and 155 km/h in Kiel were registered on January 8-9. Trees fell on railway lines, houses were untiled, highway bridges had to be closed. The lower lying parts of Hamburg were flooded and local interruptions of power supply occurred.

A second **stormy spell** occurred on the night of **January 11-12** over northwest **Scotland**, with gusts of 171 km/h at Barra and 163 km/h at Stornoway (both Western Isles).

Another **storm** with a low pressure system near Iceland affected in particular Ireland on **January 17-19**. A buoy located west of Ireland measured a wind speed peak value of 70 km/h and a wave height of more than 13 m on January 18 (Fig. 1.5). On January 20-21, this storm passed over **Germany**. Again, disruption to traffic was to be observed, this time not only in the north, but also in the south of the country. In some cities, streets were flooded, trees were uprooted, and some railway lines had to be closed temporarily. Gusts up to 194 km/h were measured on the Wendelstein mountain (elevation ca. 1800 m) in southern Germany. In Freudenstadt (southwestern Germany, Black Forest) 81 mm precipitation fell within 24 hours.

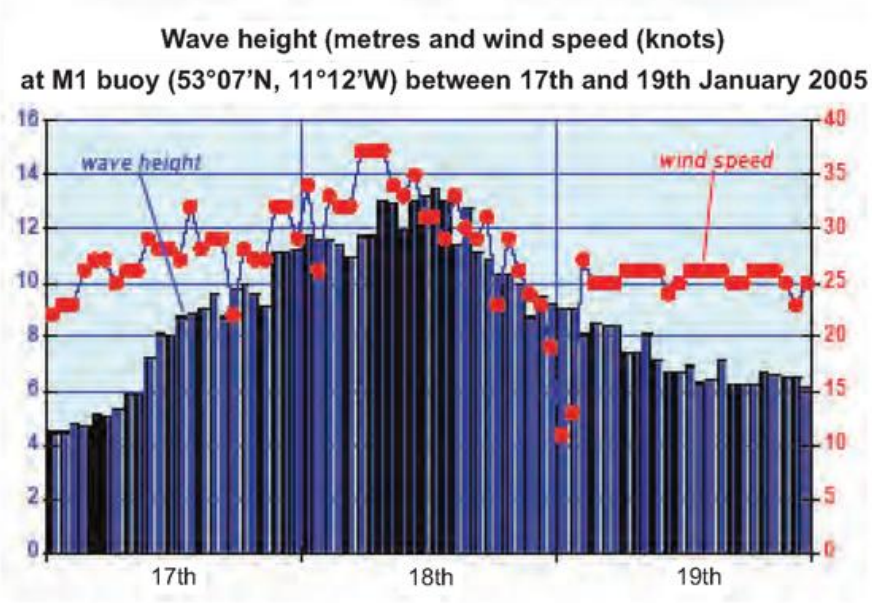

Fig. 1.5: *Wave height in metres and wind speed (knots) at M1 buoy (53°07'N, 11°12'W) on January 17-19.*
Source: Met Éireann, Ireland

Most of central Europe was also very mild on a monthly average. In the **Netherlands**, this was the 7th warmest January since 1901 (anomaly in De Bilt: +3.1°C). On the other hand, this area was also influenced by the Atlantic high pressure system, and thus this January was also the sunniest on record since 1901 at some coastal stations. De Bilt was drier than normal (80% of the normal precipitation). **Belgium** also received much sunshine (145% of the normal sunshine hours and only 66% of the normal precipitation were registered in Uccle), the monthly mean temperature was clearly above normal (+2.1°C in Uccle), only at the end of the month did some polar air masses reach this country. It was a similar situation in **Luxembourg** (152% of the normal sunshine, 72% of the normal precipitation, temperature anomaly +1.8°C). **Germany** had an exceptionally warm first half of the month, and thus the anomaly reached +2.5°C on the areal average. The mean sunshine duration was 132% of the normal. The precipitation total was near normal (109%) on country average, but with large regional differences: in the northern plains and in southwestern Germany, it was very dry (locally less than 60% of the normal), but it was wet (in parts more than 200% of the normal) in the east. **Poland** had similar characteristics: a mean temperature anomaly of +2.8°C (from the 1971-2000 mean), in the northeastern parts even +3.6°C, and in particular the first half of the month was mild. The mean precipitation total reached 142% of the normal, varying from less than 80% in the western and central parts up to more than 200% in the south. There, the highest diurnal precipitation total amounted to 53 mm in the mountains. During the second half of the month, a snow cover of 1 m was measured in this mountainous area. The **Czech Republic** reported a mean monthly temperature anomaly of +2.4°C and 165-170% of the normal precipitation. Maximum temperatures in southern Bohemia reached up to 15°C.

In **France**, the northwest was affected by the warm and humid air over the northern Atlantic, but the south was directly under high pressure influence. Thus, it was warmer than normal in the northwestern areas, but near or below normal in the south. The precipitation totals were higher than normal in the Normandy and in central France, but it was drier than normal in the other regions. Especially the southeastern areas were very dry. In Marseille, only 3 mm of precipitation fell, this was only 6% of the normal.

The Alpine regions had different weather conditions in the north compared to the south. **Switzerland** had sunny weather until the middle of January. In the higher parts of the Swiss Alps it was almost as warm as in spring. Towards the end of the month, the high pressure influence ended with a massive incursion of cold air, associated with heavy snowfall also at lower elevations. The Ticino region south of the Alps remained dry; there it was the driest start to a year for 20 years. In **Austria**, it was mild in the east (up to +2°C); in the western part the temperature was normal. Very dry and sunny conditions prevailed also in the south of the country, in Carinthia and southern Styria with less than 25% of the normal precipitation. In Klagenfurt, capital of Carinthia, 150 hours of sunshine were a new record for this town in January. In contrast, it was very wet in Upper and Lower Austria in the north with up to 200% of the normal monthly precipitation. On January 26, about 70 cm of snow fell within 24 hours (up to the morning of January 27) in the east and southeast of Austria. As a result of severe snowdrifts in the northern Burgenland, railroad tracks were interrupted, side roads were almost impassable. More snowdrifts with depths of up to 1m on January 31 caused the traffic to break down on roads in the direction of Vienna. At the international airport of Vienna, several takeoffs were delayed.

The high pressure influence extended even to the countries east of the Adriatic Sea, except towards the end of the month. **Slovenia** was slightly colder than normal in the west, but at some stations in the east the monthly mean temperature anomaly reached +2°C. The cold spell at the end of the month also touched this area. Precipitation was far below normal, in the central part of Slovenia, the Upper Soča valley (Julian Alps), most of the Gorenjska (northwest Slovenia) and Goričko (northeast Slovenia) regions less than 10% of the normal fell. Nevertheless, a snow cover persisted in the Upper Sava valley (Julian Alps) throughout the month, on January 19 a snow cover was even observed in Ljubljana. At Kredarica (elevation 2515 m) the maximum snow cover was 115 cm on January 1. The sunshine duration was well above normal in the whole country except the Julian Alps. In Ljubljana and Celje it was 3 times sunnier than normal. **Croatia** also was mostly dry; especially in the southern central part north of Split less than 10% of the normal precipitation fell at some stations. It was also colder than normal in the west and warmer in the east, but the anomalies were mostly between -1 and +1°C. In **Serbia and Montenegro** it was first unusually warm with only sporadic rain and snow in the mountains. On January 25, however, cold air with snow extended to the whole country, and ice days were registered every day.

Frontal systems encroached several times on the countries west of the Black Sea and also the central Mediterranean. **Hungary** was quite mild (temperature anomaly of +1.6°C on country average) and sunny (nearly 100 hours of sunshine compared to a normal of about 60 hours), but wet (128% of the normal precipitation). **Romania** also was mild (more than +2°C compared to the normal) and slightly wetter than normal. **Macedonia** reported temperature anomalies of +1.3°C, and around 150% of the normal precipitation. **Bulgaria** was very mild (+1.5 to 3.5°C above normal) and also very wet (150-200% of the normal). Mediterranean cyclones affected this area especially at the end of the month (January 26-31). Up to 100 mm of precipitation (rain and snow) in 24 hours were registered which led to local floods from swollen rivers and overflowed water reservoirs in various parts of the country. Wind speeds up to 100 km/h were measured in southeastern Bulgaria and at the Black Sea coast. In northeastern Bulgaria snow piles up to 2 m accumulated due to snowdrifts.

Southwestern Europe in general was strongly influenced by subsidence within the Atlantic high pressure system. As a result, much of the usual winter precipitation was missing in these areas, giving rise to the start of a long-lasting dry period, but also long sunshine durations and cold nights. **Portugal** recorded the 4th lowest average monthly minimum temperature since 1931, and also the average monthly mean temperature was lower than normal in almost the whole country. The month was also extremely dry, the 4th driest since 1931. Monthly totals were below 20% of the normal, only in some northern regions did the totals exceed 7 mm. In Lisbon and

Évora, there was no precipitation at all during the whole month; this had never happened before in January since 1901. In **Spain**, it was particularly cold in the east and only around 20% of the normal precipitation fell on average over the peninsula. Again, there were some stations without any precipitation at all, e.g. Madrid and Gibraltar. Especially at the end of the month there was a cold spell with snow and temperatures far below zero. In **Italy**, it was colder than normal as well. Northern Italy was also drier than normal (e.g. Pisa 43% precipitation of the normal), but the south was partly wet due to cyclonic influence.

A storm with gusts of more than 100 km/h passed over eastern **Greece** and the Aegean Sea on January 16-17, accompanied by heavy rain and, on the mountains, also snowfall. Thus the monthly precipitation totals were mostly above normal, but the temperatures around normal.

In **Cyprus**, mean monthly precipitation was near normal, mean temperature 0.8°C above. On January 29-30, southerly warm winds with dust affected the island, accompanied by increasing temperatures. A maximum of 22.2°C was measured at Athalassa (near Nicosia); this was the highest value since 1983.

In **Armenia**, the monthly mean temperature was slightly below normal due to cold spells affecting the country on January 8-18 and 26-29 with negative anomalies of 4 to 9°C. The precipitation total was 120-140% of the normal across the main part of the country, but in the eastern regions it was drier with only 60-90%. Strong winds with gusts up to 80 km/h were observed on 3 days of the month.

The temperatures were mostly around 1°C above normal in the **Lebanon**. Precipitation totals were about normal or slightly below. In contrast, it was rainy in most parts of **Israel** with totals reaching 120-150% of the normal. Only in the northeastern parts were they below (85-95% of the normal). Temperatures in Israel were slightly higher than normal.

February 2005

- **Mild in northern Europe and over the North Atlantic**
- **Cold in central and southern Europe and in the east**
- **Very dry in northern, western and in particular southwestern Europe and in some parts east of the Mediterranean**
- **Wet in central and eastern Europe and most of the Mediterranean**

The strong meridional circulation structure with its anomalous high pressure centre over the North Atlantic and a trough over central Europe also persisted in February. On the other hand the Russian high extended westwards to central Europe. Thus, the North Atlantic remained warm, but colder continental air moved to Europe.

It was still mild in northern Europe, but the anomalies were not as high as in January. Due to the Russian high pressure influence, it was also quite dry there.

Greenland was very mild. Danmarkshavn was 8.0°C warmer than normal, Angmagssalik 3.9°C, and also the capital Nuuk was warmer. **Iceland** too was mostly mild with unusual light snow conditions all over the country. Most parts of **Norway** also were warmer than normal. In parts of Hedmark (southeast Norway) and Finnmark (northern Norway) the monthly mean was 5.6°C

above the long-term average, further in the north at Svalbard Lufthavn even 9.3°C, equally high as an earlier record in February 1954. The monthly precipitation total was especially low in eastern **Norway** in the counties of Buskerud and Oppland with only 15-20% of the normal. Sweden reported a mild winter, but sometimes wintry conditions with snow, also in southern Sweden; this implies that some cyclonic systems within the trough over central Europe had impact on the south of northern Europe. In **Finland** an exceptionally dry period started, which lasted until April. Only two or three times in a century was the precipitation amount as low as it had been this year during that period. **Russia** was abnormally mild in the north of the European territory with monthly temperature anomalies of about +10°C. The near-coastal regions around Murmansk and Arkhangelsk reported anomalies between +2 and +5°C. The other areas of the Russian European territory had temperatures close to normal, only east of the Volga river was it was remarkably colder than usual. It was also very dry in the north of the European part of Russia with only 60% of the normal precipitation totals, at some places only 40%, whereas the southern part was clearly wetter (Fig. 2.1).

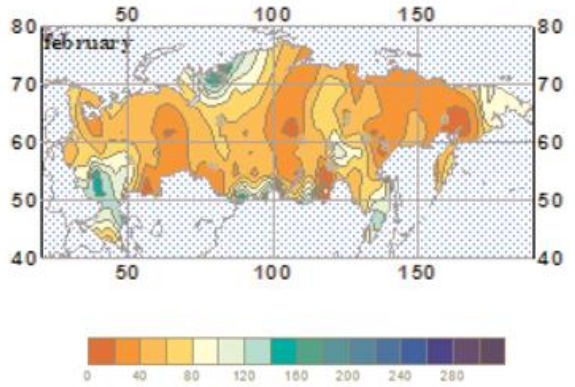

Fig. 2.1:

Precipitation totals in % of the 1961-1990 mean in Russia in February 2005
Source: Roshydromet, Russia

The Baltic countries were mainly under high pressure influence, but also under cold air advection from the east. In **Estonia**, the month was colder than usual by 3°C and precipitation only half of the normal. In **Lithuania**, too, this month was cold and dry. In its eastern regions, the lowest temperature was between -21 and -26°C and the monthly mean temperature was -5.3°C (anomaly 0.9°C). Monthly precipitation amounted to 26 mm (85% of the normal).

The northwest of Europe was influenced by the warm air over the Atlantic and its high pressure system. However, in the Republic of **Ireland** at Casement Aerodrome (southwest of Dublin), temperature and precipitation were nearly normal. In the **United Kingdom**, the monthly mean temperature was 0.7°C above average, sunshine duration slightly above (106% of the normal), and precipitation slightly below (89%). Nevertheless, in the night of February 24-25, an occluded front from the east arrived in England and brought some snow to various parts of the country. A snow depth of 50 cm was reported from Boltshope Park, 30 cm at Westgate, 26 cm at Copley (all County Durham, northeast England) and 23 cm from Carterhouse (Scottish Borders), all on the morning of February 25. On the same day, the lowest temperature of the month was measured at Kinbrace The Hatchery (Highlands) with -11.4°C; Redhill (Surrey, southeast England) recorded -9.5°C overnight on February 27-28 when high pressure influence dominated again.

Western and in particular southwestern Europe still remained under the influence of the Atlantic high pressure system, so this month was also very dry but cold due to outgoing radiation at night, but also due to some cold spells after polar air advection from the north. **France** was cold especially during the second part of the month. By the middle of February, the temperature started to fall, but it was February 22, when the cold spell really intensified, extending over the whole country. Temperatures dropped down to below -20°C in the northeast and below -10°C in the other regions, except in coastal areas. This cold spell was not exceptional, but remarkable for its duration and its late occurrence. The monthly mean temperature was 1 to 4°C below normal from the north to the south. Precipitation was lower than normal mainly in the western

regions, but also in the south. Marseille had no precipitation at all (the normal is 54 mm). In other parts of the country very frequent snowfall was observed during the cold second half of the month. In **Portugal**, mean temperatures were below normal as well and in particular also the average minimum temperatures, which were the second lowest since 1931. One cold spell continued from January, another one occurred by the middle of February. Like January, February was also very dry; the precipitation totals were below 40% in the whole country. At the end of February, more than ¾ of the country was in a drought period of severe to extreme intensity. **Spain** was also colder than normal (anomalies around -2°C) and dry, but not so extreme as in January.

Easthern, central and southern Europe became considerably colder due to cold air advection from the east to the west and occasional polar air advection from the northwest. Within the large-scale trough, which extended further to the south, much cyclonic activity was able to develop over these areas and led to a very wet month there. In **Denmark**, this month was already colder than normal. In the **Netherlands**, the temperature was around normal in De Bilt due to its position near to the North Sea, but the precipitation exceeded the normal by about one half. **Belgium** was influenced by maritime air flows at the beginning of the month, but was affected by polar air at the end of February. Thus, on average this month was around normal. Those areas which are not very close to the coast were mainly under the influence of the polar air, e.g. Uccle was cold with 1.1°C below normal and had a precipitation total of 153% of the normal. **Luxembourg** in contrast reported a slight deficit of precipitation, but an even lower temperature anomaly of -1.5°C. Seven ice days (Tmax <0°C) were recorded at the airport of Luxembourg, soil frost occurred nearly every day. **Germany** was 1.1°C too cold compared to the normal, in southern Germany in parts more than 3°C. On February 28, minimum temperatures below -20°C were measured at several locations, e.g. at Munich airport -23.2°C. The mean precipitation was 121% of the normal (in parts more than 150%); sunshine duration was only 95% of the long-term average. Snowfall occurred frequently. In **Poland** too, February was colder and wetter than usual. Temperature anomalies were between 1 and 3°C below normal, the lowest minimum of -23.3°C occurred in the south. Precipitation was particularly high in the southwest (200%); the highest diurnal total of 47mm was registered in the Sudeten Mountains. Snow depths of 10-30 cm were measured in the lowlands, in mountains they exceeded 2 m. The **Czech Republic** also reported a very cold February with an anomaly of -2.6°C and 165-170% of the normal precipitation. In the **Ukraine**, the temperature anomalies were lower (around -1°C or less), but the precipitation totals were high (140-190% of the normal). The absolute minimum temperature of that month and year (-31°C) was measured in the Carpathian Mountains. In the northern part of the Ukraine, the minima were between -23 and -29°C, in the south between -17 and -23°C. In **Austria**, the temperatures were 1 to 3°C below normal. On the mountain Sonnblick (3109m) a temperature of less than -30°C was measured on February 28, for the first time since 1996. The precipitation amounts varied from 25% in the west and south to 200% in the north and east. Continuing snowfall in the county of Styria caused traffic accidents and interruptions of transport links. In the district of Bad Aussee several localities were not reachable for some days. Avalanches were very frequent, especially on February 5-6.

On **February 12**, a convective **storm** developed from an Atlantic low and passed over central Europe. Damage was reported from all over the country in **Belgium**. In **Germany**, gusts up to 152 km/h were reported from the highest mountain Zugspitze in the Alps and 122 km/h on Rügen in the Baltic Sea. Houses were untiled, severe traffic accidents occurred. In southeastern Germany many river banks were flooded. A cold front passing the Alps resulted in a significant incursion of cold air in **Switzerland** on February 13; this marked the beginning of an unusual long period of cold winter weather there. Up to the end of February, 12-17 days with mostly light snowfall were observed in the areas north of the Alps. In Zürich there were even 19 days

with snowfall. To find a similar number of snowfall days, one has to go back to 1996 and 1986. Due to the low intensity of the snowfall, the snow depth was not extreme. In central **Austria**, heavy snowfalls occurred already on February 11 and 12.

In **Slovenia**, the temperature anomalies varied from -1.2°C at the coast to -4.4°C in the Julian Alps. The coldest period was on February 5-10. The lowest temperature at Kredarica occurred on the last day of February (-25.7°C), at Murska Sobota (northeast Slovenia) -24.1°C were registered. Although these were very low temperatures, they were not the lowest ever measured in February. The monthly precipitation normal was only exceeded in the northeast and southeast of Slovenia, but nowhere were the totals higher than 90 mm. At the coast, in Vipava Valley and in most of Soča Valley less than 20% of the normal precipitation fell. In the Upper Sava Valley the snow cover persisted throughout the month, in Ljubljana it reached 25 cm on February 26, in the mountains at Kredarica 190 cm on February 27. In **Croatia**, this February was among the 10 coldest at most of the stations, with anomalies between -2 and -5°C (Fig. 2.2). Precipitation was mostly higher than normal, especially in the northeast with more than 140% at some stations. **Hungary** also was very cold (mean anomaly -3.6°C) and wet (precipitation 128% of the normal). From **Serbia and Montenegro**, large negative temperature anomalies between -2.4 and -7.9°C were recorded; the number of ice days also was higher than normal at all stations. The lowest temperature of -35.0°C was measured at Karajukića Bunari (western part of the country) on February 7. There was snow during the whole month on the territory of Serbia and in mountainous regions of Montenegro. A new record of snow cover was reached on February 26 in Žabljak with 230 cm. The month was also colder than normal in **Romania** with excessive precipitation and severe winter phenomena. **Macedonia** reported temperature anomalies between -2 and -3°C. **Bulgaria** had an anomaly range between -1.0 and -3.5°C and precipitation totals of 150-250% of the normal. Two Mediterranean cyclonic systems affected Bulgaria, one on February 3-6 and another on February 13-17. Wind speeds up to 144 km/h were measured in both cases. In particular the second system also affected eastern **Greece** and the Aegean Sea; gusts of up to 120 km/h were measured in Attica (around Athens) which was exceptional for this area. Damage was reported from the port of Piraeus (sinking of boats) and electricity interruptions on the Cyclades.

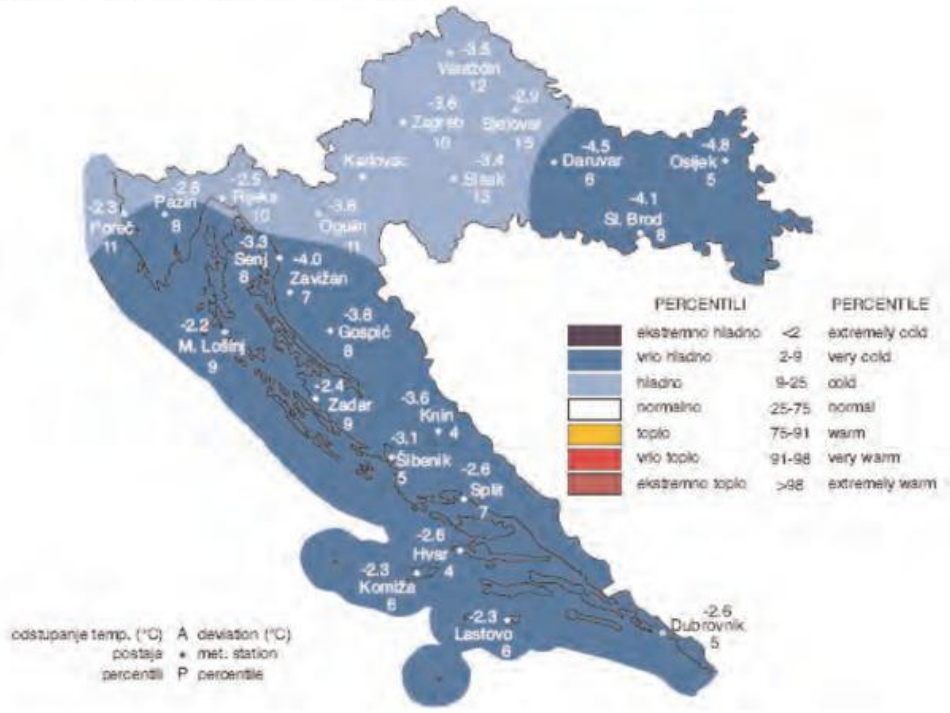

Fig. 2.2: *Monthly mean temperature anomalies in February 2005 from the 1961-1990 mean (upper numbers) and percentiles (lower numbers) in Croatia*
Source: Meteorological and Hydrological Service Croatia

The cold air also reached the Mediterranean. In **Italy**, it was about 2 to 3°C colder than normal in the whole country; it was drier than normal in the north, but wetter in the south due to some cyclonic activity in the Mediterranean. **Greece** had a cold spell on February 8-10; the temperature minima dropped below zero particularly in the northern and central mainland, in higher elevations (e.g. Florina, 689m) down to -17°C (the long-term mean is -1.7°C). **Cyprus** was 0.4°C colder than normal on monthly average, but dry (63% of the normal precipitation). On February 17-19 and again on February 28, suspended dust from north Africa affected the island.

The very southeast of the Region was not or only rarely affected by low pressure systems, so that it was cold but dry in this part. In **Armenia**, the monthly mean temperature was 1 to 2°C below normal, during February 5-15 even 3 to 8°C, in the mountain regions 9 to 12°C. The diurnal minimum temperatures reached down to between -20 and -30°C in mountain regions and between -10 and -19°C in valleys. Two warm spells occurred on February 19-22 and February 27-28 with anomalies between +6 and +11°C. Maxima in the Ararat valley and in eastern regions between 10 and 20°C were measured. It was dry during the whole month (25-70% of the normal precipitation). In some regions gusts up to 133 km/h were registered.

At the eastern Mediterranean coast, the **Lebanon** was mostly warmer and wetter than normal. In **Israel**, February was rainy in the northern and central parts of the country (120-160% of the normal precipitation) and drier than normal in the southern parts (less than 50%). Most of the rain fell in the first half of the month. Snowfall occurred in the mountains in northern Israel. The last rainfall period was on February 19-20, afterwards only minor rainfall affected Israel until the end of the rainy season. The average temperatures were close to normal, but the first half of the month was colder (night temperatures below 0°C in the mountains), the second half was warmer. On February 18-19, 28 to 30°C were recorded in the coastal plain and in the Negev.

March 2005

- **Warm in the west, cold in most of the east**
- **Dry in most of northern, central and southern Europe, wet in most of the east**
- **Cold spell with snow at the beginning of March**

The circulation structure remained mainly meridional, but the Atlantic high pressure zone of the previous winter month became weaker and moved to Europe. Instead, a cyclonic complex developed over the Atlantic. The warm Atlantic air extended to the western half of Europe and was mostly under subsidence, so that it still remained dry in these areas. Atlantic low pressure systems weakened very rapidly over Europe.

It was a very warm month in **Greenland**. Angmagssalik had a temperature anomaly of +6.9°C, Danmarkshavn +2.8°C. **Iceland** was mostly warm with very light snow conditions. There was no snow in Reykjavik for the first March since 1977. Especially the southeast was very dry. Westerly winds prevailed during this warm spell and transported sea ice from the East Greenland current eastward along the northern coast of Iceland. However, the ice cover was generally thin, and coastal shipping was affected for only a few days.

Ireland also was very dry and mostly warm. Near Dublin, at Casement Aerodrome, only 15 mm of precipitation was registered. These were only 31% of the normal, and this month was by far the driest of 2005. The monthly mean temperature anomaly amounted to +2.0°C there. However, there was a cold spell at the beginning of the month, and thus also the lowest air and ground temperatures of the year were recorded. The monthly mean temperature for the **United Kingdom** was 1.7°C above average, which was warmer than March 2004, but not as warm as 2002 and 2003. With sunshine levels at 81%, this was the dullest March for the UK since 1998. The precipitation total was 79%, and this was the 7th consecutive March to experience below average rainfall. Also here the cold spell at the beginning of March was observed with snow drifts up to 30 cm over the Downs (southeast England), causing transport disruption and school closures in Kent and Sussex. Boltshope Park (Durham) reported 40 cm of snow on March 3, the last day of snow lying there in this spell was March 14. In **Denmark**, a snow blizzard, caused by a polar low, passed the islands on March 13-14.

Central Europe was also mainly influenced by the warm and dry air. In the **Netherlands**, De Bilt was 1.5°C warmer than normal; the monthly precipitation total was 79% of the normal. The cold spell at the beginning of March was also experienced in this area. A large part of the north of the country was covered with 20-50 cm of snow on March 2-3. A snow cover of this extension is very rare in the Netherlands. The recurrence time is estimated to be less than once in 50 years. On March 4, the lowest temperature ever measured in the Netherlands in any March was recorded in Marknesse (Ijsselmeer region) with -20.7°C. The polar airflow in the first half of March was also reported from **Belgium**, but again the mean monthly temperature was above normal (+1.7°C in Uccle), precipitation was 72% of the normal. Sunshine duration and mean wind speed were low, too. **Luxembourg** was also dry (only 36% of the normal) and warm (+1.1°C above normal), but a very cold night was registered in the morning of March 1. The station Schimpach (northwest Luxembourg) recorded -18.3°C that morning. **France** as well had a very cold first half of the month, and then a warming took place. Precipitation was below normal except in the centre regions, Limousin, Auvergne and Alsace. Similarly in **Germany**: after a cold first half of the month, it became very mild especially in the southwest. Record temperature minima (lowest values since measurements began) were registered on March 1 in southern Germany, e.g. Augsburg -24.2°C, Stuttgart Airport -18.6°C. In northern Germany, this cold spell was characterised by heavy snowfall, causing chaotic traffic conditions on the roads. Another push of snowfall arrived on March 11-12, when a frontal system passed central Europe from the north to the south. On the monthly average, it was around 1°C warmer than normal in the west, and colder than normal in northern and eastern Germany. Nearly all over the country it was dry; mostly just 50-60% of the normal precipitation were recorded, in the eastern and southwestern areas partly less than 40%.

Extreme temperature minima over freshly fallen snow on March 1-2 were also measured in **Switzerland**, in particular in the plains north of the Alps. Also here, the weather character changed abruptly in the middle of March. A warm air high, situated over Italy, caused a radical rise of temperature. In the Ticino, temperatures up to 28°C were almost summerlike, a new record for that time of year. In **Austria**, March also started extremely cold with frost down to -27°C (Seefeld/Tyrol) on March 1. Some small towns in Styria were not reachable until March 9 due to high amounts of freshly fallen snow. On March 10, a large roof of a supermarket collapsed under the snow load. The prolonged melting of snow afterwards caused flooding situations near the main rivers. On March 18, the river Enns in Upper Austria partly flooded the town of Steyr. In the northwest of Lower Austria, in the region Waldviertel, streets were flooded by melting ice masses of the river Kamp along a distance of 2 km. On monthly average, the temperatures were about normal in western and southwestern parts of the country and 1°C below normal in the remaining parts. Precipitation reached normal amounts only in the northern parts of the Austrian Alps; most parts of Austria only received 25-75% of the normal. **Hungary** too, was cold (-1.8°C), but sunny and dry (74% of the normal precipitation) on average. Temperatures were also was mostly below normal in **Slovenia**, and also here the coldest period

was on the first two days of March (Fig. 3.1), the deepest snow cover was on March 4, at Kredarica in the highland it was 210 cm on March 5. Most of the lowland had more days with snow cover than normal. The warmest day mostly was March 18, at the coast it was March 29. The difference between the lowest and highest temperature this March was great, in Celje it was 45°C. Precipitation was below normal, the lack of precipitation was most evident in the north of the country. Colder than normal temperatures were also reported from **Croatia**, between -0.3°C on the islands in the west and -2.0°C in the east. The precipitation totals were mostly around normal, or, especially in the west, lower, on the islands only 30-65% of the normal.

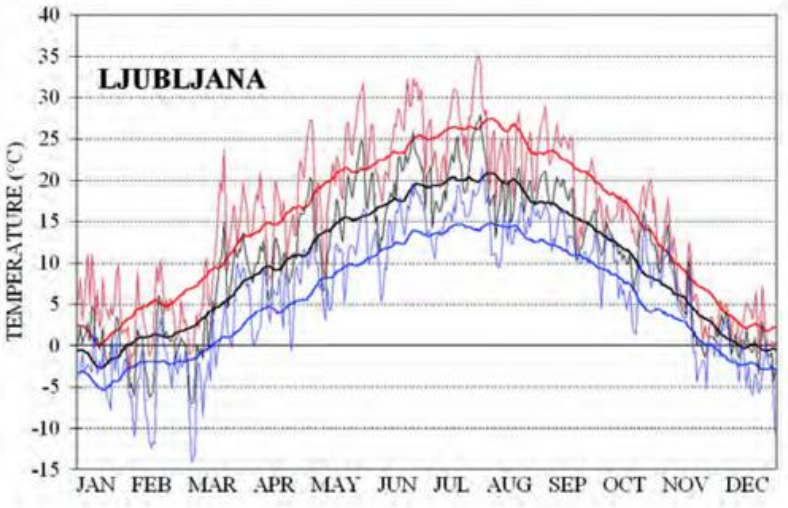

Fig. 3.1: *Daily minimum (blue), mean (black) and maximum (red) air temperature in 2005 (thin lines) and on average of the 1961-1990 mean (thick lines)*
Source: Environmental Agency of the Republic of Slovenia

In **Portugal**, the month of March continued the period of very low precipitation amounts, namely in central and southern regions. At the end of March, 52% of the territory was in drought conditions of severe to extreme intensity (according to the Palmer Drought Severity Index). The monthly mean temperature was above normal, but also here, the minimum temperatures were very low in the first days of the month, records were broken. On March 1, minima below 0°C were observed at 80% of the stations in Portugal, at 30% of the stations the minima were even below -5°C. Only in Faro (Algarve) was the minimum above 5°C (Fig. 3.2). **Spain** also was very dry and on average warmer than normal. Madrid reported a monthly temperature anomaly of +0.9°C and 10 mm of precipitation (30% of the normal). On March 1, after a cloudless night, the minimum was only 1°C. **Italy** was colder and on average mainly drier than normal . As an example, Pisa had a temperature anomaly of -0.7°C and received 66% of the normal precipitation.

Moving to the north, in **Norway**, the temperature varied greatly in the whole of the country. At the beginning of the month, after a temporary cold airflow from the north, Røros Lufthavn registered -39.4°C which was the third lowest temperature measured there. After the high pressure zone and the warm air had moved to Europe, the same station measured 13.2°C at the end of the month which was a new maximum temperature record for March.

Sweden was mostly influenced by colder air from the east. Still wintry conditions with snow in the south were reported. **Finland** also was mainly colder than normal and the exceptionally dry period of February continued. **Estonia** was very cold in particular in early March. In Jogeva (northern central part of the country, also called the Estonian “cold pole”) a colder first decade of March was only recorded in 1942 and 1987. The monthly mean temperature anomaly was -3.5°C, a minimum of -27.8°C was registered which was also the coldest of the whole year. It was also the driest month of the year with 13 mm of precipitation or 43% of the normal. **Latvia**

reported a temperature anomaly of -3.4°C, and 74% of the normal precipitation. In **Lithuania** too, March was cold (monthly mean anomaly -3°C, in its coldest period between -8 and -12°C). Here, the precipitation totals were close to normal in most regions, but some places received up to 65-80 mm (150-200% of the normal). Most of the precipitation fell in the first half of the month; the number of precipitation days of this month was 23.

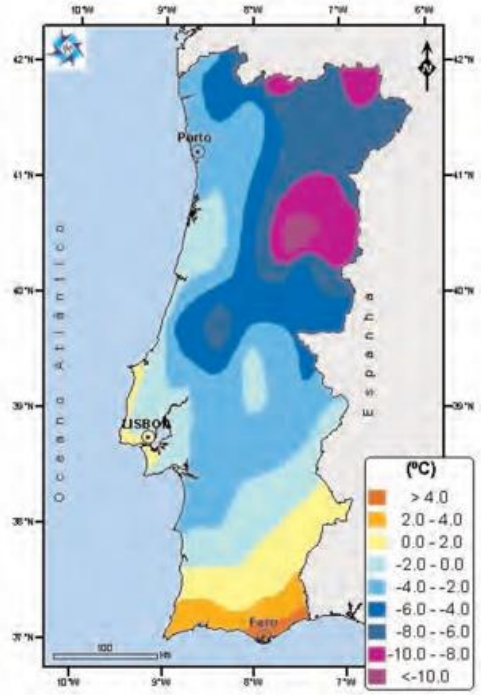

Fig. 3.2:

Minimum air temperatures in Portugal on March 1.
Source: Instituto de Meteorologia, Portugal

In the eastern part of the Region, a low pressure system developed. Thus, this area was mostly wet this month and the cold air did not become much warmer in spring. The monthly mean temperature of the European territory of **Russia** was between 2 and 4°C lower than normal. Such a cold March had not been observed before in the northwestern district since 1981 and in the central district since 1996. The largest anomalies (between -5 and -6°C) were recorded for the Nenetsky autonomous region, the area around Arkhangelsk and the Republic of Komi. Precipitation was mostly above normal, in particular in the Ural, especially in the southern part (300-500% of the normal). There were heavy snowfalls and avalanches particularly on the northern slopes of the Caucasus Mountains. The Trans-Caucasus motorway was opened only during the night. It was colder than normal also in **Poland** (between -1.4 and -3.3°C) with the coldest region in the northeast. The absolute minimum of that month was -20.6°C. Precipitation totals reached 150% of the 1971-2000 mean in the north and east, only the southeast was drier (less than 50%). It was also windy; gusts of 115 km/h in the mountains and 108 km/h at the coast were measured. In the **Czech Republic**, an extraordinary high snow cover was to be observed in the mountains, up to 345 cm on the crests of the Krkonose Mountains in northern Bohemia on March 15. The month was cold furthermore in the **Ukraine** (anomalies between -1.5 and -2°C), but the precipitation totals were very variable (80-140% of the normal). In **Romania**, an alternation of cold and warm periods averaged the monthly mean temperatures close to normal, except for the west of the country, where it was colder than normal. Precipitation totals were mostly above normal except for the northeast and southeast of the country, which had close to normal values. The month was cold in the whole territory of **Serbia and Montenegro**. In the first half of the month the number of ice and frost days was much higher than usual. Some absolute temperature minima records were broken. On March 7, the highest ever measured snow depth of 156 cm was registered in Kolašin (northern Montenegro). Only in 4 years since 1949 was the maximum snow depth more than 1 m. On the same day in

Kotor (coastal town in Montenegro), a snow cover was observed, which had never been experienced before at that location at that time of the year. The cold and wet spell on March 7 even reached **Macedonia** (Fig. 3.3), which was in clear contrast to the second warm and mainly dry half of the month. **Greece** reported an exceptionally large maximum temperature difference between the north and the south of the country on March 1, reaching 33°C between the coldest area in the northwest (-7°C) and the hottest in the southeast (26°C). This extreme situation was a combination of a cold winter onset in the north and warm air advection in the south, in particular on Crete Island, in addition to a Foehn phenomenon. Unusually high daily maximum temperatures (4-8°C above the long-term mean) over several areas of the country, mainly over the mainland, were recorded on March 16-19. In **Bulgaria**, the temperatures were down to 1.5°C below normal. Precipitation was near normal in northern Bulgaria and 50-70% of the normal in the southern parts of the country. There were stormy winds with gusts up to 130 km/h, registered mainly in the north on March 5-7 as well as abundant snowfall in the southern mountains on March 7, causing avalanches which isolated mountain tourist sites. Again stormy winds were registered on March 18-19 in northern and southern Bulgaria, enforcing a state of emergency at the Varna port. Forest fires occureed in the northwestern part of the country.

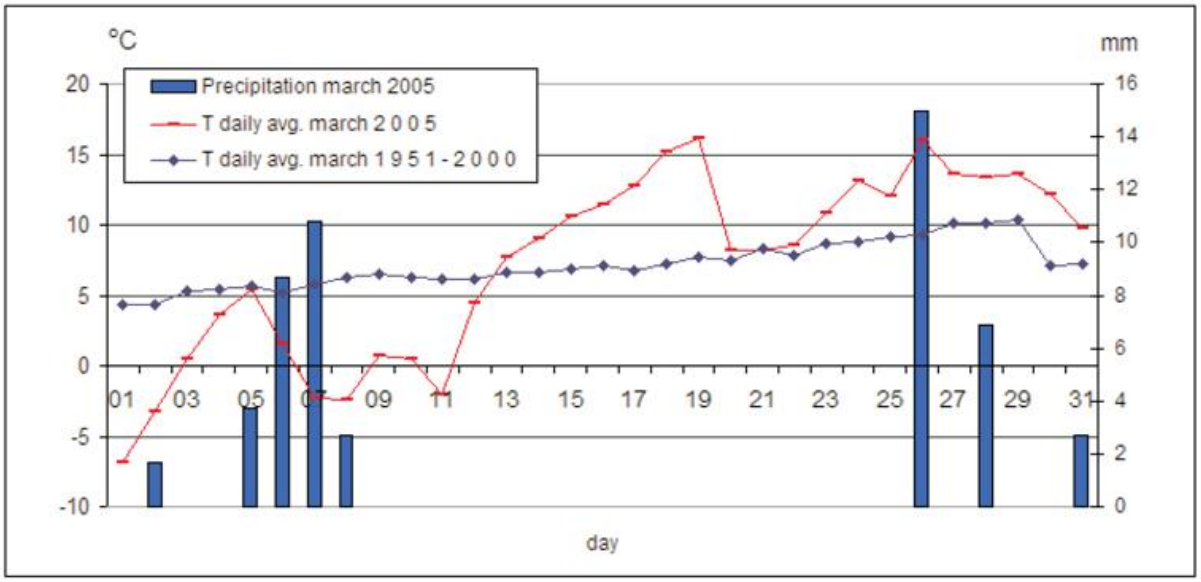

Fig. 3.3: *Daily mean air temperatures and precipitation totals March 2005 in Skopje Zajcev Rid, in comparison to the long-term temperature mean 1951-2000.*

Cyprus in the eastern Mediterranean remained mainly within a warm and dry air mass, the temperature anomaly was +1.5°C, and precipitation was 45% of the normal. The dust which affected the island on the last day of February remained suspended during the first days of March. The **Lebanon**, too, had temperature anomalies mostly around 1 to 2°C above normal and precipitation totals below normal. **Israel** too was warm and dry this month. Rainfall amounts reached 30-50 mm in most parts of the country and were recorded mostly on March 8-11. These amounts were only 20-30% of the normal in the northern parts of the country and 40-60% in central Israel. In the southern parts which normally receive smaller amounts of rain, the monthly totals were 150-200% of the normal. On March 31, 33 to 34°C were measured in the coastal plain and in the Negev. In **Armenia**, March was 0.5 to 1°C warmer than normal, except for the last few days of the month, when the daily minimum temperatures reached values between -15 and -20°C in mountain regions, at the stations Ashocq and Masrik even -26°C, and between -5 and -10°C in the valleys. Precipitation totals were 150-200% of the normal. In some regions, strong winds were measured (gusts to up to 108 km/h).

April 2005

- **Warm in the whole Region except in parts near the Mediterranean**
- **Still very dry in southwestern Europe, Greece and most of northern Europe**
- **Wet in most of western and southern central Europe**
- **Late snow in Switzerland on April 7**

During most parts of the month a ridge extended over southwestern Europe. West of this ridge, warm air and low pressure systems moved from the Atlantic especially to western and southern central Europe. Northern Europe was influenced by a secondary ridge causing warm and dry conditions.

It was particularly warm in **Greenland** with temperature anomalies between +2 and +3°C, but precipitation around normal. **Iceland** was only weakly affected by low pressure systems, so that the month was mainly warm and mostly dry, but windy. Reykjavik was 1.3°C warmer than normal. In **Norway** too, the monthly mean for April was markedly above normal in the whole country. The largest anomaly was found in the inland parts of the county of Troms (northern Norway), where the temperature was up to 3.2°C above normal. Precipitation varied greatly between the different regions of Norway. In parts of the counties Finnmark (north), Hordaland (southwest) and Sogn og Fjordane (southwest) the monthly total was 200-300% of the normal, while parts of the counties Oppland and Hedmark (both in the east) received only 20-40%. **Sweden** had temperature anomalies of around +2°C, it was mainly dry, especially at the east coast. In Stockholm, only 37% of the normal precipitation fell. **Denmark** was also warm and mainly dry. In **Finland**, the dry period starting in February continued into this month. Helsinki had an anomaly of +1.5°C and only about one third of the normal precipitation fell.

Influenced by frequent Atlantic lows, **Ireland** was warm and mainly wet, especially in the west. For the **United Kingdom** as well, April was a warm and wet month (mean temperature anomaly +1.2°C, 135% of the normal precipitation). Newcastle recorded 74 mm in the 48-hour period ending 09 UTC on April 16.

Central Europe was quite warm also. In the **Netherlands**, this April was the 5th warmest since 1901. De Bilt reported a temperature anomaly of +2.4°C. Precipitation was slightly higher than normal. In **Belgium**, too, the Atlantic air flow from the south led to warmer than normal temperatures (+1.9°C at Uccle, precipitation around normal). The mean wind speed was exceptionally low. **Luxembourg** also had a high temperature anomaly (+2.4°C) and was drier than normal. In **France**, the monthly mean temperature was higher than normal by 1 to 2°C, except in the southeast, where the anomalies were lower, but still positive. Very high temperatures were observed at the end of the month. Most regions were quite rainy, but it was dry in Poitou-Charente, Languedoc-Roussillon and in the southeast (Provence, Alpes, Côtes-d'Azur). It was also warm all over **Germany**, on average the normal was exceeded by 1.9°C. Here, the western and southern parts were particularly wet (e.g. Frankfurt 207%, Bonn 249% of the normal precipitation), while the north and east, which were still under high pressure influence in the first half of the month, were dry (less than 50%, locally less than 25% of the normal). Widespread high precipitation with flooding occurred on April 25-26 in southern and western Germany. April was a warm month also for **Poland**. The deviations of the monthly mean temperature from the normal reached up to +2°C in the west and south. The extreme temperatures ranged from -7.1°C in the centre of the country up to 22.0°C in the southeast. Numerous local ground frosts were observed, resulting in plant damage. Precipitation varied a lot from less than 20% in eastern Poland up to 180% in central and southeastern regions.

There were some remarkable precipitation events in **Switzerland** this month. On April 7, a low pressure system caused persistent precipitation south of the Alps and later the same low brought snow to the area north of the Alps, even to lower regions. Berne reported 5 cm of fresh snow in the morning of April 7, Geneva 3 cm. This had never happened so late in the year since 1931, when systematic snow observations started. Even more snow, up to 30 cm, was reported from the Lausanne area. The precipitation was caused by the collision of warm and moist air masses coming from the southwest and cold air masses from the north. On April 16-17, a further low, moving from southern France to northern Italy, again caused notable precipitation in the Jura and the midlands of Switzerland, partly as snow even in the plains. This low moved further on over **Hungary**, causing flash floods and consequently destroyed roads, houses and bridges in Mátrakeresztes (northern Hungary). The daily precipitation amount on April 18 (63 mm) was 150% of the monthly normal in April.

On the monthly average, **Switzerland** and **Austria** were warmer than normal. Temperature anomalies reached up to +1.5°C. Precipitation in Austria varied from 200% of the normal in the northwestern and southern parts to less than 75% in the Vienna region. **Hungary** reported a mean temperature anomaly of 0.5°C and 168% of the normal precipitation. In **Slovenia** too, temperature was slightly above normal in most of the country, only at the coast and on the Trnovska plateau (northeast) was it slightly below. The warmest period was during the last four days of April. Precipitation was mostly above normal, in the Koroška region (northern Slovenia) 175%, in some parts of the Julian Alps, the coast and Kočevje (southeast) slightly below. A maximum snow cover of 240 cm at Kredarica was reached on April 26. In **Croatia** the temperature was mostly less than +1°C above normal, precipitation varied greatly over short distances from 84 up to 190%. **Serbia and Montenegro** reported a very cold first decade of the month with frost and an extremely warm period with summer days (Tmax>=25°C) afterwards. In the northeastern part of Serbia, heavy precipitation and floods were observed, especially in the period April 13-27. At Veliko Gradište, a daily total of 63 mm was registered on April 18. At Kikinda, 444% of the normal precipitation was registered for the period April 11-30. Since there had already been plenty of rain during the past winter, the soil was very moist. Flooding of the river Tamis occurred, and high water levels were registered in the Timok basin as well as on the left tributaries of Velika Morava.

Some frontal systems also reached eastern Europe, especially later in the month. **Estonia** was warm and sunny only in the first half of April. Then it became abruptly cold and there was even snow. The month on the whole was still 1.0°C warmer than normal and precipitation was only 55% of the normal. **Latvia** had a similar temperature surplus (+1.1°C) and precipitation deficit (53% of the normal). Moreover, in **Lithuania** it was predominantly warm (+1.3°C) and dry (63% of the normal precipitation) that month, but in the third decade it cooled down considerably, reaching minima between -2 and -7°C. In **Russia**, this April was the warmest of this century up to 2005. Positive anomalies occurred almost all over the country. However, due to frequent cyclonic activity, it was mostly wet. A lot of snow was to be observed in the Ural and spring floods were very intensive in the east of the Russian European territory. From the **Ukraine**, temperature anomalies around +1°C in all regions were recorded. Precipitation amounts varied between 60 and 120% of the normal, on average there was a precipitation deficit.

For **Romania**, frequent cyclonic activity resulted in a month colder and wetter than normal. Large amounts of precipitation were accompanied by hail, thunderstorms and strong wind gusts. In the southwest of the country, rains were torrential and monthly precipitation excesses of more than 225% were measured (Fig. 4.1). The resulting flooding caused considerable damage. Averaged over the country, the precipitation total was 145% of the normal, which is still high. Numerous hailstorms were also reported from **Bulgaria**, causing damage to agriculture and property. Hailstorms are rather unusual for a spring month such as April there. On the monthly average, it was dry (precipitation only around 50% of the normal), temperatures

were around normal. However, there were frost conditions during the period April 24-26, especially in northern Bulgaria, but on the other hand, maximum temperatures up to 29°C also occurred in this month.

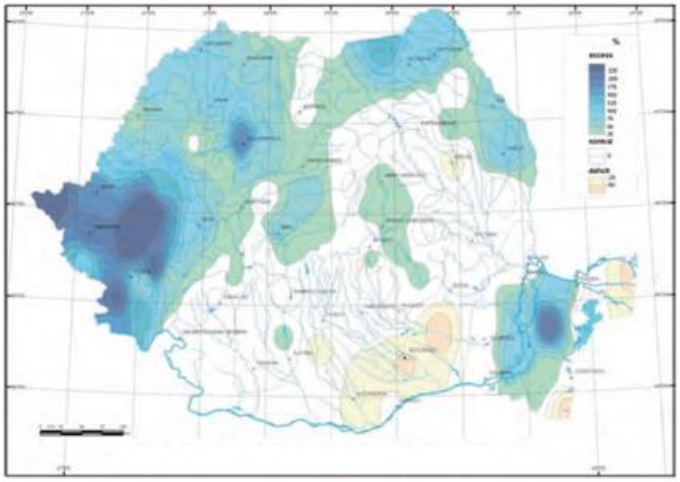

Fig. 4.1: *Deviation of monthly precipitation amounts from normal in April 2005 in Romania (in % of the normal)*
Source: National Meteorological Administration, Romania

In **Portugal**, it continued to be warm and very dry, in particular in the central and southern parts of the country. At the end of April, 63% of the territory was in a drought condition with severe to extreme intensity. It was similar in most of **Spain**; Madrid had a high temperature anomaly of +2.1°C above normal, and only 26% of the normal precipitation fell. Only northern Spain was affected by some more rain from frontal systems. In **Italy**, the temperatures were around normal, but it was very wet locally, e.g. in Sicily. **Greece** reported temporarily high daily maxima of 23-29°C on April 26-28; long-term monthly maximum means for April are only around 20°C. The month was unusually dry in almost the whole country. On Naxos, the precipitation was zero, compared to a long-term average of 17 mm (Fig. 4.2). **Cyprus** was warmer than normal by 0.6°C and only slightly drier than average (91% of the normal). On April 9-10 and April 17, suspended dust affected the island.

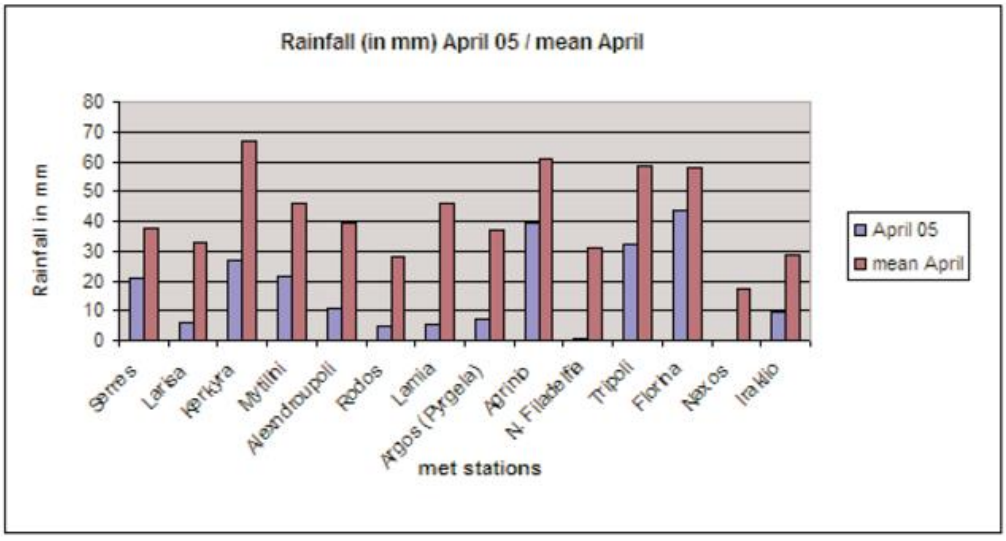

Fig. 4.2: *Monthly rainfall totals in April 2005 at various stations in Greece, compared with the long-term mean (different reference periods)*
Source: Hellenic National Meteorological Service, Greece

Armenia reported a high positive temperature anomaly of 1 to 1.5°C above normal, but there was a cold spell on April 3-9 when the temperature was 2 to 7°C below normal in most of the country, in some regions even 11°C below. The daily minimum temperatures reached between -10 and -15°C in mountain regions and between -2 and -7°C in the Ararat valley. April 23-24 were the hottest days of the month with maxima of 30 to 33°C in the valleys and 22 to 29°C in mountain regions. These values were the highest on record for these days. Precipitation was mostly near normal, only in the eastern regions far below (25-54% of the normal). The **Lebanon** was mostly around 1-2°C warmer than normal, precipitation was around normal. In **Israel**, April was characterised by rapid daily changes of temperature. There were 7-8 Sharav days with hot and dry weather. The most extreme Sharav occurred on April 12 when 37 to 38°C were recorded in the coastal plain and in the Negev. Between the Sharav days, temperatures were much lower (Fig. 4.3). The rainfall amounts were small (10-25 mm) and were recorded mostly on April 1-3.

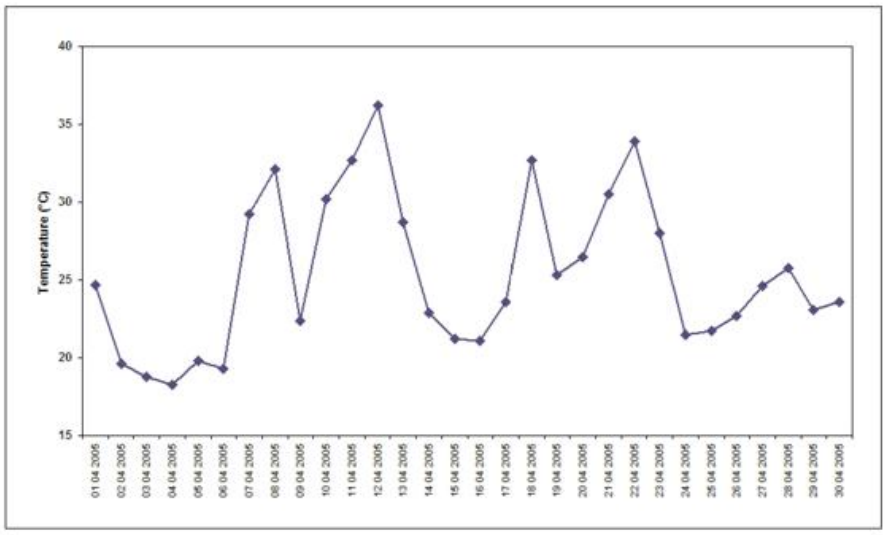

Fig. 4.3: *Maximum diurnal temperature in Bet Dagan (central coastal plain in Israel) in April 2005*
Source: Israel Meteorological Service

May 2005

- **Colder in the north, warm in the south and east**
- **High temperatures at the end of the month in central and parts of southern Europe**
- **Very wet in most of Scandinavia, eastern and northern central Europe**
- **Still dry in southwestern Europe**

During May, the circulation structure over the Region changed from a more meridional to a zonal pattern. Cold air remained mainly in the north and frontal systems moved frequently in the northern half of the Region from west to east.

Greenland was still within the warm air, therefore this month was warmer than normal, but wet in many parts of the country. The capital Nuuk reported a monthly precipitation total of 228 mm or 415% of the normal. During the period May 12-15, 165 mm were measured. In contrast, May was cold in **Iceland** with prevailing night frosts in most of the country, retarding the growth of vegetation. The island was not affected much by northern frontal systems, so that it was dry and sunny in the south of the country. At Vestmannaeyjar on the southern coast it was the driest May since the beginning of precipitation observations in 1881. The **Faroe Islands** were cold.

The monthly mean temperature was below normal also for most of **Norway** except the eastern parts of Finnmark and parts of Troms in the north. Only a few stations registered monthly maxima above 20°C. In parts of the country, the maximum for the month was the lowest for several years. Precipitation in Norway as a whole was 175% of the normal, the second highest since 1900. Many stations measured a new precipitation record for May. For the northern part of the country on average, May 2005 was the wettest registered at all. **Sweden** too, was cold except in the south and mainly wet. **Denmark** was slightly warmer than normal, but also mostly wet. In **Finland**, in the northern and eastern parts, it was raining two or three times more than usual, and, combined with melting snow, this led to all-time high water levels in some of the northern rivers and severe flooding. The western parts of the country were drier than normal, since there was local high pressure influence, and the temperatures were quite normal.

Estonia was rich in precipitation that month (nearly 150% of the normal). Thunderstorms were frequent, sometimes accompanied by tornadoes. The mean temperature was close to normal (anomaly +0.3°C). The precipitation was even more outstanding in **Latvia** (178% of the normal, temperature anomaly -0.3°C). It was the rainiest May in Latvia for 80 years. In the southeastern parts of the country it rained more than 400% of the normal. At the Daugavpils station this month had the highest rainfall amount in its history. On the other hand there was a lack of rain at the Baltic Sea coast. Especially during the first decade of the month, the difference between

Fig. 5.1: *A farm during the floods in south-eastern Latvia in May 2005.*
Source: Latvian Environmental, Geological and Meteorological Agency

the coast and the southeast was extremely high (8% versus 700%). The strong rain in the southeast resulted in a rise of the level of the river Daugava by 2-4 m above normal and flooding of small rivers in the southeastern province of Latgale, submerging parts of farms, fields, meadows and pastures (Fig. 5.1). Small dams were destroyed and some roads were washed away. High humidity after the rain together with flooded fields and a hot period caused extraordinarily large swarms of midges. More than 500 farm animals died as a result of massive

quantities of bites by these cloud-like swarms. In **Lithuania**, temperatures were around normal on monthly average, but especially the first half of May was much cooler than usual. Morning frosts between 0 and -6°C were even registered on May 20 in most regions of the country. In the third decade of the month, warmer air masses from the southwest reached Lithuania, resulting in a mean temperature anomaly of +3.5°C for this period. The highest air temperatures (28-33°C) were close to the absolute maxima for May or even exceeded them. Monthly precipitation was below normal in the west of the country, while reaching 300% of the normal in the southeastern and eastern regions. A hailstorm occurred on May 24, with a hailstone size of 30 mm at the town of Tauragė.

Russia recorded the highest monthly mean temperature (spatially averaged over the whole territory) since 1943 (Fig. 5.2). In the district of the Ural it was even the highest for 105 years. The warm weather was accompanied by frequent rain in almost the whole European territory, except for the region of the Volga River. Precipitation totals up to 300% were achieved at some locations. In the northern Caucasus area, strong precipitation caused flooding on May 9-10.

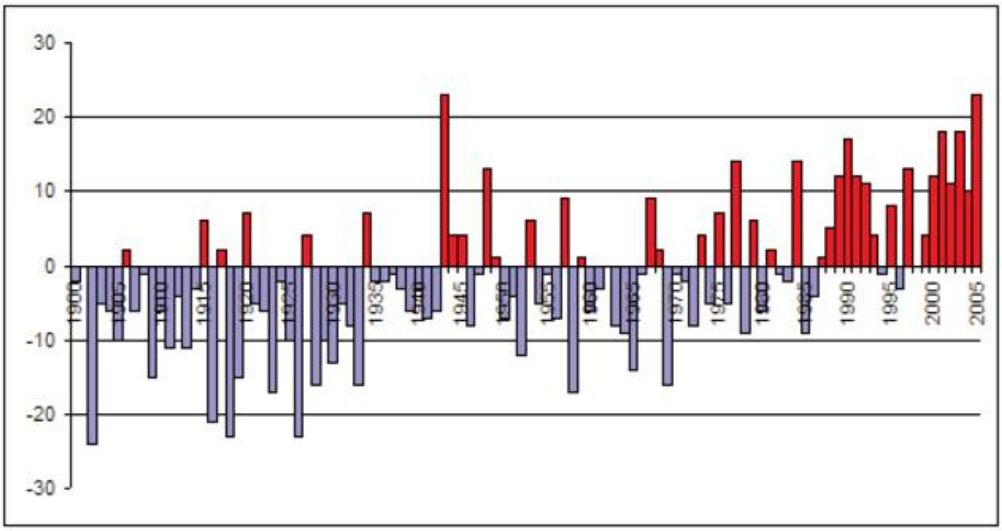

Fig. 5.2: *Anomalies of the monthly mean temperature in May in Russia 1900-2005 (in 0.1°C). Source: Roshydromet, Russia*

Atlantic cyclones moved frequently over **Ireland**, and thus, this month was mainly wet there with temperatures near normal. In the **United Kingdom** too, the mean temperature was close to normal (anomaly +0.3°C), but yet it was the coolest May since 1996. On May 18, Tulloch Bridge (Highlands) recorded -6.3°C, the lowest temperature so late in the season since 1956. On the other hand, central London recorded 31.9°C on May 27, the highest May temperature since 1947. Rainfall was near normal (102%), sunshine duration slightly above.

In northwestern central Europe, it was in general slightly warmer than normal, somewhat more towards the south, and the precipitation totals were more or less close to normal. De Bilt in the **Netherlands** was 0.3°C warmer, precipitation 89% of the normal. Uccle in **Belgium** recorded 0.5°C above normal and 85% of the normal precipitation. In **Luxembourg**, the temperature anomalies were even higher (+1.1°C), precipitation was close to normal (99%).

In **France**, the monthly mean temperature was nearly normal in the north and 1 to 2°C above normal in the south. It was mainly dry, especially in the south except for the Mediterranean coast; and also in some regions of northern France it was wet. Similarly, in **Germany**, a rainy and moderately warm weather character dominated in the north, and drier and warmer conditions in the south. In northern Germany, in parts more than 150% of the normal precipitation was recorded, locally more than 200%. In southern and central Germany, the precipitation totals were mainly below normal and temperature anomalies of more than +1°C,

locally more than +1.5°C were to be found in the south. On country average, 112% of the normal precipitation and 0.6°C above the normal mean temperature were computed. However, over large parts of the month, it was rather cool, but at the end of the month it was hot and at many stations new temperature records for May were registered. This was also characteristic for this month in **Poland**. While ground frosts were recorded until May 20, the maximum temperature exceeded 25°C at the end of the month; the highest value of 33.4°C was noted in the west of the country. It was generally wet in Poland with 200% of the normal precipitation in the central parts of the country. The highest diurnal rainfall amounted to 83 mm and was measured in the Klodzka Valley in the Sudeten Mountains. Several episodes of heavy precipitation were also reported from **Slovakia**. In the **Ukraine** the precipitation totals varied from about 60 to 120% of the normal with a near to normal temperature on average. The southern part of the country had a drought period this month.

Thunderstorms causing damage in central, northern and western **Belgium** occurred on May 2-3 after intensification of a frontal system, partly with hail. This system also passed across **Germany**, and further fronts followed. Damage from thunderstorms was reported from western Germany on May 3, from eastern Germany on May 4-5. In **Hungary**, a low developed at the same time, causing heavy local rain and serious flash floods in Mád in the region of the Zemplén Mountains on May 4. On May 18, again a heavy storm rushed through Hungary. 2500 buildings were destroyed nationwide, several villages suffered from the lack of electricity; trees, traffic sign boards, roofs were torn up by the strong winds.

Another thunderstorm with heavy rain, flooding of streets, and hail was reported on May 21 in Munich, southern **Germany**. **Austria** reported thunderstorms two days later, on May 23 in Upper and Lower Austria, also with heavy rain, hail and local devastations. In the Melk district, several localities were flooded completely. In **Poland**, violent storms occurred with wind gusts of up to 104 km/h.

In **Switzerland**, the beginning of May was dominated by warm weather. On May 3 a disturbance introduced a period with alternating but not very cold weather. There was rain of light or moderate intensity at regular intervals. This type of weather, which is more common for April, lasted until May 23. After that, a large high gave rise to an exceptionally warm and summery end of May as in Germany and Poland. For the first time in 2005, many stations reported temperatures above 30°C. Similarly in **Austria**, outstandingly hot days occurred on May 29-30 with new all-time record temperatures, e.g. in Vienna 33.7°C and Graz 33.1°C. The monthly mean anomaly reached +1.5°C above normal. The precipitation amounts showed a gradient from less than 75% of the normal in the south to more than 125% in the north of Austria. **Slovenia** also had high positive temperature anomalies; only at the coast and in Kočevje was the anomaly less than +1°C. The highest deviation was recorded in the northwest of the country. Here again, the last days of May were significantly warmer than on average and almost dry. Monthly mean precipitation was mostly below normal; only 40-60% of the average precipitation fell in the northwest.

Serbia and Montenegro had a warm beginning to May with maximum temperatures of 30°C and more, then a cold and wet spell, partly with frost until May 24, and the last days of the month were very warm again. For the period April 10 to May 21, the precipitation amounts were more than 200% of the normal, locally more than 300% (Fig. 5.3). All that influenced the water level considerably. In the area of Leskovac many houses were flooded during that period and large material damage was caused. **Croatia** had temperature anomalies mainly between 1 and 2°C, the highest on the southern islands; only in the east of the country were the anomalies below +1°C. In particular, a heat wave occurred on May 27-29. The southern parts also had little precipitation (at some stations less than 30% of the normal); in the northern parts the precipitation was very close to normal. **Hungary** had a mean temperature anomaly of only +0.5°C; precipitation was close to normal (93%). In **Romania** too, temperature and precipitation were not far from normal. On May 7, strong precipitation again caused flooding as in the

previous month. **Bulgaria** was normal to warm as far as temperatures were concerned (anomalies up to +1.5°C) and wet (150-200% of the normal precipitation). It was also a stormy month for Bulgaria with 26 days of thunderstorms and 19 days of hailstorms. Especially on May 29, widespread severe hailstorms occurred in northeastern Bulgaria; a tornado was reported too. Generally in the last decade of the month, abundant rain, swollen rivers and floods were to be observed. Up to 255% of the normal monthly precipitation was registered.

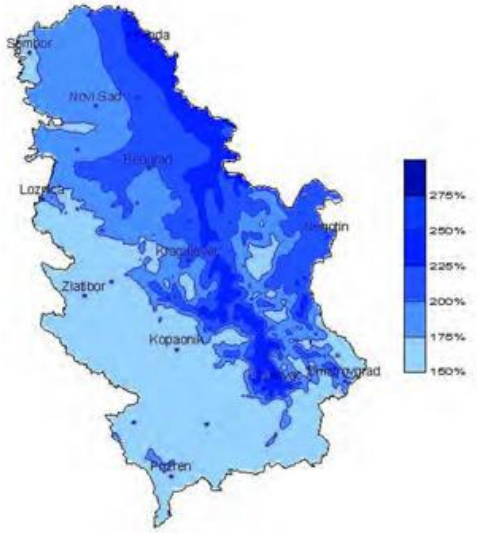

Fig. 5.3:

Precipitation in Serbia and Montenegro for the period April 10 – May 21 in % of the 1961-1990 mean
Source: Republic Hydrometeorological Service of Serbia

Southwestern Europe was still in a southwesterly warm air flow during the first decade of the month. The average monthly temperatures in **Portugal** were above normal (1 to 2°C) in the whole territory. The precipitation amounts were below normal in the northern and central regions, but well above in some parts of the south. In Elvas (Alentejo region), the precipitation which fell during 2 days was above normal for the whole month. Yet, at the end of May, still 68% of the territory was in a drought period with severe to extreme intensity. **Spain** also was warm (1 to 3°C above normal) and mostly dry, especially in the southeast. So was also **Italy**; only the south was partly wet. In **Greece**, unusually high temperature maxima (28 to 32°C) were recorded on May 17-19, well above the long-term means of 22 to 26°C. But it was also a wet month in Greece, particularly the third decade with increased thunderstorm activity in several areas over the mainland (mainly eastern) part of the country, and also the Cyclades and Crete. Hail also was reported locally. In Alexandroupoli (northeastern coast of Greece), 140 mm of precipitation fell that month, which was more than 400% of the long-term 1951-1997 mean. **Cyprus** was slightly warmer (+0.3°C) and wetter (111% of the normal) than on average. In the **Lebanon** the temperatures were around normal, precipitation mostly lower. In **Israel**, May was slightly cooler than normal with only 2 Sharav events occurring during the month. On May 4, extreme rainfall intensities were recorded in the northern parts of the country. In Eilon (northwest Galilee), 16 mm were recorded within 10 minutes and 27 mm within 50 minutes.

The monthly mean temperature was near normal also in **Armenia**. Cold weather was observed on May 3-6, when the mean diurnal temperatures were 5 to 7°C below normal. The last week of May was warm here also; daily maximum temperatures for these days were 28 to 32°C in the Syunik region, 27 to 30°C in the Ararat valley and 20 to 26°C in the mountain regions. Precipitation amounts were 110-120% of the normal. Hailstorms with hailstone diameters of 1-3 cm occurred in some regions from time to time. Strong winds with gusts of up to 104 km/h were registered on 7 days of the month.

June 2005

- **Warm and dry in southern, western and central Europe, partly cold and wet in the north and east**
- **Extreme cold spell around June 9 in the Alps and to the south of them**
- **Heat wave in western and central Europe and heavy thunderstorms**

In June, the mainly zonal circulation continued. Warm air dominated in the south and temporary high pressure influence extended from the Atlantic to central Europe. Low pressure systems passed frequently over northern and eastern Europe, especially over parts of Scandinavia and Russia.

The continental areas of Scandinavia were cooler than normal in the south, but not in the north. Parts of this area were quite wet. **Norway** had a monthly mean temperature below normal in the southern part, while the north of the country was slightly warmer than normal. The largest negative anomaly was found in the mountainous areas of southern Norway, where the monthly mean was 2.0 to 2.5°C below normal. The precipitation sum for the country as a whole was 120% of the normal. For the northern part of Norway this was the 4th wettest June registered with the largest anomaly in the county of Nordland amounting up to 300% of the normal. **Sweden** too was mainly slightly cooler than normal except in the north. The main part of the country was wet, only the southern and western areas including the Swedish west coast were dry. **Denmark** was cooler than normal on the whole, drier than normal in the west, but wetter in the north of Jutland. The other parts of the country had near normal precipitation. **Finland** was cooler and wetter than normal in the south, but warmer and drier in the north.

The Baltic countries were mainly within the colder air, but precipitation was spatially variable, depending on the tracks of the low pressure systems. In **Estonia**, it was slightly colder than normal (-0.4°C), and precipitation was higher (130% of the normal), but there was also much sunshine, and so this month was notable for high UV index values: for a period of 10 days, the index was higher than 7. **Latvia** was 0.6°C colder than normal, precipitation totals were 116% of the normal. **Lithuania**, too, had a monthly temperature anomaly of -0.6°C. Especially the first half of the month was chilly, with sporadic morning frosts; later on, the weather became warmer. Monthly precipitation was very unevenly distributed, since it had a predominantly convective character. In the western and northwestern regions of Lithuania, the monthly total was less than normal, but in some northern and southern parts, 150-200% of the normal amount was registered. Heavy rains were sometimes accompanied by strong winds and hail with hailstone sizes of up to 15-20 mm. On June 9, some southern regions received 54-60 mm of rainfall within 5-10 hours, when an upper air low was situated over the country.

Owing to the frequent advection of cold air in the central and southern areas of the European territory of **Russia**, June was chilly and rainy there. Thunderstorms accompanied by downpours with hail and squally winds occurred nearly everywhere in these parts. In the eastern areas of the European territory, air temperatures of 0 to 2°C and ground temperatures of -4°C were reported during the first two decades of the month. The north of European Russia was drier than normal. On June 26, a heavy storm occurred in the region of Moscow.

Most of the North Atlantic was still warmer than normal. In **Iceland**, it was warm and sunny in the south this month, but gloomier in the north and east, especially in the coastal districts. It was warmer than normal also in **Greenland** and on the **Faroe Islands**. **Ireland** was particularly warm and dry this month. At Casement Aerodrome, the monthly mean temperature was 2.0°C higher than normal, although relatively dull with the monthly precipitation total only 48% of the normal. On June 27, it was exceptionally sunny over most of Munster (south Ireland) and

Leinster (east Ireland) with more than 15 hours of sunshine. It was also quite warm in the **United Kingdom** (+1.5°C above average), although this was not quite as warm as June 2003. Rainfall and sunshine levels were both close to normal, with 101 and 96%, respectively. Central London recorded a temperature of 33.1°C on June 19, which was the highest of 2005. Hawnby (North Yorkshire) recorded 60mm of rain in just one hour on the same day, with considerable flood damage and disruption after the River Rye burst its banks.

Western and central Europe were warm and dry nearly everywhere. In the **Netherlands**, De Bilt was 1.6°C warmer than normal; the precipitation amount was 76% of the normal. Especially the period June 18-24 was marked by a heat wave reaching 25°C or more, on three days there were maxima of 30°C or higher. The station Gilze-Rijen in the south of the country recorded 34.7°C on June 20; this was the highest temperature of the year. This heat wave was also reported from **Belgium**; the duration was from June 18 to June 27. Nearly the whole of June was dry; in some parts of the country this was quite severe for the vegetation. However, here again it was not as outstanding as in 2003. On a monthly average, it was much warmer, sunnier and drier than normal (e.g. Uccle +2.6°C, 68% of the normal precipitation). **Luxembourg** also was warm and dry; the temperature anomaly at the airport was quite high with +3.1°C, the precipitation total was only 46% of the normal, but this was not an exceptional value. The highest temperature of the country in 2005 was 35.1°C, measured on both June 21 and 28. At the airport, 6 hot days (Tmax >= 30°C) were registered, reflecting that a heat wave of several days passed over the country. Furthermore, this heat wave was also reported from **France** for the second half of the month. From June 16 onwards, the temperatures increased rapidly, culminating to values above 35°C in large parts of the southern half of France on June 27-28. These days were among the hottest for June since 1950. The monthly mean temperature was higher than normal by 2 to 4°C from north to south. It was also a very dry month in nearly all parts of the country.

In **Germany**, the first half of the month was rather cool with snow falling at an altitude of 1000m and night frosts even in the southwest, but it was very hot towards the end, so that the average monthly mean temperature was slightly (+0.9°C) above normal. However, there were quite high positive anomalies (up to more than 3°C) in the southwest of the country, while the northeast and the coasts were partly slightly colder than normal. The average precipitation in Germany was 61% of the normal (with large local variations), ranking this month as the 9th driest June since 1901. **Switzerland** had similar characteristics of the monthly course: More or less unsettled and cool weather in the first half of the month and afterwards the subtropical high which drove the temperatures to summery values up to more than 30°C. On the monthly average it was warm and dry. In **Austria** again, in spite of some cold days with night frost down to 1000 m above mean sea level around June 9, monthly means reached up to +2°C above normal in the west and up to +1°C in the east. The country-wide precipitation rate was 50-75% of the long-term means. The **Czech Republic** and most parts of Slovakia were also warmer and drier than normal.

Slovenia had a significant temperature anomaly between +1 and +2°C for most of the territory. Again there was a cold period towards the end of the first third of the month; the second half of June was warm. Precipitation was distributed unevenly; it was mostly below normal, except for Lendava (northeast Slovenia). Most of the territory received more than half of the normal precipitation; in some regions (Vipava valley, Postojna, Kočevska) only one third of the normal precipitation fell. In **Hungary**, the temperature normal was exceeded only slightly (+0.1°C). On June 9, however, the lowest maximum temperature of the century was recorded with 7°C in Pécs. The average precipitation amount was 84% of the normal, so that June was the only dry summer month of the year in Hungary. The cold spell around June 9 was experienced also in **Serbia and Montenegro**. In the period June 5-11 the temperatures were 10 to 14°C lower than normal and were even below the 2nd percentile (Fig. 6.1). Precipitation, too, was extreme in the first decade of the month; it was extremely high especially in the Vojvodina (northern Serbia).

In higher mountainous regions it was snowing. At Žabljak on June 9, a new absolute diurnal snow fall maximum of 13 cm was recorded. After this period, it was warmer than normal and very dry in the whole country until the end of the month. The number of summer days was considerably higher than normal all over Serbia.

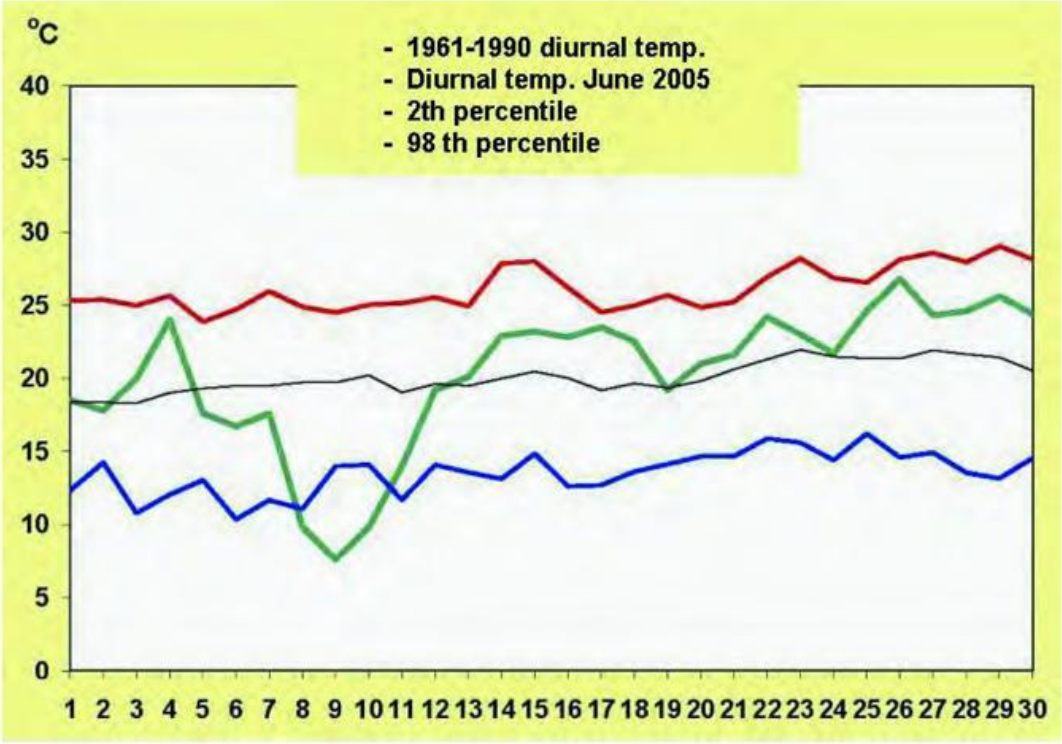

Fig. 6.1: *Diurnal air temperature June 2005 in Belgrade*
Source: Republic Hydrometeorological Service of Serbia

Some severe **thunderstorms** occurred in **central Europe**. The first one was initiated by a cold front passing over central Europe from the west to the east on **June 3-4**. Hail was reported from **Belgium**, especially in northern Flanders. In **Germany**, up to 39 mm of precipitation were measured in the north, streets and cellars were flooded, and also hail was falling. Gusts up to 115 km/h were registered, causing wind damage also in the central and southern parts of Germany. On **June 15**, hail fell in Apače (**Slovenia**) after a squall line passage; on the next day a severe storm developed over Ljubljana and Maribor. Another thunderstorm front passed over Germany on **June 24-25**, locally with large amounts of rain. A lot of damage after vigorous thunderstorms on June 25 with heavy rainfall was reported from **Austria**, especially from the counties of Salzburg and Carinthia. Near the small town of Zell am See (Salzburg), flash floods destroyed the banks of a creek and two bridges. The meteorological station at this location recorded a precipitation amount of 87 mm within two hours. On the same day, several localities within the district St. Veit an der Glan (Carinthia) were devastated partially by heavy rainfalls. A cold front developed with a low pressure system over the Alps and moved southwards to **Slovenia**, where severe thunderstorms damaged some parts of the Štajerska (Lower Styria) region on **June 27**.

Perhaps the most severe storm of the month was on **June 29-30**, towards the end of the heat wave. First, on June 29, a low pressure system brought heavy thunderstorms with local torrential rainfall to **Ireland** (Fig. 6.2). The automatic station at Dublin (Phoenix Park) recorded an hourly precipitation total of 47 mm between 17.35 and 18.35 UTC and a 10-minute fall of 17 mm. On the same day, a frontal system passed through **Belgium**, and the vegetation was

damaged by hail showers with hailstones up to tennis ball size. The hail on some fields looked like a wintry snow cover (Fig. 6.3). In the evening, the storm reached western and southern **Germany** with daily precipitation amounts of up to 71 mm in the Eifel and hail especially near the Alps. Widespread flooding occurred. At the airport of Frankfurt/Main, starts were postponed for 45 minutes. There were also severe thunderstorms even in **Slovenia**; they developed over the Idrija (western Slovenia) and Dolenjska (southeast) region.

Eastern central Europe belonged mainly to the cooler parts of the Region in this month. Polar air masses affected these countries, so that the heat wave of western Europe did not move so far. In **Poland**, the monthly mean temperature was lower than normal down to -0.9°C in the northeast, only the southwest was warmer by about +0.7°C and the highest temperature was noted in Poznań in the west with 33.6°C. But as most of the fronts were not so intensive in Poland this month, June was a month with little rain; only 25% of the 1971-2000 mean fell in some areas in the north and east of the country. This was the start of a drought that continued for the rest of the year. However, local downpours caused some high daily precipitation amounts; the monthly maximum was observed in the Carpathian Mountains with 112 mm. The **Ukraine** and **Romania**, too, were slightly cooler than normal, precipitation was around normal. **Bulgaria** was considerably cooler (1 to 2°C below normal), although on some days up to 35°C were reached in the south of the country. Precipitation again was around normal, only partly (in Dobrudja, northeast Bulgaria) did the totals achieve up to 140% of the normal. Sometimes the diurnal precipitation values exceeded 30 mm. There were 21 days of thunderstorm activity and 14 days with hail. Strong winds up to 108 km/h were registered, generally associated with severe thunderstorms. The wettest period was on June 5-11, after the development of a low pressure system, with a flood event near the capital city of Sofia.

The western and central parts of southern Europe were warm and mainly dry. In **Portugal**, the average monthly air temperatures were well above normal in the whole territory by 2 to 3°C; on average this was the 2nd highest value of the mean temperature since 1931. Two outstanding heat waves occurred on May 30 – June 11 and June 16-23. The number of days with Tmax >=35°C was around 2-5 times the average monthly value. June was also another very dry month in Portugal. Lisbon received only 1 mm of precipitation during the whole month. At the end of June, 97% of the territory was in drought conditions with severe to extreme intensity. Similarly, also in **Spain** it was very hot and dry. On the whole, the month was not as extreme as June 2003, although in the southwest of the country the temperatures set records in a 45-year series (Fig. 6.4). Locally, anomalies up to +5.3°C (in Avila) were recorded. The highest temperatures were measured during June 15-23 for most areas of the peninsula and in the last three days of the month in the Mediterranean areas. Italy was mostly 1 to 2°C warmer than normal, in the north even more than +2°C. It was mainly dry, only in southern Italy was it wet.

In **Croatia**, the temperature had an anomaly range from near normal in the east up to +2.3°C in the west and the precipitation was far below normal with a few exceptions, in some central areas of the country even less than 25% of the normal was registered. **Macedonia** was slightly warmer (around +0.3 to +0.4°C) and drier than normal. **Greece** was mainly very dry, but the temperatures were around normal.

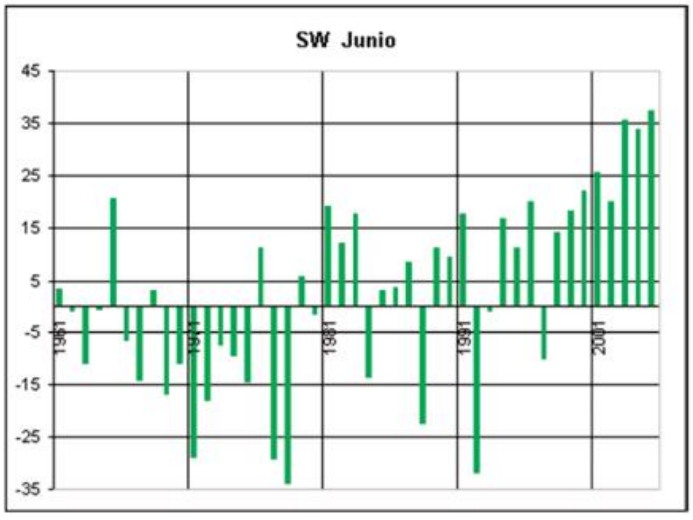

Fig. 6.4:

Average temperature anomalies in June in the southwest of Spain
Source: Instituto Nacional de Meteorologia, Spain

In the eastern parts of the Mediterranean, it was not so warm. **Cyprus** was slightly cooler than normal (-0.3°C) and wet (267% of the normal) which means the duration of the wet period of the year persisted longer into the summer than usual. Especially during the first 5 days of the month it was extremely wet. The **Lebanon** had temperatures and precipitation amounts mostly near normal. **Israel** was slightly cooler than normal.

In **Armenia**, the mean monthly temperature was near normal. Very hot periods appeared during June 10-12 and 16-17 when the daily mean temperature was 4 to 5°C above normal. The maxima reached 34 to 36°C in the Syunik region (southeastern Armenia) and the Ararat valley, 26 to 28°C in the rest of the country. Precipitation was slightly above normal in most parts of the country. Strong winds with gusts up to 108 km/h were registered in some regions. Hailstorms with hailstone sizes of 22-28 mm occurred on 5 days in this month.

July 2005

- **Warm in nearly the whole Region**
- **Very dry in most parts near the Mediterranean**
- **Very wet in some parts of northern, central and southeastern Europe, heavy thunderstorms, frequently with hail**

The zonal circulation of the previous month changed to more meridional, but very variable patterns during July. Cold arctic air masses did not affect Europe considerably, so that it remained warm also in the northern parts. Frontal systems, locally with thunderstorms, heavy rain and hail, passed over various parts of the Region; but the Mediterranean regions were only rarely touched by heavy precipitation.

The first half of July was wet in **Iceland**, but the later part of the month brought warm summer weather to the southern area of the country.

In the whole country of **Norway** the monthly mean for July was above normal. In parts of the counties of Trøndelag and Nordland (central Norway) it was 3°C above average. Stations both in the main country and Svalbard measured a new record for the maximum temperature in July. The precipitation anomalies differed a lot between the west and the east of Norway. For the county Møre og Romsdal (west) the month was the driest for 80 years, while locations in the eastern part and in the county of Nordland registered records of diurnal precipitation. **Sweden**, **Denmark** and **Finland** were warm, but mainly wet this month.

Large parts of eastern Europe were warm and mainly dry. In **Estonia**, the temperature anomalies reached +2.1°C; the precipitation total was 86% of the normal. **Latvia** reported +1.8°C and 95%. **Lithuania** had a mean temperature deviation of +2.1°C from the long-term average and very variable precipitation. The first half of July in Lithuania was warm and dry, while the second half was also warm but rainy. In most regions of Lithuania the diurnal mean temperature frequently exceeded 20°C. The highest diurnal amount of precipitation within this country was 80 mm. **Russia**, too, was characterised by hot and mostly dry weather; only in the southern Volga area were the temperature anomalies negative. The **Ukraine** was also warm and mainly dry, especially in the northwest of the country where the temperature anomalies exceeded +2°C locally; in other parts they were mainly around +1°C or lower, in the easternmost

part even negative. Average mean temperatures were around 20°C. The east of the country was also wetter than normal, while the rest of the country was dry, partly with only around 60% of the normal.

Ireland had the hottest weather of the year during the first half of July, especially on July 10-12, when maxima reached over 25°C in most places; a number of stations measured their highest maxima since 1995 on these days. The monthly mean temperatures were up to about 1°C above normal. But this month also brought some heavy rainfalls in the east and south; over 50 mm were measured near the southern coasts on July 24. At Casement Aerodrome, 78.5 mm was the monthly total which was 167% of the normal. In contrast, northern Ireland and most of the **United Kingdom** were drier than normal (81% on average in the UK, the driest July month since 2000), only the southern and southeastern parts were wetter (England-Wales precipitation was 119% of the normal). The mean temperature of the UK was 0.9°C above normal. Gravesend-Broadness (Kent) recorded a diurnal maximum of 31.7°C on July 14.

Central Europe was warm and wet in most parts. De Bilt in the **Netherlands** and Uccle in **Belgium** both had a monthly mean temperature anomaly of +0.9°C. A heat wave started in the middle of July and continued until August, but it was not so exceptional as in the summer of 2003. The precipitation totals were 212% of the normal in De Bilt and 165% in Uccle, caused by a few thunderstorm periods with heavy rain. In western Belgium, more than 100 mm in 24 hours were registered locally. For **Luxembourg**, this was a very wet month too, although spatially very variable due to the convective character of the precipitation and despite a dry period from July 9 to July 22. The monthly totals reached up to 189 mm locally. In Luxembourg City, July 2005 was the 5th wettest July since 1854. The temperature anomaly also was quite high with +1.4°C at the airport.

France reported mean temperature anomalies mostly around +1°C. The northern parts of the country were partly very wet too, but the south was very dry. Only 1 mm during the whole month fell in Marseille (normal is 14 mm), and also Bordeaux had only 43% of the normal precipitation. **Germany** as well was warm and rich in precipitation this month. Temperature anomalies again were +1°C on average, in northern Germany even more than +1.5°C, in the south partly less than +0.5°C. As elsewhere the monthly averages exceeded 20°C locally, especially in the Upper Rhine Valley. The areal mean precipitation was 136% of the normal; in the northeast of the country more than 300% were reached locally. For some stations it was the wettest July since the beginning of measurements. Flooding occurred in particular on July 10 in southern Germany. In western Germany, in contrast, it was partly drier than normal. July was also hot and mainly wet in **Poland**. The temperature anomalies amounted up to +2.5°C in the centre of the country. For a period of 11 days the temperature exceeded 30°C, on July 28-30 even 35°C. The highest maximum was 36.6°C in the southwest. Monthly precipitation totals reached up to 200% of the normal in the west, while in the northeast only 75% were achieved. The **Czech Republic** and **Slovakia** were mainly warm and wet.

In **Switzerland**, the month started warm, but on July 4 a disturbance accompanied by heavy thunderstorms caused a remarkable temperature drop. In parts of Grisons (southeastern Switzerland), snow fell down to elevations of 1700 m above sea level. Within this highly unstable layered air mass, tornado funnel clouds were observed on July 5 over the Lake of Geneva and in the region of Zürich. After this, the weather remained unsettled, but rather warm. A stable high pressure influence did not persist for long. Towards the end of the month, however, on July 27-28, the temperature reached top values of the year; the country's maximum was reached in Geneva with 36.2°C. Monthly means were also above normal in **Austria** where anomalies amounted to about +1°C. Precipitation totals were high in large parts of Austria (125-225%), in the valleys of Mur and Muerz rivers in Styria even up to 300%. Only in the westernmost part of Austria were the precipitation amounts around normal. Heavy thunderstorms with flooding in

a region from the province of Salzburg to Lower Austria were reported on July 5 and 12. In the early morning of July 12, the flood water in the river Salzach flooded 350 houses of the small town of Mittersill (county Salzburg); the town centre was flooded 150 cm high (Fig. 7.1).

Fig. 7.1:

Town centre of Mittersill (near Salzburg, Austria), flooded on July 12
Source: Central Institute of Meteorology and Geodynamics (ZAMG), Austria

An unusually **heavy hailstorm** occurred over the **Alps** on **July 18**, when a frontal system moved from the north to the south. Near the upper part of Lake Geneva in **Switzerland**, a large area was devastated. Gusts of up to 160 km/h and hail caused enormous damage in local vineyards. In **Austria**, north of the Styrian capital of Graz, hailstones of the size of hens´ eggs smashed roofs, windows and windscreens of cars. In the town Frohnleiten in this area, the streets were covered with hail up to 20 cm high.

On **July 27-30**, very warm but potentially instable air masses caused wide-spread **thunderstorms** over **central Europe**, partly with hail. **Germany** reported thunderstorms with heavy rain, wind gusts and hail on July 27. The hailstones were partly the size of hazelnuts as registered north of Frankfurt/Main. In **Belgium**, more than 45 mm precipitation in less than one hour were measured in Brussels on July 29, and hailstones of 3 cm diameter in the north of the province of Antwerp. The day before, there were also thunderstorms with hail in Belgium and even a tornado at Ath (province of Hainaut, west Wallonia). **Luxembourg** reported up to 64 mm in 24 hours locally and up to 53 mm in one hour on July 29. At the airport of Luxembourg, the highest hourly and daily amounts in any July month since 1947 were achieved. The warm air masses moved from the southwest to central Europe, but even reached northern Europe. Heavy rain was thus reported also from **Sweden** with 135 mm in 3 hours in central Skåne and 80 mm in one hour near Falkenberg at the Swedish west coast. In **Finland** too, frequent heavy showers occurred in late July. Eastern **Lithuania** suffered from a very strong hailstorm on July 30 with gusts up to 90 km/h and hailstone sizes up to 9 cm. **Poland** too reported strong gusts up to 122 km/h.

It was warm and quite wet also in southeastern Europe. In **Hungary**, it was 0.5°C warmer than normal and 156% of the normal precipitation fell on average, the beginning of a rainy late summer period. **Slovenia** reported temperature anomalies between +0.5 and +1.5°C. Here too a heat wave towards the end of July contributed significantly to the monthly means. There were some sudden changes from warm to cold weather and vice versa. The first third of the month was cool, the middle of July was warm. Precipitation was distributed unevenly and was mostly above normal. In some regions, about 200% of the normal precipitation fell. Severe weather

occurred on July 22 in some parts of the regions Gorenjska, Dolenjska and Notranjska (all in western Slovenia), partly with hail, but most of the damage was caused by flash floods. **Croatia** had temperature anomalies around +1°C, in the east also less. Precipitation was especially high in the northeastern and the western coastal parts, locally above 200% of the normal. **Romania** also was around 1°C warmer than normal, and the precipitation amounts were especially high in the southern parts of the country, again partly more than 200% of the normal, on average around 150%. Similar anomalies were to be found in **Serbia and Montenegro**. The first half of July, however, was cold there. July 7 was the coldest day when the diurnal minimum temperature was around 10°C in most places. From July 15 on, the weather became stable and the temperatures higher. Precipitation was distributed mainly over the first and second decade of the month, while it was considerably below average in the third decade. A new record was registered in Sombor (northwest Serbia) on July 2, with a daily precipitation amount of 69 mm and a monthly total of 199 mm. In some areas also storms with strong gusts, heavy precipitation and hail occurred. **Macedonia** was also around 1°C warmer than normal; precipitation was around normal or higher, especially in the east. **Bulgaria** had temperature anomalies up to +1.5°C, and it was very wet: up to 450% of the normal was measured in northeastern Bulgaria. This was by far the highest July amount there since 1950 (Fig. 7.2). In particular the first half of the month was exceptionally wet. The already water-saturated soils facilitated widespread floods. There were 28 days with thunderstorm activity and 19 days with hailstorms this month.

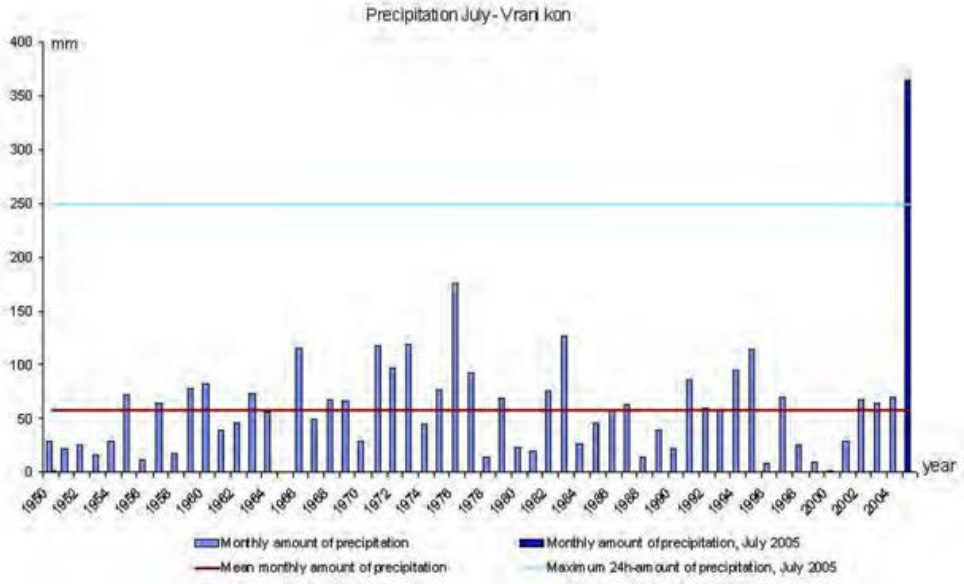

Fig. 7.2: *Precipitation totals July 1950-2005 in Vrani Kon (northeastern Bulgaria)*
Source: National Institute of Meteorology and Hydrology, Bulgaria

Southern Europe was mainly warm and very dry, although locally high precipitation amounts fell. In **Portugal**, July was extremely rainy only in the Minho region, parts of the centre regions and the Algarve, but still dry to extremely dry in the remaining territory. Temperatures were above normal in almost the whole country. The highest value of the maximum temperature was 41.2°C in Beja (southern Portugal) on July 20. **Spain**, too, was warm and very dry. In Madrid, there was zero precipitation this month and it was 2.2°C warmer than normal. **Italy** had temperatures mostly 1 to 2°C above normal and low precipitation, only in southern Apulia and western Sicily were the precipitation amounts high. **Greece** was about 1°C warmer than normal, but precipitation was very variable, locally above 400% of the normal. **Cyprus** reported +0.8°C above normal and only 0.1 mm precipitation (4% of the normal) for the whole month.

Further in the east, the **Lebanon** was warmer than normal, mostly 1 to 2°C, sometimes less. Precipitation was low as usual, frequently zero. **Israel** was also warmer than normal, so that this was the 11th warmest July since 1995, but it was not so extreme as July 2000 and 2002. There was a hot spell on July 3-4 with temperatures reaching 37-39°C in the Negev and 41-43°C in the Jordan Valley. On July 5 there was a temperature drop of 8-10°C within a low-pressure system in the inland areas of Israel and 4-5°C in the coastal plain. Such a sharp change in temperature does not happen very often in the summer months, which are normally characterised by very stable temperatures. Before that, the last time such an extreme change occurred was in July 1995.

In **Armenia**, July was 1.5 to 2°C warmer than normal. Daily maximum temperatures in the Ararat valley reached 38 to 40°C, in mountain regions 28 to 31°C. Extremely hot weather occurred on July 17. Megri (near the Araz River, south Armenia) had a record maximum of 43.3°C. Precipitation was only 50-60% of the normal. However, on July 25, heavy rainfall in Dilijan (northern Armenia) resulted in 50 mm of precipitation during one hour and 25 minutes, and a hailstorm on July 3 in hailstones of 3.5 cm diameter, causing extensive damage.

August 2005

- **Warm and dry in most of the west and the east, cold and wet in most of the central parts of the Region**
- **Some storms with heavy rain in northern Scandinavia and the Baltic countries**
- **Heavy precipitation with flooding in the Alpine region and east of it**

The frontal zone remained mainly over northern Europe; zonal and meridional flows changed with high variability. Several times, strong cold low-pressure systems affected not only northern Europe, but also central and central eastern Europe when the meridionality became stronger. Some of these low-pressure patterns even moved to the central Mediterranean after a cut-off. In contrast, the western and eastern parts of the Region were not so much affected by such low-pressure systems; quite often high-pressure influence resulted in warm and dry weather in these parts.

Scandinavia had mostly near normal conditions, but with some exceptions. In **Iceland**, August was close to average in the south and west, but wet and cold in the north and east, due to the northern cyclone tracks. Akureyri (in the north) recorded the lowest number of sunshine hours in August since 1969. **Norway** reported a precipitation amount of 200% of the normal for parts of the county of Nordland (northern central Norway), while Hardangervidda and the mountainous area northward to Sognefjord (southwest) received only 60-70%. Tromsø in the northern part of Norway registered the second highest diurnal precipitation amount since the start of the series in 1920. Some cyclones caused damage in **Sweden**. In early August, due to prolonged rains there was a dam failure during repairs to a dam in the river Dalälven at Alvesta (southern Sweden), but no one was killed. Late in the evening of August 26, a small but intense cyclone caused storm gusts in northernmost Sweden and around 7000 households lost their electric supply. Heavy showers were also reported from **Finland** in the beginning of August, just during the world championship games in athletics in Helsinki. On August 28, a tornado was

seen during an international golf tournament in Helsinki. It caused damage to the light constructions and also some injuries. **Denmark** was slightly cooler than normal with precipitation around normal or less.

The Baltic countries were mainly warm but wet, since some of the northern cyclones also affected these regions. In **Estonia**, there was a flooding in Pärnu after heavy rain. On August 9, a tornado destroyed roofs near the station at Tartu-Toravere. Another tornado was active near Tallinn. The mean temperature anomaly of Estonia was +1.2°C and the mean precipitation total was quite high with 157% of the normal. From **Latvia** as well, high rainfall was reported, especially in the first half of August. This period had twice the normal rainfall in nearly the whole country, at some locations even 300-400% of the normal. Monthly precipitation was 151% of the normal, the mean temperature anomaly was +0.6°C. The most intensive rain occurred on August 8, due to a frontal system extending from northern Europe to the Black Sea. On this day, about a third of the normal August rainfall was measured within 24 hours. The Liela Jugla River rose by 4.67 m during August 4-12, exceeding the level of this year's spring floods. Fields, meadows and vegetable gardens were flooded just as it was time for harvesting. **Lithuania**, too, had a very rainy period in that time, while the rest of the month was dry and warm. The monthly mean temperature was close to normal. A heavy rain period occurred on August 8-11. In all southern and many western regions of the country the daily precipitation amount reached 65-100 mm, the town of Nida (near the Baltic Sea) received 80 mm within 12 hours. On these 4 rainy days all together a total of 200-230 mm was registered, which corresponds to 250-300% of the normal for the whole of August (Fig. 8.1). This heavy rainfall was accompanied by strong winds of 55-80 km/h. There had never been such prolonged and heavy summer rain in Lithuania before during the entire observation period. The water level in rivers rose by 2.5-4 m; lowland settlements were flooded, forcing evacuation of several villages and farmsteads. Strong winds caused broken trees and disruption of power transmission. The total damage was estimated at 42 million €.

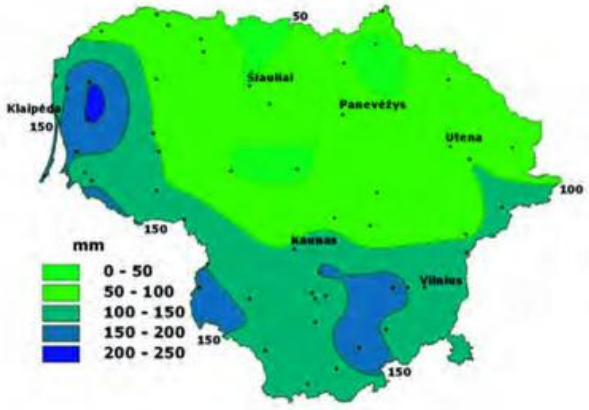

Fig. 8.1:

Precipitation totals during August 8-11 in Lithuania
Source: Lithuanian Hydrometeorological Service

In **Russia**, a stable anticyclone over the centre of the European territory resulted in very dry and hot weather. The temperature was above normal everywhere (mostly around +1°C), in the northwestern and southern federal districts monthly temperature anomalies were partly between +3.0 and +3.5°C. Precipitation totals reached only 25-50% of the normal at some locations.

Western Europe was mainly warm and dry. In **Ireland**, at Casement Aerodrome, only 46% of the normal monthly precipitation fell and the temperature anomaly was +0.9°C. The mean temperature of the **United Kingdom** was 0.6°C above normal, but yet this was the coolest August since 1999, as the previous August months were even warmer. Rainfall was slightly below normal at 94%, in England and Wales 82%. A gust of 126 km/h was recorded at Lerwick (Shetland Islands) on August 29, as a deep depression moved east to the north of Scotland. Central London recorded a temperature of 32.2°C on August 31. In **France**, it was warmer than normal only in the west and south. In most of the country, especially in the northeast, the temperature was below normal, due to some cold spells coming from northern Europe.

Precipitation was below normal except in the north of the country, the Rhône-Alpes and Midi-Pyrénées. In **Portugal**, it was extremely rainy in some regions in the northeast, the centre and some inner parts of the Alentejo (southern Portugal); the remaining territory was very dry. Monthly mean temperatures were above normal in almost the whole territory. The mean maximum temperature was the 2nd highest, the average mean temperature the 3rd highest since 1931. Spain, too, was warmer than normal; anomalies up to +1.8°C were reached in the central and southwestern parts of the country. It was again a very dry month in Spain, mostly less than 50% of the normal precipitation fell; Madrid was again without any rain as in July.

Central Europe was often affected by depressions from the north and thus mainly cool and wet this month. In the **Netherlands**, **Belgium** and **Luxembourg**, temperature anomalies were around 0.5°C; precipitation amounts were variable, but not so outstanding compared to the normal. The first half of August was warm, but not so hot as in 2003. From Belgium, a high number of 23 thunderstorm days was reported this month; it was the maximum of the time series, as the normal value is only 12 days. In central and western Belgium, a thunderstorm with flooding occurred on August 19-20 and tornadoes were seen on August 11 and 12. **Germany** was 0.8°C colder than normal this month, in the western and southern parts locally more than 1°C. It was the first August since 1993 which was colder than normal. With respect to precipitation the month was around average, despite the heavy rains in Bavaria which caused catastrophic flooding in the second half of the month. However, locally more than 150% of the normal precipitation fell, but also less than 50% fell in various parts of the country. **Poland** was very cold in the western part (anomaly -1.1°C); on spatial average it was close to normal, but it was the coolest August since 2002. The precipitation was very diverse within the country; it ranged from 20% in the central parts up to 240% in the mountains in the southeast with local flooding. The highest daily precipitation (147 mm) was also noted in the south. In the **Czech Republic** it was slightly colder (e.g. Prague -0.5°C), precipitation was around normal. **Slovakia** had normal temperatures, but precipitation totals were partly very high. A monthly total of 215 mm was registered at Turany (northern central Slovakia) and Ondavou (eastern Slovakia); this was the second highest total in that territory since 1901. The **Ukraine** was warm with temperature anomalies between +0.5°C in the west and more than 2°C in the east. The absolute maximum for 2005 was measured this month with 39°C in the south. Precipitation totals were mostly above normal, partly more than twice as much, only the eastern part was drier.

The Alpine region was mainly cool and wet. In **Switzerland**, cool and rainy weather prevailed especially in the first part of August. There was snowfall down to the higher passes in the Alps. On occasional clear nights, the temperature dropped to values which were close to the all time minimum for August. At the end of the month a high developed over western Europe and it became warm and sunny. In **Austria**, monthly mean temperatures were normal or up to 1°C below the long-term average. Precipitation reached at least 125-175% of the normal in large parts of the country, in western and northern parts even 230%. From Reutte (Tyrol), a monthly amount of 408 mm was reported; this was the second highest since May 1999.

A period of **heavy precipitation** in the **Alpine region** occurred on **August 20-23**. It was caused by a cut-off low west of the Alps. At its eastern flank, warm and very humid subtropical air crossed the Alps. The first heavy precipitation with thunderstorms occurred in northern Italy. More than 35 mm in 12 hours fell in Verona during the night of August 20-21. The following day, precipitation also affected the Alps, especially **Austria**. Graz in Styria registered 35 mm in 6 hours. A landslide blocked the main rail road connection from Bruck an der Mur to Graz. Three localities around Lake Neusiedl (county of Burgenland) were partly flooded. On August 22, diurnal amounts reached between 180 and more than 200 mm in the province Vorarlberg and in western Tyrol. In the Montafon valley, near the village of Gargellen, the main road was washed away over a distance of several 100 meters (Fig. 8.2). By the evening, all traffic connections to Tyrol had been closed as well as several sections of the Rhine valley highway. The centre of the low had then moved over northern Italy to Croatia. The main lifting processes

Fig. 8.2: *Main road washed away in the village of Gargellen (Montafon Valley, Austria) after the heavy rain on August 22*
Source: Central Institute of Meteorology and Geodynamics (ZAMG), Austria

were now at the northern and western flanks of the low and thus over large parts of the Alps and southern **Germany**. Orographic lifting of the warm moist air at the northern slope of the Alps intensified the precipitation. Near the Alps, more than 100 mm of rain were measured locally on August 21-22 (e.g. Garmisch-Partenkirchen, Oberstdorf). An area of heavy flooding extended from the Alps to the Danube River. Dams were broken, train connections interrupted, roads and houses were flooded, and bridges were damaged. In many towns and districts, disaster alarm was activated. In parts the water levels exceeded those of the flooding on Pentecost 1999. Garmisch-Partenkirchen and some villages in its vicinity were more or less cut off from the outside world. Large parts of the village of Eschenlohe were 1.5 m under water. In **Switzerland**, especially the Bernese Oberland and central Switzerland, were massively affected. In the area from the valley of the Simme to the Canton of Uri, hardly any valley was spared from severe destruction. Landslides, mudflows and brooks swelling to torrential streams submerged villages, farmland, bridges, railway lines and roads. Entire valleys were cut off for several days. Some of the pre-Alpine areas were affected as well, in particular from the Emmental to the Lake of Zug, but also the town of Weesen at the western end of the Walensee. In some places the affected area extended even further north to the midlands. In the city of Berne, the river Aare flooded an urban district and also the river Reuss damaged some houses. Other lakes (Thun, Lucerne, Biel) overflowed their banks. Extensive damage was also reported from northern Grisons and the Engadin. Precipitation amounts reached record values for the 48-hour period August 21-23 (morning) of between 150 and 200 mm or more (Fig. 8.3). On the Säntis mountain (2500 m) a daily amount of 186 mm was measured. The precipitation event did not end until the evening of August 23, when the low moved further to the east and weakened. Another factor for the flooding was the saturation of the soil, since there had been high precipitation also during the weeks before, so that the precipitated water was directly transferred into the surface run-off. Such a weather situation, sometimes referred to as "Vb type" has caused devastating precipitation many times in the past, so it is not unusual. But the high precipitation amounts over such a very large area can be taken to be an extremely rare event with a statistical recurrence time of more than 100 years.

Further to the east, it was also cool and very wet in **Hungary**. The mean temperature anomaly was -0.7°C, the mean precipitation total 259% of the normal, in the southeast of the country even 400-450%. Due to many heavy rains more than 100 buildings were destroyed, 25 000 ha were covered by water; several rivers rose above their banks. The maximum diurnal amount of rainfall of this year was 164 mm at Mezöhék on August 4. **Slovenia**, too, was cool with

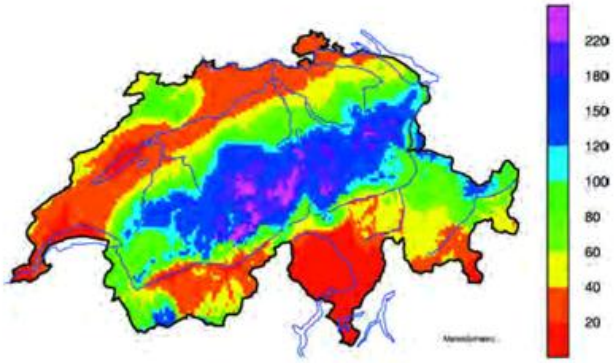

Fig. 8.3:

48-hour accumulated precipitation in mm on August 21-22 (06 UTC until 06 UTC the following day) in Switzerland
From: MeteoSwiss, Switzerland

temperature anomalies between -0.5 and -1.0°C. Precipitation was distributed unevenly and was mostly above normal; only a small part of the Upper Soča Valley had less precipitation than average. In some areas twice the normal amount of precipitation fell. There were also some episodes of severe weather with intense precipitation and hail. **Croatia** also was cool, temperature anomalies were mostly around -1°C, and wet, especially in the northeast with precipitation amounts locally of more than 400% of the normal. **Romania** had temperatures around normal, but also frequent torrential rainfalls; 200 and even 300% of the normal precipitation was reported over large areas. In **Serbia and Montenegro**, monthly mean temperatures were also around normal, but maximum temperatures were higher and minima lower than average. Due to frequent cyclonic activities coming from the central Mediterranean and due to the penetration of humid air from the Atlantic, an extremely high number of precipitation days (mostly 15-20) was recorded. Monthly precipitation amounts were considerably higher than average, locally they were 400% of the average, some new records were set. In Montenegro, a new absolute diurnal precipitation maximum of 47 mm was registered at the Rožaje station (northeastern Montenegro).

Towards the south, **Macedonia** was also cool and wet (e.g. Skopje -0.9°C and 215% of normal precipitation). **Bulgaria** had temperatures around normal and precipitation totals of 150-300% of the normal except in the northwest where it was around normal. Some storms moving through the Balkans brought stormy and wet weather mainly to western and central Bulgaria. The most severe period was on August 4-7 with up to 356 mm of rain in less than 48 hours in a narrow frontal band, causing flooding, e.g. of the Maritza river in the very populous and economically active Upper Thracian Valley. The city Plovdiv (southern central Bulgaria) was partly flooded as well.

The Mediterranean was mainly warmer than normal, wet in the west, but mostly dry in the east. **Italy** was mainly warm, only the northeast was cooler, but this August was considerably cooler than in the previous year. Precipitation was very variable. **Greece** was mainly warm, wet in the north and dry in the south. On August 1-3, the only short summer heat wave episode was recorded in several areas of the country, mainly on the mainland. Maximum temperatures of up to 39°C were measured; average maxima were around 33°C. Unusually heavy rain and thunderstorms occurred on August 5-6 over parts of northern Greece and the Thessaly peripheries. From **Cyprus**, a temperature anomaly of +0.6°C was reported, precipitation was low as usual. The **Lebanon** and **Israel** were mostly 1 to 2°C warmer than normal; only in the interior region in higher altitudes was it cooler. Precipitation was low as usual.

Armenia was warm and wet. The monthly mean was 1.5 to 2°C above normal. Precipitation was 120-160% of the normal in most of the country, only the Syunik region and the Ararat Valley were drier than normal (20-50% of the normal). Heavy rainfall was observed on August 4 in Amasia (north of Udel, northwestern Armenia, 37 mm of precipitation in 2 hours). Large hailstones (20-30 mm in diameter) were found in the Ararat Valley on August 21.

September 2005

- **Mainly warm, except over the northern Atlantic and in southwestern Europe**
- **Most of the Region dry, but wet in most of the Mediterranean and southeastern Europe**
- **Some heavy precipitation in western and southeastern Europe**

In September the frontal zone remained mainly over northern Scandinavia, while most of the other parts of Europe were often under high pressure influence, keeping these areas mostly warm and dry. Troughs and low pressure systems appeared over the Atlantic, but in most cases they weakened rapidly when they came to Europe. Some cut-off lows reached the southern parts of the Region and caused heavy rain locally in particular in the Mediterranean.

Iceland was on the cold side of the frontal zone most of the month and therefore colder than normal. It was the coldest September since 1982. It was very sunny in the south, but there was early snow in the north.

In **Norway**, the monthly mean was above normal for the larger part of the country. Monthly precipitation was very variable. It was the second highest registered in parts of the counties Nordland, Hordaland and Sogn og Fjordane (western and central Norway) while parts of the county of Hedmark (southeastern Norway) noted the driest September for the last 50 years. An extremely high diurnal precipitation amount was registered in the western part of the country on September 14 due to the former tropical storms Maria and Nate; for some stations this was a new record. The highest value was 179.5 mm at Opstveit in Hordaland. **Sweden** also was warm, but dry, especially in the south, and so was also **Denmark**. **Finland** was warm too; the anomalies reached around +2°C in the southern parts. Starting in the middle of the month, an unusually long warm autumn period occurred with temperatures above 15°C during several days. It was drier than normal in the south, while in the north precipitation was around normal.

Large parts of northeastern Europe were especially warm and dry due to prevailing high pressure influence. **Estonia** was 2.4°C warmer than normal, and only 39% of the normal precipitation fell. In **Latvia**, this was the 10th warmest September for 80 years (anomaly +2.1°C) and 55% of the normal rainfall was measured. **Lithuania** reported a temperature anomaly of +2.3°C, although on September 17-18 the night temperature dropped down below zero (between -1 and -8°C). The mean monthly precipitation totals were 42% of the normal; there were only 2-7 days with 1 mm of rainfall or more.

In **Russia**, this September was the warmest of the whole observation period since 1900 (anomaly +2°C, Fig. 9.1). It was also an outstandingly dry September in Moscow (only 12 mm of precipitation in the whole month, corresponding to 18% of the normal), the 3rd driest since 1891. Only 6 days with more than 0.1 mm of precipitation were counted there (normally 16 days). In most parts of the European territory of Russia 25-50% of the normal precipitation was registered. Smog formation in the cities was a consequence of this drought. The **Ukraine** also was warm and very dry. Temperature anomalies were around +1°C in the west and +2°C in the east. The precipitation amounted to 10-45%.

Western Europe was also affected only weakly by cyclonic activity. **Ireland** was around 1°C warmer than normal; precipitation was higher than normal only in the west, but below normal in the east. In the **United Kingdom**, too, September was a well above average month (mean anomaly +1.6°C), and it was the warmest September since 1999. However, there were some very warm and also some very cold days. Northolt (London) recorded 29.7°C on September 4, Kinbrace The Hatchery (Highlands) -3.5°C and Altnaharra (Highlands) -2.6°C, both on September 9. Rainfall was slightly below normal at 92% on average, but some high diurnal

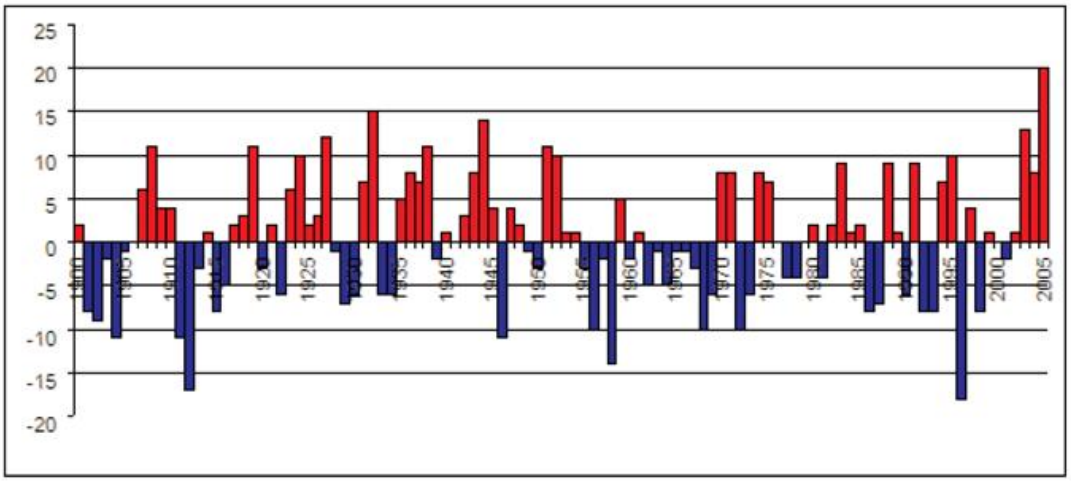

Fig. 9.1: *Anomalies of September monthly mean temperature (in 0.1°C) in Russia 1900-2005*
Source: Roshydromet, Russia

precipitation amounts were registered: 86 mm in Cambridge on September 9, 85 mm in Chieveley (West Berkshire) on September 10. In the **Netherlands**, this month was the 8th warmest September since 1901; the anomaly was +1.7°C in De Bilt. In terms of sunshine, it ranked 8th . The temperature anomaly was even higher in **Belgium** (+2.1°C) and **Luxembourg** (+2.5°C). Precipitation was around normal in the Benelux countries, despite thunderstorms on September 10. At the airport in Luxembourg the highest hourly precipitation amount in September since 1947 was measured that month with 19 mm, 16 mm fell in 30 minutes.

France was warm, especially in the northern half (+2°C). Only the south was partly slightly colder. It was very dry in the western and northern regions, but wet in other areas, in particular in the south. Some heavy rainfalls occurred in the south at the beginning of the month, especially in the Gard and Hérault regions . The first period began in the night of September 5-6 and continued until the morning of September 7. Totals of 200-300 mm were measured in these areas. Another fall of 100-200 mm occurred one day later on September 8 in Gard. Accumulated over the whole period, 500 mm were exceeded locally. These heavy rains caused many floods.

Central Europe was warm, too, and rich in sunshine due to extended high pressure influence. In **Germany**, the mean temperature anomaly was +1.7°C; it was the 10th warmest September since 1901. The mean precipitation was 90% of the normal but with large regional differences. Most of Germany was very dry, locally with less than 40% of the normal, but in the eastern parts of the country local heavy rains caused some totals of more than 150% of the average. In **Poland**, normal temperatures were exceeded by even 3°C in the central and northeastern regions. A maximum of 30.4°C was measured in the west of the country, but also a minimum of -1.3°C in the east. Precipitation sums were generally lower than normal. In the centre of the country only 50% of the normal precipitation was registered, at the eastern borders even less than 25%. This caused progressive soil drying. The **Czech Republic** and **Slovakia** were warm (around +1.7°C) and precipitation was around normal on average.

Switzerland had a similar mean temperature anomaly and was mainly drier than normal. Especially the beginning of the month was warm. In the middle of the month, a cold front, coming from the northwest, reached Switzerland. It was accompanied by heavy rainfall and triggered a remarkable drop in temperature. In the morning of September 17, snow fell down to 1700 m above sea level. This cold front was also remarkable in **Austria**; traces of snow were reported from places down to 1100 m above sea level. Monthly mean temperature anomalies were not higher than +1.5°C. The precipitation amounts ranged from 40% of the normal in the west up to 175% in northwestern and northeastern parts of the country.

The southeastern parts of Europe were mostly warmer than normal, but wet and mostly cloudy due to frequent cut-off lows. **Hungary** reported a mean temperature anomaly of +0.7°C and 122% of the normal precipitation on average. In **Slovenia**, the monthly mean temperature anomaly was between +0.5 and +1°C, in high mountains also slightly negative anomalies were found. Precipitation was distributed unevenly and was mostly above normal, only at the coast, in the Koroška region (northern Slovenia) and in the Upper Soča Valley was there noticeably less precipitation than average. On the other hand, in some areas double the amount of the usual precipitation was registered. On September 2-3, there were severe thunderstorms with heavy precipitation locally, especially in Ljubljana and its surroundings and in the western part of Kamnik (north) and the Savinja Alps. During the period September 17-22, a large low pressure system was established over the central Mediterranean and affected the surrounding countries. Thus, this period was cold and mostly cloudy in Slovenia with frequent precipitation. In **Croatia**, the temperature anomalies were mostly positive, but not higher than +1°C; the highest values were to be found in the very north of the country and at the coast. Precipitation amounts were very variable, ranging from 52 to 175%. Similar temperature anomalies were registered in **Romania**; in this country it was very dry in the north, but very wet in the south (Fig. 9.2). Especially during the last decade of September, the rainfalls were torrential in that region. Exceptional 24-hour amounts of 150-200 mm were recorded at the Black Sea coast and over 100 mm in the south of the country, causing flooding and landslides. The highest monthly amount was 330 mm at the Mangalia station at the Black Sea; this was more than 1000% of the normal. **Serbia and Montenegro** were also warmer than normal in the whole country. In the coastal part of Montenegro, it was extremely warm with 28 summer days and 12 tropic nights. Precipitation was frequent this month, in its second half also heavy, especially during September 18-25. New precipitation maximum records were set at most stations; e.g. at Smederevska Palanka (central Serbia) a daily sum of 93 mm was measured and exceeded the previous record by a factor of more than 2. In **Macedonia**, the temperatures were around normal, but it was also wet on average. **Bulgaria** was colder than normal in contrast to the other countries, with anomalies of -1.5°C in north Bulgaria and -0.3 to -0.4°C in the south. Precipitation totals were high due to some convective events, sometimes with hail, especially during the cyclonic period on September 19-25. The warm sea water at this time of the year facilitated the development of strong convective systems which produced heavy and uninterrupted rain for 48 hours at the northern Bulgarian Black Sea coast. The reported cumulative amount of precipitation e.g. in Shabla was about 900% of the monthly normal.

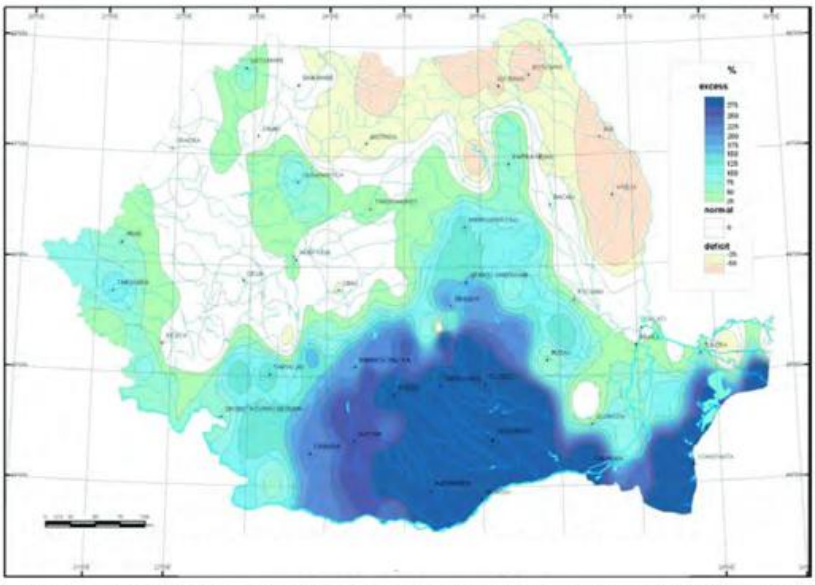

Fig. 9.2: *Deviations of monthly precipitation totals from normal in September 2005 in Romania*
Source: National Meteorological Administration, Romania

The Iberian Peninsula had temperatures around normal and was mainly dry. **Portugal** had high maximum temperatures, but low minima, implying many sunny days and clear nights. Most of the territory was still in extreme drought conditions in continuation of spring and summer. In the northern and central regions of the country the drought situation attenuated for the first time this year due to some rain in the first half of the month. However, on September 30, still 97% of mainland Portugal was affected by severe or extreme drought; this had never happened before for 60 years. In **Spain**, most of the country was slightly colder than normal. Mostly it was dry, but in the east there were some areas wetter than normal. On September 7-8, several tornadoes and waterspouts were seen in the southwest of the province of Barcelona. The airport was hit by a tornado that came from the sea with winds above 150 km/h and a trajectory nearly 50 m wide and 8 km long.

The central and eastern Mediterranean was frequently affected by low pressure systems, so it was mainly wet, but nevertheless quite warm. **Italy** was warmer than normal; in parts the anomalies exceeded +1°C. The main part of Italy was wet, especially in the Apulia region, only in northern Italy and in particular in Sicily was it dry. **Greece** also was warm and unusually wet. Locally the monthly totals exceeded 100 mm (Fig. 9.3). On September 22-23, heavy thunderstorms with hail affected several areas of the Attica periphery with flooding events in these areas. **Cyprus** was slightly warmer than normal (+0.3°C); precipitation was around normal or less. The **Lebanon** was mostly 1 to 2°C warmer than normal, in higher regions partly more than 1°C colder. Precipitation was mainly low as usual, locally slightly higher. Israel was warm and mostly dry as usual, too. On September 16, a Sharav event occurred with temperatures reaching 35 to 36°C in the coastal plain and 38 to 39°C in the Negev. On September 17-18, the temperatures dropped sharply and rainfall was reported from the coastal plain. In Haifa and the Carmel region, 15-20 mm were measured; these were large amounts for this time of year.

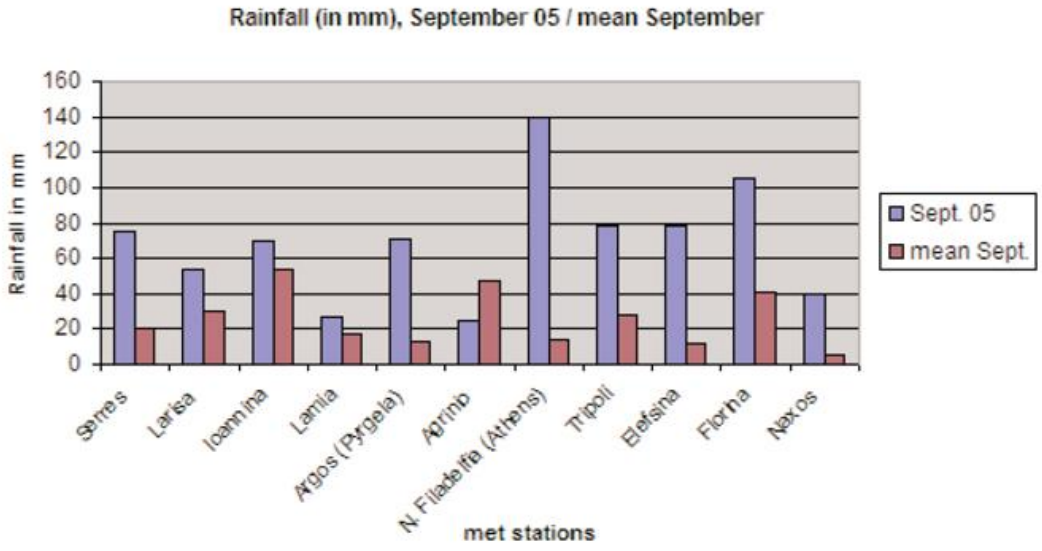

Fig. 9.3: *Precipitation totals at various stations in Greece in September 2005 compared with long-term means (different reference periods)*
Source: Hellenic National Meteorological Service, Greece

In **Armenia**, the monthly mean temperature was near normal, partly above (e.g. Yerevan +1.1°C). High temperatures were measured on September 17-18 (2 to 5°C above normal). The maxima were 32 to 33°C in the valleys and around 26°C in mountain regions. Monthly precipitation totals were 180-200% of the normal in the main part of the country, except Ararat Valley which was drier than normal. Strong winds of about 55-70 km/h with gusts of around 80 km/h were measured on 4 days of the month.

October 2005

- **Warm in nearly the whole Region except parts of the North Atlantic and around the eastern Mediterranean**
- **Most of the Region dry, parts of northern, western and southeastern Europe wet**
- **Hurricane Vince reached southern Spain on October 11**

In October, deep troughs were formed very frequently over the North Atlantic resulting in lower temperatures in that region, and parts of western Europe were influenced by warm, but moist air with frequent precipitation, which put an end to the long-lasting drought of the previous months in these areas. The main part of Europe was quite often under high pressure influence with frequent warm and dry weather, except the very north which was dominated by polar air masses. Southeastern Europe and the eastern Mediterranean were frequently affected by cut-off lows east of the high pressure zone; thus these parts of the Region were colder than normal and rainy.

For **Iceland**, October was the most unfavourable month of the year, being cold and windy. Snow and heavy winds caused considerable problems for traffic in the north during the later part of the month. Unusually heavy precipitation resulted in local flooding of the village of Höfn in the southeast around the middle of the month.

Ireland and the **United Kingdom** were wet, but generally warm, since these parts of Europe were often located on the eastern side of Atlantic troughs in a southerly airflow. In **Ireland**, Casement Aerodrome was 1.5°C warmer than normal; the precipitation total was 122% of the normal due to some heavy rainfalls in the east and south. 100 mm precipitation fell near the southern coasts during the 4-day period on October 17-20 (Fig. 10.1). For the **United Kingdom**, this was another warm month as well (+2.2°C on average, central England +2.5°C). It was the warmest October since 2001 and the 3rd warmest in series back to 1914. Heathrow (London) had 21.0°C on October 27, which was its highest temperature for so late in the year since 1949. It was also wetter than normal with 127% of the long-term average (England-Wales 148%), and some heavy precipitation was noted, too. Carlisle (Cumbria) recorded 109 mm in 24 hours on October 12 at 09 UTC. Furthermore, it was the dullest October since 1982 and the 7th dullest since 1914. At the Eskdalemuir station (southern Scotland) it was the dullest October since 1929 with only 36.5 hours of sunshine.

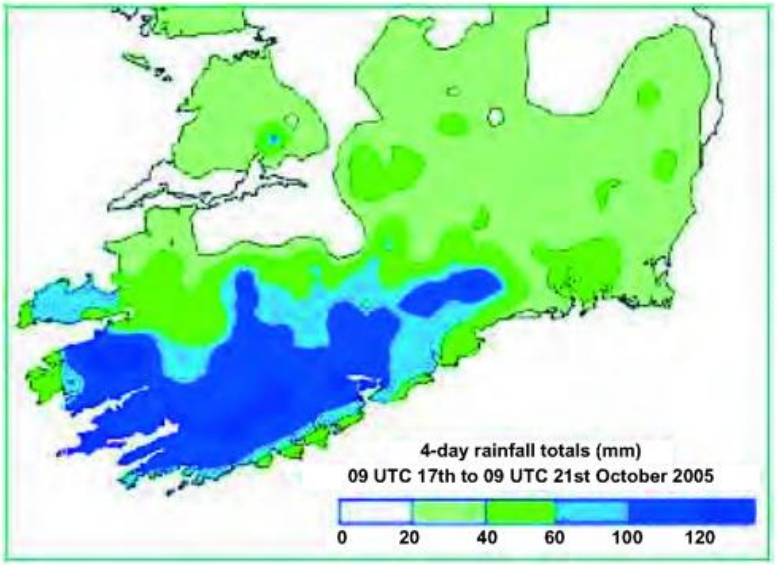

Fig. 10.1:

4-day rainfall totals in mm in southern Ireland on October 17-21 (09 UTC to 09 UTC)
Source: Met Éireann, Ireland

Southwestern Europe was warm and wet as well. In **Portugal**, it was warm until October 9; the warmest days were October 1 and 5 with anomalies above +5°C. The highest anomaly was recorded from Portalegre (Alentejo region, southern Portugal) on October 1 with +8.5°C. The highest maximum of this month was 35.3°C at Alvega (central Portugal). Monthly precipitation totals were mostly above normal, in some regions even above 200% of the normal, putting an end to the long-lasting extreme drought period of the previous months. Extremely high diurnal precipitation amounts above 50 mm were registered on October 28 and 30 at several stations. Similarly, it was warm and mainly wet in **Spain**; only the southeast was very dry. On October 11, tropical storm Vince passed over the south of the Iberian Peninsula, but abated on the same day. Vince brought heavy rain to Andalusia, e.g. 86 mm in 12 hours in Cordoba and also some strong winds, especially near the southwest coast (e.g. a mean wind speed of 55 km/h in Jerez de la Frontera). Some more heavy rain and flooding occurred in the middle of the month in northeastern Spain after the passage of another low pressure system.

In the continental parts of Scandinavia, the monthly temperature mean was above normal almost everywhere. In **Norway**, the maximum temperature at Molde Lufthavn (southern central Norway) was 25.6°C on October 11 which was a new maximum for October within the country. It was also drier than normal in most parts of Scandinavia, but some stations in northern Norway (counties Nordland and Troms) were very wet and had the second highest amounts ever registered in October, partly due to some very high diurnal amounts (e.g. 101 mm in Barkestad in Nordland on October 6, a new record). **Finland** reported two warm spells this month, one continuing from September until the middle of October and the other starting at the end of October. High pressure influence also caused much sunshine in northern Europe this month. In **Denmark**, this October was the sunniest since observations began.

North-eastern Europe also was frequently under high pressure influence and thus mainly warm, sunny and dry. In **Estonia**, it was 1.5°C warmer than normal, precipitation was 87% of the normal on average. **Latvia** recorded +0.6°C and 67% of the normal precipitation. **Lithuania** had a temperature anomaly of +0.8°C and only 52% of the normal precipitation. During the first decade of the month, the highest temperatures in Lithuania reached 18-22°C. The mean diurnal temperature did not fall below 10°C before October 10, at the seaside on October 12-16; this was up to 15 days later than usual. Only the third decade was rainy. **Russia** was extremely warm; in some parts, especially in the eastern European territory, anomalies of more than +5°C were reached. Dry conditions prevailed except in the southern federal district where 200-500% of the normal precipitation was registered in the northern Caucasus and the region of the lower Volga River. In Krasnodar (southwest Russia), 77 mm of precipitation fell in one hour on October 4.

Central Europe as well was very warm, sunny and dry. In the **Netherlands**, De Bilt reported a temperature anomaly of +2.8°C. The month was the 3rd sunniest October since 1901. Precipitation was 78% of the normal. At Uccle in **Belgium**, this was the 2nd warmest October since 1833; the anomaly was +3.2°C. Especially the last decade of the month was particularly remarkable with a mean temperature of 15.2°C; such a value would be typical for late August, but not for October. 67% of the normal precipitation indicated that this month belonged very clearly to the drier ones. In **Luxembourg**, the temperature anomaly was even higher with +3.4°C. At the airport of Luxembourg, the mean maximum temperature was the highest since 1947 with 16.8°C. On October 31, a daily maximum of 20.8°C was measured which was certainly not usual so late in the year. Precipitation was low with 57% of the normal. **France**, too, was outstandingly warm with anomalies above +3°C in most parts of the country, ranking this month the second warmest October since 1950. It was dry in most of the country, only in the Mediterranean areas was it wetter than normal; in the western regions, precipitation was near normal.

In **Germany**, the mean temperature was 2°C above normal on average; in the west of the country, the anomalies were above +3°C as in other countries of western central Europe, but partly only around +1°C in the east. It was the 7th warmest October since 1901. Precipitation was 72% of the normal, locally even less than 50%, and it was the 2nd sunniest October since 1951. On October 22, a tornado was reported in the evening in the Rhön Mountains, leaving a trace of devastation 1 km long and 150 m wide, and another one on October 26 in the Lower Saxony region near Bremervörde. **Poland** reported temperature anomalies of +2°C in the west and +0.5°C in the southeast. Maximum temperatures reached up to 22.9°C. Precipitation was very low; in many regions only 10-20% of the long-term average fell. The drought which had already started already in September, became more severe. On the other hand, a high diurnal precipitation amount of 45 mm was measured at the coast this month. The **Czech Republic** and **Slovakia**, too, were warm and very dry.

In **Hungary**, the monthly mean temperature was only slightly above normal (+0.3°C), but also here the month was very dry (20% of the normal precipitation on average).

Slovenia had temperature anomalies mostly between +0.5 and +1.5°C, in the Julian Alps +1.9°C. Precipitation was distributed unevenly and was mostly below normal. Most of the precipitation was brought by southwesterly airflows; therefore this month was almost dry in the northeast of the country. In Lendava (northeast), there was no precipitation at all, in Murska Sobota only 3 mm. In Lesce (west), Kredarica and Kotlje (north), precipitation amounts exceeded the normal values; most of the precipitation was concentrated during the first third of October. In **Serbia and Montenegro**, the monthly mean temperature was only slightly above normal. On October 15-19, cold air came to this area, causing the first frost in the mountainous parts of Serbia and Montenegro. The precipitation quantity was considerably less than normal in most places, especially in the northern parts of Serbia.

In large parts of the Alpine countries, only the beginning of October was wet, while the rest of the month was dry and warm. Monthly temperature anomalies in **Switzerland** were mainly between +1 and +2°C; monthly precipitation totals were variable, but mostly low, e.g. only 20% of the normal in Ticino. **Austria** had temperature anomalies up to +1.5°C. Precipitation was low in western, northern and eastern Austria (25-75% of the normal), in Lower Austria even less than 25%. Vienna reported only 3 mm for the whole month. During the first 5 days, a deep depression over the northern parts of the Adriatic Sea caused heavy rainfalls over southern Austria, leading to monthly amounts of 125-200% of the normal, and also to significant amounts of rain and snow in Switzerland.

In the central Mediterranean region, temperatures were around normal, but due to some depressions it was mainly wet. **Italy** was mainly slightly warmer than normal, but by far colder than in the October of the previous year. Precipitation was mostly around normal, but locally higher than 200% of the normal. In **Croatia** the temperature anomalies varied from -0.4°C at the coast up to more than +1°C in the north of the country. Precipitation was higher than normal especially at the coast, locally more than 400% of the normal precipitation fell (e.g. in Hvar, Adriatic Sea). In contrast, it was very dry in the northeast, partly with less than 10% of the normal. Further to the south, it was mainly wet in **Macedonia** at around normal temperatures.

In some areas around the Black Sea, frequent cut-off lows caused prevailingly rainy weather. In the **Ukraine**, it was warmer than normal, but the anomalies were only around +1°C or lower. Precipitation totals were higher than normal except in the very west; locally more than 200% of the normal was reached. **Romania** had temperatures around normal; precipitation was low in the northwest (less than 50% of the normal), but higher than normal in the eastern parts, locally more than 200% of the normal amount fell. **Bulgaria** also had temperatures around normal, but locally it was colder by 1°C. First frosts occurred already on October 7-11 in the regions Pernik (west) and Ruse (north). Precipitation was normal or slightly higher; in the region of Dobrudja

(northeast) 140% of the normal was recorded. At some locations, maximum diurnal totals of up to 50-80 mm were registered. In the first half of the month, 6 days with thunderstorms and 4 days with hailstorms were reported.

The eastern part of the Mediterranean region was colder than normal and mostly dry, but locally very wet. **Greece** was especially dry in its southern regions; temperature anomalies down to around -1°C were registered. **Cyprus** was 0.8°C colder than normal; only 47% of the normal precipitation fell. Most of the **Lebanon** also was colder than normal; precipitation was very high at the coast, but mostly around normal inland. **Israel**, too, was colder even though there were two Sharav events during the month with temperatures of more than 35°C. Rainfall amounts were 120-150% of the normal in northern Israel and less than 50% in the central and southern parts of the country.

In **Armenia**, October was slightly warmer than normal. In some regions the daily maximum temperatures (particularly on October 13) were the highest ever recorded there for the whole observation period. Precipitation totals were 100-150% of the normal in the northern and central parts, but the southern regions were drier than normal. Strong winds with gusts of 90-108 km/h were measured on 8 days in that month.

November 2005

- **Mild in the north, colder than normal in the south**
- **Dry in central Europe, wet in some parts of the north and the south**
- **Strong storm over northern Europe on November 14-15**
- **Strong storm over central Europe on November 25-27**

In November, especially in the first half of the month there was frequently a southwesterly flow of warm and moist air to northern Europe, causing milder but often rainy weather in that region, while central Europe remained under drier air masses. In the second half, the whole European continent was often affected by large troughs, so that cold air masses often reached the south, resulting in colder than normal conditions and frequent precipitation in these areas.

In **Iceland**, the weather was very unsettled and gloomy, but it was slightly milder and drier than normal, this was also the case in **Greenland** and the **Faroe Islands**. The monthly mean temperature in **Norway** was markedly above normal in the whole country. In parts of eastern Norway and in Varanger (county of Finnmark), the monthly mean was the second highest since 1900. 30 stations, from Lindesnes lighthouse in the south to Slettnes lighthouse in the north, recorded a new record for the maximum temperature in November. The monthly precipitation total was the third highest ever registered for Norway as a whole. Stations in the western part of Norway had new records for the month. It was also mild in **Sweden**; anomalies were partly above +4°C especially in the north. Precipitation was mainly low there since most low pressure systems coming from the west did not affect Sweden. **Denmark**, too, was warmer (up to +2°C in the north of Jutland) and mainly drier than normal. **Finland** had the highest temperature anomalies of Scandinavia in this month, exceeding +6°C in the central and eastern parts. The

monthly mean temperatures in central Finland were mainly above 0°C and the highest since 1900. The country experienced a mild period until the middle of the month; the maximum temperature reached 10°C during several days.

Extremely **high diurnal precipitation** was recorded on **November 14-15** when a strong low pressure system moved over continental **northern Europe**: At the Opstveit station in the county of Hordaland in western Norway, 223 mm were measured on November 15. This was the second highest diurnal precipitation ever registered in Norway. It was a fairly serious storm also for **Sweden**. 30 000 households, mainly in Värmland, were without electricity for some hours.

It was mild and mainly dry in the Baltic countries. In **Estonia**, it was +2.4°C warmer than normal, precipitation was near normal (96%). **Latvia** had a lesser temperature anomaly of +1.5°C and 83% of the normal precipitation, but was very sunny at times. The first decade of November was the sunniest such period in Latgale (southeastern Latvia) for the last 50 years. **Lithuania**, further to the south, had a temperature anomaly of +1°C and 62% of the normal precipitation. Especially the first half of the month was mild with little precipitation, but the second half was colder and wetter. Rain was then gradually replaced by sleet and snow.

Russia was very mild, especially in the north (e.g. anomaly of +6.7°C at Arkhangelsk). The monthly temperature averaged over the whole Russian territory was the 3rd highest for 30 years. It was also dry in most regions of the European territory of Russia. Heavy precipitation was noted only in the northern parts; there 150-250% of the normal precipitation fell during this month. The **Ukraine** was slightly colder than normal in the west, but warmer in the east (up to +2°C). Precipitation, too, was lower than normal in the west (less than 60%), but higher in the east (locally more than 200%).

Northwestern Europe was in general not far from normal this month. Casement Aerodrome in **Ireland** was 0.3°C colder than normal, precipitation was 77% of the normal. In the **United Kingdom**, this was the month with the least anomaly of the year, but it still managed to be just above average with +0.1°C. Central England was colder than normal by -0.4°C. Anyway, it was the coldest November for the UK since 1998. Rainfall also was close to average at 97% (in England-Wales 94%), but sunshine was exceptionally above at over 140%. This made it the sunniest November for the UK in the series back to 1914. On November 19, Grantown-On-Spey (Highlands) recorded a minimum temperature of -10.5°C. It was a cold night during a high pressure situation. Some days later, on November 25, a cold front had passed over the UK, followed by 10 cm of snow in west Wales. The snow caused significant traffic disruption in Cornwall. The corresponding depression was located in the northern **Netherlands**. 50-90 mm of precipitation fell in a broad band over the middle part of that country in 24 hours. In the eastern part of the Netherlands, precipitation fell as snow and sleet, resulting in an ice/snow layer of about 25 cm in some places. The heavy weight of this layer resulted in the collapse of many roofs. A number of power lines came down, leaving the village of Haaksbergen (Twente region in the eastern Netherlands) without any power for nearly three days. This event contributed quite a lot to the monthly mean precipitation which was 98 mm this month in De Bilt, 121% of the normal. The monthly mean temperature was +1°C higher than normal.

Central Europe was dry with temperatures near normal on average. **Belgium** was affected by maritime as well as continental air masses, so that the monthly mean conditions were near normal there. The first decade of the month was exceptionally mild with a mean temperature of 11.6°C, the highest value since 1901. **Luxembourg** was 0.6°C warmer than normal. The country was located mainly within the dry air mass, so only 66% of the normal precipitation fell.

In **France**, most temperature anomalies were negative (around -1°C). Precipitation was unevenly distributed, in most parts of the country below normal. Long lasting precipitation in the middle of the month caused flooding in southern France. **Germany** had a near normal temperature on average this November (+0.1°C, warmer in the north, colder in the south), here again the first half of the month was very mild, but the second half was already wintry with

frequent snowfall. In particular towards the end of the month (November 25-28) a severe storm resulted in 30-50 cm of freshly fallen snow. Air and road traffic were strongly affected, especially in northwestern Germany; the airport of Düsseldorf had to be closed for 4 hours. Power lines broke down due to extreme icing; about 250 000 people were without electricity. However, most of the month had very dry conditions (65% of the normal precipitation on average, locally less than 30%) and was sunny in most parts of the country. For some stations in the northeast of Germany this was the sunniest November since the beginning of measurements. **Poland** had temperatures around normal; in the north it was warmer than normal up to +1°C. Most of the country received less than 40% of the normal precipitation.

The Alpine countries were mainly colder and drier than normal on average. In **Switzerland**, again, the month started mild and dry, but on November 17 a disturbance reached the Alps, followed by a flow of cold polar air. In the eastern plain, there was snowfall down to the lowlands, bringing the winter's first thin snow cover. The amount of freshly fallen snow was generally small, so that in the whole country November was remarkably poor in precipitation. Since October had already been very dry, the lakes had very low water levels. The Lake of Constance reached almost the lowest level since 1864 when systematic observations began. In **Austria**, the month had negative temperature anomalies down to -1.5°C. In most parts of the country, only 25-75% of the normal precipitation was registered, only in the southern and southeastern parts were the precipitation amounts around normal. Precipitation in southern Austria mainly fell as snow, leading to new record snowfalls in these areas. On November 26-27, 57 cm of snow fell in Villach (Carinthia) in 24 hours. In **Slovenia**, too, an abundant snow cover was recorded during the last days of November, even in the lowlands, which was quite unusual. In the Upper Sava valley, the deepest snow cover since observations began was reached with 103 cm. Most of the monthly precipitation was concentrated in the last decade of the month. The monthly totals were distributed unevenly. At the coast, nearly 150% of the normal was registered, while in other parts precipitation was below normal. The mean temperature in Slovenia was close to normal on average; the first decade was warmer, the last colder and cloudy. At the beginning of the last decade, some very strong Bora episodes were recorded; traffic in the Vipava valley was occasionally hindered due to the strong winds.

The countries in southeastern central Europe were mainly dry too and also mostly colder than normal, e.g. the **Czech Republic** and **Slovakia**. **Hungary** reported a temperature anomaly of -0.7°C and 58% of the normal precipitation on average. In **Romania**, there were negative temperature anomalies around -1°C; precipitation was near normal on country average, drier in the west, wetter in the east. **Bulgaria** had temperature anomalies between -1 and -2°C with the coldest values in the south. Precipitation was around normal in northern Bulgaria, and around 130% of the normal in the south of the country. A snow cover appeared in elevations above 800 m for 8-14 days; the snow depth reached 10-20 cm on average.

The southwest of Europe was colder than normal and had an uneven distribution of precipitation anomalies this month. In **Portugal**, particularly low maximum temperatures were measured on November 13 and 26, below 10°C at several stations, and also low minima resulted on the following morning of these days. The number of frost days (Tmin <= 0°C) was 6-11 in the northern and inner central regions of Portugal (Fig. 11.1) and was 2 to 3 times above normal. Precipitation amounts were above normal in central and southern Portugal, and near normal in the north of the country. **Spain** had temperature anomalies down to -2°C. Precipitation totals were especially low in parts of southern Spain (less than 30% of the normal) and highest in the east of the country (locally more than 200%).

The temperatures in the areas around the Mediterranean were mainly near normal or colder. In **Italy,** precipitation was higher than average in Emilia Romagna, the lower part of Veneto and in the very southern part of the Puglia region. An extreme event occurred in Lazio: The Viterbo station measured 122mm in 24 hours and a monthly total of 319 mm, resulting in flooding. **Croatia** had slightly negative temperature anomalies down to -0.7°C. Precipitation was mostly

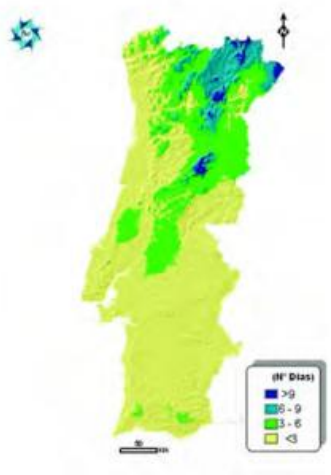

Fig. 11.1:

Number of frost days in Portugal in November 2005
Source: Instituto de Meteorologia, Portugal

around average, but the south was quite wet (150% of the normal or more) while the northeast was dry (50% or less). **Serbia and Montenegro**, too, were colder than usual in the whole country. At most places in Serbia there was a precipitation deficit in that month. In the first half of the month there was almost no precipitation, while in the second half there were more rainy days. At the end of the second and the beginning of the third decade there was snowfall, so that a slight snow cover formed both on mountains and in lower regions but did not last for long. In Montenegro, high intensity precipitation of 209 mm fell on November 16-17 in Niksic. This was the consequence of a large cyclonic activity centre in the western Mediterranean. It was the 2nd highest 24-hour amount of the time series; such an occurrence can be expected only once in 50 years. **Macedonia** reported temperature anomalies around -1°C and it was quite dry. **Greece** also was colder than normal and partly very wet. Athens was 1.6°C colder and 179 mm of precipitation fell that month, which was about 350% of the normal. **Cyprus** was 0.8°C colder than normal with 171% of the normal precipitation amount. On November 19, heavy showers affected the town of Limassol causing floods and damage to properties. The **Lebanon** too, was mostly colder than normal (around 1 to 2°C); precipitation was around normal or slightly higher. In **Israel**, November was slightly colder than normal. The first part of the month was very cold with 3 to 5°C below normal; on the other hand, the last 7-8 days of the month were much warmer than normal. On November 28-29, the temperatures reached 31 to 33°C in the coastal plain and in the Negev. In Jerusalem, 28.3°C were measured on November 28, which was the highest value for the second half of November since 1966. Rainfall was above normal in the northern parts of the country and in the southern coastal plain (110-130% of the normal); in other parts 50-70%. In the last week of November there was no rain at all in the inland areas of Israel.

In **Armenia**, the monthly mean temperatures were slightly above normal. High temperatures were measured on November 1. The maxima reached 20 to 25°C in valleys, which were the highest on record, and 16 to 19°C in mountain regions. But immediately after this warmth the temperature decreased considerably, and on November 6, snow was seen in the mountains. Precipitation totals were mainly lower than normal.

December 2005

- **Warmer than normal in most of the Region, especially in the north, colder in parts of western and southern Europe**
- **Wet in most of the east and the north, dry in most of the west and south**
- **Storm over northern Scandinavia on December 12**

In December, the large-scale circulation was mainly meridional which is not typical for this time of the year. After the passage of a large trough over Europe in the first decade of the month, a high pressure system was established over the Atlantic and northwestern Europe, while the trough remained quasi-stationary in the east of the Region for nearly the rest of the month. Thus, it was wetter than normal in most of the eastern and some of the northern parts of the Region and less rainy than usual towards the west. Mild air from the Atlantic mainly moved to the northern areas, while cold air from the northeast penetrated within the trough far to the southwest, particularly after Christmas. Thus this part of the Region became colder than normal on the monthly average, and all over Europe the last week of the year was more or less wintry.

It was very mild and quite wet in parts in **Greenland**. Temperature anomalies reached up to +6°C. In **Iceland**, the weather in December was again unsettled, but relatively warm with almost no snow in the south. Christmas day in particular was unseasonably mild with temperatures reaching 10 to 13°C in many parts of the country. A storm at Christmas caused some damage in the northwest.

Atlantic warm and humid air masses advanced further to the **Arctic** as well. The monthly mean temperature at Svalbard was around -3.8°C; this was an outstanding anomaly of +9.5°C, implying the 2nd to 5th warmest December (depending on the station) since measurements began. The island station Jan Mayen, located at about 70°N, was 4.4°C warmer than normal. At this station, a new record of diurnal precipitation with 57.5 mm was also registered on December 10 after the passage of a small low pressure system, which was the highest value since 1921. In continental **Norway**, too, the monthly mean temperature was above normal in almost the whole country, in parts of eastern Norway up to +3.5°C. In some counties of central Norway (Møre og Romsdal, Trøndelag and parts of Nordland), the monthly precipitation totals were markedly above normal. It was mostly mild in **Sweden** too. Temperature anomalies reached up to around +4°C in central Sweden. Most parts of the country were also wet except for the Swedish west coast, which was drier than normal. **Finland** was warmer than normal and mainly wet, only the southwest was dry. **Denmark** was warm and dry, only after Christmas did cold weather with a lot of snow begin.

On **December 12**, a **storm** moved over **northern continental Scandinavia**. 118.5 mm of diurnal precipitation were measured this day at Leiråmo in Nordland (Norway). In Sweden, the wind-exposed Stekenjokk station in southwestern Lapland recorded a mean wind velocity of 140 km/h. About 9000 households in southern Lapland were temporarily without electricity.

In the Baltic countries it was mostly mild with precipitation less than average in most parts except the south. December in **Estonia** was warmer than usual (+0.4°C above normal) and was remarkable for lots of snow. However, the monthly precipitation amount was not higher than 78% of the normal on country average. **Latvia** was +0.3°C warmer than normal with 85% of the normal precipitation total. In **Lithuania**, too, the weather was predominantly mild (anomaly +0.7°C), though unsettled. On December 18, a significant freezing period began. Precipitation was 65-80% of the normal in some central and northern regions of the country, but in most parts it exceeded the normal up to 1.5 times. There were only 3 days without precipitation, but the diurnal amounts were mostly below 5 mm.

In **Poland**, monthly mean temperatures were close to normal, only the south of the country was colder (-1.2°C below the 1971-2000 average). The beginning of December was generally mild with maximum temperatures of 9.6°C in the south and 8.3°C at the northwestern coast. The lowest minimum of the month was -16.7°C at the western border of Poland. The month was wet; some monthly precipitation totals reached 200% of the normal. In the second half of the month, strong winds with snowfall occurred (gusts of 100 km/h). The **Czech Republic** was mostly cold and wet. On December 16, a snowstorm affected the country. **Slovakia** had temperatures around normal, but the precipitation amounts were high (locally around 300% of the normal). Averaged over the whole territory of Slovakia, a monthly precipitation total of 122 mm was reached, which was the highest since 1881.

The remaining part of eastern Europe was mainly mild, but wet. In **Russia**, the warm period of the previous autumn months continued in the European territory with anomalies between +1 and +4°C. Precipitation amounts were comparable to normal or above. Especially south of Moscow (e.g. Tula), the monthly totals were 2-2.5 times higher than normal. Only in some regions east of the Volga River, was there little precipitation. The **Ukraine** was mostly 1 to 2°C warmer than normal. Precipitation totals, too, were mostly higher than average, at several stations around 150% of the normal.

Hungary was slightly warmer than normal (+0.3°C), but precipitation was 164% of the normal. In **Slovenia**, the monthly mean temperature was mostly above normal, but not more than +1°C. It was, on the other hand, significantly below normal in the northwest; at the mountain station of Kredarica the anomaly was -3°C. Precipitation was distributed unevenly; in most cases it was above normal (up to more than 160%) and most abundant in the Soča Valley; the least amount was observed in northeastern Slovenia. During the last days of the year, it was snowing all over the country due to a cold low over the central Mediterranean; at some measuring sites this was the deepest snow cover ever registered in December. Most parts of **Croatia** were warmer than normal up to +0.8°C, but in the coastal regions it was colder than normal, mostly between -0.5 and -1.0°C. It was wetter than normal in nearly the whole country, in parts around 200% of the normal precipitation fell, locally even more. **Serbia and Montenegro**, too, were warmer than usual. Monthly mean temperatures ranged from -4.3°C on Kopaonik (mountain in southern central Serbia) to 6.7°C in Podgorica in Montenegro. Precipitation quantities were considerably high, especially in the first decade of the month and in the western parts of Serbia. On Kopaonik a monthly total of 125.1 mm was measured, which was a new record. A snow cover remained on the mountains during the whole month; in other parts of the country it was formed in the second half of the month.

Romania was slightly warmer than normal on country average; precipitation was especially high in the west (locally more than 170% of the normal), but low in the east. **Bulgaria** was mild with temperatures up to +2°C above normal and normal precipitation. Only in the Struma valley were precipitation sums up to 130% of the long-term average. There were, however, some cold days; on 1-3 days the minimum temperatures were below -10°C, but there were also maxima of 15 to 18°C on some days. On December 18, a snow storm affected the country, and on December 27-29, a Mediterranean low pressure system induced strong southerly winds, Foehn in the north and rain at high altitudes in the southern mountains, provoking rapid snow melting, landslides and flooding. Apart from that, a snow cover existed in the mountains during nearly the whole month, in other parts on 5-15 days. The snow depth varied mostly between 25 and 50 cm. In **Macedonia**, positive and negative anomalies were registered for temperature as well as for precipitation.

Northwestern Europe was mostly under Atlantic high pressure influence, and thus mainly mild and dry. In the Republic of **Ireland** at Casement Aerodrome, this December was +0.3°C warmer than normal; the precipitation total reached 84% of the normal. In the **United Kingdom**, too, the mean monthly temperature was +0.3°C above normal, central England was slightly colder with -0.2°C. The month was very dry (69% of the normal precipitation) and sunny (more than 130%

of the normal sunshine duration), one of the sunniest Decembers in the series back to 1914. On December 29, cold air from the northeast came to the UK; -13.2°C were measured at Ravensworth (North Yorkshire) that day. Copley (Durham) recorded a 16 cm snow cover at 09 UTC on the same day.

It was also mainly mild or around normal in temperature and mostly dry in northern central Europe, e.g. in the **Netherlands** (+0.8°C in De Bilt with 71% of the normal precipitation). In **Belgium**, temperatures were around normal, precipitation was normal or below normal (e.g. Uccle 68%), although relative humidity was high on average. **Luxembourg**, too, had around normal temperatures; precipitation was 86% of the normal.

The month was rather mild in northern **Germany** (more than +1°C above normal in the northwest) while in southern Germany it was a little bit colder than normal. On country average the monthly mean temperature was normal. Precipitation was below normal in most parts of the country, 89% of the normal on spatial average, in the west locally less than 50%, in eastern Germany up to around 150%. Snow and freeze frequently affected traffic on roads in many parts of Germany, especially at the end of the year. On December 15-16 a storm caused a lot of damage to roofs, trees and traffic. Some Christmas markets had to be closed. Wind gusts up to 148 km/h were measured on mountains in eastern Germany (Brocken, Fichtelberg).

The Alpine regions were mostly cold and wet on average, but not all the time. After a cold first December day with a high pressure situation, **Switzerland** was influenced by a southerly airflow due to a low coming from the west. There was snow in the southern part of Switzerland; at the same time there was Foehn in the north, which broke down when a frontal system appeared, resulting in rain up to 1300 m above sea level. Some new low pressure systems affected the country on December 6-9; snow fell north of the Alps down to the lowland, while there was sunshine in the south. Then the weather became dry and moderately cold until December 16-17, when northwesterly winds brought a lot of snow to the northern slopes of the Alps; in the plains, snow fell only in the east. A white Christmas was only recorded in areas above 600 m above sea level in most parts. A new incursion of cold air followed on Boxing Day (December 26); temperatures decreased continuously. On December 30, the minima reached between -10 and -15°C in the midlands. In Samaden (Engadin/Grisons), the minimum was -31°C and in La Brévine (Jura near the French border) -35.9°C, the lowest temperature in Switzerland in 2005. On New Year's Eve, the temperature was rising again. In **Austria**, monthly mean temperature anomalies down to -2°C were recorded, especially in the western part of the country. The monthly precipitation totals were mostly 50-125% of the normal, but up to 200% in the east of Austria. Heavy snowfall occurred particularly in the provinces of Salzburg, Upper and Lower Austria.

In parts of western and southern Europe it was very cold and mostly dry. In **France**, the monthly mean temperatures were below normal by -1°C in the north and down to -4°C in the south. Most of France had lower than normal precipitation, except in the regions near the Manche, Limousin and Aquitaine. On December 1-2, Brittany was hit by a severe storm south of an Atlantic low pressure system. Wind gusts reached 120-160 km/h at the coasts of Finistère and 100-120 km/h at the coasts of Armor and Morbihan. There were cuts in power lines due to falling trees. Not much later (December 2-3), the front of the same low caused heavy precipitation in southern France; diurnal totals were e.g. 74 mm in Cannes and 72 mm in Nice. Later on, this front caused high precipitation also in **Italy** and **Albania**.

In **Portugal**, mean and maximum temperatures were around normal, but minimum temperatures were below normal in almost the whole country. The number of frost days ranged from 0 to 20 days (Fig. 12.1) and was 150-300% of the normal in the northern and central regions. A cold spell started in the middle of the month and persisted until Christmas. Precipitation amounts were mostly below normal, except in the Algarve region, where they were

near or above normal. **Spain** had mean temperatures mostly around normal; only in the northeast were anomalies of more than -2°C recorded. In nearly the whole country it was drier than normal, especially in the south and the east less than 50% of the normal precipitation fell.

It was cold but wet in **Italy**. In northern Italy, the lowest December temperatures for 55 years were measured at Vicenza and Brescia with -12.2 and -15.2°C, respectively. Heavy snow fell in the north of the country, causing traffic problems. **Greece** was mainly dry with temperatures around normal. On December 20-23, however, the cold air came far south and very low minimum temperatures (8 to 12°C below the long-term average) were recorded for several consecutive days in some areas of Greece, particularly in the north and in the central mainland. The absolute values were partly lower than -8°C at altitudes above 600 m and even slightly below zero in the lowlands.

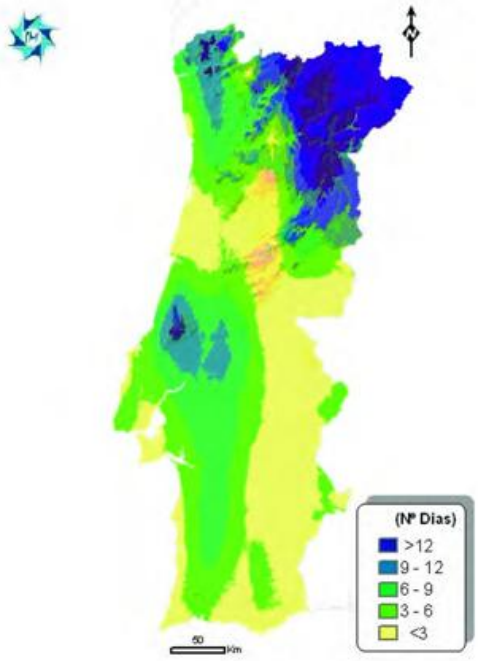

Fig. 12.1:

Number of frost days (Tmin<=0°C) in Portugal in December 2005
Source: Instituto de Meteorologia, Portugal

Apart from this cold spell, it was mild and dry towards the eastern Mediterranean. **Cyprus** reported an outstandingly high temperature anomaly of +2.0°C this month and only 22 mm of the monthly precipitation which was 21% of the normal. This was the lowest amount for the last 10 years and the 7th lowest since the beginning of the previous century. The dry spell started already in November and continued until the end of the first half of December; it was combined with extremely high temperatures up to +5°C above normal for this period. The **Lebanon**, too, was very mild, the temperature anomalies partly exceeded +3°C, especially in high mountains. Precipitation was mostly around 20% lower than normal in the whole country. **Israel** as well was much warmer than normal (between +2.5 and +3.5°C), in the mountains even up to +4°C. In Jerusalem it was the warmest December since 1960 (Fig. 12.2). The first half of December was even 7 to 10°C warmer than normal in the inland areas of Israel. On December 3, 28.3°C was measured in Jerusalem; this was the highest diurnal maximum in December since the beginning of measurements at that station in 1950, and even at other stations in Israel such a high temperature had never been recorded before 1950. It was also very dry in Israel in the first half of the month. From November 22 to December 14 (3 weeks) there was no rain at all. Such a long dry period during the rainy season is not frequent, and it typically occurs only once in 7-10 years; especially during the main winter months (December-February) it is rare. The second half of December was much cooler and rainy. All in all, rainfall amounts this month were above normal in northern and some parts of central Israel (120-140%). In other parts of the country, rainfall amounts were below normal.

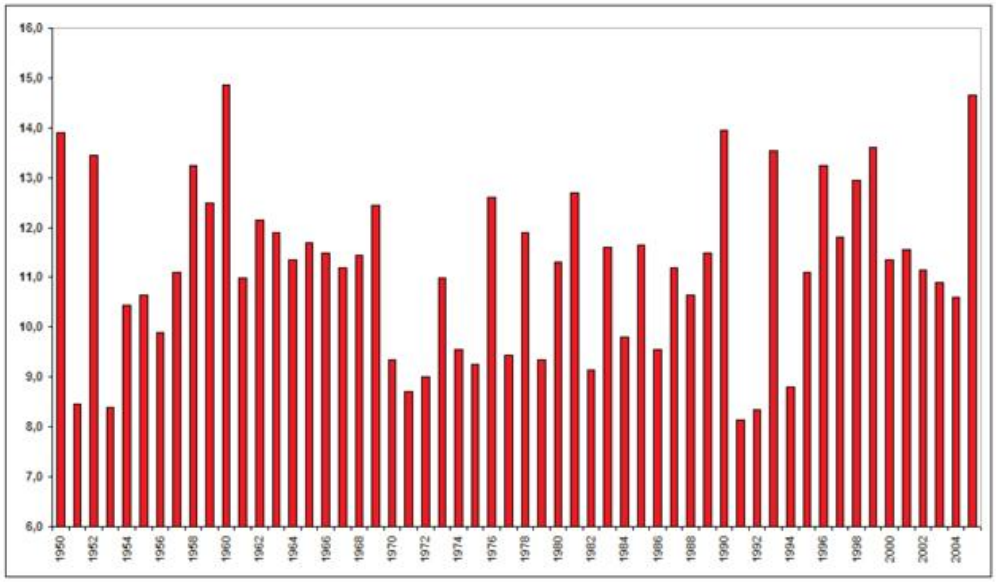

Fig. 12.2: *Mean monthly temperature in Jerusalem in December 1950-2005 (°C)*
Source: Israel Meteorological Service

Further to the east, it was very mild and drier than normal, also in **Armenia**. The monthly mean temperature was in many cases between +3.0 and +3.5°C above normal, in some areas between +8 and +10°C. Especially in the first and second decade of the month the weather was warm. Daily maxima reached 18 to 22°C in the eastern regions, 13 to 15°C in the Ararat valley and 9 to 13°C in mountain regions. Some trees started blooming in the Lori region. The first half of the month was also very foggy in the Ararat valley, visibility being less than 50 m. Because of heavy fog for more than 10 days, all flights were cancelled at Zvartnoc Airport in Yerevan. Only in the third decade of December did the diurnal mean temperature sink below zero in mountain regions, which was one month later than usual.

Ozone trends

W. Steinbrecht, H. Claude, U. Köhler
German Meteorological Service, Hohenpeissenberg

Ozone is a key trace gas in our atmosphere. As the strongest absorber of ultraviolet (UV) radiation, it protects life on the earth's surface from excessive levels of this potentially harmful shortwave radiation. By absorbing and emitting thermal infrared radiation as well, ozone is also an important greenhouse gas. In general, ozone is a heat source, both in the stratosphere and in the troposphere. Ozone is further an important player in atmospheric chemistry. It is a lead substance for urban pollution and photochemical smog, and it is the precursor for the OH radical, the key atmospheric "cleaning agent" in the troposphere.

Since ozone is a fairly abundant trace gas, from 50 parts per billion by volume in the troposphere to 10 parts per million in the stratosphere, and has also strong spectral absorption features, ozone measurements are relatively easy. The beginning of a global ozone observation network based on UV spectrometers was laid down in the 1920s (Dobson and Harrison, 1926). However, the global network of Dobson spectrometers did not start until the 1957/1958 International Geophysical Year. The perception that anthropogenic Chloro-Fluoro-Carbons (CFCs) might destroy our stratospheric ozone layer (Molina and Rowland, 1974; Crutzen 1974) and the discovery of the Antarctic ozone hole (Chubachi, 1984, Farman et al., 1985) have raised widespread scientific interest and public awareness. They have mandated an internationally and globally co-ordinated ground- and space-based monitoring system of the ozone layer. This coordination was very successful and has been in place for over 20 years (WMO, 2003). The resulting WMO Global Ozone Observing System (GO3OS) has been a nucleus for the WMO Global Atmosphere Watch (GAW) programme.

The evolution of near-global annual mean total ozone is shown in Fig. 13.1. Since the 1960s, zonal mean ozone from 60°N to 60°S has declined by about 4%. Note that a much larger decline has occurred near the poles, particularly in spring. Largely, this decline is a consequence of chemical ozone destruction by man-made chlorine and bromine contributions (magenta curve for equivalent effective stratospheric chlorine, EESC, in Fig. 13.1). However, meteorological changes related to climate change have also contributed to the decline (WMO, 2003).

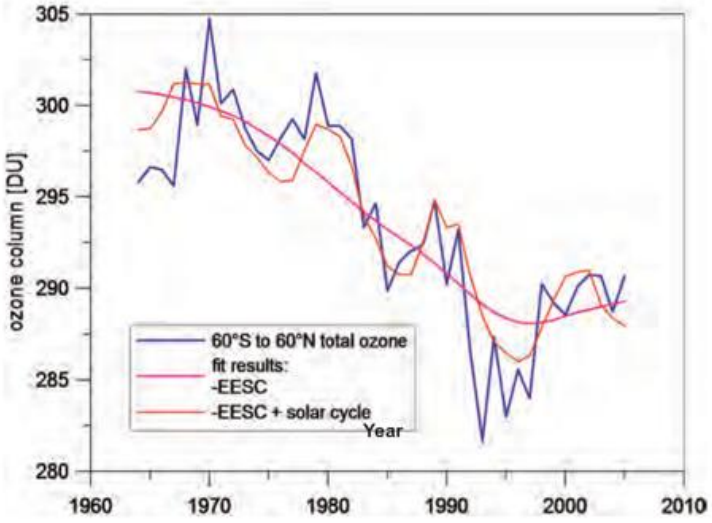

***Fig. 13.1**: Evolution of the near-global annual mean total ozone column. Ozone data (blue line) are obtained by combining ground- and space-based data sets (WMO 2003). The major long-term variations are due to anthropogenic chlorine and bromine, here described by equivalent effective stratospheric chlorine (EESC, magenta line), and the 11-year solar cycle (red-line, combined with EESC).*

Following the international ban on the production of harmful CFCs, chlorine levels in the lower stratosphere peaked around 1996 and are decreasing continuously. In Fig. 13.1 this corresponds to the minimum of the EESC curve (magenta), which is inverted to account for the negative effect on ozone. Since 1996, the trend of lower stratospheric chlorine has changed. However, at this point it is not clear what fraction of the observed ozone levelling since 1998 (blue line in Fig 13.1) is due to chlorine changes, which part is due to recovery from the effects of the 1991 Mt. Pinatubo volcanic eruption, causing the record low values of 1993 and 1995, and what fraction is due to transport changes or due to the 2000 to 2003 maximum of the solar cycle (red line in Fig. 13.1). It will take several years of additional data to resolve these ambiguities.

Most of the atmospheric total ozone column resides in the stratosphere at an altitude of between 12 and 40 km. Above this altitude range, the timescale on which ozone reaches photochemical equilibrium varies tremendously, from years or months near the tropopause to about one day at 40 km. Therefore, ozone in the upper stratosphere is largely controlled by photochemical reactions, whereas ozone variations in the lower stratosphere are largely determined by transport processes. Examples for the evolution of ozone in two selected stratospheric layers and one tropospheric layer are given in Fig. 13.2. At an altitude of 40 km, where ozone is mainly under photochemical control, a fairly straight long-term decline is apparent. It is caused by the destruction of ozone due to increasing chlorine levels over a time. Details are discussed below.

In the lower stratosphere at 20 km, in contrast, transport variations exert a major influence on ozone, although chemical depletion also plays a large role. For the long-term decline of lower stratospheric ozone from 1967 to 1996, e.g. by about 12% at 20 km, it is estimated that about two thirds are due to chlorine (and bromine) increase, and about one third is due to transport changes (WMO, 2003). As for the near global ozone (Fig 13.1), it is not clear which fraction of the levelling observed since 1998 is due to chlorine reduction, and which fraction is due to other factors.

While the two upper levels shown in Fig. 13.2 are representative of ozone at midlatitudes of the northern hemisphere, the evolution of tropospheric ozone in Fig. 13.2 is representative for central Europe only. There, ozone levels increased substantially until the late 1980s. This increase is mainly due to increasing emissions of nitrogen oxides and organic carbon substances. Since the 1990s, European emissions have been reduced. Tropospheric ozone levels in Europe have responded totally with a decrease or have remained more or less constant. However, small variations must be seen in the light of measurement uncertainties of ozone sondes. For some of the finer details, measurement uncertainties of the ozone sondes may play a role. A different behaviour of tropospheric ozone is found in other parts of the world. Over Canada, for example, tropospheric ozone decreased by about 10% during the 1980s, but has increased by about 10% during the 1990s (Oltmans et al., 1998; WMO, 2003). The reasons for this different behaviour in various parts of the world are widely unknown.

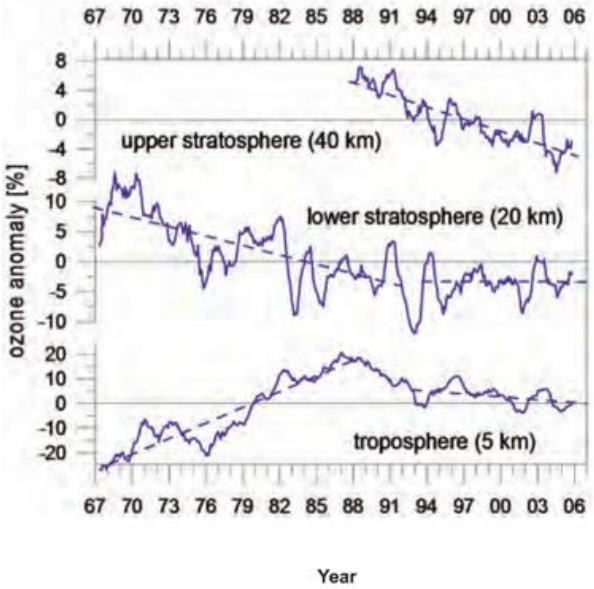

***Fig. 13.2**: Ozone anomalies from 1967 to 2005 at three atmospheric levels above Hohenpeissenberg, measured by ozone-sondes (5 and 20 km) and laser radar (40 km). Anomalies were defined by subtracting the average annual cycle from the monthly mean time series. To reduce short-term fluctuations, the data were smoothed by a 13 -month running mean. Hohenpeissenberg is located in southern Germany at 47.8°N, 11.0°E, 1000 m a.s.l.*

As already mentioned, for total ozone or for ozone levels in the lower stratosphere, a search for beginning positive effects of the recent turnaround in chlorine (or EESC) does not provide conclusive results at this point. There are simply too many competing influence factors. More conclusive evidence for a beginning recovery, however, can be found in the upper stratosphere, where ozone levels are most closely tied to chlorine levels by efficient catalytic destruction cycles. Fig 13.3 shows upper stratospheric ozone residuals for five stations from midlatitudes in the southern hemisphere to the northern hemisphere. These residuals were obtained by averaging all available long-term records from ground- and space-based instruments, and by subtracting the average annual cycle, as well as ozone variations due to the quasibiennial oscillation of equatorial winds and due to the 11-year solar cycle (Steinbrecht et al., 2006). To a large degree the residuals are then determined by chlorine levels. Indeed, for most stations, the residuals follow the inverted chlorine (EESC) line in Fig 13.3. In particular, the levelling of chlorine since about 1996 is mirrored by a levelling of ozone, with values well above the extrapolated ozone trend-line from the 1980s. The steep decline has obviously not continued after 1997. Because most other factors can be eliminated, the levelling gives a very strong indication that ozone is following the chlorine turnaround. The Vienna convention and the Montreal protocol have been effective for the upper stratosphere. There, the ozone layer is showing first signs of a recovery. However, as indicated by the data a the most northerly station (Hohenpeissenberg), other factors, not well understood, do interfere with the recovery signal.

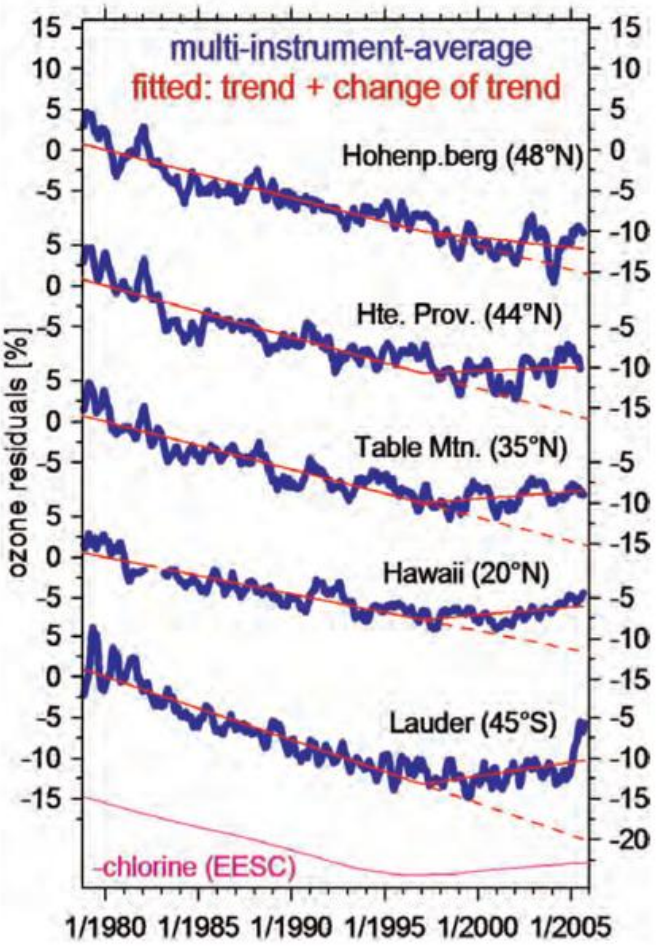

Fig. 13.3: *Upper stratospheric (35 to 45 km) ozone residuals obtained by a mix of ground- and space-based instruments for five stations of the Network for the Detection of Stratospheric Change (NDSC). Ozone residuals were defined by subtracting the average annual cycle, as well as effects from the 11-year solar cycle and the quasibiennial oscillation. Residuals very closely follow the chlorine (EESC) loading. Results from fitting a linear trend and a change of trend term after 1996 are shown as well (red line). After Steinbrecht et al. (2006).*

Chlorine levels are expected to continue declining. They are expected to return to the near natural pre-1980 levels over the next 50 years. This should bring up ozone levels. Nevertheless, further attention to the ozone layer is required. Climate change will affect the ozone layer in the future by both changing temperature and transport patterns. The expected cooling of the stratosphere will slow down ozone destruction cycles in the future, and when chlorine is back to 1980 levels, total ozone and ozone in the upper stratosphere are expected to reach higher levels than in 1980. This will change the vertical distribution of atmospheric heating and may affect the global circulation. As the past has shown, surprises are always possible. One thing is clear, however: an accurate, co-ordinated, and global ozone measurement system, i.e. a Global Atmosphere Watch programme will be required in order to gain knowledge about the true evolution of our ozone layer in the future.

Activities and Results of European Climate Centres

Report on ECSN activities 2005

Walter Kirchhofer, MeteoSwiss

- General remarks

The European Climate Support Network Programme, ECSN, allows improved co-operation in the field of climate and related activities, in order to expand Members` capabilities to support the European user community through enhanced provision of high quality climate data and products, services and advice. ECSN has initiated a series of projects in order to respond to the most frequent user needs.

The 10th ECSN Advisory Committee (EAC) Meeting took place in Copenhagen, Denmark, 8-10 June 2005. The meeting was well organized by the Danish Meteorological Institute. It was a fruitful meeting, also with regard to new activities.

The combined Conference of the European Meteorological Society (EMS) together with the European Conference on Applied Meteorology (ECAM) took place in Utrecht, The Netherlands, in September 2005. This EMS/ECAM Conference also contained a substantial part of climatological contributions, managed by ECSN.

The 5th ECSN Data Management Workshop took place in De Bilt, The Netherlands, in December 2005. The following main topics were presented and discussed: data rescue, databases, gridding and UNIDART. About 80 participants discussed the actual state of climate data management in Europe. This successful workshop was very well supported and organized by the Dutch Meteorological Institute.

- European Climate Assessment & Dataset (KNMI)

The "European Climate Assessment & Dataset" (ECA&D) project of ECSN aims at increasing the knowledge of past changes in extremes over Europe through the analysis of historical climatological records. The objective of the ECA&D project is to realize a sustainable operational system for data collecting, archiving, quality control, analysis and dissemination. The integration of these activities proved to be essential for the present and the next European Climate Assessment report issued in 2006. Data collecting refers to long-term daily resolution time series from meteorological stations throughout Europe. The scope of the ECA&D project is to analyse mainly the temperature and precipitation climate for Europe in the twentieth century from 1901 onwards, focusing not only on changes in the mean, but also on changes in extremes and climate variability.

- Generate Climate Monitoring Products (DWD)

The "Generate Climate Monitoring Products" (GCMP) project aimed at providing standardized climate monitoring products for the European area, in order to meet the requirements of the Services, scientific institutions and the public. In the course of the project a Web site was created as a platform for easy access to climate monitoring information supplied by the European National Meteorological and Hydrological Services (NMHSs) for the regional and national areas: http://www.gcmp.dwd.de.

- Climate Atlas of Europe (Météo-France)

The "Climate Atlas of Europe" project has been completed for the period 1971-2000, and contains monthly long-term mean values for precipitation, temperature, wind and sunshine duration as well as additional statistical information on these parameters and the occurrence of phenomena such as fog, thunderstorms, hail and snow. A CD-ROM, containing the datasets from nearly 700 European weather stations, is available.

- ENSEMBLES (KNMI, MeteoSwiss)

The "Development of daily high-resolution gridded observational datasets for Europe" project was initiated in 2004 within the European Integrated Project called "ENSEMBLES". The gridded datasets will include several climate variables, as minimum/maximum temperature, precipitation, air pressure and snow cover, and the datasets will go back as far as station data availability allows (45 years or possibly even longer). The resolution of the datasets should be high enough to capture extreme weather events. So far, nearly 700 European stations have been collected in the ENSEMBLES database. Since 4200 stations would be needed for a station density of one station per 2500 km², many more data will have to be collected.

A Web site for the ENSEMBLES gridding project was launched in October 2005: http://www.knmi.nl/samenw/ensembles_rt5/WP51.html.

- Alpine Tmap (ZAMG)

The Austrian Meteorological Institute has taken the initiative to launch a new ECSN project "High Resolution Temperature Climatology in Complex Terrain - demonstrated in the “Greater Alpine Region" test area. The project will provide a high quality data product for a special European region. The "Alpine Tmap" project proposal has been approved by the EUMETNET Council, and the project started on 1st January 2006, with Austria as the leading country. The main deliverable will be a mean monthly temperature field in a 1km resolution, first for the WMO period 1961-1990, and secondly for the "modern period" 1971-2000.

- New project activities

With the purpose of realizing a EUROGRID programme and studying the feasibility of such a concept, a preliminary project for a showcase has been worked out by the Swedish Meteorological Institute in close co-operation with ECSN. The EUROGRID Showcase proposal was discussed at the 26th EUMETNET Council meeting. The importance of the content of the project was supported enthusiastically, but it was stated that the links with other similar activities have to be improved and integrated in a revised proposal.

Meteorological Aspects of the Extreme Flood in August 2005 in Southern Bavaria

C. Beck, J. Grieser, J. Rapp, B. Rudolf
Deutscher Wetterdienst

1. The Flood Event

During the second half of August 2005 severe flooding occurred in the northern central Alps. Following heavy precipitation on 21 August, major Swiss cities such as Interlaken, Luzern and the capital Berne were flooded. On the following day a number of rivers in southern Bavaria, including the Lech, Iller, Isar, Inn and also the Danube flooded vast areas. Among other cities Garmisch-Partenkirchen, Kempten and Regensburg were affected by major inundations. In some regions the river gauges even exceeded the level of the century flooding of 1999.

2. The Synoptic Situation

Although the flooding caused disastrous effects regionally, the observed precipitation totals did not exceed former maxima of gauge observations at any station. Instead, the extraordinary flooding resulted from the particular interaction of several meteorological and hydrological processes. A detailed discussion can be found in Rudolf et al. (2006).

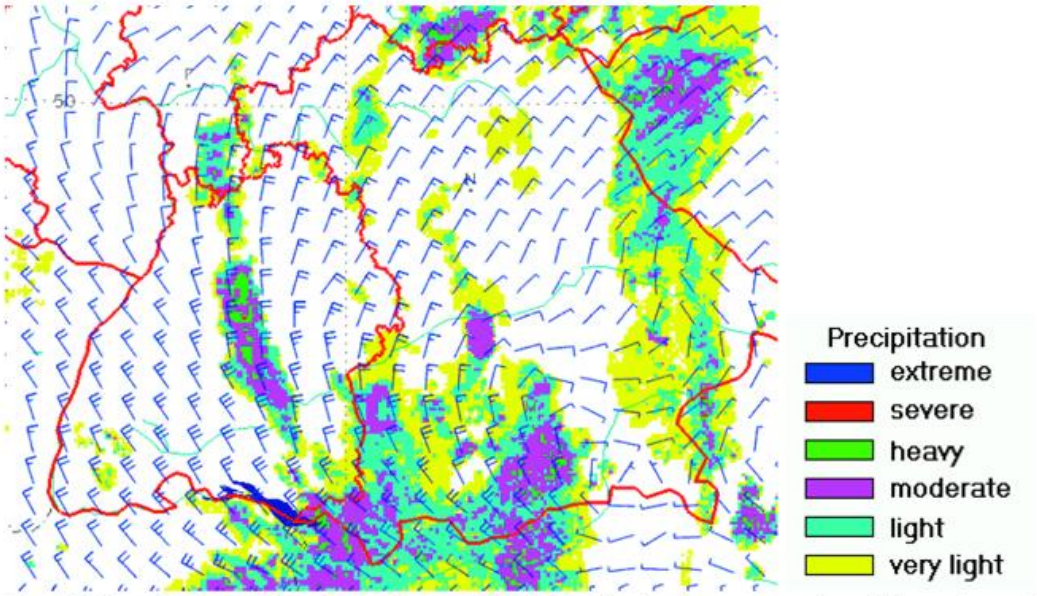

***Fig. 14.1**: Radar estimates of precipitation rate (yellow = very low, blue = low, pink = moderate, green = heavy) and wind field in an altitude of 1500 m from model output (DWD Local model, LM, 850 hPa) for 23 August 2005, 02:00h Middle European Summer Time (MEST).*

Several days before the high precipitation amounts occurred, a cut-off low had separated from the meandering flow over the southwestern part of Europe. Crossing the northern part of the Mediterranean, this low pressure system took up a considerable amount of humidity. Due to cyclonic steering, warm and humid air masses were first transported east- and northward around the Alps, and subsequently shifted westward and finally southward (see Fig. 14.1). Cooling of air masses during the transport resulted in condensation and continuous rainfall. In addition, forced lifting of the advected air masses at the northern slope of the Alps led to a

further amplification of condensation processes and to extreme precipitation events locally. The emergence of the resulting floods was furthermore promoted through soil characteristics. Following a period of high precipitation during July and the beginning of August 2005, soils were already water saturated. Thus all the precipitated water was transferred directly into surface run-off.

3. Forecast and Warning

The weather development that led to the flooding was well observed and forecasted. The local model (LME) of the German Meteorological Service (DWD) predicted precipitation amounts close to the observed ones. As a consequence DWD informed the responsible agencies well in advance and gave the public warning of heavy precipitation. Fig. 14.2 (left panel) shows the precipitation forecast issued on 22 August 2:00h Middle European Summer Time (MEST) for the 24h period starting 22 August 8:00h MEST. The right panel of Fig. 14.2 shows the interpolated observed precipitation from 1377 stations within the same period. The good agreement of both these maps obviously demonstrates that the diurnal precipitation total of this event was well forecasted. The regional Unwetterwarnzentrale (severe weather warning centre) of the DWD located in Munich issued its first warning on 21 August at 8:00h - well in advance of the event.

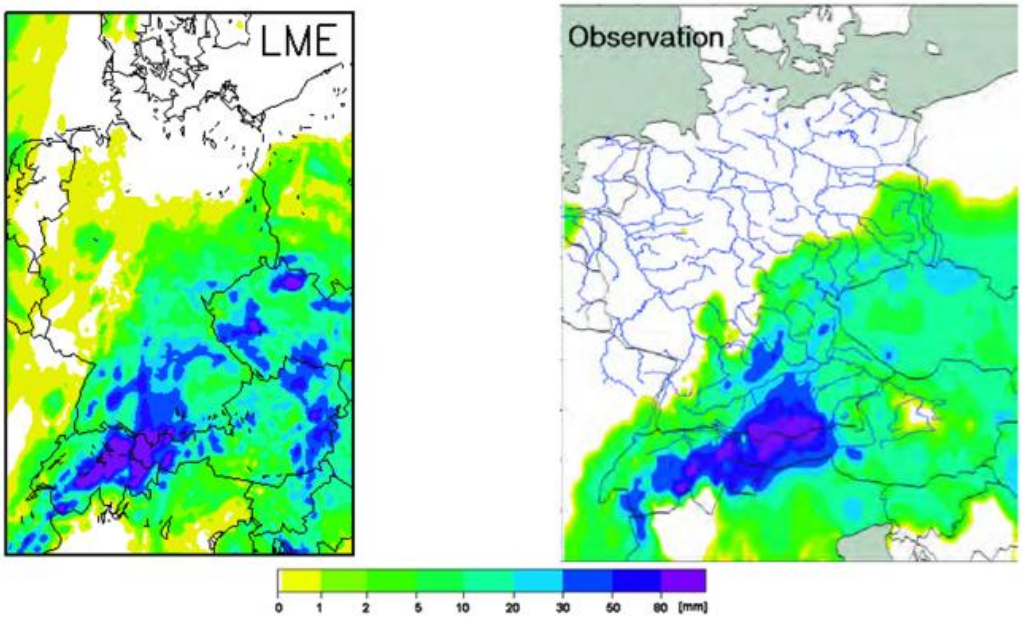

***Fig.14.2**: Precipitation forecast issued 22 August, 2:00h for a 24-hour period starting 6 hours later (left panel) and observed precipitation interpolated from 1377 stations (right panel).*

4. Climatological Evaluation

Fig. 14.3 shows the observed precipitation of 22 August for several stations within Bavaria and Austria. Only a small region in southern Bavaria and the Tyrol faced extraordinary extreme precipitation, which was most pronounced around Reutte and Oberstdorf with values above 100mm/day and an observed maximum precipitation of 189mm/day at Reutte/Tyrol. However, precipitation rates of more than 100mm/day are not unusual within the Alps. Stations situated in the Alpine foothills such as Kempten (with 67.5mm/day) faced less extreme precipitation. Also at very high altitude stations such as Zugspitze (2962m altitude) precipitation was less extreme (45.8mm/day).

For some of the stations shown in Fig. 14.3 long time series of daily precipitation observations exist. Those time series allow an estimation of recurrence periods. At the Kempten station observations are available since 1896. From these nearly 40 000 observed diurnal precipitation totals, 14 exceed the observation of 22 August 2005. This suggests a recurrence period of less than 8 years. The precipitation amount at Mount Zugspitze is usually exceeded twice a year.

However, at Garmisch, Oberstdorf and Oberstaufen the precipitation amount of 22 August 2005 was exceeded only once in their records consisting of more than 25 000 days each. At the station of Garmisch a considerably higher precipitation sum was observed during the precipitation event of 21 May 1999, which led to devastating floods. Assuming stationarity, i.e. the probability of an extreme precipitation event should not depend on time, we estimate a recurrence period in the order of 100 years, given the observed records. Since the most extreme observed precipitation totals reflect small scale convective precipitation events, the estimated recurrence period reflects the probability that the stations under consideration are affected by those events. However, if the meteorological situation had been only slightly different, another but neighbouring region would have been hit. Therefore, the probability that such an event will occur not exactly at the same location but shifted along the northern bounds of the Alps is higher. As a consequence the recurrence period for such an event to occur somewhere in the Alpine region is considerably below 100 years.

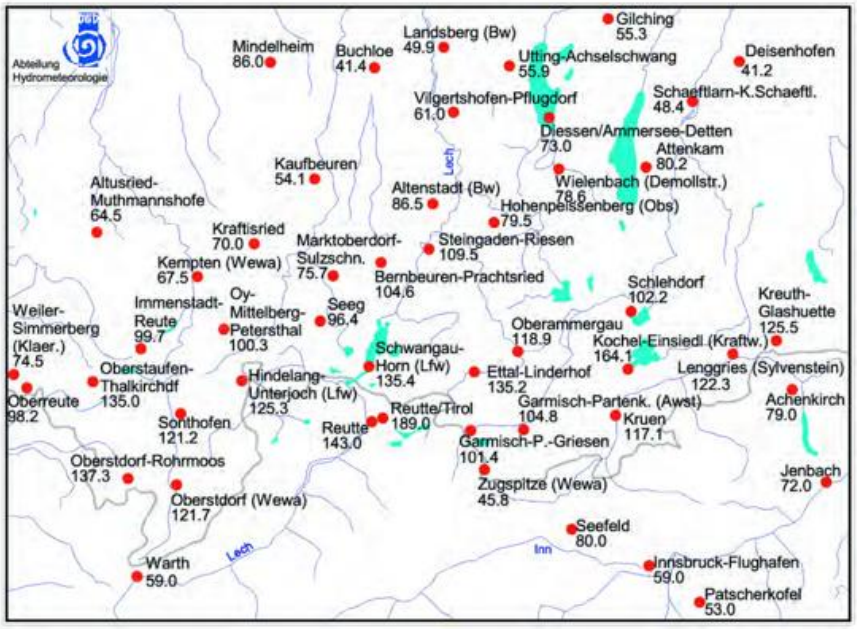

***Fig. 14.3**: Observed precipitation in mm/day on 22 August 2005.*

Against the background of global climate change the question may be asked as to whether or not the probability for an extreme precipitation event such as that under consideration has risen or fallen. In fact there is some conceptual framework arguing that heavy precipitation events should become more intensive in the case of global climate change (Trenberth, 1999).

In order to investigate whether or not the most extreme precipitation events lead to higher precipitation sums within the recent years, Fig. 14.4 shows the records of the highest observed diurnal precipitation total per year for the 3 stations at Oberstdorf, Garmisch and Kempten. These time series do not reveal a systematic increase in the intensity of the highest diurnal precipitation totals per year.

Finally, we focus on the second point that was essential for generating the flood: the saturated soils. These resulted from precipitation during the weeks before the extreme event. If monthly precipitation totals increase, also soil saturation increases on average. This in turn promotes the vulnerability of river catchments to floods triggered by short-lived but extreme precipitation events.

In order to investigate the regional trend in monthly August precipitation for the central northern Alpine and pre-Alpine region, a 50-year gridded dataset with 0.5° spatial resolution of observed monthly precipitation totals created on the basis of homogeneity tested, long and nearly gap-free records is used (Beck et al., 2005). Spatially averaged August precipitation totals for the region bounded by 9°-12° East and 46.5°-48° North are calculated and the respective time series since 1951 is shown in Fig. 14.5. A negative linear trend of about 7% over the period 1951 to 2000 becomes visible, reducing average August precipitation from about 150 mm at the beginning of this period to about 140mm at the end. However, given the high precipitation variability, this negative trend is not significant on a 90% level of significance.

Trömel and Schönwiese (2005) showed that temporal changes in precipitation variability exceed changes in precipitation averages, which may suggest a decoupling of extreme and average precipitation. Grieser and Beck (2003) found significant increases in both, days with extreme precipitation and precipitation totals on days with extreme precipitation. However, they defined a day with extreme precipitation as a day having a recurrence period of 100 days. Thus their statistics based on daily data for the period 1901 – 2000 describe less extreme events. Moreover, they found significant trends in winter only and for the shorter sub period from 1961 to 2000.

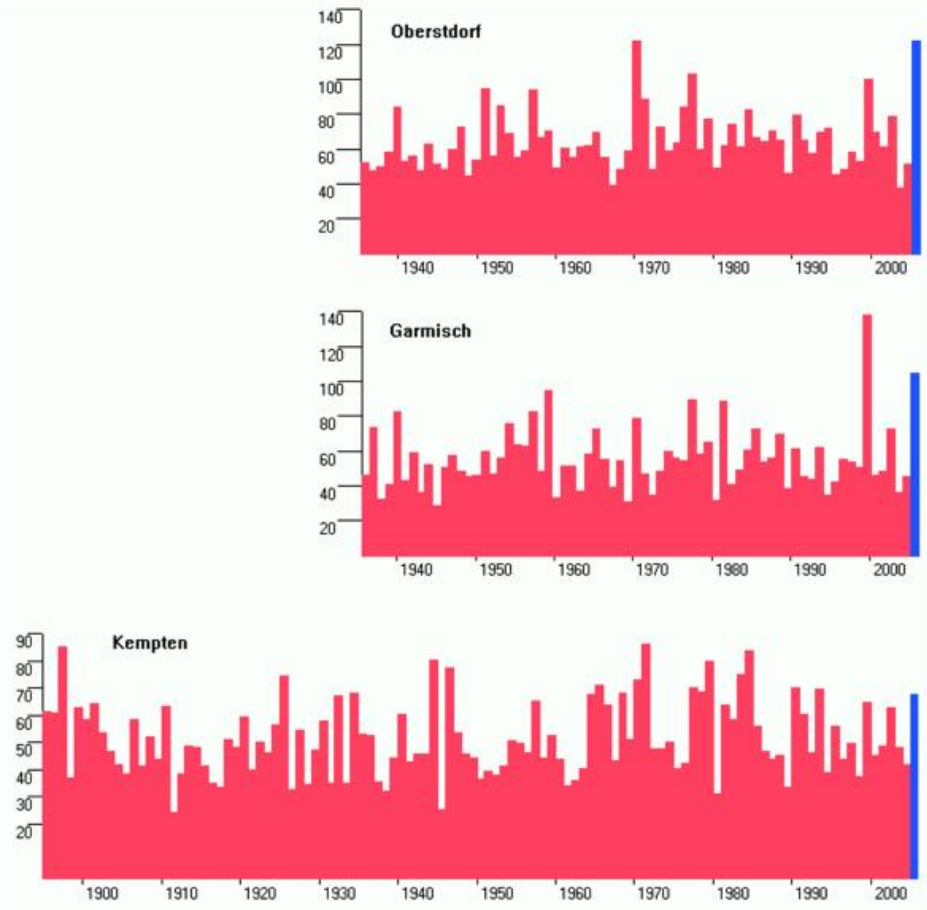

Fig. 14.4: *Time series (red) of highest diurnal precipitation total per year (in mm/day) for the stations at Oberstdorf, Garmisch and Kempten. The blue column is the precipitation total of 22 August 2005.*

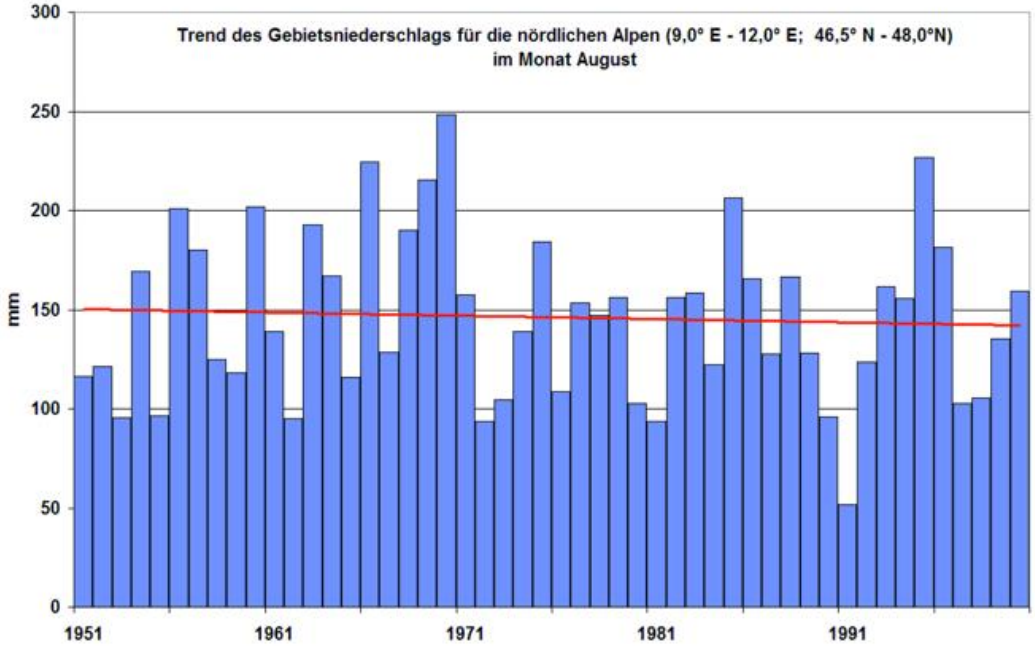

Fig. 14.5: *Time series of monthly mean August precipitation for the region 9°-12°E and 46.5°-48°N (blue columns) and linear trend (red line).*

5. Summary and Conclusion

The flood that occurred in the second half of August 2005 at the northern Alps resulted from extreme rainfall (with a recurrence period of up to 100 years for a small region) on saturated soils. The extreme rainfall itself was caused by a rather rare meteorological situation implying the advection of warm and humid air masses from the Mediterranean that circled eastward around the Alps and cooled down on the northern side, which led to condensation and continuous rainfall. Furthermore, due to forced lifting at the northern slopes of the Alps, precipitation reached outstanding intensities locally.

The potential hydrometeorological effects resulting from this synoptic situation were recognized early by the German Meteorological Service (DWD) and respective warnings were issued well in advance of the event.

As the flooding arose from the combination of unfavourable hydrological preconditions (water saturated soils) on the one hand and a triggering meteorological event (extreme daily precipitation) on the other hand, long-term variations of both factors were investigated in order to place this event in a broader context of global climate change.

Given long records of station observations within the affected region, neither a long-term positive trend of monthly mean August precipitation (which can be used as an indicator for water saturation of soils) nor positive trends in the very extreme diurnal precipitation totals can be detected. Therefore, this individual event cannot be regarded as a consequence of long-term global climate change. However, previous work suggests an increase in more moderate extreme precipitation (recurrence times of 100 days) especially in recent years, but mainly in the winter half-year.

Foreword

The year 2006 was a very exciting year for both climatologists and readers of record books. In various countries and places it was the warmest year or at least one of the warmest, even in very long time series. To give only a few examples: it was the warmest year in the 348-year Central England temperature series and also in De Bilt in the Netherlands, where measurements began in 1706. This already implies that 2006 was an outstanding year, actually having been the warmest for at least 300 years in more than one location.

However, there were some more remarkable features in 2006 concerning our Region. Over large parts of Europe, the year 2006 started very cold with wintry conditions, but this was more than balanced out by most of the following months, especially July and the last four months of the year, which were extremely warm, particularly in central and northern Europe. These months or seasons were, of course, also record-breaking: with one record following the other.

The northernmost parts of our Region were already very mild at the beginning of the year. On Svalbard it was more than 12 °C warmer than normal in January and again in April 2006, and more than 5 °C on the annual average. This was even more than in the years 2004 and 2005, which were already very mild. Nowadays we classify these events as extreme. But, when we look at future climate projections, it could well be possible that in about 100 years such events will no longer be considered as extreme, but normal. The Arctic parts of our Region are expected to be those where climate changes will be largest and fastest, and if we look back on our climate monitoring results, we find strong signs that the recent climate change is already apparent and continuing steadily.

Records of this year did not only concern temperature. Some months, seasons or other longer periods were extremely sunny and dry over large areas; others were extremely wet and dull. Both, extended droughts and flooding can be found during 2006 in various parts of our Region, which caused considerable damage. Luckily, we did not have so many severe storms as in other years.

However, 2006 saw another record which is the most pleasant: the high number of countries participating in this 13th issue of the Annual Bulletin. 44 out of 49 countries sent their contributions in time to our editors Dr. Peter Bissolli and Peer Hechler of DWD (Deutscher Wetterdienst) who once again took over the task of compiling all these very informative contributions into a concise summary comprising the most important anomalies and highlights of this record-breaking year. I would like to express all my warmest thanks to all contributors, reviewers and editors for their excellent work and co-operation concerning this Bulletin issue, also to the authors of the special reports, which are included again as in the previous years. With this issue appearing already in summer 2007, we have further reduced the delay between the reporting year and the distribution of the Bulletin.

I wish you pleasant reading of this interesting documentation.

Daniel Keuerleber-Burk
President of WMO Regional Association VI

Outstanding Events and Anomalies

Temperature

- Very warm year with record anomalies in many places in the Region, particularly in the Arctic area
- Especially July and autumn were record breakingly warm in many countries, especially in Central Europe and parts of northern Europe.
- December extremely mild especially in northeast Europe

Precipitation

- Long dry periods (up to 35 consecutive days without rain), especially in some parts of the east
- Wettest spring in parts of Switzerland for more than 140 years
- Flooding of Danube and Elbe rivers in April
- Driest summer ever recorded in southern and western Finland
- Wettest August in some places in Central Europe

Sunshine

- Extremely sunny July, but extremely dull February and August in Central Europe

Wind

- Severe storms in France on the Atlantic coasts on October 3-4 and on December 8 with gusts up to 150 km/h
- Severe storms over northern Central Europe on October 30 – November 1 and on December 30-31 with gusts up to 156 km/h

Annual Survey

Temperature

2006 was again a warm year nearly all over the Region (Fig. 0.1). The highest anomalies (deviations from the 1961-1990 long-term mean) were recorded on Svalbard, reaching outstanding +5 °C and exceeding even the record values of 2005. This is in line with a recent strongly decreasing trend of Arctic Sea Ice extent which has been reported by, among others, the National Snow and Sea Ice Data Center (USA). In most of northern, western and central Europe, but also in parts of the Middle East, the anomalies were between +1 and +2 °C. In eastern and southeastern parts of the Region and over large areas of the North Atlantic, the anomalies were also mainly positive, but less than +1 °C. Only a few locations in the southeast of the Region (e.g. in Romania, Greece, Turkey, Armenia) recorded slightly negative or zero anomalies.

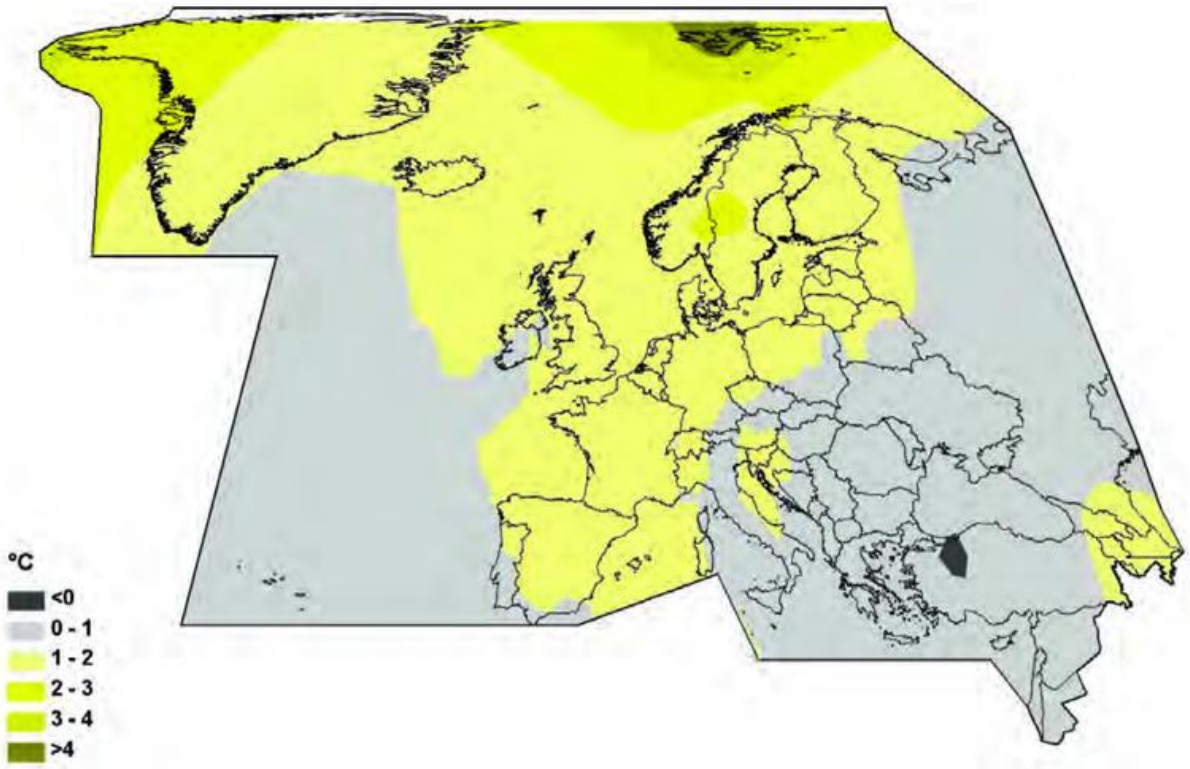

Fig. 0.1: *Mean annual temperature anomalies in 2006 (reference period 1961-1990) in WMO Region VI (interpolation of CLIMAT data).*
Source: Deutscher Wetterdienst

Although 2006 was warm on average, especially Central Europe and its adjacent regions had a very cold start of the year until March. In contrast, July and the last four months of the year were outstandingly warm, in many cases the warmest period ever recorded. In the Czech Republic, for example, the average air temperature of the period September-December 2006 was the highest since 1974. Typical examples of this special annual cycle are Poland (Fig. 0.2), Hungary (Fig. 0.3), Belarus (Fig. 0.4) and the Ukraine (Fig. 0.5). In the Middle East, it was just the other way around: here, it was warm from February onwards during most of the year, whereas the end of the year (November and December) was quite cold.

Many temperature records were beaten this year at many stations in some of the months, seasons or even over the whole year. 2006 was the warmest year within the 348-year Central England temperature time series, and record annual average temperatures were also observed

Source: Ukrainian Hydrometeorology Centre

for most areas of the United Kingdom and for some stations in Ireland. In particular, the annual average minimum of the Central England temperature was the highest on record (Fig. 0.6), while the maximum temperature was only the 5th warmest.

For Norway as a whole, 2006 was the warmest year (anomaly +1.8 °C) ever recorded, together with 1934 and 1990 (Fig. 0.7); especially for western Norway it was by far the warmest year. Since 2002, the Norwegian annual mean temperature has been considerably above normal

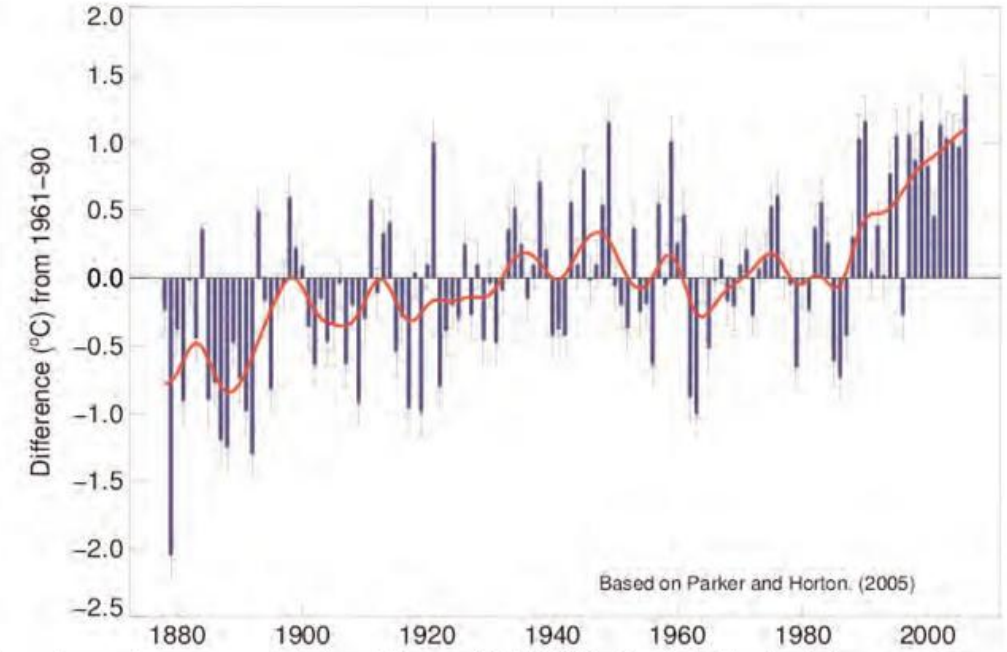

Fig. 0.6: *Annually-averaged daily minimum 1878-2006 Central England temperature anomalies (reference period 1961-1990, blue bars) with 2 standard-error range (grey bars) and smoothed values (21-point binomial filter, red line).*

and has increased steadily. In Sweden, 2006 was the 6th warmest year (since 1860). Nevertheless, the average temperature in Sweden for the whole period from 1991 to 2005 was 0.9 °C warmer than normal, partly more than 1 °C (Fig. 0.8).

The annual mean temperature for Denmark on the whole was also a new record: it amounted to 9.4 °C, which was +1.7 °C above normal and 0.1 °C higher than the previous record in 1990 (Fig. 0.9). With 2006, 17 of the last 19 years in Denmark were warmer than normal, thus continuing the sharply rising warming trend of recent decades. In Tórshavn on the Faroe Islands, 2006 was with 7.5 °C the third warmest year since 1873 after 2003 and 1933. Nine of the months in 2006 were warmer than normal on the Faroe Islands, with only the spring months having been colder. On Greenland it was also very warm in 2006, but it was not the warmest year on record: 2003 was warmer in Nuuk, 2002 and 2005 were warmer in Danmarkshavn.

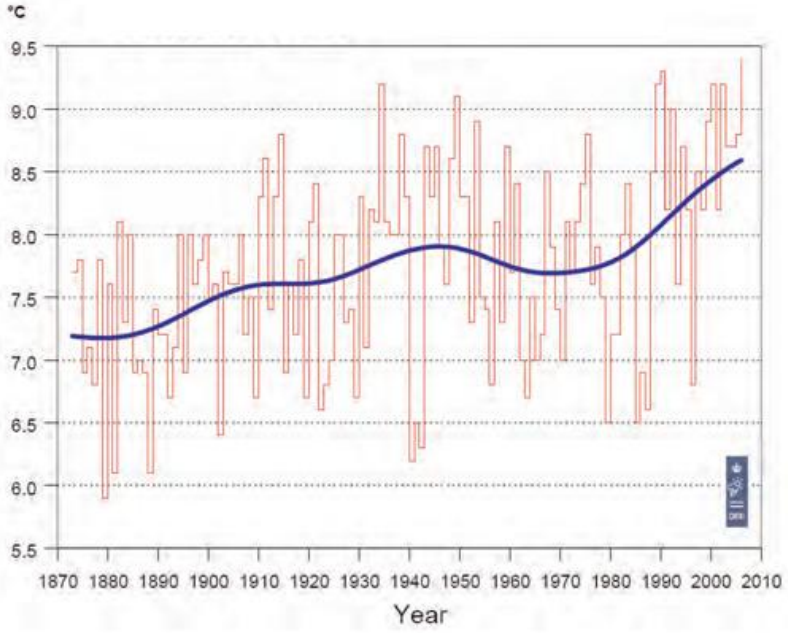

Fig. 0.9: *Annual mean temperatures in Denmark (1873-2006) with Gauss-filtered values (bold line). Source: Danish Meteorological Institute*

In Germany, the areal mean value was 9.5 °C in 2006 (anomaly +1.3 °C); it was the 5th highest since 1901. The number of summer days (Tmax >= 25 °C) was mostly twice or three times as high as compared to the normal, while the number of frost days was around the long-term average. In Switzerland, 2006 was the 5th warmest year, too (since 1864, Fig. 0.10). Luxembourg (airport) reported 44 summer days (normal: 28.5) and 12 hot days (Tmax >= 30 °C, normal: 4).

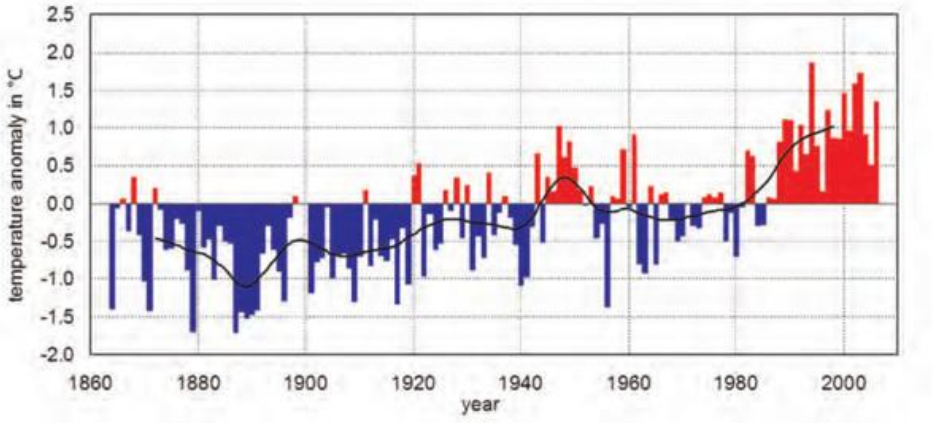

Fig. 0.10: *Annual mean temperatures in Switzerland (1864-2006) and smoothed values. Source: MeteoSwiss*

In Brussels-Uccle, Belgium, the annual mean temperature reached 11.4 °C (normal: 9.8 °C), exceeding the former record of 11.3 °C of 1989. De Bilt in the Netherlands had 11.2 °C on average, thus also recording the warmest year since the start of measurements in 1706 (Fig. 0.11). France recorded 2006 as the 3rd warmest year since 1950 after 2003 and 1994; it was 1.1 °C warmer than the 1971-2000 average. Slovenia observed partly quite high anomalies, too (> +1.5 °C for some minimum and maximum temperatures, Fig. 0.12), so 2006 was the 5th warmest year since 1951, for example, in Ljubljana and at the coast.

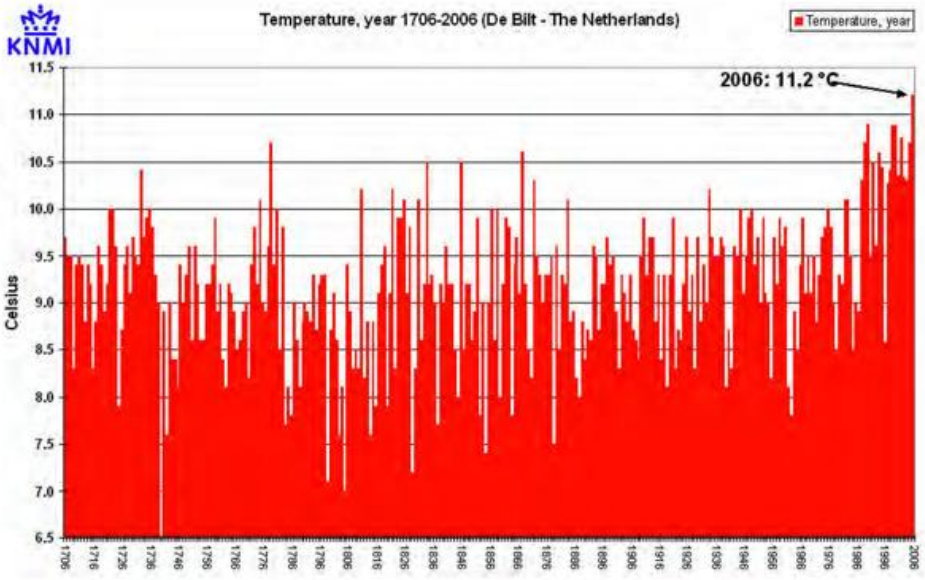

Fig. 0.11: *Annual mean temperatures in De Bilt (Netherlands) 1706-2006.*

2006 was also one of the warmest years in the south. In Portugal, it was the 5th warmest year since 1931. For Peninsular Spain and the Balearic Islands, it was the warmest year since 1980 (Fig. 0.13), with particularly warm temperatures in the eastern half. The mean trend of this time series is 0.37 °C / 10 years.

In some places in the southeast of the Region, 2006 was also among the 10 warmest years of the time series although the anomalies were only a few tenths degree of a centigrade. In Zagreb Gric (Croatia), 2006 was the 7th warmest year since 1862, in Armenia the 7th warmest since 1929. It was also one of the warmest years in Malta; though still 0.5 °C colder than in 2001 which was the warmest year. The same applies to the sea temperature around Malta.

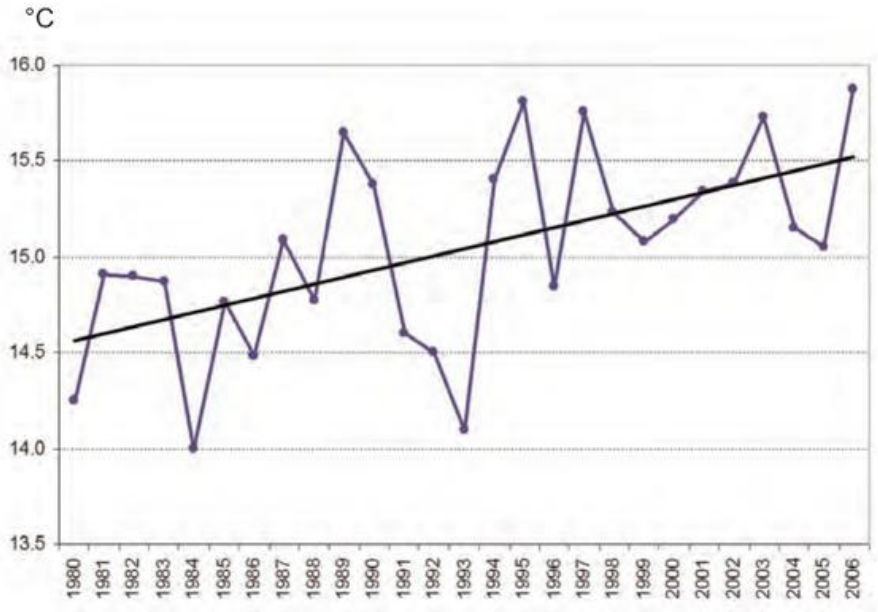

Fig. 0.13: *Areal annual mean temperatures for Peninsular Spain and the Balearic Islands and trend line.*
Source: National Institute of Meteorology, Spain

Daily maximum temperatures above 40 °C were reached in some places in the south at several occasions. Jordan recorded 45 °C as the highest annual value on 4 days in 2006 (May 25, June 6, August 18 and September 29).

Precipitation

Annual precipitation amounts in 2006 were around normal (80-125% of the 1961-1990 normal) in most parts of the Region. Higher-than-normal amounts occurred notably in northern Greenland, Svalbard, and in parts of Iceland, Norway (western Finnmark) and Sweden, whereas in other places it only occurred locally (Fig. 0.14). In Sweden, 2006 was the 6th wettest year on record for the country as a whole. The year was relatively dry on the Norwegian west coast, in the Baltic countries, in and near the western Mediterranean, on the southern slopes of the Pyrenees and the Alps, in Cyprus, in some areas near the Black Sea and the Caspian Sea, in parts of Lebanon (especially in the autumn and winter months), Israel and Jordan. In the high mountains of Lebanon, consequently only 66% of the normal annual snowfall was recorded in 2006.

Estonia recorded in 2006 30-35 consecutive dry days in the vegetation period; only 2002 was drier during the last 50 years. In particular, large parts in the north of the country received less than 70% of the normal annual precipitation. In Latvia, 2006 was the 7th driest of the last 83 years, causing low water levels in rivers. The Gauja River near the city of Sigulda had the lowest water level measured since 1940 during the period July-October (Fig. 0.15). In the south, especially in the Po Valley in Italy, too, a low annual amount of precipitation caused extensive drought conditions in that area with reduced water availability for drinking, agriculture and thermoelectric power stations. On the other hand, flooding events occurred in Romania from March to August. In particular the flooding of the Danube from April to June partly affected many adjacent countries, especially in April.

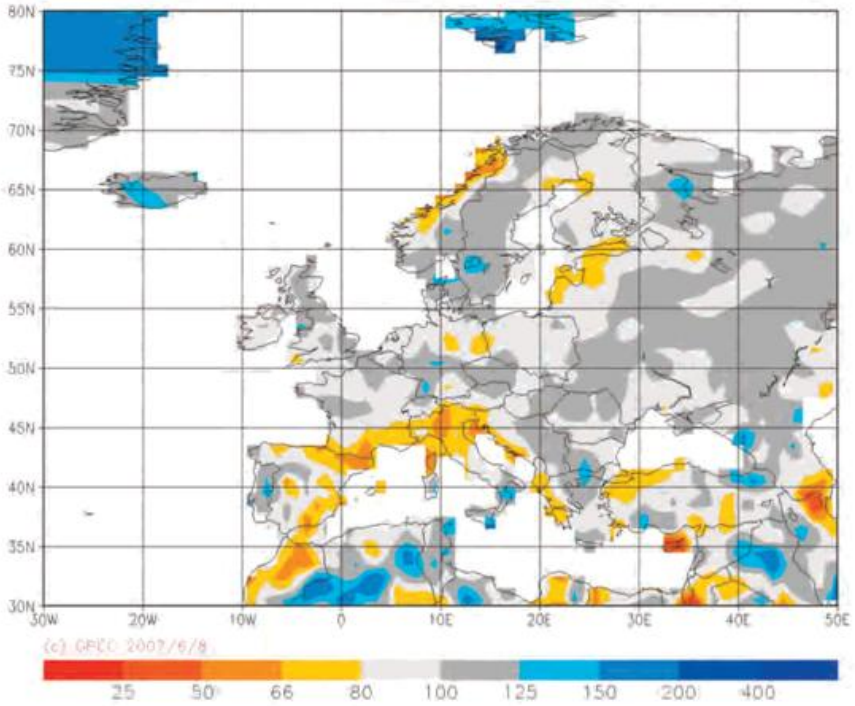

Fig. 0.14: *2006 annual precipitation amounts in WMO Region VI in per cent of the 1961-1990 normal. Source: Global Precipitation Climatology Centre (GPCC), Germany*

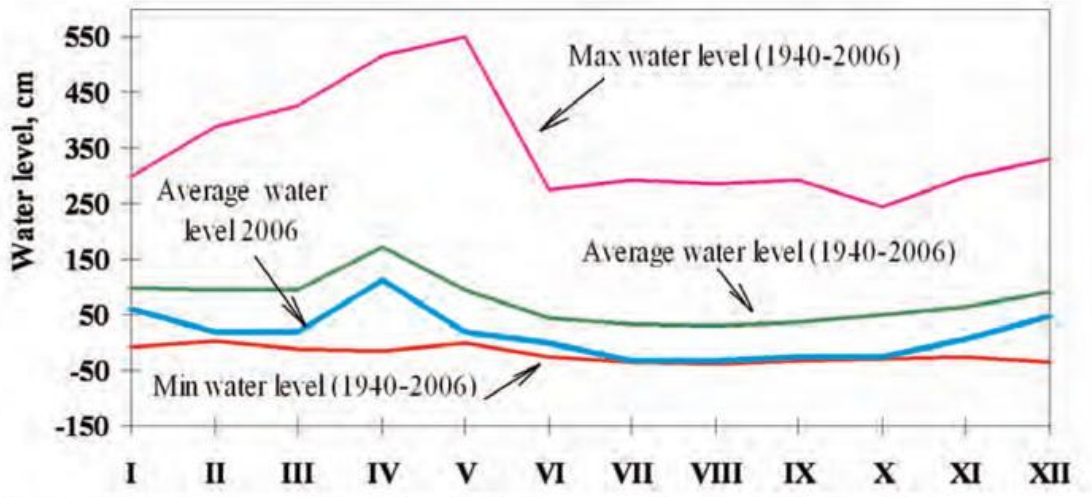

Fig. 0.15: *Water level anomalies in the Gauja River near the city of Sigulda, Latvia. Source: Latvian Environment, Geology and Meteorology Agency*

The monthly distribution of the annual precipitation was quite unusual in some countries. In Ireland, January and February were very dry, especially in the east of the country, whereas widespread heavy rainfalls during the last three months of the year led to flooding in places in midland and western areas. Albania, which has normally the wettest months in winter, received monthly records in March and, in part, higher amounts in the summer months as compared to the winter months (Fig. 0.16). Some parts of Israel had a period of 35 consecutive days without rain from November 16 to December 20 which in the north of the country was by far the longest dry period in the winter season from November to March since 1928/29 (Fig. 0.17).

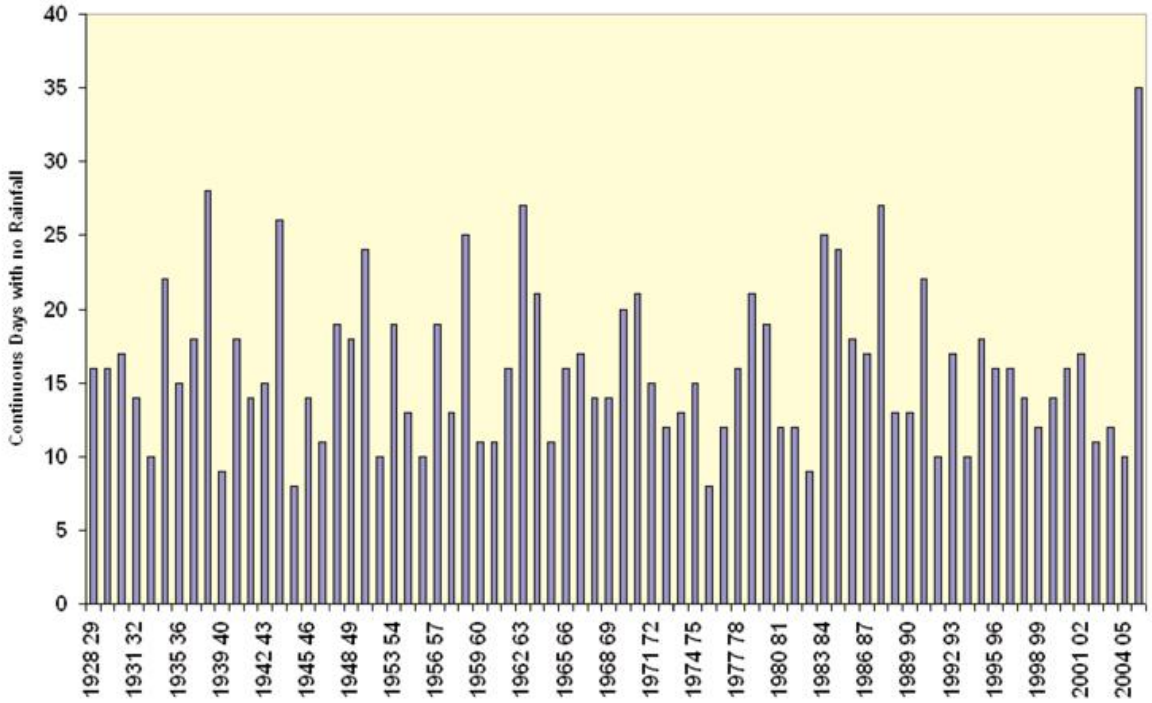

Fig. 0.17: *Longest period without rainfall in Kefar Giladi (northern Galilee in northern Israel) in the winter season November – March 1928/29-2005/06. Source: Israel Meteorological Service*

Sunshine duration

2006 was a sunny year as compared to the normal in many parts of the Region. In some places, it was the sunniest or one of the sunniest within many years.

In the north, 1494 hours of sunshine were recorded in Reykjavik (Iceland), which is 118% of the normal. This excess mainly occurred in spring. In the south of Iceland, it was the sunniest spring since 1924. In contrast, the sunshine total in Akureyri in northern Iceland was slightly below normal.

The sunshine duration was also unusually long in Estonia: since 1955, only the year 2002 was sunnier in Tartu.

In Ireland, annual sunshine totals were around 10% above normal all over the country. April, June and July were particularly sunny months relative to the normal and only March was duller than normal at all stations. Shannon Airport had its sunniest year since 1968, while at Dublin Airport it was the sunniest year since 1959. 1770 hours at Rosslare was the highest annual total within the country. In the United Kingdom, Aberdeen Airport smashed their December sunshine record, with around 90 hours of sunshine being recorded, which is just over double their December average.

In Denmark, 1703 sunshine hours were recorded in 2006 for the country as a whole which is 114% of the normal. July was record breakingly sunny with 321 sunshine hours. In Tórshavn on the Faroe Islands, the sunshine duration in 2006 set a new record with 1064 hours (127% of the normal) throughout the whole year. Germany had an areal mean sunshine total of 1771 hours (116% of the normal) in 2006; it was the 3rd sunniest year since 1951 after 2003 and 1959.

The year 2006 was also very sunny in the Netherlands with a total of 1782 sunshine hours (115% of the normal) particularly in July, whereas February and August were very dull. The coastal station Valkenburg recorded 340 sunshine hours in July; such a monthly total had never been reached there before. Belgium (Uccle) also had a remarkable deficit of sunshine in February (30 hours, normal: 73 hours) and August (94 hours, normal: 188 hours), whereas many sunshine hours (309, normal: 195) were recorded in July. Thus, this was the dullest February and August in Belgium since 1887 and the third sunniest July after 1959 and 1911 (Fig. 0.18). A similar distribution was observed in Luxembourg, although records were not broken. In France, only the southern half and the west of the country received more sunshine than normal.

Austria had an excess in annual sunshine of 15-30% as compared to the normal all over the country, and in Slovenia the normal was also exceeded nearly everywhere, in Celje even by up to 19%. In Hungary, too, most of the year was sunnier than normal, especially the warm months July, September and October.

In the south of the Region, Malta recorded a daily average of 8 hours and 18 minutes of sunshine in 2006, which corresponds to an annual total of 3029.5 hours and was slightly more than the average in the past 78 years.

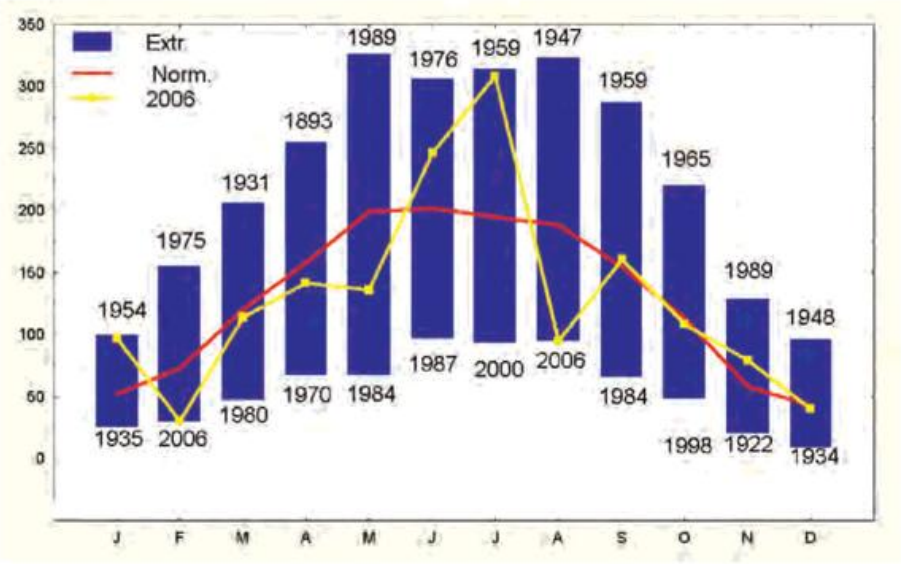

Fig. 0.18: *Annual course of sunshine duration (in hours) in Uccle (Belgium) in 2006 and averages of the normal period 1961-1990, showing the sunniest and dullest years since 1887 (bars). Source: Royal Meteorological Institute Belgium*

Wind

Norway recorded only one strong storm on January 11, causing significant wave heights above 13 metres and damage in the Lofoten area. Within the Norwegian sea area, the highest wind speed on oil platforms in 2006 was measured in the Haltenbank area on January 31 with 110 km/h and also wave heights above 13 metres.

In Germany, strong thunderstorms were recorded on July 5-6. Gusts up to 110 km/h were measured at Lake Constance, and in western parts of the country the wind was strong enough to overthrow trees. In some places, the semi-final soccer match of the World Championship could not be shown at public viewing sites due to thunderstorms and flooding. Apart from this event and a few other thunderstorms and tornadoes in July and August, strong winds in Germany were mainly restricted to the last third of the year. The ex-hurricanes Helene and Isaac caused stormy gusts in October, just like a low pressure system over southern Sweden in the same month. Two severe storms with gusts up to 156 km/h were recorded over the coastal areas of Germany, one on October 30 – November 1 and another at the end of the year on December 30-31. The former one caused the highest flooding at the coast of East Friesland for more than 100 years, but thanks to the fortified dykes no severe damage occurred. However, this storm caused severe high water situations in Denmark in the Øresund, the straits, the sea south of the island Sjaelland and in the Baltic Sea. High waves were also observed in the northern North Sea on October 31.

On October 3-4, a severe storm touched France. It had developed from a low pressure system over the Golf of Gascony. Gusts were particularly high in the region of Aquitaine (150 km/h on the southern Atlantic coast and 130 km/h up-country). The storm then moved to the northeast of France causing severe flooding in the region of Alsace and Lorraine. Another storm in France occurred on December 8 with gusts up to 140 km/h, particularly on the Atlantic coasts and in the northwest. Luxembourg (airport), too, recorded the strongest storm late in the year on December 8, but only with gusts up to 93 km/h.

In Hungary, two heavy storms were recorded in summer, one on July 22, the other on August 20 (the Hungarian National Day), the latter with gusts up to 120 km/h.

The south of the Region was hit by waterspouts that reached the sea surface in the coastal area near Castelldefells in Catalonia (Spain). On May 3, a strong storm caused the rivers in southeast Spain to overflow. Later, on September 21, the remnants of hurricane Gordon interacted with a deep Atlantic low, causing strong winds and severe damage particularly in Galicia (northwest Spain).

The highest wind gust in Malta was 83 km/h on February 1.

In Greece, a winter storm with gusts up to more than 100 km/h passed the northern and central Aegean Sea and then moved westwards the Ionic Islands on January 24. It was accompanied by heavy snowfall which caused damage to the electric power network. This storm also affected the European part of Turkey, causing there a short blackout. Another storm with more than 90 km/h occurred in Greece on February 26 over the Attica region (around Athens). Trees fell down. Five severe storms with damage to plants, mostly trees, were recorded in Turkey in March and April, and three more in November and December. Strong winds also occurred occasionally in various areas of Cyprus, particularly in January, February, March and October. Tornados were recorded on February 7 in the south-eastern coastal area of Cyprus, associated with heavy rainfall, hail, floods and damage to houses and crops, and again on October 31 in the southern coastal area.

In Israel, a tornado hit in western Galilee (north Israel, Fig. 0.19) on April 4. In the Lebanon, south-westerly winds up to about 110 km/h were measured in spring, easterlies up to about 100 km/h in autumn. Syria, too, was affected by strong gusts up to 109 km/h caused by many

low pressure systems during 2006. In Armenia, a hailstorm with heavy rain in the north-east of the country on May 9 resulted in mudflow causing damage to livestock. Strong winds were also observed in November in this country with gusts up to 145 km/h on November 4.

Three tropical storms entered the Region over the Atlantic in 2006: Alberto (June 18), hurricane Gordon (September 20) and hurricane Helene (September 25). Two more hurricanes (Florence in September and Isaac in October) were classified as extratropical depressions before entering the Region.

Seasonal Survey

Temperature

The year 2006 was characterised by a change from a cold winter over most of continental Europe to a warm summer and autumn.

Winter 2005/06 was cold over most of the continental areas of the Region, in many places the anomalies were < -1 °C, locally < -2 °C; this was outstanding (percentiles <2%, see seasonal maps), especially in northern Poland and around the Black Sea. Over the Mediterranean the temperature was around normal. On the contrary, nearly the whole Atlantic area, most of Scandinavia, the United Kingdom and Ireland, parts of the Iberian Peninsula as well as the countries in the very southeast of the Region, e.g. Armenia, were warmer than normal.

The highest anomalies were observed in Svalbard, exceeding partly +9 °C. All the Svalbard stations recorded the warmest winter since measurements started. In Iceland, too, this winter was very mild: in Reykjavik and Akureyri, it was the 4th warmest since the inception of continuous measurements. Only 36 days of full snow cover were recorded in Reykjavik (normal 55).

Spring 2006 was cold over parts of northern, eastern central and north-eastern Europe with anomalies mostly not more than 1 °C colder than normal, only occasionally the deviation from normal was < -1 °C. The majority of the rest of the Region was warm that spring, with the highest positive anomalies occurring in Svalbard again, reaching up to more than +6 °C. The abnormally warm Atlantic flow continued.

The mean spring maximum temperature anomalies on the Italian islands Sardinia and Sicily partly exceeded twice their standard deviations (Fig. 0.20).

Summer 2006 was warm nearly everywhere in the Region. The anomalies were mostly above +1 °C, in some places in northern, western and central Europe and in the southeast of the Region also > +2 °C and very exceptional (percentiles >98%). Negative anomalies occurred only at a few locations, e.g. in Greenland.

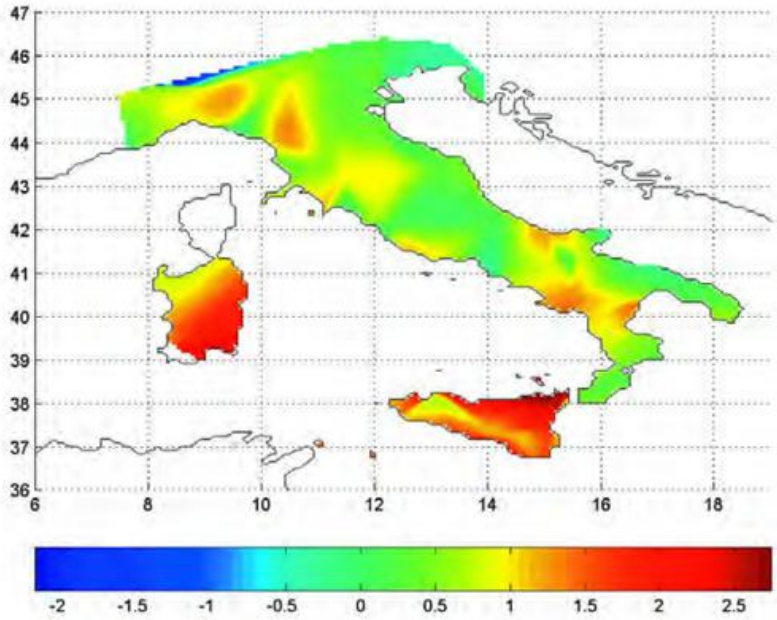

Fig. 0.20: *Seasonal mean of maximum temperature anomalies (reference period 1961-1990) in spring 2006 in Italy, divided by their standard deviations.*
Source: National Centre of Meteorology and Aeronautical Climatology, Italy

The seasonal mean temperature at Svalbard Lufthavn was 6.3 °C; together with 1922 this was the warmest summer since 1912.

Finland counted 59 summer days (Tmax >= 25 °C) and hot days (Tmax >= 30 °C) were recorded in each of the three summer months. Especially the latter phenomenon is quite unusual in Finland and happens only every 10th year on average.

In Sweden, new records for mean summer temperature were observed at some stations in the southernmost part, e.g.in Lund, as compared to more than 140 years of observations. Summer 2006 was the 4th warmest summer in Norway since 1900 and the 5th warmest in Latvia for the past 83 years. With 17.2 °C (anomaly +1.9 °C) it was also the 5th warmest summer in the Central England temperature record. In the Netherlands, it was the 3rd warmest summer since 1901.

In the south, too, this summer was one of the warmest, being for example the 5th warmest in Portugal since 1931. The average minimum temperature reached even its 2nd highest value.

In Armenia, this summer was the hottest for 70 years (anomaly +2.7 °C, Fig. 0.21). Syria was also considerably warmer than normally due to the extending Indian Monsoon effects with heat waves that, from time to time, result in temperatures of 3-5 °C above normal for short periods of time.

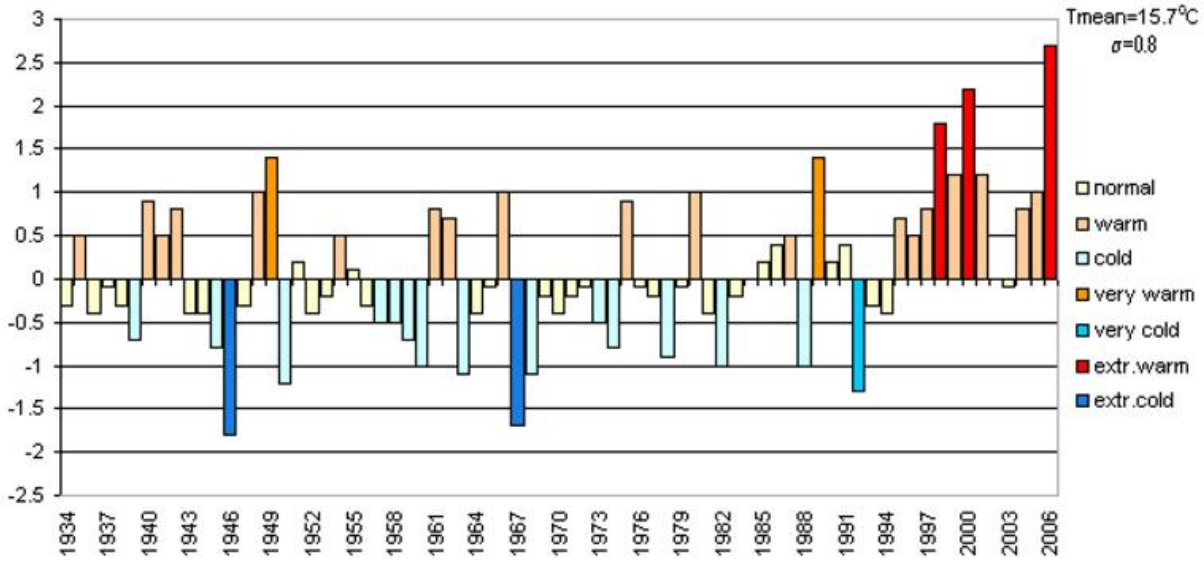

Fig. 0.21: *Summer temperature anomalies (°C, reference period 1961-1990) in Armenia. Source: Armstatehydromet, Armenia*

Autumn 2006 was also warm in allmost all parts of the Region. Mostly, the anomalies were above +1 °C, in large parts of Europe already above +2 °C, and in Central Europe even above +3 °C at many stations. Negative anomalies were restricted to very few places, e.g. in northern Russia and near the eastern Mediterranean.

In several European countries, autumn 2006 was record breaking in temperature. It was the warmest autumn in the Central England temperature record dating back to 1659. The seasonal mean was 12.6 °C (anomaly +2.3 °C). Sea surface temperatures in coastal waters in the United Kingdom were also warmer than in any previous autumn in the records. In some places in Norway, it was the warmest autumn since measurements started in 1867. In Denmark, autumn 2006 was the warmest since 1873 and had an average as high as 12.2 °C (anomaly +3.4 °C). It was also the warmest autumn in the Netherlands (13.6 °C), here for the last three centuries. According to the time series of Brussels-Uccle, Belgium, such a warm autumn statistically does not occur more frequently than once in 500 years. The same applies to other locations in Central Europe (e.g. in Germany). The areal mean in Germany was 12.0 °C (anomaly +3.2 °C), which is by far the highest since 1901 (Fig. 0.22). France recorded by far the warmest autumn since the start of the time series in 1950 (mean anomaly +2.9 °C). Switzerland again set another record: the previous record of autumn 1987 was exceeded by about 1 °C. Austria, too, measured the highest autumn mean temperatures ever, except for the regions of Styria and Carinthia. Bologna (Italy), had its second warmest autumn (anomaly +2.0 °C) since 1948 after autumn 2000. Portugal recorded the 3rd warmest summer after 1997 and 1983; the seasonal mean minimum reached the highest value for 76 years.

Autumn 2006 was also exceptional in eastern parts of the Region: Estonia had the second warmest autumn since 1865 (anomaly +2.8 °C). With a seasonal mean of 9.2 °C, autumn 2006 was the warmest in Latvia for the past 72 years. To find a warmer autumn, one has to go back to 1934 when it was half a degree warmer. Belarus, too, had an exceptional warm autumn

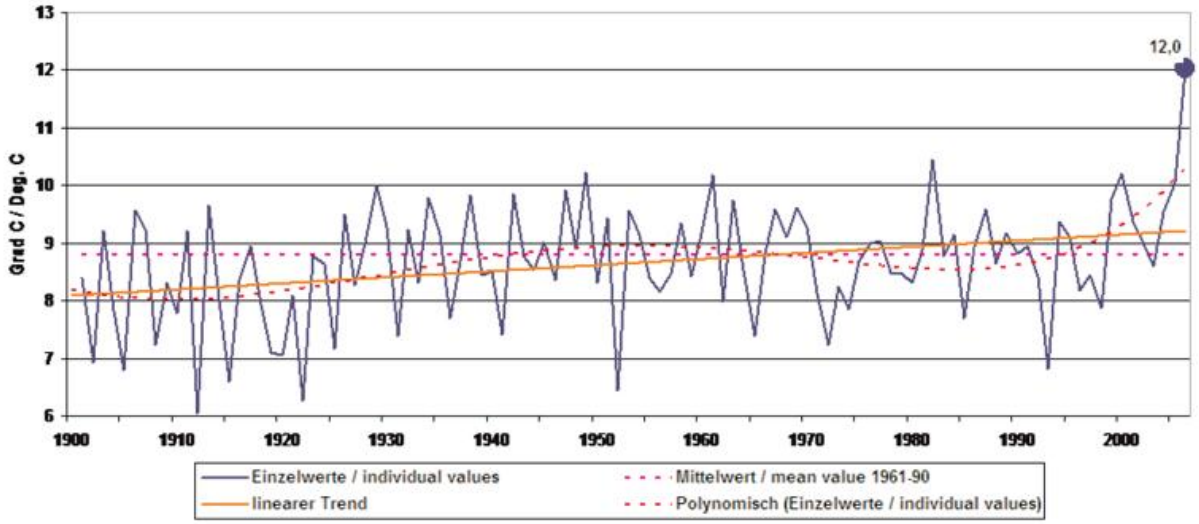

Fig. 0.22: *Autumn temperatures (°C) 1901-2006 in Germany with linear and polynomial trend. Source: Deutscher Wetterdienst*

which statistically occurs only once in 60 years. In most parts of European Russia, in contrast, this autumn was warm, but not like it was in 2005. In Zagreb-Gric (Croatia), autumn 2006 was the second warmest since 1862 after autumn 1926.

Precipitation

Precipitation anomalies in 2006 varied strongly from season to season.

Winter 2005/06 was dry (<80% of the normal) in almost the whole of western Europe, around the Baltic Sea, and in most of Turkey and Cyprus. It was wet in the north, i.e. in Greenland, Svalbard and western Iceland, but also in many places in the eastern half of the Region and the western Mediterranean.

Parts of western Norway received only 50% of the normal precipitation, while other parts of the country (Finnmarksvidda, Trøndelag) had considerably more than the normal, up to 238% (station Kautokeino).

In Ireland, it was particularly dry in the south of the country (Fig. 0.23). It was the driest winter since at least the early 1990s at most Irish stations and the driest since 1964 at both Mullingar and Kilkenny, and also in the United Kingdom.

Spring 2006 was mainly wet in most of the Region, except the west coast of Norway, the Baltic countries (e.g. Lithuania: 60-95% of the normal) and most of the south of the Region where it was partly very dry, e.g. in some parts of Italy.

A larger part of southeastern Norway received 125-150% of the normal, parts of west Norway only 70-80% of the normal precipitation. In lower parts of southern and eastern Norway the snow amount was the highest recorded for many years.

Some stations in Switzerland (e.g. Zurich and Berne), recorded the highest precipitation amounts in spring since 1864. In the western- and northernmost parts of Austria, precipitation totals amounted to up to 200% of the normal.

Summer 2006 was very dry in some larger areas, especially in most parts of northern Europe, the United Kingdom and Ireland, on the coasts of the western Mediterranean, and large parts of the southeast of the Region. Armenia recorded only 60% of the normal precipitation. Some wet areas occurred in eastern Central Europe, near the central and eastern Mediterranean and in parts of the Iberian Peninsula.

Fig. 0.23: *Percentage of normal rainfall (1961-1990) in Ireland in winter 2005/06. Source: Met Eireann, Ireland*

In southern and western parts of Finland, summer 2006 was the driest ever recorded. In Helsinki Kaisaniemi, the whole summer precipitation was only 35 mm which was the lowest summer total since 1845. Hailuoto station on the northwest coast of Finland recorded countrywide the lowest sum with 25 mm for the whole summer. The longest continuous period without any precipitation in Finland was observed in Kauhava in the west of the country. It was also very dry in northeastern Sweden: only 35 mm in Haparanda, near the Finnish border, during the whole summer, which is the lowest amount since 1860. This drought resulted in the largest forest fire since 1933 in Sweden with an area of about 15 km² devastated near Haparanda.

The precipitation totals in most parts of Lithuania fell to 45-95%, in the western borderland even down to 30%.

In the Netherlands, at least one meteorological station recorded 50 mm or more precipition on 13 days, which sets a new record.

Albania recorded an unusually wet summer, especially in mountainous areas.

Autumn 2006 was especially dry in Greenland, on the Norwegian west coast as well in the majority of Central Europe and most areas around the Mediterranean except the northeast. Most of the other parts of the Region were wetter than normal.

In parts of eastern Norway, autumn 2006 was the 4th or 5th wettest since 1867.

Precipitation amounts in Austria were only 40-80% of the normal in southern and eastern parts of the country, partly also in the north.

It was the driest autumn in Dubrovnik (Croatia) since 1961 (Fig. 0.24). Less than 50% of the precipitation was recorded in Albania.

In Portugal, autumn 2006 recorded the 3rd highest precipitation amount of all autumns since 1931. Some places recorded even the highest or second highest precipitation total with up to 300% above the normal (Fig. 0.25). In Spain, too, the autumn precipitation was rather plentiful that year; however, this was welcome after a long drought period that lasted for two years.

On one day Deir Elzour (Syria) recorded a precipitation total of 56 mm.

Monthly Surveys

January

- **Cold in most of Europe, but very mild in the north**
- **Dry in most of the Region, wet in some northern areas, in the western Mediterranean and parts of the southeast**

Ridges over the Atlantic extended to the north, forming large high pressure systems over northern and later also over central Europe. Mild und humid Atlantic air masses moved very often at the west flank of these high pressure systems far to the northernmost parts of the Region. Extremely high temperature anomalies were registered over these areas, particularly in Svalbard; it was up to more than 12 °C warmer than normal there, which was extremely mild (Fig. 1.1), the warmest January ever recorded and even warmer than any previously recorded April. The Arctic Sea ice extent was the lowest since the beginning of satellite measurements in 1979. Within these mild air masses, numerous low pressure systems moved over Iceland, Greenland and Svalbard; and thus, up to more than 400% of the normal monthly precipitation amounts were reached there (Fig. 1.2). Ny-Ålesund in Svalbard measured a new record for diurnal precipitation since 1969 with 34 mm on January 16. Sometimes these low pressure systems also touched parts of northern continental Europe. However, in most parts of Norway, Sweden and Finland it was mild, but dry, since low pressure influence was only weak. Stations in the county of Finnmark (northern Norway) registered a new record for maximum temperature.

Most of the rest of the Region was dominated by continental air masses this month coming from the east and moving at the south flank of the north European high to eastern, central and even western Europe. Locations in the easternmost parts of the Region in west Kazakhstan and Russia experienced the negative monthly temperature anomalies of the Region at below -5 °C, parts of west Kazakhstan even down to nearly -10 °C (Fig. 1.3). In most of eastern central Europe, anomalies were between -5 and -2 °C. The remaining parts of the Region were also colder than normal, except northern Scandinavia, the United Kingdom and Ireland, the Atlantic and a small area in the southeast, but including western and southern Europe. Although the anomalies were smaller there, they were nevertheless outstanding. It was e.g. the coldest January since 1997 in the Netherlands. In Luxembourg (airport), 26 frost days were counted, but none of these was below -10 °C. Portugal recorded minimum temperatures below zero at approximately half of the stations, down to -8 °C and up to 21 frost days, which were 2-3 times as many as normal, particularly in the centre and the south of the country; some of these days were also ice days (maximum temperature <= 0 °C).

Especially the last third of January was very cold; in Russia and the Ukraine the whole second half of the month was cold with night temperatures frequently below -30 °C. The lowest minimum temperature in Poland, however, was down to -32.1 °C in the central part of the country on January 1. Latvia had a warm start to the year, but on January 17 a very cold arctic air mass flowed in, which reduced the air temperature by about 25 °C in one and a half days. The coldest period was during January 19-22 when the daily average air temperature was 15-19 °C below normal and the minimum air temperature reached -32 °C. These were not only the coldest days in 2006, but also the coldest January 19-22 period ever recorded in Latvia. Since the snow had melted before this cold spell came, there was no snow cover which could protect plants and thus they suffered from frost damage during the cold spell. Lithuania, too, recorded low temperatures on January 20-21 down to -31 °C in the east, with only little snow and soil freeze depths down to 95 cm. This cold spell appeared even in Norway, which was otherwise very mild on average. Strong cold winds from the landward side resulted in very strong icing conditions in the northern coastal areas of Norway on January 18-20.

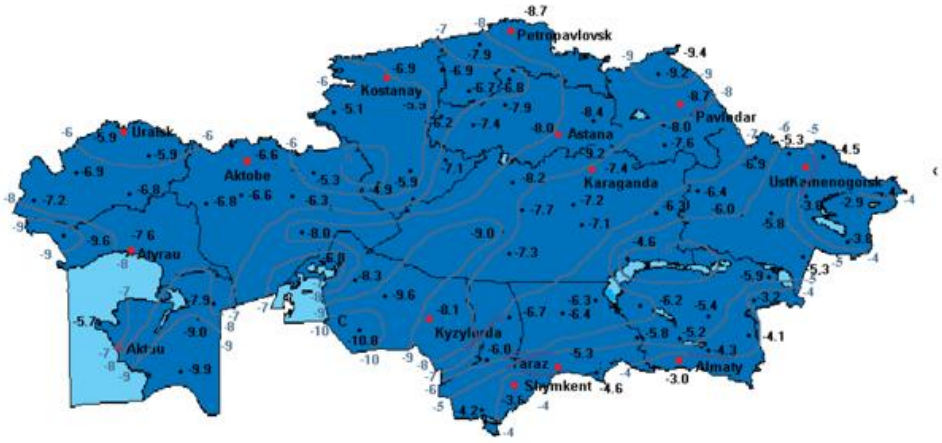

Fig. 1.3: *Monthly mean temperature anomalies in January 2006 (reference period 1961-1990) in Kazakhstan.*
Source: Kazhydromet, Kazakhstan

Central and southeastern Europe experienced this cold period too. In southern and eastern parts of Germany, daily minimum temperatures below -20 °C were measured at several stations on January 22-25. The Rhine-Main-Danube channel was closed during that time. Hungary had its annual temperature minimum of -25.1 °C on January 24. The cold spell was also registered on January 23-28 in the whole of Serbia, with minimum temperatures below -10 °C, in the highland down to -39 °C, which was nearly a new record. Temperature decreased frequently to below -25 °C in Romania during the last decade of the month, with a minimum of -33 °C on January 27. The Black Sea froze at the shore, floating ice formed along the Danube, causing an interruption to river traffic for the first time since 1984. Moldova, too, had a cold spell at that time (January 20-27) with temperatures down to -30 °C; this is recorded only once in 20-25 years on average. Macedonia also experienced an extreme cold spell during January 23-29; the daily mean temperature in Skopje dropped from 4 °C on January 22 to -10 °C two days later (Fig. 1.4). In many eastern and central European countries there were some deaths due to this cold weather.

Source: Hydrometeorological Service of Republic of Macedonia

At the end of the month, Scotland, too, became very cold; temperatures below -12 °C were recorded on January 31.

Beside the low temperatures, extended snowfall was also a remarkable feature this month. The year started already with heavy snowfall in Central Europe. In Poland, a snow cover appeared at the beginning of the month and remained during the whole of January. In southern Germany, the roof of an ice pavilion collapsed on January 2 due to a heavy snow load. Repeated heavy snowfall was also reported from Upper and Lower Austria and the province of Salzburg from January 3-17, leading to numerous accidents, collapses of roofs and damage to forests. Slovenia, too, had quite a persistent snow cover throughout the month which was deepest in the beginning of the month. On January 5, falling temperatures and a snowstorm caused serious road accidents in Bulgaria and blocked the road traffic across the country. This snowstorm was also reported from Romania. In Serbia, snow cover in the mountains remained for the whole of the month.

January 27-30 was a period of heavy rain and snow fall in France, particularly where the southern half of France was concerned. Switzerland recorded its first extraordinary snowfall of th season in the southern part of the Alps at that time. After two days of intense snowfall, the Ticino region had a snow cover of 60-90 cm on January 28. It was the greatest snow depth in the Ticino lowlands since 1986. The snow masses caused considerable interruptions to traffic, many roads were impassable. However, not only the quantity, but also the low density of the snow was exceptional, due to temperatures significantly below zero, especially at the beginning of the event.

Further to the south, some areas in Sicily (Italy), Greece and Turkey were covered by snow. Heavy snowfalls were also reported from Armenia, especially during January 23-26, when all flights were cancelled at Zvartnots airport. On January 29, snowfall occurred even in coastal and lowland regions of Portugal; these are places where such phenomena do not happen often. In Lisbon, for example, the previous occurrence of snowfall was on February 1-2, 1954.

Since the continental air masses were also very dry, the precipitation amounts in most parts of Europe were far below normal; less than 50% of the normal precipitation fell in many places. England, Wales and Northern Ireland had their driest January since 1997. In the east, also Belarus recorded its driest January (for 60 years) with only 22% of the long-term average. Slovenia was especially dry in the second and third decade; there was almost no precipitation during that period. In the south, this January was the 2nd driest in Portugal for 17 years.

Higher than normal precipitation, on the other hand, was registered in the western Mediterranean, partly more than twice the normal, due to a trough moving from central Europe to this area at the beginning of the year. This January, Malta had 22 rainy days, some of them being accompanied by thunder and hail. There were also some heavy local positive precipitation anomalies in Greece and south of the Caucasus, because some of the low pressure systems of the western Mediterranean moved further to the east. In the Ararat Valley (Armenia) twice the amount of the normal monthly precipitation total was recorded. Cyprus received heavy rainfall with hail on January 11 in the eastern parts of the island, causing floods and damage to properties and crops. A large number of 16-20 days with rainfall was reported from northern and central Israel, compared to a normal of 13-15 days. There was a continuous rainfall period of 12 days from January 7-18 in central Israel which occurs only once in 10-12 years.

February

- **Cold in most of Europe, very mild over the North Sea and in the southeast**
- **Dry in most of northeastern and western Europe, other parts of Europe locally wet**

High pressure influence was still dominating most of February in northern and western Europe, and mild and humid air masses were still moving to the northernmost parts of the Region. The temperature anomalies in Svalbard were not as high as in January, but still very high at more than +5 °C; in western Greenland more than +4 °C were registered (Fig. 2.1). Iceland recorded its 4th warmest year in Reykjavik since recordings began in 1870. Bergen-Florida in Norway measured 13.2 °C, which was a new record for February in Bergen since 1867.

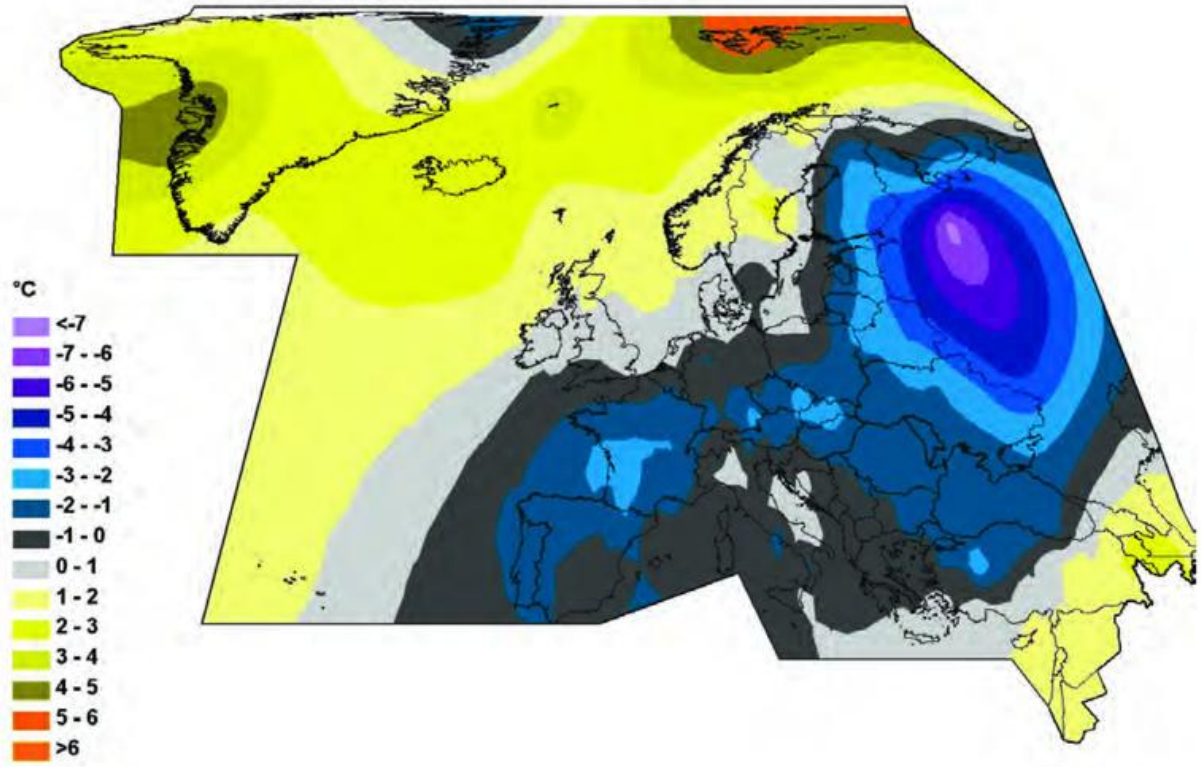

Fig. 2.1: *Monthly mean temperature anomalies in February 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

It was also still wet on Svalbard, Greenland and parts of Iceland (Fig. 2.2). In Norway, a station in the county of Sør-Trøndelag received 361 mm during 4 consecutive days until February 1, resulting in serious flooding in that area.

At the east flanks of north European high pressure systems, cold dry air flowed particularly to eastern Europe, but also further to the west and south. It was very cold in northern European Russia with monthly mean anomalies down to -7 °C and less than 50% of the monthly precipitation; only further to the south, in the western regions of the north Caucasian district, was it very wet. In Estonia, no temperatures above zero were recorded in large parts of the country during the whole month. A minimum temperature of -26.8 °C was measured in Poland on February 6, and also in the Ukraine there were minima far below -20 °C in that month. Towards the west, in Scotland, temperatures below -12 °C were measured on February 1.

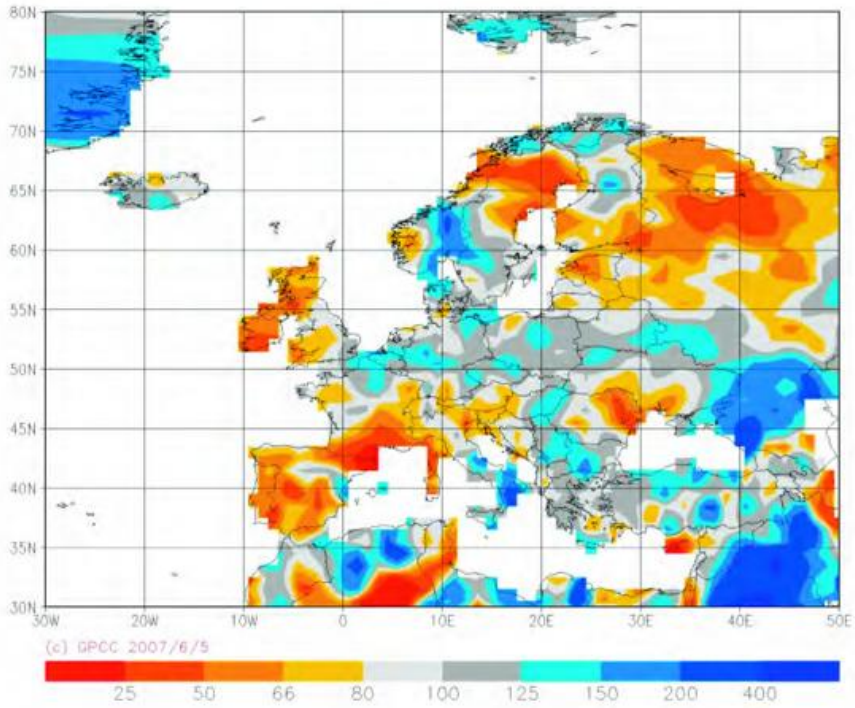

Fig. 2.2: *Monthly precipitation amounts for February 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

The rest of Europe also remained cold on average, but in contrast to January, more low pressure systems could develop and move within some large cold troughs. Thus, it was locally and regionally wetter than normal in parts of central and southeastern Europe. A lot of snow fell even in the lowlands, e.g. in southern Germany snow depths reached up to 150 cm on February 7-11, causing traffic problems and collapsing of buildings and roofs due to high snow loads. Heavy snowfall also occurred in Austria at the northern border of the Alps. In Poland, the snow cover remained during the whole month. Snow storms were reported from Romania on February 16 and 25-28. In Serbia, it snowed during most of the month.

Some parts of the western Mediterranean, too, remained cold and wet, e.g. the Balearic Islands, southern Italy and Crete (south Greece). St. Valentine's night was the coldest night of the year in Malta with a 2 m air temperature of 3.8 °C, and on February 15, the air temperature at grass height level was -1 °C.

In contrast, western Europe was mostly under Atlantic high pressure influence with low precipitation. Especially southern France was very dry. However, France, the Iberian Peninsula and even the southwest of the United Kingdom were mainly within the cold air mass. The number of frost days in the inner northern central regions of Portugal amounted to 21 days as in January 2006, again 2-3 times the normal number.

The areas of the Middle East were mostly no longer affected by the cold spell this month. It was warmer than normal there, in Armenia and Azerbaijan up to more than +2 °C, only the Ararat Valley was 1.5 °C colder than normal. However, 35 cm of accumulated snow were recorded in northern Jordan (Ras-Muneef, elevation 1150 m) on February 8-9. The high mountainous regions of Armenia received a monthly total of 160% of the normal precipitation. On February 3 there was extensive flooding in south Israel (near Eilat) which caused considerable damage.

March

- **Cold in most of Europe, very mild in Greenland, in southwestern Europe and in the southeast**
- **Dry in most of northern Europe and most parts around the Mediterranean**
- **Western, central and eastern Europe mainly wet**

The warm Atlantic air flow to the north relocated to a more westerly position this month. The highest positive anomalies were registered in western Greenland this month; they were very high, at up to more than +8 °C. Eastern Greenland and Svalbard were less than +2 °C warmer than normal, quite a large reduction compared to the previous two months. The mild air masses brought higher than normal precipitation amounts to Greenland, while Iceland and Svalbard remained mainly dry.

Large cold troughs extended frequently from the northeast over Europe, making March the third cold month in 2006 for most of Europe. The highest negative anomalies were found generally over northern Europe, down to below -4 °C (Fig. 3.1). In northern Finland at Enontekiö, almost -40 °C was reached in early March, in northern Norway (county of Finnmark) the lowest minimum of the year, -41.4 °C, was measured at the station Cuovddatmohkki on March 3. For Norway as a whole this was the coldest March since 1962. In the middle of the month, snow depths were around 50 cm in large parts of southern Sweden. Only around March 20 did the snow start to melt rapidly there. Winter weather prevailed during the whole month in south Finland and the temperature rose to 10 °C anywhere. In Estonia, the ground was frozen twice as deeply as normal (95 cm). For Lithuania it was the coldest month of the year, mean daily

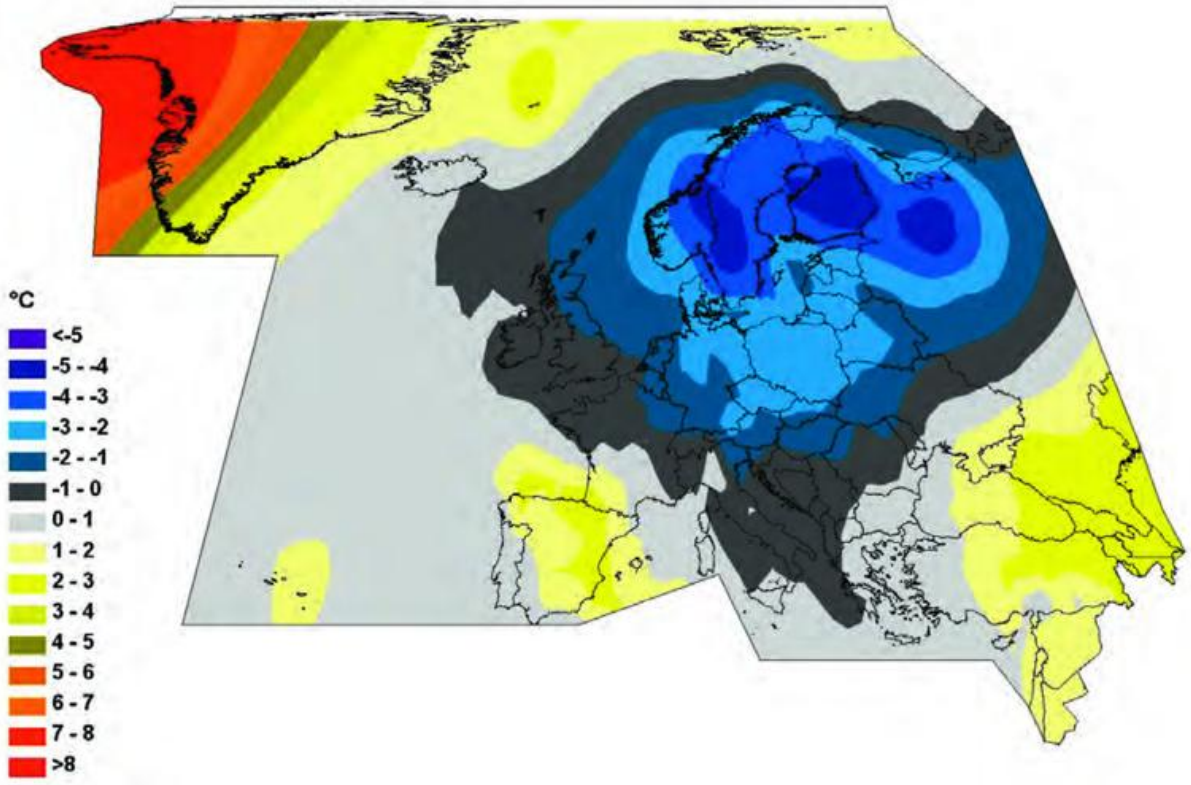

Fig. 3.1: *Monthly mean temperature anomalies in March 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

temperatures rose above 0 °C only at the end of the month on March 27-28; this was almost one week later than normal. Poland recorded a minimum temperature of -20.7 °C in the first decade of March, but a maximum of 19.3 °C at the end of the month and thaw was not registered before March 27. In the Netherlands, the lowest temperature of the year of -11.8 °C was recorded late on March 4. Also in Scotland, March was actually colder than any of the three standard winter months December-February 2005/06; this had not occurred in Scotland since 1975/76. For the second successive year, the lowest air and ground temperatures of the year at almost all stations in Ireland were recorded in early March. In the Alps, wintry weather conditions continued in the first and second decade with frost down to -24 °C in Seefeld/Tyrol. The cold air affected even the south of Europe: in northwest Greece, a temperature drop of more than 12 °C within one day was registered on March 7.

Most of northern Europe was drier than normal (Fig. 3.2) because the low pressure systems took a more southerly route than usual, especially those coming from the Atlantic. Due to the dryness, the largest known grass fire in Iceland started on March 30; about 67 km² were burned.

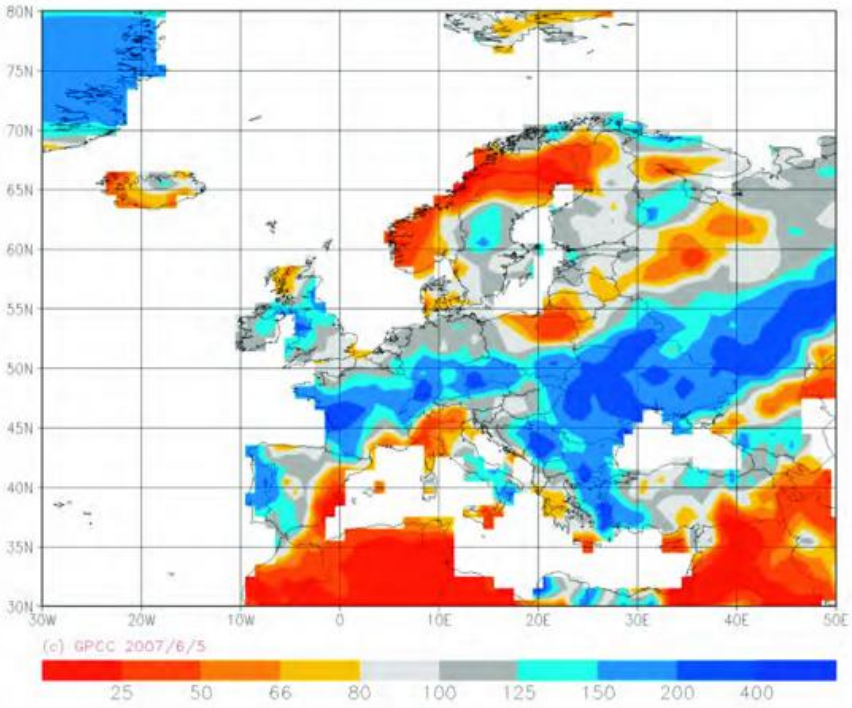

Fig. 3.2: *Monthly precipitation amounts for March 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

Over the eastern North Atlantic, high pressure influence became rare; low pressure systems moved to central, western and eastern Europe at the south flank of the cold air. The monthly precipitation amounts were high over these areas, in same places more than 200% of the normal. At some locations in France it was the highest monthly total for 50 years. Precipitation fell very often as snow. Luxembourg Airport had 10 days of snow this month (on one day a depth of 24 cm) compared to a 1971-2000 average of 5 days. A period of heavy snowfall occurred in western and central Europe in particular on March 3-6. Some places in Scotland saw snow depths rising to 25 cm or more during the first week of March. In northeastern France, record March snow depths since 1950 of 45 cm were registered in Mulhouse and Belfort. Record snow depths were also reported from southern Germany, e.g. 50 cm in Munich on March 5. Many flights at German airports were cancelled or delayed. Another heavy snowfall occurred on March 12 in northern Germany, causing widespread traffic obstructions. A tornado was registered on March 27 in northern Germany (Hamburg) within a temporary warmer air mass, which is rare in that season and such a cold month. Ongoing heavy snowfall already on

March 4-5 led to the most significant quantities of fresh snow measured this year in northern and eastern Switzerland. 54 cm of fresh snow fell in Zurich within one day, 49 cm in Basle and even 60 cm in St. Gall. Heavy snowfalls occurred also in some regions of Austria during the first week of the month, and also Slovenia recorded quite abundant snow especially on March 5; the snow cover did not disappear before the second half of the month, even in Ljubljana. The Slovenian mountain station Kredarica received a maximum snow depth of 440 cm, which was noticeably above normal. In Serbia, snow remained in lower parts until March 20 and on mountains during the whole month. Maximum snow depths in the mountains of Serbia this month were close to the absolute maxima ever recorded.

Around the middle of the month, a storm with heavy rain, snow, flooding and landslides affected especially Romania and Bulgaria, initiated by a Mediterranean cyclone. Widespread thunderstorms were registered in Romania and northern Bulgaria on March 23 and 29, in some places with hail. On March 28, Austria and the Czech Republic were also affected by continuing precipitation, and flooding occurred along the river Thaya. At the end of March, heavy rain and snowmelt caused flooding of the Danube and Elbe rivers with damage particularly in Germany. Also Cyprus in the eastern Mediterranean experienced heavy rainfall and severe thunderstorms on March 27, affecting the area around Nicosia with floods and damage to houses.

The Iberian Peninsula was not affected much by the cold air. Precipitation systems mainly affected Portugal and western Spain, whereas eastern Spain remained very dry (in parts less than 25% of the normal precipitation) and warm (anomalies up to more than +2 °C). For almost the whole country of Portugal this was the first rainy month for a long time; it put an end to the drought conditions in this country which had lasted from the end of 2004 until February 2006.

Most of the areas in the Mediterranean were very dry, except some areas in southern Italy, Albania and western Turkey. In Albania, up to 250% of the normal precipitation were registered. Temperatures were around normal in these parts.

The southeast of the Region was also not touched by the cold air. Temperature anomalies reached up to more than +2 °C over large parts there and precipitation was low, except in the Caucasus region. Extremely high temperatures were reported from Armenia on March 7-9 and March 25, reaching 18-24 °C in southern and central parts of the country.

April

- **Warm in nearly the whole Region, especially in the northernmost parts**
- **Dry, especially in western Europe and near the Black Sea**
- **Wet, especially in parts of northern and central Europe**

In April, a zonal air flow dominated for most of the time, but the frontal zone lay far to the north for that time of year. Warm air often reached especially the northernmost areas of the Region again. As in the winter before, Svalbard experienced extremely high temperature anomalies again, up to more than +12 °C (Fig. 4.1) as in January. 0.0 °C exactly was the monthly mean at Svalbard Airport, (anomaly + 12.2 °C) the highest April temperature since 1911 and even higher than any previously recorded temperature in May. Low pressure systems often moved over Greenland and Iceland; Greenland especially had precipitation amounts of more than 400% of the normal (Fig. 4.2) in parts. Iceland, the Faroe Islands and the Shetland Islands were colder than normal, since they were often located in the colder air mass north of the frontal zone. There was some snow in the north of Iceland during the first half of the month.

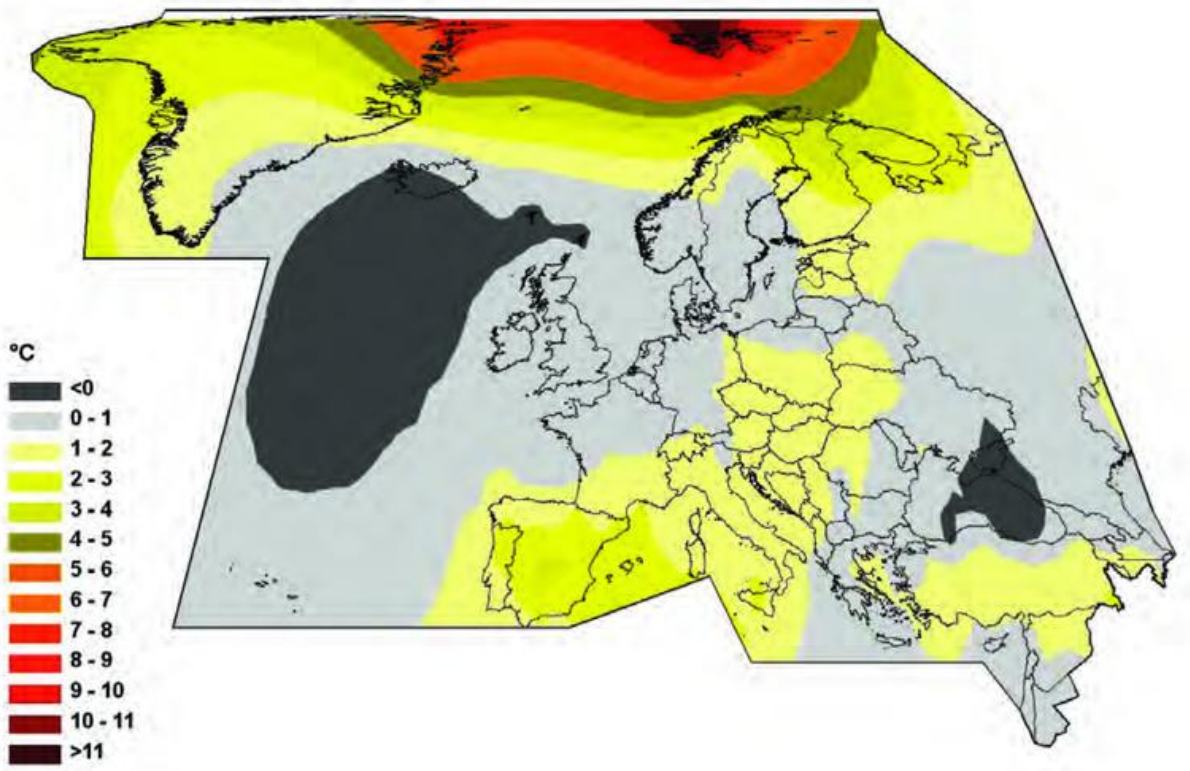

Fig. 4.1: *Monthly mean temperature anomalies in April 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

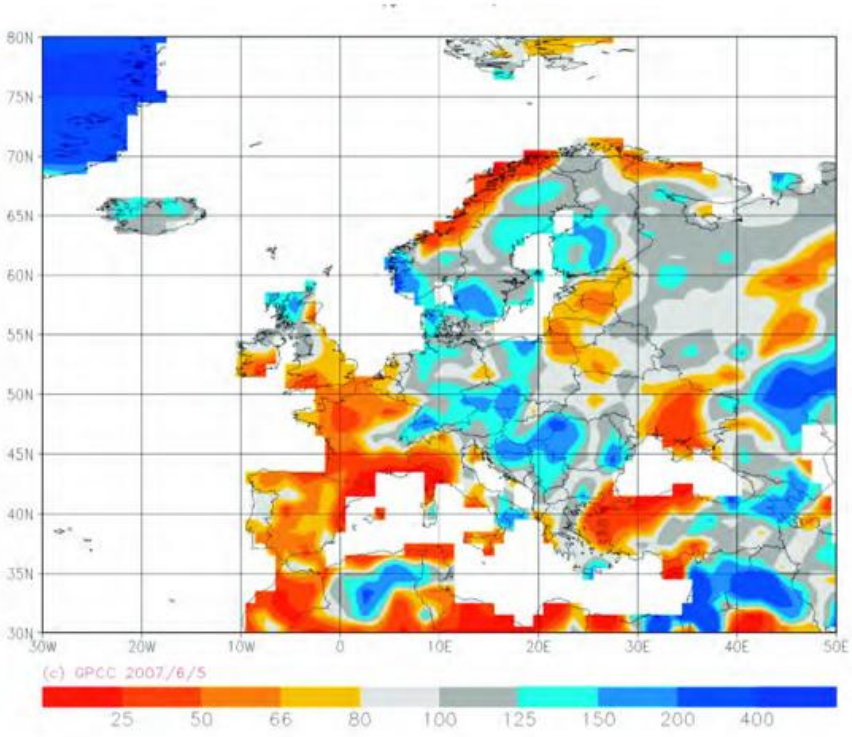

Fig. 4.2: *Monthly precipitation amounts for April 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

The majority of the Region lay within the warmer air mass most of the time and was thus warmer than normal on average, although the anomalies were mostly less than +1 °C, partly between +1 and +2 °C. In northern Norway (parts of east Finnmark), the monthly mean temperature was the second highest since 1867. Especially the second half of the month was warm in some countries, e.g. in Slovenia. Summer days (>= 25 °C) in the second half of the month were recorded in Serbia in most places. To the south, in Crete (Greece), maximum temperatures above 30 °C were measured on April 12 due to foehn. Maxima of 27-31 °C were reached in Armenia (Ararat and Syunik valleys) during a heat wave on April 10-16. During a Sharav event in Israel, the midnight temperature on April 22-23 rose to a peak value of 33-35 °C in the coastal plain, probably the 2nd highest since 1962. On the other hand, a cold spell appeared in Turkey on April 24-26, causing frost damage to trees.

Low pressure systems with precipitation often came from the North Sea to southern Scandinavia and Central Europe, causing higher than normal precipitation amounts in these areas. Sweden recorded the largest spring floods since 1985 along several streams and rivers in its southeastern areas early in April, also resulting from the melt of the large snow amounts which started in March. Heavy precipitation and snow melt led to widespread flooding also along the Danube and Elbe rivers in the first half of the month. The countries affected by this flooding were Germany, Poland, Czech Republic, Austria, Hungary, Serbia, Romania and Bulgaria. Daily precipitation totals on April 3-4 and April 6-7 at stations in Bulgaria close to the River Danube varied between 10 and 30 mm; mean monthly water levels along the River Danube were around 3 m above the long-term mean. Towns in Bulgaria had to be evacuated (Fig. 4.3), some streets were only accessible by boat. Much damage was also reported from Romania, the discharge from the Danube reached nearly historical record levels there on April 15-16. In Serbia, monthly precipitation totals of more than 130 mm were reached locally, exceeding a previous record of the year 1942.

In contrast, most of western and southwestern Europe was mainly dry, since these areas were more often under anticyclonic influence. The northern coasts of the western Mediterranean were particularly dry with amounts of less than 25% of the normal precipitation. The western Mediterranean and especially Spain were considerably warmer than normal with anomalies of locally more than +3 °C.

Fig. 4.3: *The town of Lom (Bulgaria) awaiting evacuation after flooding of the River Danube. Source: National Institute of Meteorology and Hydrology Bulgaria, photo from AP*

In eastern Europe, the cyclonic systems were mostly weaker, therefore high precipitation totals appeared only locally or regionally. Outstanding dry areas (<50% of the normal precipitation) can be found north and south of the Black Sea. On the other hand, the areas east of the Mediterranean experienced high precipitation amounts this month. 260% of the normal monthly precipitation was reported from the Ararat Valley in Armenia.

Extremely heavy precipitation occurred on April 1-2 in Israel. It was the result of an upper air trough over the eastern Mediterranean, accompanied by a surface depression over Syria and Iraq. In the centre of Jerusalem, 128 mm were accumulated on these two days, the largest daily rainfall amount here at least since 1950. At the northern part of the Dead Sea, 65-90 mm were recorded for the same time. Another upper air trough followed on April 4, resulting in thunderstorm activity with hail (hailstones of 4-5 cm in diameter) and a tornado in the western Galilee (see Annual Survey, Wind). A third heavy rainfall period occurred on April 24-25 in the northeast of Israel with 100-130 mm of precipitation in that period, the highest amounts since 1971; more than 50 mm fell within 3 hours, causing flooding in the surrounding area.

May

- **Mostly warm, colder in Iceland and eastern Europe**
- **Wet in most of Europe, dry in the south**

The first half of May 2006 was characterised by two large low pressure systems over the Atlantic and eastern Europe and high pressure over central Europe in between, whereas the airflow was more zonal in the second half of the month. The temperature anomaly distribution of the monthly mean thus reflects especially the patterns of the first half of the month with two colder than normal areas, one over Iceland and the Faroe Islands and the other over most parts of eastern Europe. In Russia, severe frosts were still recorded nearly everywhere, particularly in the Volga-Vyatka region down to -7 °C. The first half of the month was exceptionally cold in Serbia, partly with frost, whereas the second half of the month was considerably warmer, with tropical days in many places. However, the first 10 days of May were warm in Iceland; temperatures in sheltered areas in the southwest of the island reached 20 °C which is highly unusual for this time of the year. Later, around May 20, it became unusually cold for the season with heavy snowfall in the north of Iceland. Most of the other parts of the Region were up to +2 °C warmer than normal on monthly average (Fig. 5.1).

The air masses in the northernmost areas of the Region were still mainly warm, but the temperature anomalies were no longer so high as in April. They exceeded still +4 °C in Svalbard and +3 °C in western Greenland, and the precipitation amounts were also still higher than normal there. The monthly mean temperature in Svalbard and Hopen was the highest ever registered in May.

As in April, it was warmer than normal especially on the Iberian Peninsula and in the western Mediterranean, reaching anomalies of more than +2 °C, in some of parts of Spain more than +3 °C. Some daily maxima were record-breaking, e.g. 39.5 °C in Cordoba was a new record for the month of May. Also for Portugal it was the warmest May (for 41 years). These areas were also very dry due to frequent high pressure influence. This month was the 2nd driest May in Portugal since 1931, after 1990.

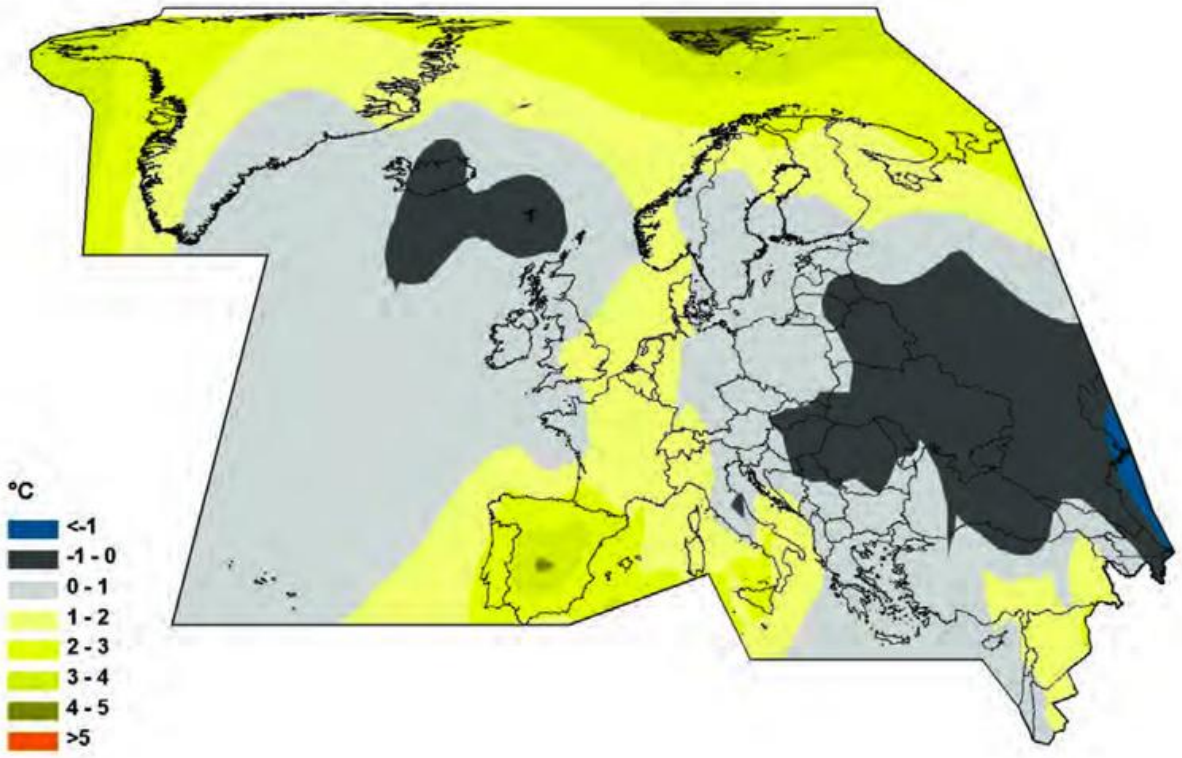

Fig. 5.1: *Monthly mean temperature anomalies in May 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

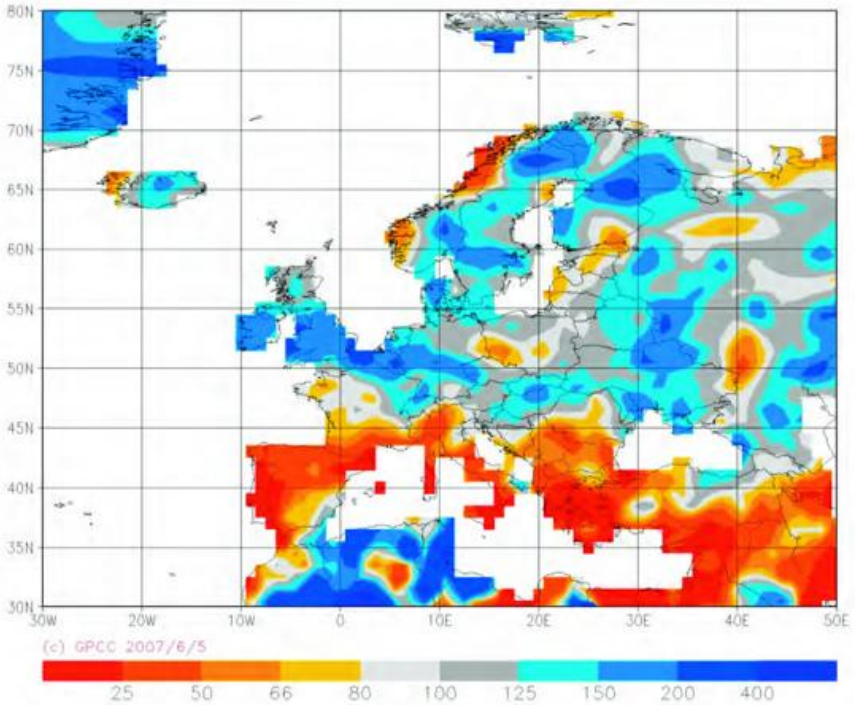

Fig. 5.2: *Monthly precipitation amounts for May 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

Most parts of northern, western, central and eastern Europe were clearly wetter than normal (Fig. 5.2) due to precipitation within the two large low pressure systems mentioned above and also some smaller cyclonic systems passing with the zonal flow over Europe in the second half of the month. A severe thunderstorm on May 20-21 caused damage in France, Belgium and Germany, particularly due to strong gusts. A tornado was also observed in northwest Germany. At the end of the month (May 26-29), heavy rain led to flooding in southeast Germany (north and east Bavaria). On May 31, cold polar air flowed to northern Switzerland and caused snowfall in the Bernese Oberland at altitudes below 600 m. A fresh snow cover at these altitudes in Switzerland is very rare at that time of year, having occurred only 4 times in 50 years. Slovenia, too, experienced a significant drop in temperature during the last days of May.

Further to the east, an aircraft crashed down into the Black Sea due to heavy rain on May 3. Later on, heavy rain, followed by hail causing losses to agriculture, fell in the central region of the Republic of Moldova on May 30; at the station Ungheni, 65 mm of precipitation fell in 45 minutes, normally this is the quantity of the monthly total.

Especially in some countries in eastern Europe, this month started warm and dry, but became cool and wet at the end. May began warm and dry in Estonia. No rain occurred for 18 days there. However, at the end of the month, up to 270% of the normal precipitation for this period was registered on the island of Hiiumaa. Also in Belarus, the first decade of May was the warmest this year, and the third decade the coldest. Poland, too, had a generally bright first part of the month with little precipitation, whereas the second half of the month was colder and wet.

The eastern half of the Mediterranean and the southeast of the Region were very dry too this month and also warmer than normal everywhere. Only during the first decade of May was damage due to hailstorms reported from Turkey. Unusual daily maximum temperatures of up to 38 °C were recorded in Greece on May 23-25. Especially the last pentade of the month was extremely hot in Armenia, with temperatures of 22-27 °C in the mountains and 32-34 °C in the Ararat Valley. In the second half of the month there was no rain in some regions of Armenia, which is very unusual, since April and May are normally the rainiest months of the year in this country.

June

- **Mostly warm, especially in southwestern Europe and in the east**
- **Mostly dry with locally or regionally wet areas, especially in southeastern Europe**

June 2006 was dominated by a meridional circulation pattern over the Region. After a wet and cold start to the month in central Europe, a strong high pressure system over the east Atlantic moved to Europe and then further east, some more ridges followed during this month and led to the beginning of a hot summer weather period in large parts of Europe to coincide with the start of the soccer World Championship on June 9. The frontal zone was quite far to the north, so nearly the whole Region was warmer than normal. Colder than normal areas were only found in east Greenland, northern Norway and a few locations in the Mediterranean. Some low pressure systems within the frontal zone passed Iceland, Svalbard and northern Scandinavia, causing higher than normal precipitation.

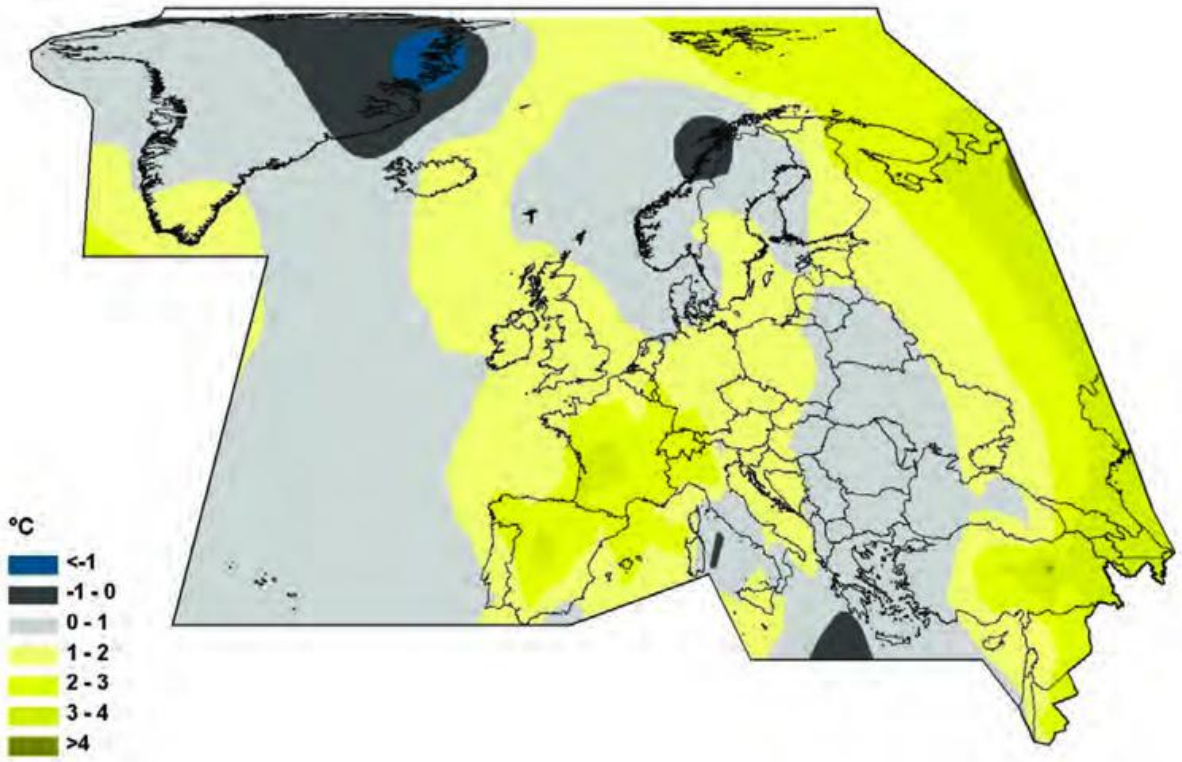

Fig. 6.1: *Monthly mean temperature anomalies in June 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

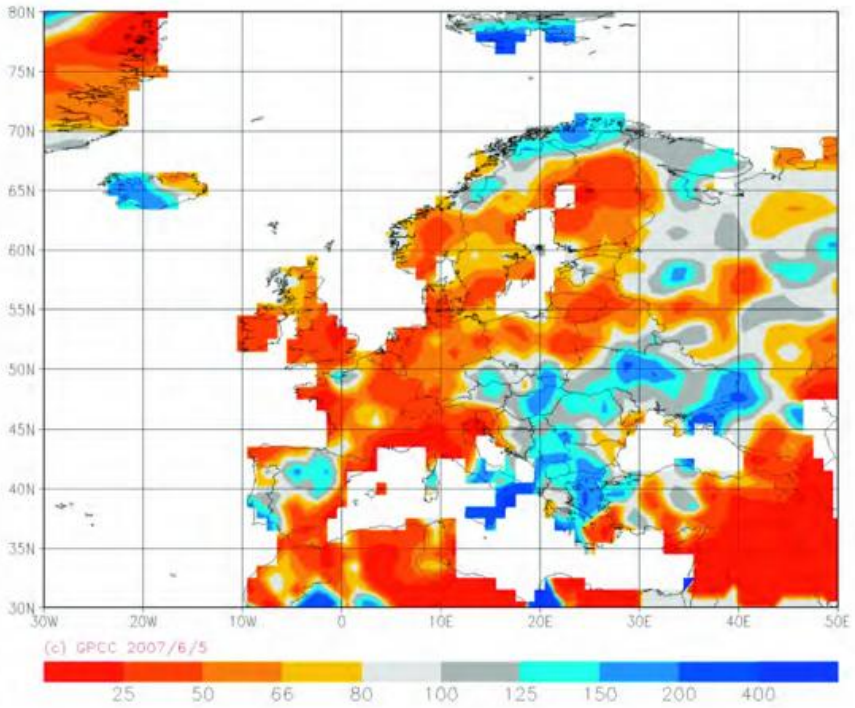

Fig. 6.2: *Monthly precipitation amounts for June 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

Temperature maxima above 30 °C were measured very often this month, even in the northern parts of the Region. Norway recorded the highest maximum temperature of the year at 32.2 °C in the county of Nord-Trøndelag on June 12; central London recorded a daily maximum of 32.4 °C on the same day. High maximum temperatures exceeding 31 °C on June 21-22 were reported from Estonia, and mean daily temperatures were exceeding 20 °C at the same time in Lithuania. Poland had a maximum of 33 °C. European Russia, too, experienced a very warm June; it was the third warmest of its spatially averaged time series and already warm at the beginning of the month. On June 4-6, the temperature rose to 40 °C in the Volgograd and Saratov regions. In the area around Astrahan (near the Caspian Sea) very warm winds were recorded. In North Caucasia, the maximum temperature was above 30 °C for as long as 15-18 days, without any precipitation. By the end of the second decade, soil drought began in the Volgograd region. In Slovenia, the highest ever daily mean and daily maximum temperatures were measured.

Most of the Region was dry too, especially most parts of western, central, northern and northeastern Europe, where the high pressure influence was strongest. Western and southwestern Europe also had large temperature anomalies, partly exceeding +3 °C, notably in France and Spain, locally also in Italy. Another area of similar large anomalies was to be found in the east of the Region (Fig. 6.1).

The dry and sunny period in central Europe was only occasionally interrupted by thunderstorms, e.g. on June 16 when hail stones of the size of tennis balls were registered in Leipzig (eastern Germany); also Austria (Styria) was effected by hail showers that day. Heavy rain with flooding was recorded in Austria on June 28 (county Burgenland in the east) and on June 30 along the valley of the river Thaya in Lower Austria. For this reason, only the west of Austria was dry on monthly average, while the east had a monthly total of more than 200% of the normal precipitation. Severe thunderstorms, locally with hail, occurred particularly on June 29 in Slovenia, but over the whole month it was dry in this country.

Generally, it was mainly wet in large parts of southeastern Europe (Fig. 6.2) and the temperature anomalies were still mostly positive, but smaller there. Heavy rain with flooding near the Danube and Tisza rivers were reported from Hungary on June 7 and another high daily precipitation amount of 107 mm on June 27. Serbia was cold and wet in the first decade as in central Europe, but warm and dry afterwards; the highest maximum temperature in Serbia was 36.2 °C in Cuprija on June 27. In the middle of the month, storms with heavy rain, thunder, hail and landslides lasted for about one week in Romania and Bulgaria. A rain intensity of 30-40 mm/h and hailstones as big as walnuts were reported from Sofia. Also in the Republic of Moldova, heavy rain with hail and strong wind occurred, up to 50 mm of precipitation fell on June 20, which corresponded to 75% of the monthly total.

Daily maximum temperatures of up to 40 °C were reported from Greece on June 19-20 over several areas of the country, mainly over the mainland. The monthly normal maximum is around 30 °C. Malta recorded its highest temperature of the year on June 30 at 38.5 °C, which was far below the record of 43.8 °C in August 1999.

The Middle East was very dry and warm. Parts of Armenia were more than 4 °C warmer than normal, during the first decade even 5-8 °C warmer. A severe drought occurred in this region, only at the end of this month did a cold front cause heavy rainfall, and hailstorms on June 23 and 26, with hailstones of up to 25 mm in diameter, causing losses of crops.

July

- **Very hot, especially in central Europe, cold in Russia**
- **Mostly dry, in the south partly wet**

In July 2006, a more or less stable, mostly meridional circulation pattern was established. Central Europe and surrounding areas were under high pressure influence during nearly the whole month. This situation caused an extremely hot and sunny July, especially in the second half. Temperature anomalies over large parts of central Europe reached more than +5 °C, marking a record heat wave. In some places, this was the warmest July ever registered, e.g. in the central England time series (for 348 years), in De Bilt (Netherlands) for 300 years, in Uccle (Belgium) since 1833, in Luxembourg (airport) since 1947, in France since 1950, in Germany (areal mean) since 1901 and in Vienna since 1775. Also in Switzerland in the lowlands north of the Alps and in most of the Alpine valleys the highest ever July averages were registered, whereas on the southern slope of the Alps the temperatures did not reach the previous highest values recorded in July 1983.

This hot July was exceptional mainly due to the long duration of the heat wave rather than its absolute maxima. At various locations in the Czech Republic, the temperatures frequently exceeded 35 °C, especially in the second half of the month. At most stations in Slovenia both the monthly mean temperature and the number of hot days (maximum temperature >= 30 °C) were among the highest ever observed. In the southern half of France again, maximum temperatures exceeded 35 °C during many days (Fig. 7.1). The duration of the heat wave is also documented by the high number of 27 summer days (>= 25 °C) in Luxembourg (airport); normally only 10 days are to be expected there on average. In the Netherlands, the heat wave during July 15-30 containing 8 tropical days (maximum >= 30 °C) was the longest in a century. Denmark reported the warmest July since 1994, with an average of 19.8 °C, 321 sunshine hours and 15 summer days.

Source: Météo France

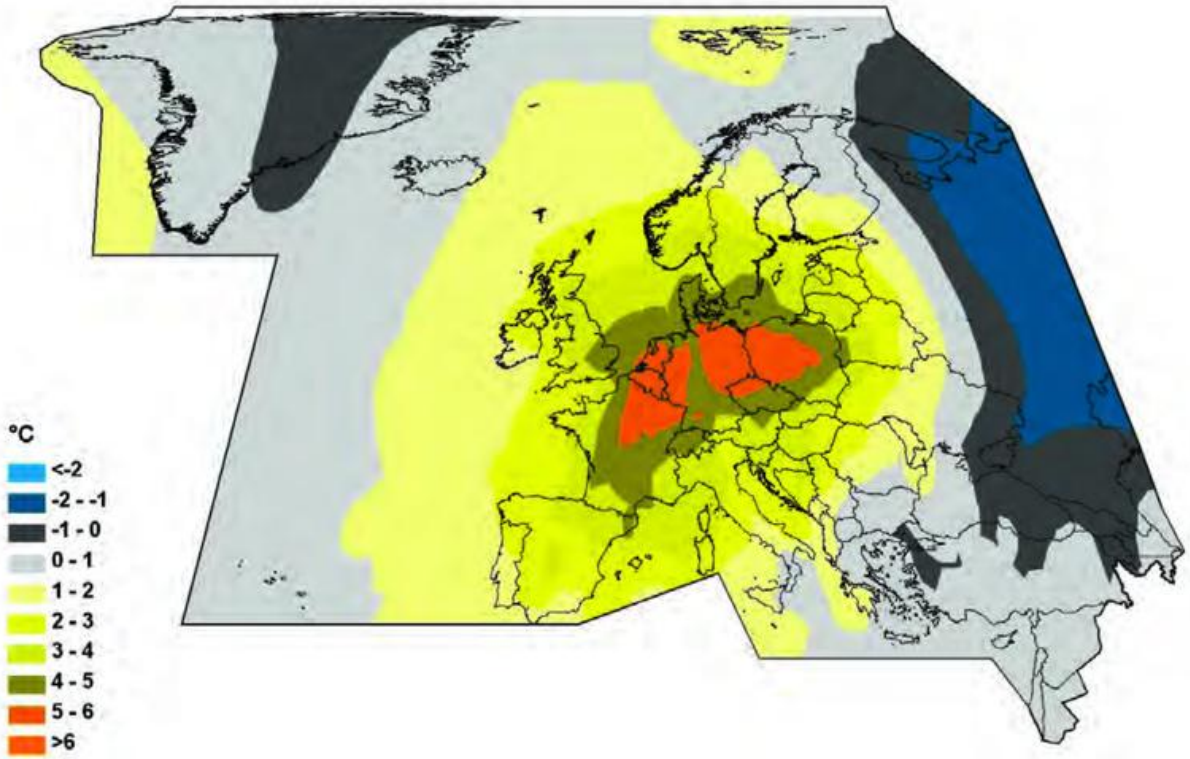

Fig. 7.2: *Monthly mean temperature anomalies in July 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

In the surrounding areas the anomalies were smaller, but still quite high (Fig. 7.2). Sea surface temperatures in the North Sea and Baltic Sea reached record levels too. For the coastal areas in southern Norway it was the warmest July since 1867. A maximum temperature of 35.1 °C was measured in Vöru (southeastern Estonia). In Latvia, 35.3 °C was the highest maximum; it was measured on July 9. July 2006 was the 5th hottest July in Latvia. Poland, too, had a heat wave in the first decade and another in the third decade with maximum temperatures above 36 °C. In western and southwestern parts of Belarus, it was the warmest July since records began, and also in other parts of the country such a hot July occurs only once in 15 years on average.

Some absolute maximum temperatures, nevertheless, were also new records or at least very close. A new UK maximum temperature record for July of 36.5 °C was recorded in Wisley, southwest of London, on July 19, but it was less than the highest known UK value for any month (38.5 °C), which was recorded in August 2003 at Faversham in Kent. The same day, the highest temperature since June 1976 (32.3 °C) was measured at Elphin in Ireland. Luxembourg recorded 35.6 °C as the maximum of the year, and this was also well behind the absolute maximum of 37.9 °C in August 2003. In contrast, the Netherlands set a new national temperature record this July with 37.1 °C in Westdorpe in the southern part of the country, again on July 19. The highest maximum of the year in Hungary was 36.9 °C on July 22, measured in Budapest.

The heat wave even reached the southern parts of the Region. Serbia had an outstanding heat wave on July 20-29; maximum and minimum temperatures exceeded normal values considerably (Fig. 7.3). In Bulgaria the heat wave was during July 25-28 and was the cause of at least 7 field and forest fires. In some coastal and lowland parts of Albania the highest mean maximum temperatures of their time series were registered. It was also the hottest July in Bologna (Italy) since 1999. In Portugal, the duration of the heat wave of 11 days in the Alentejo region was the most significant since 1941 in July. This month was the 3rd warmest in Portugal

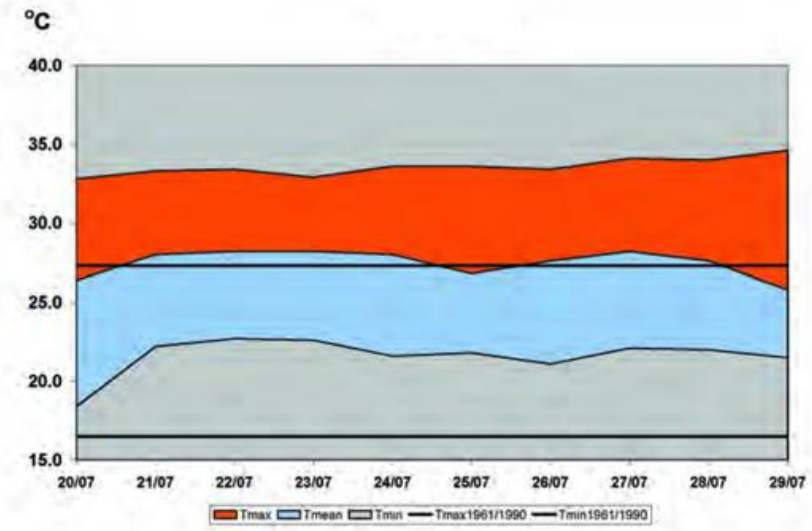

Fig. 7.3: *Maximum, minimum and mean daily air temperature from 20 to 29 July 2006 in Belgrade, Serbia, compared to normal values 1961-1990.*
Source: Republic Hydrometeorological Service of Serbia

since 1931 after 1989 and 1990. It was also the month of July with the longest sequence of tropical nights (minimum temperature >= 20 °C) since 1990 in almost the whole of Portugal, causing high physiological discomfort.

Only in the easternmost part of the Region and partly in Greenland it was colder than normal. Russia and west Kazakhstan had the strongest negative of the Region, but they were not lower than -2 °C. On July 20, the cold spell reached Latvia too; the temperature fell to 2.5 °C and some frost was observed on the grassland. Such a low temperature had not been measured in Latvia at that time of the year for the last 55 years. In Israel the July temperature was close to normal; here it was the first July since 1994, which was not significantly warmer than normal.

Most of Europe was not only warm this month, but also very dry (Fig. 7.4). In Sweden, the dryness, which already started in June, became problematic for the farmers; only late in July did heavy thunderstorms become more frequent. Less than 25% of the normal precipitation fell around the Baltic Sea. Some districts in Estonia received only 3% of the normal precipitation. In Latvia it was the 2nd driest July for 83 years, in some places, e.g. in Riga, it was absolutely the driest ever measured. The hot and dry weather resulted in 1700 registered fires in Latvia, 2.5 times more than in July 2005, and in severe agricultural losses. Drought conditions also resulted in Poland. In the south, it was also dry in northern Italy in the whole Po Valley. On July 22, the Po River reached its minimum daily discharge of 168 m²/s at Pontelagoscuro close to the Po delta; this was the lowest recorded at this location since 1918. Malta was without any rain this month.

In some other parts of the Region, it was very dry too, but sometimes interrupted by heavy precipitation events. Heavy thunderstorms were reported from eastern Finland with large hailstones up to 7 cm in diameter. In the central parts of Europe a few local areas with high precipitation were recorded, mainly due to local thunderstorms. Switzerland was in most areas extraordinarily dry and sunny, but locally exceeded the normal amount of precipitation, due to showers and thunderstorms. On July 24, 30 mm of rain fell within one hour in some parts of Budapest in Hungary, but the monthly total was low. In northern Romania, heavy precipitation caused flooding on July 1-3, and also Bulgaria, the Ukraine and Turkey, partly also Italy were affected by this precipitation event during the first week of the month; especially the Black Sea coast suffered from the flooding of camping sites. The station Malko Turnovo in Bulgaria reported 301 mm of precipitation on July 3, the highest daily amount in that region since 1915.

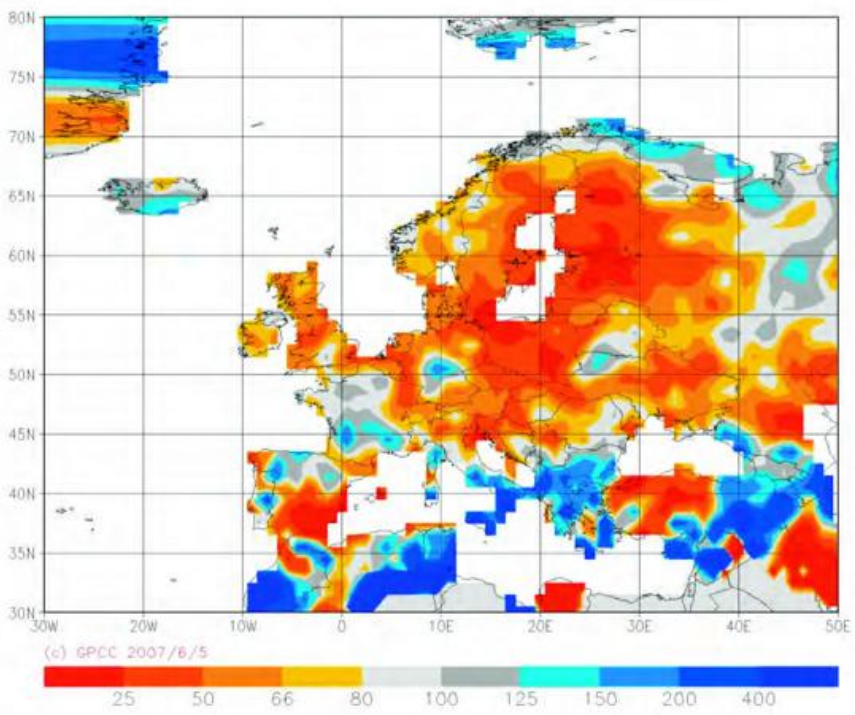

Fig. 7.4: *Monthly precipitation amounts for July 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

In the south of European Russia, dry weather persisted this month, while frequent and torrential precipitation was observed in the northeast.

Larger wet areas with respect to the monthly precipitation total were only to be found in the north (parts of Greenland, Svalbard) and parts of the south (especially southern Italy, Greece, Cyprus and parts of the Middle East). The spatial average precipitation in Cyprus, occurring mainly in the first week of the month, was 15 mm, but this was almost 600% of the normal. In the Ararat Valley in Armenia about 400% of the normal monthly precipitation total was recorded, due to some heavy rainfall events.

August

- **Cool and wet in central Europe**
- **Warm and dry in northern Europe and in the southeast**

In August 2006 the weather situation changed abruptly and put an end to the July heat wave in central Europe right at the very beginning of the month. The high pressure configuration was replaced by a large low pressure pattern coming from the northwest to central Europe and leading to a cool and wet period there. This new circulation pattern remained mainly the same for the whole month, since new lows followed from the northwest. Nearly the whole of central Europe was cooler than normal, in parts more than 2 °C (Fig. 8.1), and all the western, central and also some eastern parts of Europe were very wet, with more than 200% of the normal precipitation over large areas (Fig. 8.2), partly over 400%.

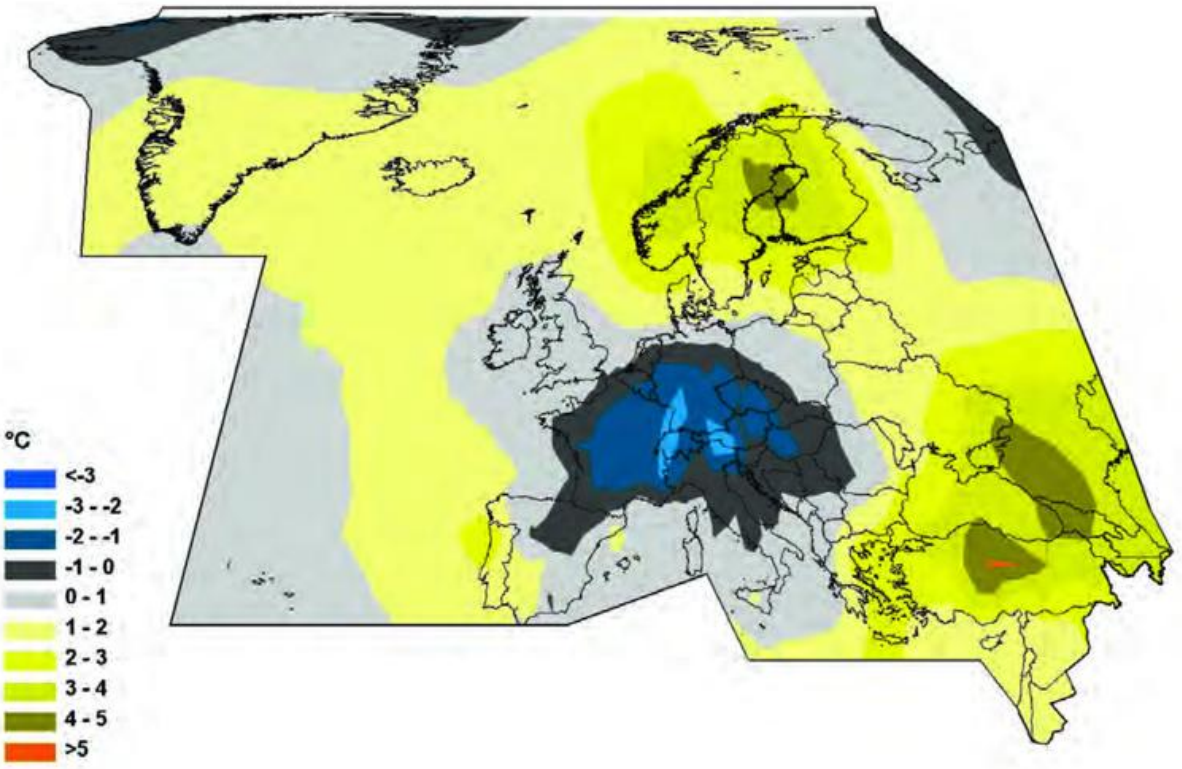

Fig. 8.1: *Monthly mean temperature anomalies in August 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

In some countries this August was one of the wettest ever recorded. In Germany and in the Netherlands, it was the wettest August since 1901, in Denmark the 3rd wettest since 1874. 191 mm fell in Belarus during the whole month; this was 273% of the normal and this amount had never been measured since 1891. At the coast of Slovenia, the highest monthly total ever registered was recorded with 325 mm. In Serbia, monthly precipitation totals achieved new records locally, e.g. in Loznica. In west Albania up to 450% of the monthly precipitation normal was registered this month.

The high rainfall totals of this month were partly due to a high number of rainy days, but also to local heavy rainfall events in various places of the Region. The southern parts of Sweden and Norway were wet, due to many and heavy thunderstorms and showers. Some stations in Sweden measured more than 100 mm in one day. In the southernmost province of Skåne, the drought which had lasted for a long time earlier that summer was replaced by such wet conditions that harvesting had to be delayed. In Lund (southern Sweden) the monthly total of 264 mm was a new record for August. Over 100 mm of rain also fell in the country of Surrey in the UK in around six hours on the afternoon of August 13. Luxembourg Airport reported a high number of 26 rainy days (normally there are 12). Three days of continuous precipitation led to numerous local floods in the counties of Salzburg and Lower Austria up to August 6. Poland recorded downpours exceeding 250 mm a day in some places. Torrential precipitation also fell in many places in Romania, resulting in high monthly totals locally (Fig. 8.3). Extreme rain with daily totals up to 100 mm was reported from northeastern Bulgaria on August 28. Heavy rain occurred also in the northern regions of the Republic of Moldova on August 26, followed by hail of 6 cm in diameter and strong winds. In the Mediterranean, Italy reported intense precipitation with hail and strong gusts of wind occurring in the countryside close to Ferrara in the Po Delta on August 3 (Fig. 8.4), causing damage to buildings and disruption of traffic on the main roads. In terms of temperature, Bologna in Italy recorded its coldest August mean minimum temperature since 1985 and the coldest mean maximum since 1978.

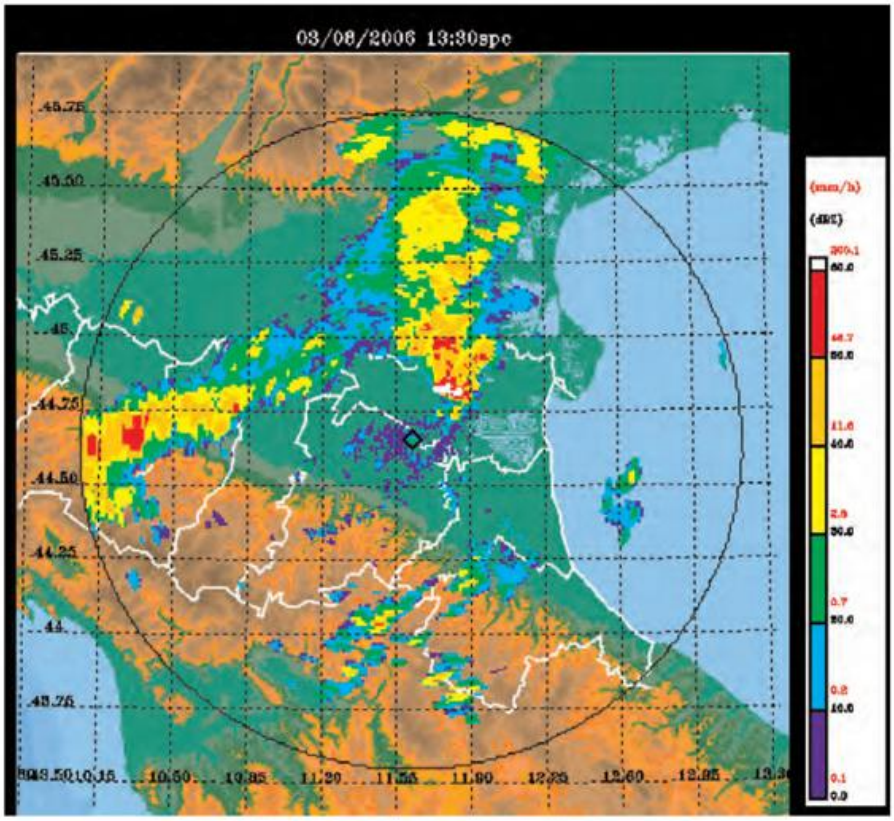

Fig. 8.4: *Radar image of the Po Delta in Italy with interpretation of precipitation intensities, taken at the climax of the heavy precipitation event on August 3.*
Source: Regional Agency of Prevention and Environment, Bologna, Italy

In contrast, northern Europe came under high pressure influence from time to time, so it was warm and dry there. The temperature anomalies exceeded +4 °C in parts; the precipitation was partly less than 25% of the normal. In parts of Norway it was the 2nd warmest August since 1867, for the country as a whole the 5th warmest.

It was also hot and dry in the southeast of the Region with similar anomalies as in the north. Within European Russia, it was especially warm in the south in northern Caucasia and the Lower Volga regions. Locally the anomalies were above +5 °C there. The maximum temperatures were over 30 °C for a longer period of time, in the first half of the month even 37-43 °C, together with long soil droughts, while further in the north, central European Russia (Kaluga region) experienced the rainiest August for 100 years. In the Ukraine, August was the warmest month of the year (in sharp contrast to central Europe), with maximum temperatures of up to 40 °C in the east of the country. A short summer heat wave on August 19-21 was reported from Romania and Greece, mainly on the mainland, with daily maxima around 40 °C. Also in Turkey there was a severe heat wave at that time, causing a forest fire near Izmir. Cyprus reported heat wave conditions during 10 days from August 19-28, when maximum and minimum temperatures were 2-5 °C above normal on average. In Israel, it was the 3rd warmest August in the mountains and the Jordan Valley since 1964. An unusual event occurred on August 20 with 15-20 mm of rain in the Galilee in northern Israel, considering that there is normally no rain at all in Israel in August. In Armenia, the maximum temperatures were about 40-42 °C in Yerevan and the Ararat Valley, the latter was without any rain during the whole month. However, in the northwestern part of Armenia, 80 mm of precipitation was recorded on August 19 (this was 140% of the monthly normal!).

The west part of the Iberian Peninsula was warm and very wet due to heavy thunderstorms, whereas the east was less anomalously warm but very dry. Especially in the first half of August and at the end of the month, long heat waves occurred in Portugal, interrupted by a cooler period on August 15-19. These days were also very rainy.

September

- **Warm nearly everywhere in the Region, especially in northern and central Europe**
- **Dry in parts of northern and most of central Europe and partly in the southeast**
- **Wet, especially in northeastern Europe and around the Mediterranean**

In September 2006, the large-scale circulation pattern changed again considerably. Central and parts of northern Europe frequently came under high pressure influence, whereas low pressure systems were concentrated particularly over the Atlantic, the northeast of Europe and the Mediterranean, in the latter case mostly in the form of cut-off lows. The main result of this configuration was a switch from a cool wet August to a very warm and dry autumn especially over Central Europe. Other parts of the Region remained warm as before, so that higher than normal temperature anomalies were to be found nearly everywhere in the Region (Fig. 9.1). In

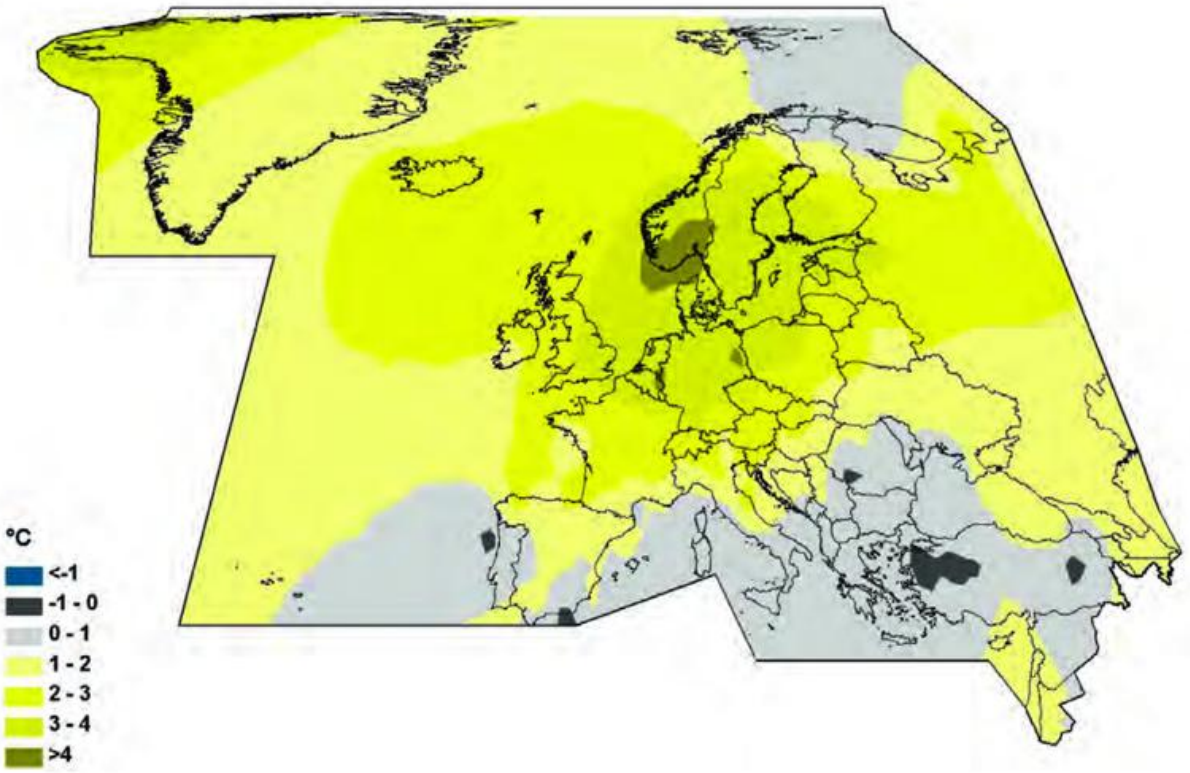

Fig. 9.1: *Monthly mean temperature anomalies in September 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

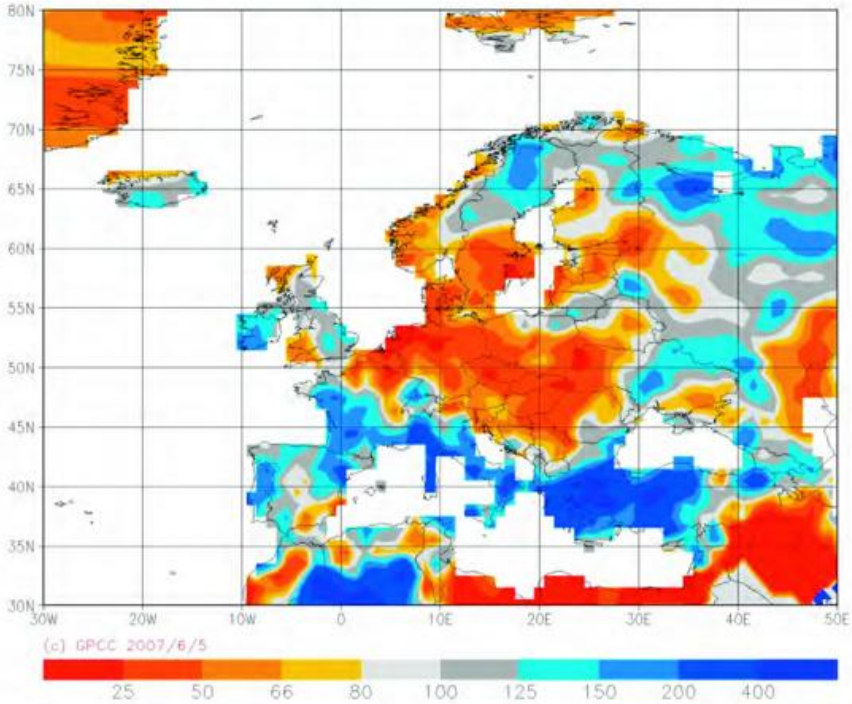

Fig. 9.2: *Monthly precipitation amounts for September 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

most of central and southern north Europe they exceeded +3 °C, in parts +4 °C. These areas were also very dry, partly with less than 25% of the normal precipitation (Fig. 9.2), although a few local thunderstorms with heavy rain occurred.

The Arctic sea ice extent of 5.9 million km² was the second smallest ever measured, only slightly under the previous year 2005.

For parts of southern Norway, the monthly mean temperature was the highest since 1867, and also in southern and central Sweden new records were set. In Denmark, this September shared the temperature record with September 1999 with 16.2 °C as monthly average. On the Faroe Islands, this September was record-breakingly warm at every station of the Danish Meteorological Service. This could be explained by the fact that there was an advection of warm air masses from the south to the Faroe Islands throughout the month. Reykjavik (Iceland) recorded its 4th warmest September since the beginning of measurements in 1870 and the warmest since 1958. In Brussels-Uccle, Belgium, it was the warmest September since the beginning of observations in 1833. Germany, too, reported the warmest September (since 1901), and also in the central England temperature series (348 years) it was the warmest, in other areas of the UK as well. Also for the Netherlands (De Bilt) and Luxembourg Airport it was the warmest September since the beginning of the time series, in France it was the 2nd warmest since 1950. In Tartu, Estonia, it was the 2nd warmest September for 140 years after 1934, in Latvia it was the 3rd warmest. Poland still had maximum temperatures up to 29 °C this month, but also minima down to 3.3 °C. Frosts down to -3 °C were reported from west Kazakhstan on September 18 at night time.

Some parts of northeast Europe and some areas near the Atlantic and around the Mediterranean were also warm, but wetter than normal, particularly in Greece and Turkey, with more than 400% of the normal precipitation in parts (Fig. 9.3). Heavy thunderly rain fell in southern France on September 13-14. On Corsica, locally more than 400 mm of precipitation fell during these two days. High precipitation intensities of more than 100 mm / 24 hours were also recorded in northern Italy on September 14-18. In Portugal, daily precipitation totals exceeded even the normal monthly total in some places from September 21-25.

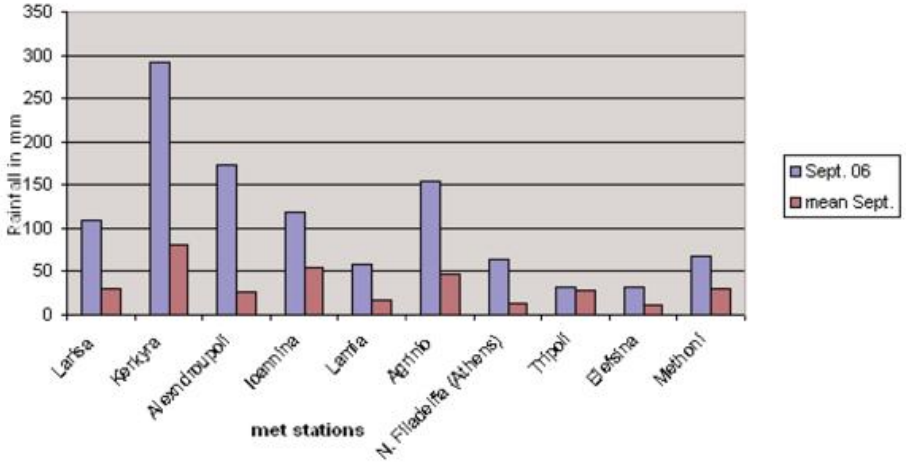

Fig. 9.3: *Monthly precipitation amounts for September 2006 compared to the corresponding long-term mean (various reference periods) at some stations in Greece.*
Source: Hellenic National Meteorological Service, Greece

A few stations in the southern part of the Region (Spain, Romania, Turkey) recorded monthly mean temperatures slightly below normal.

In Portugal, a heat wave which started at the end of August continued until September 10, with anomalies of 10-13 °C of the daily maximum temperature in almost the whole territory, in some locations they were record-breaking. Greece had unusually high maximum temperatures on September 4-7 in some places, partly exceeding 35 °C; the normal maxima are below 30 °C. An extreme Sharav event occurred on September 28-29 in Israel, with temperatures reaching 39-41 °C in the coastal plain and 40-42 °C in the Negev.

October

- **Warm in most of the Region except northern Scandinavia, parts of the Atlantic and the eastern Mediterranean**
- **Wet in most of the Region**
- **Dry in Greenland, western Norway, eastern central Europe, the western Mediterranean, Cyprus and west of the Caspian Sea**

High pressure influence and an airflow of mild maritime air continued mainly over central Europe. Most of the Region remained in a warm air mass. The highest anomalies were again in central Europe with more than +3 °C, as in the previous month and this time also in parts of southern Europe (Fig. 10.1). Another centre of such high anomalies was to be found in southern European Russia.

This October was one of the warmest in central Europe for more than 100 years. In Belgium it was the second warmest after 2001, in the Netherlands, France, Germany and Latvia it was the 2nd warmest, too. The active vegetation period in Lithuania ended 2-3 weeks later than usual, only the end of the month saw the first snow in many regions of that country. Some countries

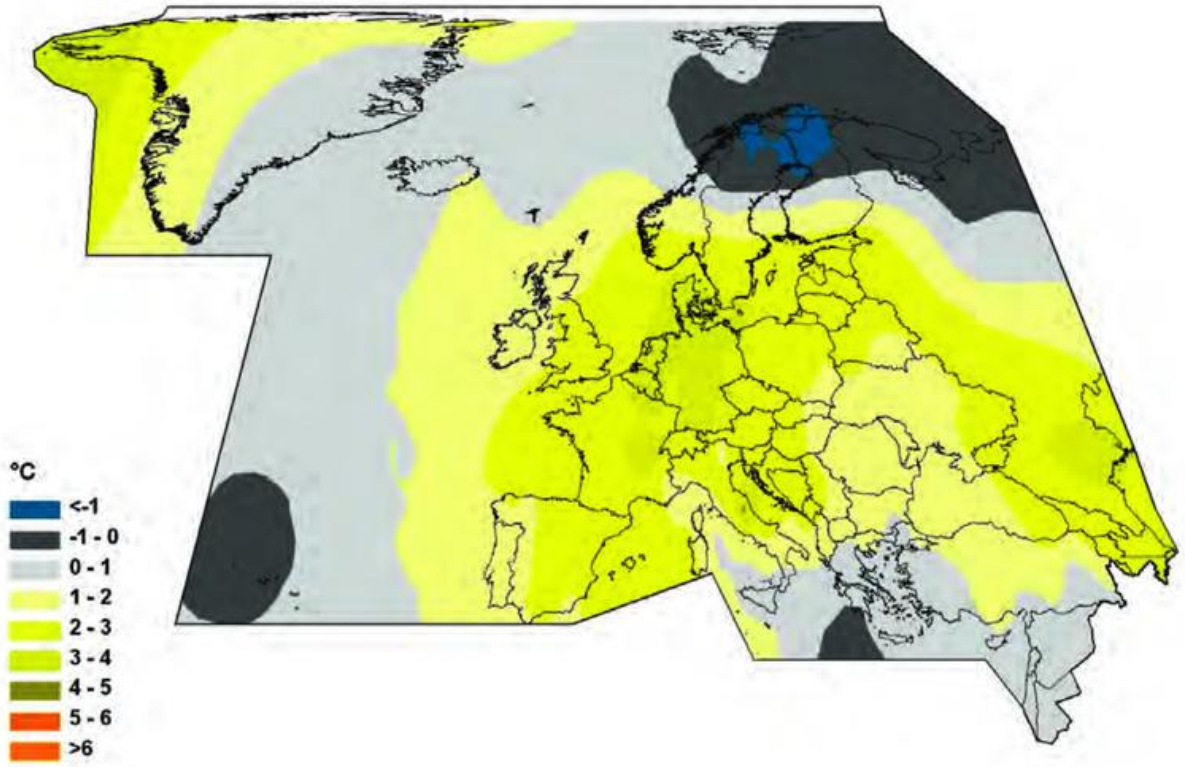

Fig. 10.1: *Monthly mean temperature anomalies in October 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

even recorded this October as the warmest of their time series, e.g. Denmark and Albania. Also the coastal areas of the Norwegian counties of Rogaland and Hordaland experienced the highest registered monthly mean temperatures since 1867. In southern regions of Poland maximum temperatures were still exceeding 25 °C at the beginning of the month. Romania recorded a daily maximum of 34 °C on October 4 in Zimnicea. Serbia had a heat wave from October 21-26 with maximum temperatures >= 25 °C throughout the whole country. Also later in the month, on October 26, some stations in Switzerland registered summery temperatures in the afternoon. 28.8 °C were measured in Vaduz, capital of Liechtenstein; it was the highest October temperature since the beginning of measurements in 1979. In the south, the highest October mean minimum temperature since 1931 was recorded in Portugal; the highest daily value was 19.1 °C at Porto on October 30.

The border line between this warm air mass and the cold Arctic air was still in northern continental Europe. In northern Scandinavia, the temperature anomalies were partly below -1 °C. It was also colder than normal over parts of the Atlantic, notably on some of the western Azores Islands and in small areas of the eastern Mediterranean. On the other hand, it was warm and dry on Greenland.

Due to frequent high pressure influence, it was very dry in eastern central Europe and particularly over the western Mediterranean (Fig. 10.2). Large parts of Italy received less than 25% of the normal precipitation. However, some Atlantic low pressure systems moved over western, central, northern and eastern Europe, resulting in large wetter than normal areas over most parts of Europe. In Sweden and in the western half of the Iberian Peninsula, more than 300% of the normal precipitation fell. Vihti (southern Finland) had a monthly precipitation total of 228 mm which was the highest amount ever recorded in the whole country, but also Helsinki was very wet (Fig. 10.3).

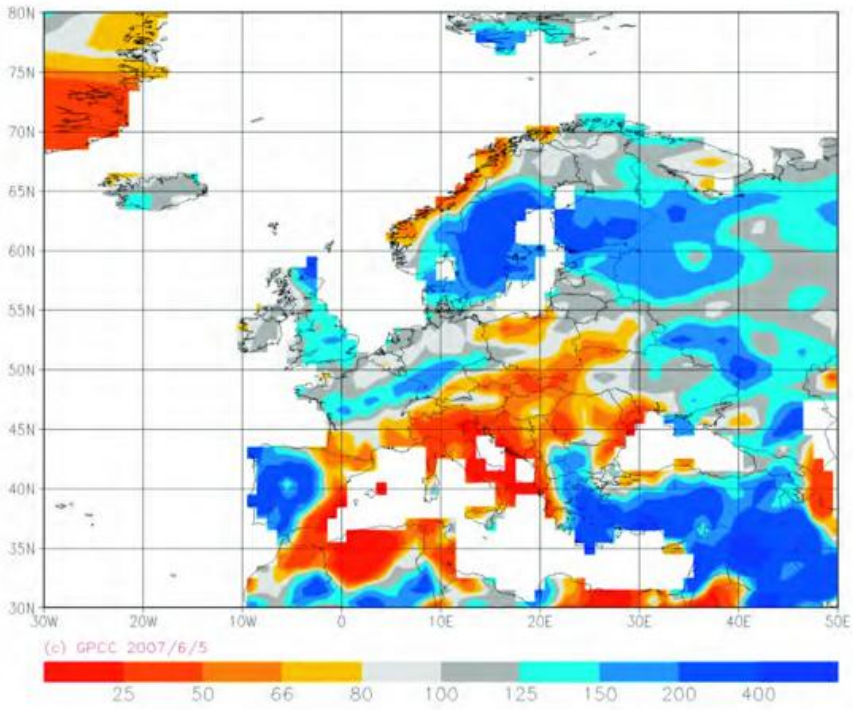

Fig. 10.2: *Monthly precipitation amounts for October 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

In the south, the highest values of the daily maximum precipitation totals ever recorded in any October month were exceeded in some places in Portugal on October 23 and 25, with up to 142 mm in Guarda (central eastern areas; previous record was in 1953). 64 mm fell within 2 hours in Coimbra (central western Portugal) on October 25 at 01-03 UTC, the highest amount since 1973. It was also the 4th rainiest October in Portugal since 1931, especially the period October 19-27 was extremely rainy.

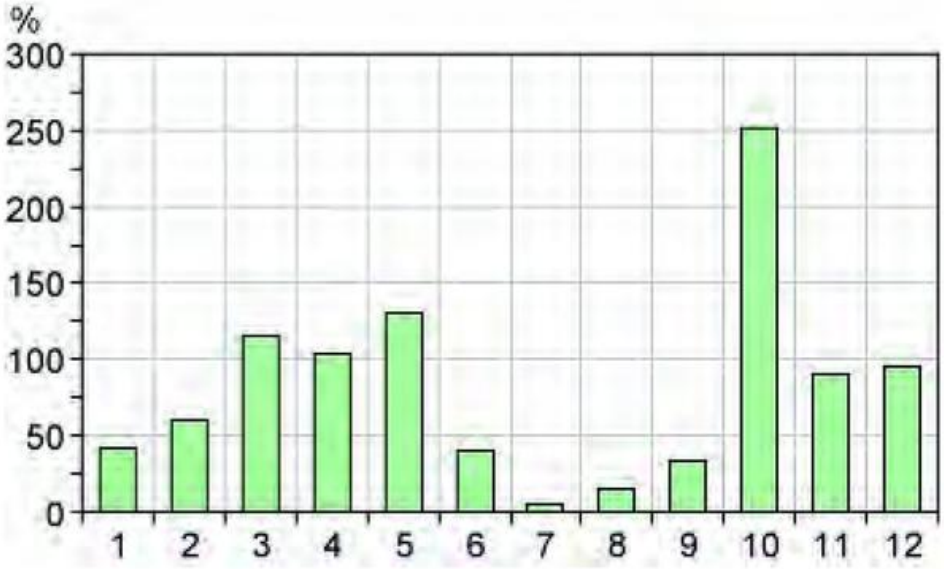

Fig. 10.3: Monthly precipitation amounts for 2006 in per cent of the normal 1971-2000 at the station Helsinki Kaisaniemi, Finland.
Source: Finnish Meteorological Institute

The highest monthly precipitation anomalies (monthly totals up to more than 400% of the normal) within the Region were registered near the eastern Mediterranean this month. Many towns in northern Greece were flooded after heavy rain on October 7-8. More heavy rain events in Greece followed on October 17-18 and October 21, and in Turkey, Syria and the Lebanon at the end of the month. Cyprus received 109 mm of precipitation on spatial average; this was more than 300% of the normal and the second highest October total since 1901. It was mainly due to three heavy rainfall events with hail, causing floods and damage to properties and crops. Israel was very rainy too, with monthly totals of 50-100 mm in northern and central parts, locally even 100-150 mm, compared to a long-term average of 20-40 mm. During the last 60 years, there were only two years in which rainfall totals in October were larger. 32 mm of precipitation fell during a few hours in Masrik in the basin of Lake Sevan in Armenia on October 4.

November

- **Warm in most of the Region, cold in southern Greenland, Iceland, parts of Russia and the southeast**
- **Wet in most of the north, dry in most of the south**

The warm air flow over Europe to the north continued in November. In this month, mild air masses reached even the northernmost parts of the Region. Temperature anomalies in Svalbard exceeded +6 °C (Fig. 11.1). Large areas, especially in northern and central Europe, were more than +3 °C warmer than normal; for some areas all three autumn months had reached this anomaly. Also most of the rest of Europe was considerably warmer than normal.

The coastal areas of the Norwegian county Østfold up to Hordaland had monthly mean temperatures which broke all records since 1867. Denmark reported a record-breaking November monthly mean temperature of 8.1 °C since 1938, despite a wintry start in the first days of the month, with snow and frost during night-time. In Brussels, Belgium, this November was the 4th warmest ever registered, in Germany the 3rd warmest, in the Netherlands and France the 2nd warmest. This November was considerably warmer than normal in Vienna (Austria) for almost the whole month (Fig. 11.2). For Estonia, it was the end of the month which was the warmest for 55 years, and also in Latvia, it was the warmest third decade for 83 years. Only the beginning of November (in particular November 3-6) was cold in these parts; temperatures down to -15 °C were measured in southeastern and northern Lithuania and even below that in Poland, whereas the high value of 19.3 °C was the maximum measured in the second half of the month in west Poland. The first decade of November was also cold in Belarus, the only cold one in this autumn. Serbia, too, was mild, especially in the second half of the month. In the southwest, Portugal recorded its 2nd highest November mean minimum temperature since 1931, after 1983, and its 3rd highest monthly mean temperature.

It was colder than normal in the northwest of the Region, particularly in southern Greenland and Iceland (due to a very cold spell in the middle of the month including a snowstorm), and also in the east and the southeast, here especially the eastern part of European Russia, the complete area of the eastern Mediterranean and the Middle East. Albania reported the coldest November of the time series down to 4.5 °C below normal.

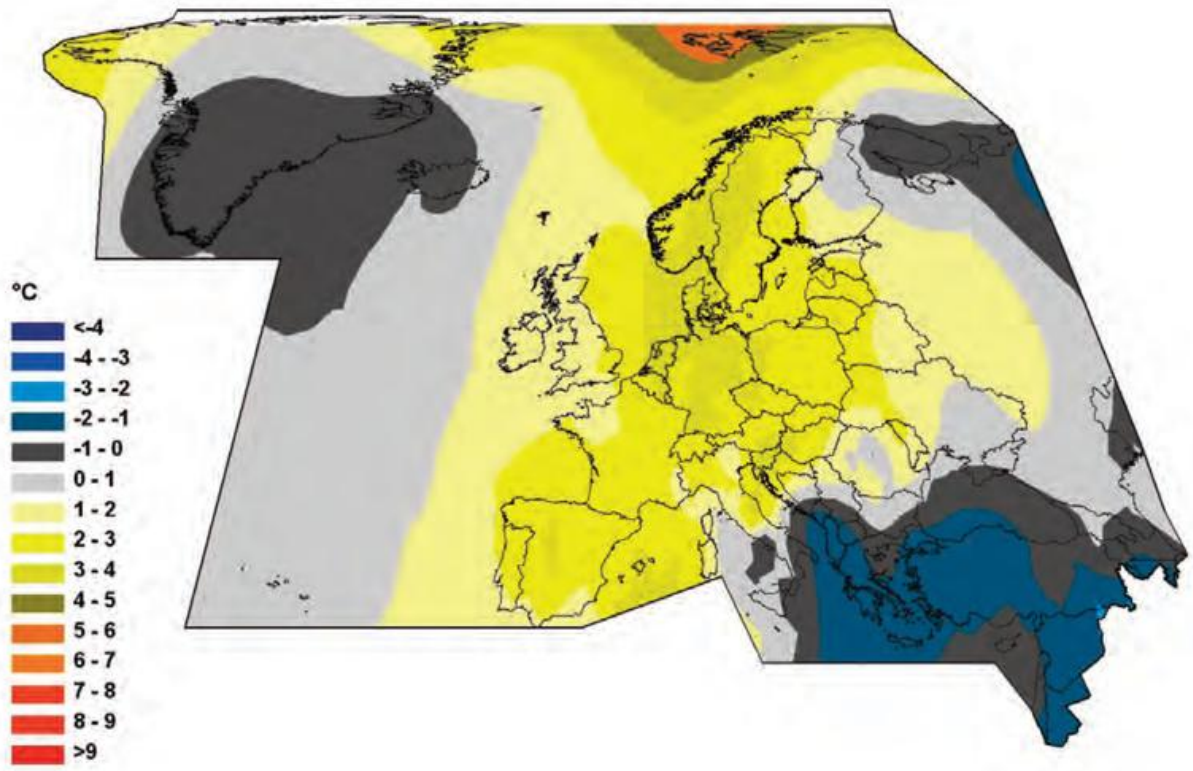

Fig. 11.1: *Monthly mean temperature anomalies in November 2006 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst

Due to the warm air flow over Europe, the frontal zone was more relocated to the north than usual and low pressure activity was frequent, particularly in the north. More than 200% of the normal precipitation was registered in Svalbard (Fig. 11.3), and also most of the rest of the northern areas were wetter than normal, except Greenland and the coast of northern continental Scandinavia. For Norway as a whole, the monthly precipitation total was 140% of the normal, the 4th highest since 1900. The whole country of Finland was covered with snow (40-50 cm in the southeast) which was unusual, although the snow had melted away by the end of the month.

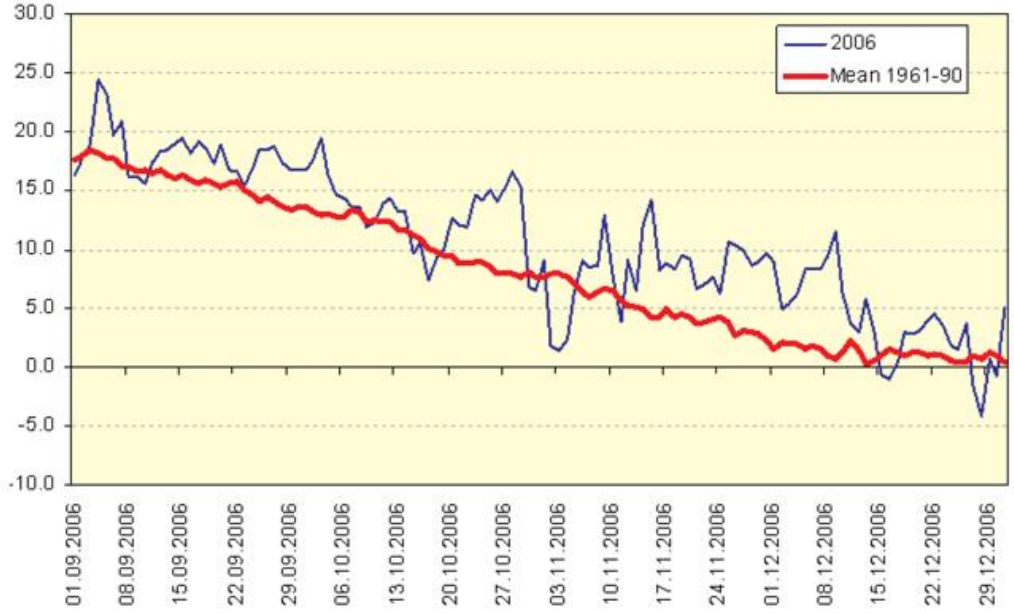

Fig. 11.2: *Daily mean temperature in Vienna (Austria) September – December 2006.*
Source: Central Institute of Meteorology and Geodynamics, Austria

Other wet areas were to be found at the Atlantic and in eastern Europe. Western Scotland experienced its wettest November, with some stations recording well over twice their average rainfall. The station Bishopton, near Glasgow, registered a monthly total of 301 mm.

Most of the southern half of the Region was very dry due to frequent high pressure influence. Precipitation totals in Armenia were 40-60% of the normal. From time to time, local heavy rain and thunderstorms with flooding events occurred in Greece and in Turkey at the beginning of the month. Also Cyprus was relatively wet during the first half of the month, but extremely dry during the second half. Portugal, too, had some heavy precipitation; the total on November 3 in Alvalade (south) was 84 mm and exceeded the highest daily November total recorded before in 1982. Another wet period occurred in Portugal on November 21-29, so that the month as a whole was wetter than normal in contrast to nearly all the other southern countries of the Region. In Faro (Algarve), 44.2 mm were recorded in only one hour on November 29, 09-10 UTC, with 29 mm in just 10 minutes.

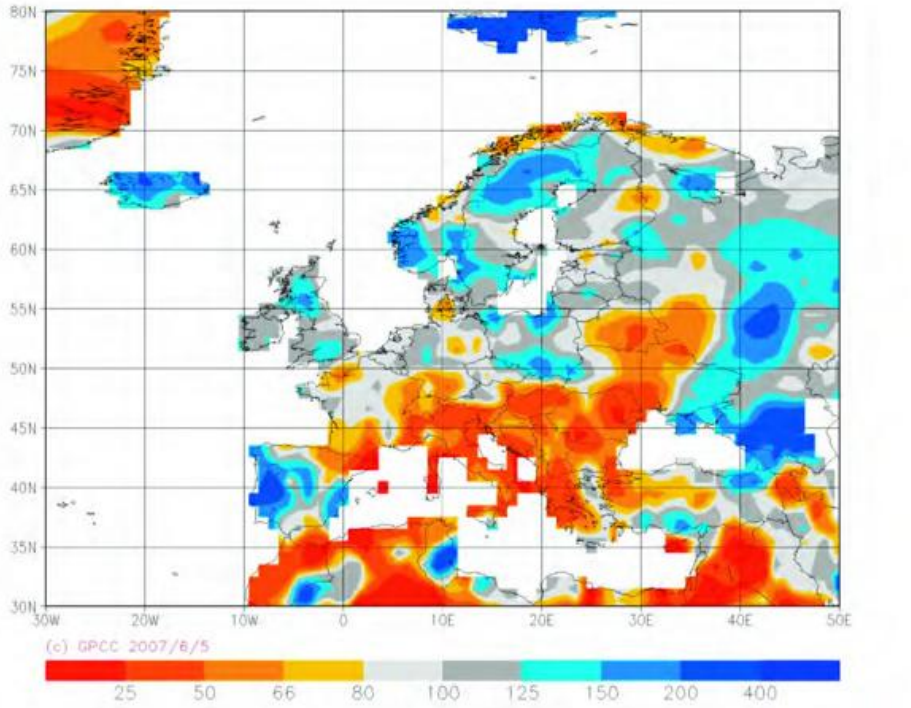

Fig. 11.3: *Monthly precipitation amounts for November 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

December

- **Mostly very mild, especially in the northeast**
- **Very cold in the southeast**
- **Wet in most of the north, dry in most of the south**

In December, the warm air flow over Europe continued but shifted more to the northeast of the Region. Thus, it became extremely mild in northern and northeastern Europe this month. The highest temperature anomalies within the Region were registered in Finland and northern Russia at more than +8 °C (Fig. 12.1). At Helsinki Kaisaniemi, the monthly mean temperature was 4.0 °C, the highest ever measured since 1829. In northern European Russia on spatial average, it was the warmest December since 1930 (Fig. 12.2). Moscow recorded 1.2 °C as monthly mean temperature; this was also a record in the time series, comprising more than 100 years of observations. On December 15, the maximum temperature even reached 9 °C in Moscow. Also in Estonia, such a mild December had not occurred for 140 years (Fig. 12.3), in Latvia for 83 years, at some stations for even a longer time. On December 5 and 6, record temperatures in Latvia were reached with 10-12 °C. Minimum temperatures were as high as 8-10 °C in places in that country; such values are usually measured there in September. Lithuania and Belarus, too, reported their warmest December on record, and also Norway and Sweden, except some of the northernmost parts. Poland recorded maximum temperatures up to 17 °C and no more than 5 days with snow. In Iceland, the first part of December was rather cold, but it became unusually mild after December 17. Heavy rain in the north of Iceland around December 20 resulted in snowmelt, flooding of roads and landslides, causing both loss of property and livestock in various areas.

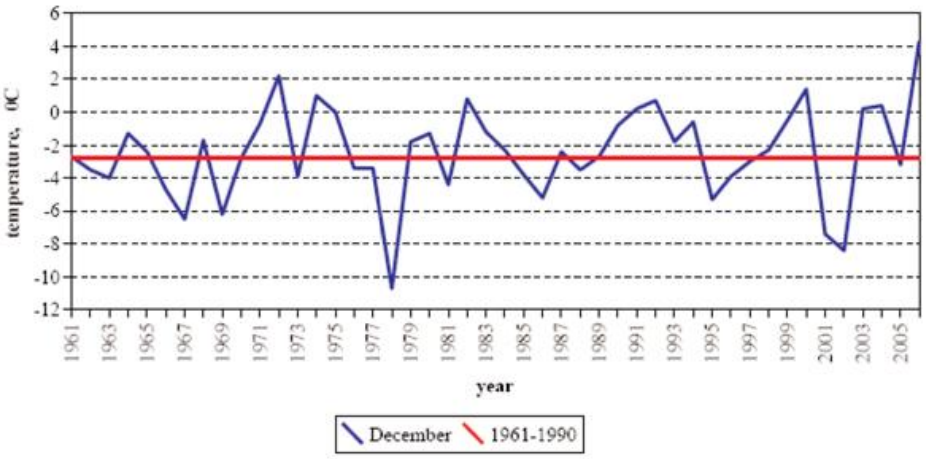

Fig. 12.3: *Monthly mean temperature in Estonia in December.*
Source: Estonian Meteorological and Hydrological Institute

It was also more than 3 °C above normal over most of central and eastern Europe, even in parts of west Kazakhstan, partly also over southern parts. In Denmark, too, this December was record-breakingly warm, nearly 2 °C warmer than the previous record of 1934. For Germany, it was the 3rd warmest December since 1901. Hazel flowering was reported frequently in Germany this month and a pollen warning had to be issued, which was very early in the season. Only at the end of the year (December 27-28) did stronger snowfall and freezing rain appear in Germany, causing many traffic accidents. The airport in Luxembourg had no snow day at all that month, which was very unusual. In the Alps, even at altitudes of 2000 m, could snow rarely be found during the first half of December.

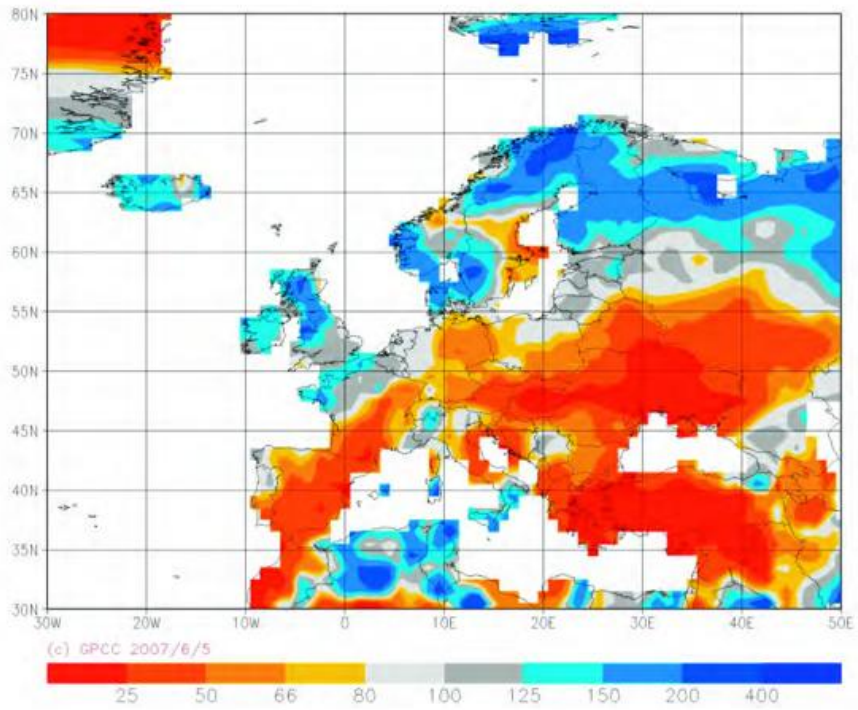

Fig. 12.4: *Monthly precipitation amounts for December 2006 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Germany

The mild air also brought a lot of precipitation to northern Europe, in parts more than twice the normal amount (Fig. 12.4). With 166% of the normal precipitation, Norway experienced its 2nd wettest December since 1900, after 1975. It was also extremely wet in southwestern Sweden, where serious flooding occurred after heavy rains on December 11. The southern half of the Region was mostly very dry due to continuous high pressure influence, except in some places in the western Mediterranean and the Alps. In western Carinthia, Austria, precipitation rose to more than 175% of the normal, caused by a depression over northern Italy around December 9. Israel had a very long dry period until December 20, but large precipitation amounts in the last third, especially on December 26-27 with snowfall in the mountains, including Jerusalem. Snowfall was also recorded in Jordan on these days (28 cm in Shoubak in the south), and the highest daily precipitation total of the year in Jordan was 80.2 mm registered at Salt in the central part of the country on December 26. In contrast, only 7.5 mm of precipitation (7% of the normal) fell in Cyprus during the whole month of December, it was the second lowest amount since 1901.

Widespread fog conditions were observed in Bulgaria during most of the month. During the week of December 11-17, up to 250 flights at the international airport of Sofia were cancelled or diverted.

Some areas in southwest Europe and particularly in the Middle East were colder than normal, mainly due to continental cold air flowing south of high pressure centres from the east to these parts. Especially in eastern Turkey it was partly more than 3 °C colder than normal. Cyprus had at first 3 weeks which were very warm, but towards the end of the month a low pressure system affected the island, and the temperatures dropped below zero on the whole island, causing frost damage to crops. In Israel too, especially the second half of the month was cold. In the northern valleys, the northern Negev and the inland aeras of the coastal plain in Israel there were three periods of ground frost, partly also air frost, which caused damage to potato crops and this happens statistically only once in ten years on average. Jordan recorded its lowest minimum temperature of the year at Shoubak (elevation 1365 m) in the south on December 30 at -12.4 °C. Unusually cold weather was also registered in the Ararat Valley in Armenia (up to more than 5 °C below normal); minimum temperatures fell to -26 °C at an altitude of 800-1000 m there.

Report on ECSN activities

Aryan van Engelen, KNMI

Introduction

The European Climate Support Network is a programme under the auspices of EUMETNET, the Network of (22) European Meteorological Services. In this programme the members co-operate in the field of climate and related activities, in order to expand their capabilities to support the RAVI/European user community through enhanced provision of high quality climate data, products, services, advice and knowledge. Core activity is the initiating and running of a series of projects in order to address the most frequent and urgent user needs of the whole RAVI/European domain. ECSN organises a number of events such as the annual ECSN plenary meetings of its members (EAC), the biennial European Conferences on Applied Climatology (ECAC) in collaboration with the European Meteorological Society (EMS) and the biennial Data Management Workshop.

ECSN is collaborating with the WMO RAVI Working Group on Climate Related Matters (RAVI-WgCRM); especially to address the NMHSs of RAVI that are not (yet) members of ECSN.

MeteoSwiss was responsible member of ECSN.

The 11th ECSN Advisory Committee (EAC) Meeting took place in Exeter, UK, 21-23 June, 2006. The meeting was well organized by the UK Met Office. At the meeting, as a new initiative, a strategic partnership with the RAVI-WgCRM was discussed.

The 6th European Conference on Applied Climatology, together with the Sixth Annual Meeting of the European Meteorological Society, took place in Ljubljana, Slovenia, 4-8 September 2006. This was the most successful ECAC so far, not only because of the large number of participants of about 500, but also because of the high scientific level.

On 28 September 2006, the EUMETNET Council decided to continue the ECSN Programme for a fourth phase, starting on 1 January 2007, for a four year period, with KNMI as Responsible Member.

On 9 December 2006, ECSN launched a joint press release: “Autumn 2006 extraordinarily mild in a large part of Europe”

Projects

S-EUROGRID (SMHI)

The outlines of the Showcase EUROGRID (S-EUROGRID) project were prepared in 2006. The project will start on 1 January 2007 and run for a period of two years. Responsible member is SMHI. Contributing members are Austria, Denmark, Finland, France, Germany, Iceland, Ireland, The Netherlands, Norway, Portugal, Spain, Sweden and Switzerland. Italy and United Kingdom will be participants “in kind”.

S-EUROGRID’s main ambition is to illustrate what the full-scale EUROGRID concept means, which is intended to be a future European shared resource for gridded climate and historical and environmental data.

HRT-GAR (ZAMG)

A new ECSN project, the "High Resolution Temperature Climatology in Complex Terrain – demonstrated in the test area Greater Alpine Region" (HST-GAR), was launched on 1 January, 2006. The project aims at providing high quality data products over mountainous areas in Europe. The principal deliverable will be a monthly temperature field in a 1 km resolution over the 1961-1990 WMO Normal Period and the 1971-2000 Normal Period.

The kick-off meeting was attended by the assembled participants from Austria, Bosnia, Croatia, Czech Republic, Herzegovina, Hungary, Italy, Norway, Slovenia and Switzerland.

Data were collected from 1885 stations, of which 1733 were able to be adopted. A paper "First steps towards a new Temperature Climatology of the Greater Alpine Region (GAR)" has been prepared.

GCMP / EuCLIS (DWD)

The "Generate Climate Monitoring Products" (GCMP) and its successor platform the "European Climate Information System" (EuCLIS) project is aimed at providing standardized climate monitoring products for the European area, in order to meet the requirement of the Services, scientific institutions and the general public. In 2006, 19 NMHSs contributed to this platform (Austria, Belgium, Denmark, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Luxemburg, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and United Kingdom). A prototype of EuCLIS was presented at the 6th ECAC conference in Ljubljana, where many NMHSs of RAVI expressed their interest to become new contributors. Since then DWD is undertaking activities to turn the prototype into a sustainable operational platform that will probably be launched in 2007.

ECA&D (KNMI)

The European Climate Assessment and Dataset (ECA&D) project of ECSN aims at the creation of a sustainable operational system for data collecting, archiving, quality control, analysis and dissemination. Data collecting refers to long-term daily resolution time series from meteorological stations throughout Europe and bordering areas. Based on this dataset ECA&D will serve as a platform to increase the knowledge of and communication on past changes in (soft) extremes over Europe through the analyses of the historical climatological records. Data were collated with the collaboration of 53 participants (NMHSs predominantly) from 42 countries and datasets, included from EMULATE, STARDEX, GHCND, GSN and MAP. Now the dataset comprises series from some 2200 stations.

ECA&D is widely recognized as a EUMETNET baseline dataset, not only by the European NMHSs but also by a number of strategic bodies such as WMO, EEA and the EU Research Community; the ENSEMBLES and the MILLENNIUM projects.

ENSEMBLES (KNMI, MeteoSwiss)

The focus of the EU-FP6 project "ENSEMBLE-based Predictions of Climate Changes and Impacts" (ENSEMBLES, 2004-2009) is to develop an ensemble prediction system for climate change, based on the principal, state-of-the-art, high resolution, global and regional Earth System models, developed in Europe, validated against quality controlled, high resolution gridded data sets for Europe. Based on the ECA&D dataset MeteoSwiss and KNMI collaborate

in assessing the quality of the dataset (1960-2000) that will be the basis of a daily gridded dataset for the whole of Europe with a 25 km resolution. It is expected that the ENSEMBLES gridded dataset will serve as a baseline dataset for the ECSN project EUROGRID.

Millennium (KNMI)

The EU-FP6 project “Millennium – European climate of the last millennium” (2006-2010) addresses the question as to whether the magnitude and rate of recent climate change will exceed the natural variability of the European climate over the last 1000 years. In 2006 the partners of ECA&D supported this project in collating long instrumental climate time series. This support was also expressed at the 1st MedCLIVAR Workshop in Carmona, focusing on a reconstruction of the Mediterranean climate during the last 1000 years.

At the end of 2006, the ECA&D dataset was officially recognised as deliverable.

The Ozone Layer over Central Europe

Ulf Köhler, Hans Claude and Wolfgang Steinbrecht - Deutscher Wetterdienst

The development of the ozone layer over Central Europe continues the positive trend as observed since the beginning of the nineteen nineties. This trend is documented by the Hohenpeissenberg total column ozone time series (Fig 14.1). This 15-year increase includes the distinct ozone minimum after the eruption of Mt. Pinatubo in 1991, which additionally aggravated the negative trend since the end of the sixties. The mean values of the last years are around 2% below their longterm mean and 5% lower than at the beginning of the measurements.

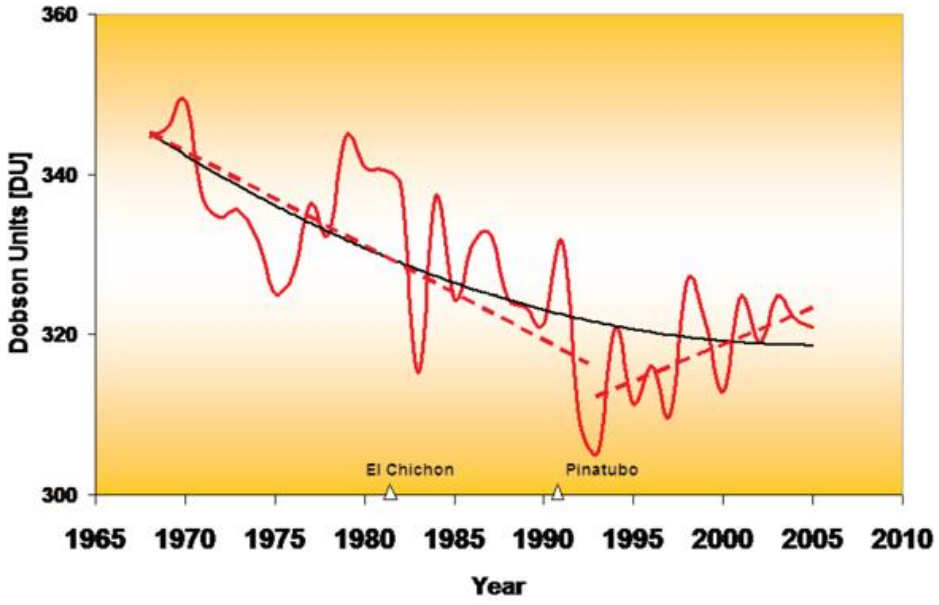

Fig. 14.1: *Annual means of total column ozone above Hohenpeissenberg measured by Dobson and Brewer since 1968 (red curve). The regression lines (dashed red) and the polynomial fit (black) approximate possible trends.*

The causes of trends and fluctuations are the development of the ozone depleting potentials (ODP's) combined with natural influences like solar cycle, and dynamic impacts like e.g. the North Atlantic Oscillation (NAO) and the quasi biennial oscillation of stratospheric winds (QBO) (WMO 2007).

The reduction of effective stratospheric chlorine as a consequence of political protocols (Vienna 1985, Montreal 1987, London 1990, Copenhagen 1992) has begun but its effect on total column ozone has so far been very low.

Figure 14.2 shows the time series of daily total ozone over Central Europe in 2006. It reflects a quite normal year with some outliers in both directions, but most of the daily averages, at least in the first half of the year, are within the bounds of the extreme years 1970 and 2000. However, three significant features are noticeable:

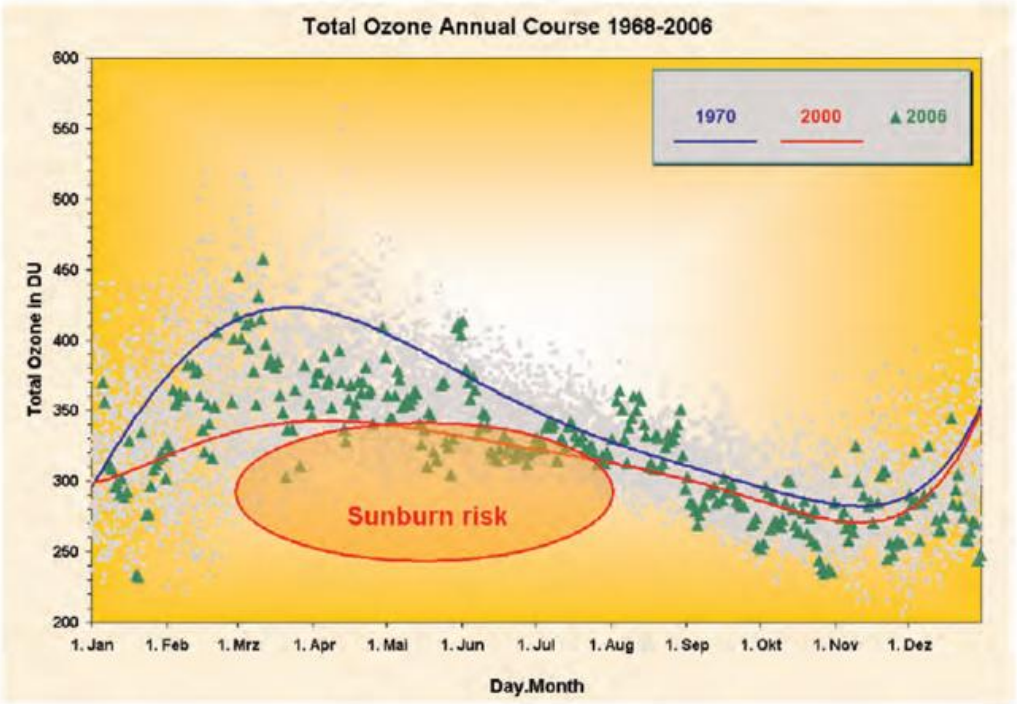

Fig. 14.2: *Daily means of total column ozone above Hohenpeissenberg in 2006 (green triangles) and between 1968 and 2006 (grey dots). The blue line shows the annual course of the maximum year 1970, the red line the minimum year 2000.*

- Two days in January show extraordinarily low thickness of the ozone layer. The deficit on January 19 and 20 was almost –30%. These low values of about 230 DU over Hohenpeissenberg correspond with a so-called mini ozone hole over Western Europe/UK with a minimum below 200 DU. A record minimum of 177 DU was observed in the UK. On the first look this mini hole might only be attributable to a streamer event, which transports ozone poor air from the tropics/subtropics to Western and Central Europe (Fig 14.3). Looking at the development of the ozone distribution above the Northern Hemisphere over a longer period, however, reveals a combination of dynamic effects (streamer) and additional chemical ozone depletion (ozone poor air caused by heterogeneous chemistry coming from northern latitudes). A detailed analysis of ozone sonde profiles and trajectories proved that 2/3 of the ozone reduction come from the UTLS region (streamer effect in the upper troposphere/lower stratosphere) and 1/3 from chemical ozone depletion in the middle and higher stratosphere (Keil et al., 2007). This shows that record ozone minima are possible over Europe at any time.

- High ozone values were observed at the beginning of June and throughout the entire August, whereas ozone was subnormal during the six weeks of the Football World Cup in Germany. This ozone pattern correlates with the weather extremes during the summer 2006. It started with snow fall at Hohenpeissenberg on the 1st and 2nd of June, followed by sunny and hot summer weather due to high pressure systems. August, in contrast, was dominated by low pressure systems with cold weather and much rain over central Europe.

- From September onwards the ozone layer gives evidence of a record fall and winter in weather. As low total ozone values are normally connected with high pressure systems and, subsequently, a warm troposphere, the predominantly subnormal values confirm that the four last months in 2006 were too warm. Fall 2006 was the warmest ever measured in the 225-year long weather records of Hohenpeissenberg. The same applies to the following seasons, i.e. winter 2006/2007 and spring 2007. Since the

amount of total ozone is a combination of different effects at various altitudes, the average total ozone column of these months is indeed low but record minima were not observed.

The coming years will reveal whether the expected recovery of the ozone layer will appear in the data records or not. The global climate change with its various aspects, however, remains a factor of uncertainty, which could compensate the effects of the beginning chemical recovery of the ozone layer. Moreover, the risk of temporary episodes with very low total ozone associated with enhanced UV radiation, harmful to human health, remains.

Foreword

Like the previous years, 2007 again was a very remarkable year for climatologists . In many places of our Region it was the warmest or second warmest year since the beginning of measurements and probably one of the five warmest years since 1850 in Europe.

The most outstanding warmth occurred in January and April. January 2007 was the warmest January in the global average and in many countries of our Region it was the warmest ever recorded. Monthly mean temperature anomalies above +10°C in some of the eastern parts of the Region were the proof of an extraordinarily mild winter month there, with many other parts of Europe also having been considerably warmer than normal. April was extremely warm, sunny and dry especially in western, central and southeastern Europe. In summer 2007, in particular the southeastern countries were concerned by some strong and long lasting heat waves. Numerous forest fires were reported from many countries. December 2007 was very mild in northeastern Europe, making the start to another mild winter season in this area.

Nevertheless, there were some colder-than-normal periods recorded in 2007. One example is the cold February 2007 in northeastern Europe whereas western, central, and sometime later also eastern Europe experienced a colder second half or at least a colder autumn. This is once more a clear demonstration that climate change is a lot more than just a simple global warming. Keeping in mind that cold winter months and cool summers can even occur in a warmer climate, we are aware that a continuous climate monitoring is still very important and not at all a boring job.

Also for precipitation, we had a lot of outstanding anomalies and events in 2007. Although the year as a whole was more or less near normal on average in many areas, many very dry and wet episodes occurred. An extremely dry April in many parts of Europe was followed by a very wet May. Some locations in central Europe were without any precipitation in April, which is far from typical for this month in this climate zone. The summer months were characterised by high precipitation amounts with flooding particularly in northwestern Europe. In many other parts of the Region, frequent violent thunderstorms with heavy rain, hail and tornadoes were recorded, of course with serious consequences for agriculture and daily life. One of the strongest storms ever, named “Kyrill”, hit Germany on Januar 17-19, affecting also large parts of western, central and eastern Europe and the Alps. Furthermore, the areas south of the Alps were concerned due to a north foehn situation resulting in extremely mild temperatures with serious consequences for skiing sites in northern Italy. This example shows that such an event can easily cause important impacts to large parts of our Region, and its monitoring requires contributions from several countries.

The 14th issue of this Annual Bulletin is one result of such a cross-national activity. Our Region consisted of 50 countries in 2007, and I am very happy to notice that we have received contributions from 49 countries this year. This is again a new record and an excellent response to the call for input sent out by the DWD (Deutscher Wetterdienst, the German Meteorological Service) in December 2007. Our editors, Peter Bissolli and Peer Hechler of DWD, succeeded in including the important facts of all thoroughly prepared material and presenting herewith a concise and representative summary. I am convinced that this bulletin helps you inputting your domestic findings in the greater climatological context of the RA VI.

Let me express my warmest thanks to all contributors, reviewers and in particular to the editorial team of DWD for all the work and the kind co-operation.

Daniel Keuerleber-Burk
President of WMO Regional Association VI

Outstanding Events and Anomalies

Temperature

- Warmest or second warmest year, winter and spring on record in many countries
- Extremely warm January and April, particularly in the east and in central Europe respectively
- Severe summer heat waves especially in southeastern Europe
- Cold February in northeastern Europe

Precipitation

- Very dry April in many countries, partly without any precipitation in central Europe
- Severe flooding events particularly in northwestern Europe
- Many severe thunderstorms with heavy rain and hail in many countries

Sunshine

- Sunniest April ever recorded, particularly in central Europe

Wind

- Storm “Kyrill” in January affecting large parts of western, central and eastern Europe

Annual Survey

Temperature

Anomalies

Like the previous years, 2007 was considerably warmer than normal (reference period 1961-1990) in nearly the whole Region. Annual mean anomalies ranged between +1 and +2°C over most of Europe, the North Atlantic and Greenland, over some smaller areas they exceeded +2°C (Fig. 0.1). National examples are given in Fig. 0.2 (Sweden), Fig. 0.3 (Estonia) and Fig. 0.4 (Bosnia and Herzegovina). The highest anomalies were recorded over Svalbard amounting to over +4°C. Smaller anomalies of less than +1°C were observed mostly in western and southern parts of the Region (even in the southeast, e.g. Azerbaijan, Fig. 0.5) and over some areas of the North Atlantic (including e.g. the Faroe Islands and some coastal stations of Greenland). Only very few places were slightly colder than normal, e.g. in Spain and Turkey.

The annual average land surface temperature (derived from the CRUTEM3 data set of the Hadley Centre in the United Kingdom, CRUTEM3 = Climate Research Unit temperature Version 3, land air temperature anomalies on a 5° by 5° gridbox basis) for the year 2007 was +1.2°C above the 1961-1990 normal for the European region 35-75°N, 10°W-30°E and is virtually certain to be one of the five warmest years since 1850.

Warmest or second warmest year on record in some countries

It was the warmest year on record in the Benelux region (Fig. 0.6 for Luxemburg), eastern Austria, the Czech Republic, Denmark (Fig. 0.7), parts of Ireland and several countries in eastern and southeastern Europe (e.g. at the coast of Slovenia, in Hungary, Bulgaria, Moldova, Ukraine). 2007 was the second warmest year on record in terms of the areal mean in some other countries, at least in some places, e.g. in Germany, the United Kingdom, Russia, Belarus, Slovakia, Croatia, Serbia, but also in Svalbard (average temperature at Svalbard airport was -2.5°C, in some places even slightly above zero). Annual mean temperatures in Norway were above 0°C even in large parts of the north (Fig. 0.8). However, it was not an outstandingly warm year in Spain; it was rather the coldest since 1996.

Annual cycle of temperature

The first half of 2007 was exceptionally warm in all western and central European countries (e.g. in Brussels, Belgium, Fig. 0.9). Especially the first third of the year experienced many new temperature records. January and April were the warmest months on record in many countries, and also the winter 2006/07 and spring 2007 seasons. In the second half of the year, a cooling relative to the normal annual cycle extended from western to eastern Europe. In western Europe, this cooling started in July, in most of central, southern and southeastern Europe in September (even in Poland, Fig. 0.10), and in eastern Europe in November. In Belarus and the Ukraine, January and March were exceptionally mild months and also the months May to August were clearly warmer than normal, whereas April was very near to normal as compared to western and central Europe (Fig. 0.11 for the Ukraine). Turkey was particularly warmer than normal in the summer half year from May to October (Fig. 0.12). In contrast, warmer- and colder-than-normal months in Armenia occurred throughout all seasons (Fig. 0.13). On the Iberian Peninsula, warmer-than-average temperatures were recorded in winter, spring and most

of fall; on the other hand summer and the months of November and December were cooler than normal. In Iceland (station Reykjavik), only May was colder than normal. In Ireland only July, and in northeastern Europe only February were very cold months (e.g. in Helsinki, Finland, Fig. 0.14; Latvia, Fig. 0.15).

Frost

The number of frost days (minimum temperature below 0°C) was exceptionally low in western and central Europe. Only 27 frost days were recorded at Brussels (Belgium) for the whole year and 42 frost days at Luxemburg airport, the normal is nearly twice as many. Neither ground nor air frost was seen during the whole summer half year (April-September) at Luxemburg airport.

Heat waves

Unusual heat waves (maximum temperatures 40-47°C, some set new records) occurred in southeastern Europe and the Middle East in June and July, and another weaker one in August. There were 23 to 52 hot days (maximum temperature greater than or equal to 30°C) in Moldova, 3 to 5 times more than the normal. In the Ukraine, 20 to 86 hot days were recorded, and 22 days with a maximum temperature of greater than or equal to 35°C in the south of the country. Even in eastern central Europe the number of hot days was high: 55 hot days were recorded in the Czech Republic on average in 2007; the normal is only 12 days per year.

Sea surface temperature of the North Sea and the North Atlantic

The mean sea surface temperature of the North Sea was the highest since 1971 with 1.7°C above the long-term mean. In winter 2006/07 and the month of December 2007 there was no ice formation recorded there. The high water temperature persisted until June, but decreased to nearly normal in the second half of the year due to colder northerly winds.

In the North Atlantic, the warmth coincided with the continuing warm phase of the Atlantic multidecadal oscillation, which began in the mid 1990s.

Precipitation

Most of the Region recorded annual totals near normal, mostly slightly higher (Fig. 0.16). A few locations all over the Region, however, were quite wet with annual totals exceeding 125% of the 1961-1990 normal. Many places in southern Europe and in the Middle East were drier than normal.

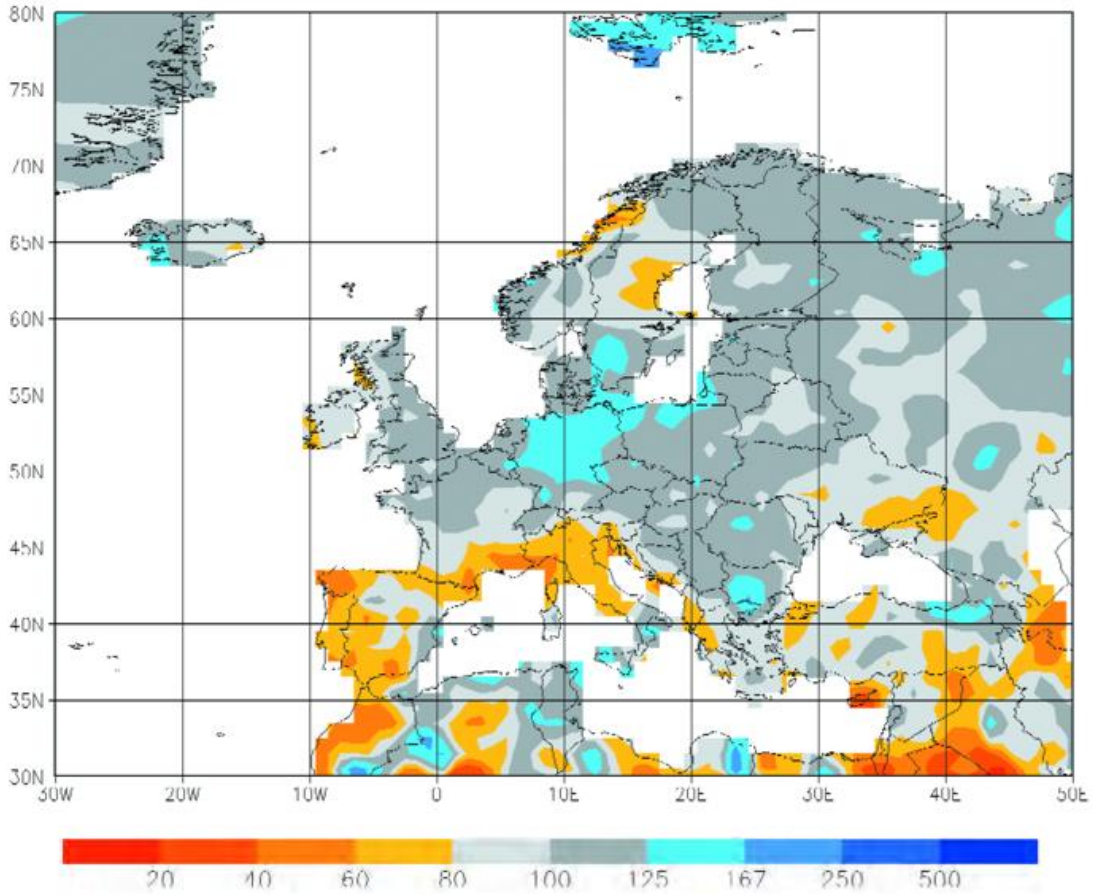

Fig. 0.16: *2007 annual precipitation amounts in WMO Region VI in per cent of the 1961-1990 normal. Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany*

Nordic countries

Precipitation in the Nordic countries was very variable. After a very dry summer in Iceland, the last third of the year was the wettest ever recorded in the southern and western parts of the country. Annual precipitation in Denmark was 155 mm above the normal of 712 mm. Here, in contrast to Iceland, much of the excess was due to an extraordinarily wet summer, the third wettest since 1874. Station records in Denmark show that annual precipitation has increased approximately 100 mm since measurements started in 1870. Annual precipitation for Sweden as a whole was not exceptional; but large regional deviations from the long-term mean occurred. In southern Sweden, several stations reported the rainiest summer since records began, and some records for monthly and annual precipitation were broken; 1725 mm of annual precipitation was a new Swedish record this year (station Baramossa, Halland region, southwest Sweden). In Norway, the wettest seasons were winter and spring. Svalbard on the whole was considerably wetter than the normal annual mean.

Northwestern and central Europe

Although annual precipitation totals were near normal in most of northwestern Europe, England and Wales saw their wettest May to July period ever registered since 1766 with a total precipitation of 415 mm. The result was severe damage due to flooding. It was the severest flooding in southern and central England for 60 years.

In Germany, it was the 4th wettest year since the beginning of the 20th century; nine months of the year were wetter than normal with May being the wettest since 1901. An extremely dry April (nearly no precipitation at all in many parts of central Europe) did not wholly counterbalance the annual excess.

170% of the normal annual total was recorded in northeastern Austria. A new record annual total of 957 mm was measured at Eisenstadt in the Burgenland region in eastern Austria, although there was no precipitation at all in April (Fig. 0.17).

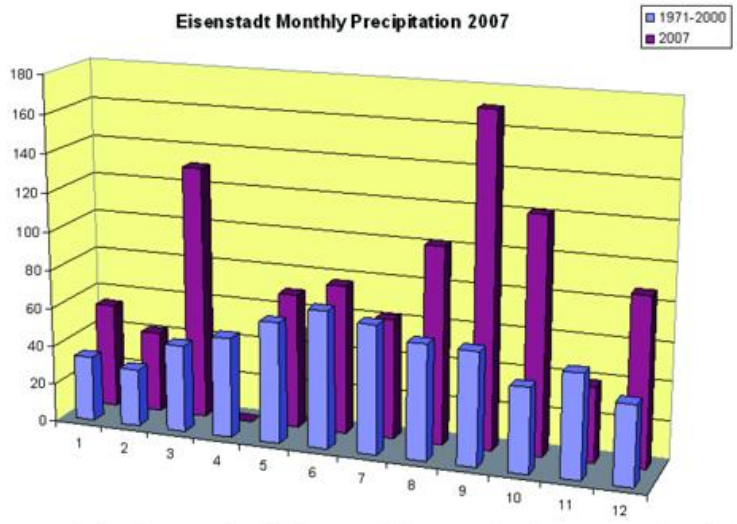

Fig. 0.17: *Monthly precipitation totals 2007 at Eisenstadt (eastern Austria) compared to the 1971-2000 normal.*
Source: Central Institute of Meteorology and Geodynamics, Austria

Southeastern Europe

Parts of Romania, northern Serbia, Bulgaria, and also northeastern Turkey experienced above-average annual precipitation totals of up to about 150% of the normal. Sofia (Bulgaria) received more than double the average amount of rainfall in every month from August to November, and precipitation amounts in Romania were considerably higher than normal in these months, after a drier than normal period from April to July.

Southern Europe and Middle East

In southern Europe and the Middle East, especially large parts on the Iberian Peninsula, southern France, northwest Italy, Israel, Jordan (Fig. 0.18) and Azerbaijan were very dry, receiving locally less than 60% of the normal annual total. Vigo (Galicia, northwestern Spain) recorded only 1038 mm of rainfall (54% of the 1971-2000 average), which was the lowest since measurements began in 1951. For the whole of Portugal it was the second driest year since 1931 (behind 2005, Fig. 0.19). Southeastern Switzerland had 75% of the normal monthly total; it was one the ten driest years in Lugano where regular measurements started in 1864. In the Italian region of Emilia-Romagna (near Bologna), the lowest annual precipitation total since 1925 was recorded with less than two thirds of the normal. Monaco also received very low precipitation totals: only 337 mm were registered at the station in the exotic garden of Monaco for the whole year, this was around half of the long-term mean 1911-1985 at the nearby station of the oceanographic museum. Especially the first third of the year and the summer months were very dry there (Fig. 0.20). Turning to the eastern Mediterranean, Cyprus was also extremely dry with less than 40% of the annual total. Athens (Greece) had no rainfall from the beginning of June until mid October (129 days). From late June through to early September, over 3000 fires were reported in Greece, causing 79 fatalities and destroying more than 2700 km² of forest and farmland. Albania also was very dry especially in the summer half year

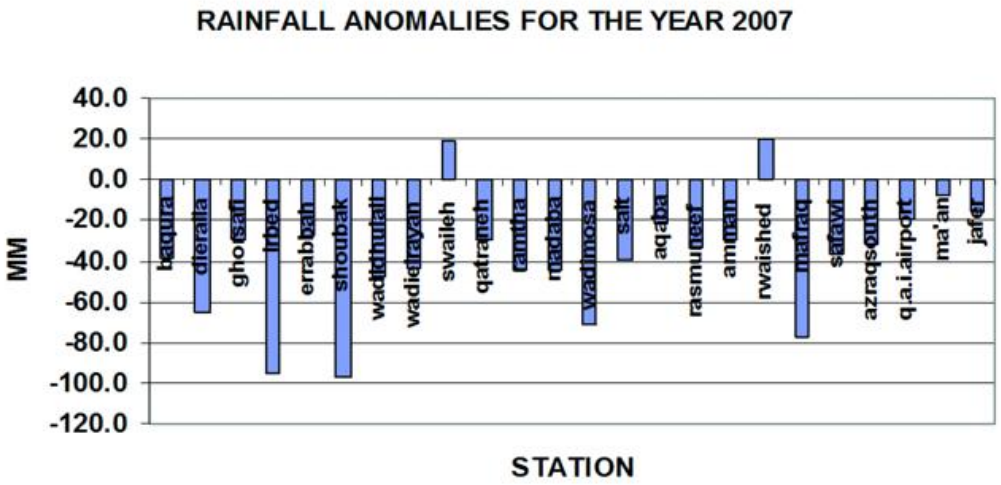

Fig. 0.18: *Annual precipitation anomalies 2007 (reference period 1961-1990) at stations in Jordan. Source: Meteorological Department Amman, Jordan*

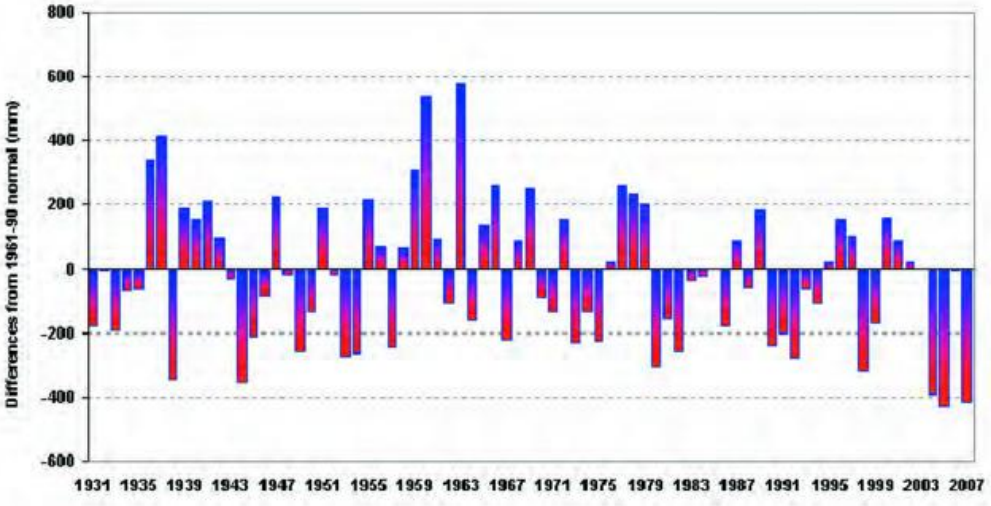

Fig. 0.19: *Mean annual precipitation anomalies in Portugal (1931-2007). Source: Instituto de Meteorologia, Portugal*

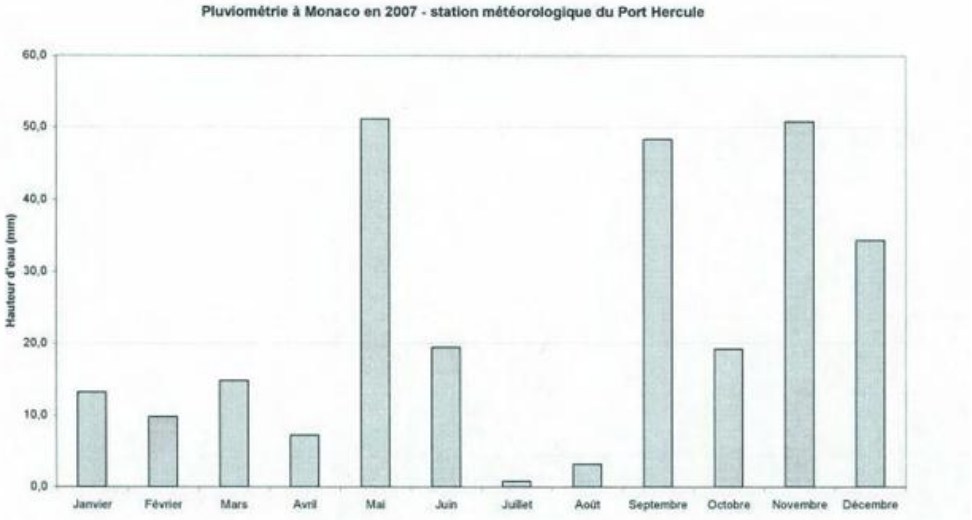

Fig. 0.20: *Monthly precipitation totals 2007 in Monaco (Port Hercule station). Source: Direction de l'Environnement, Monaco*

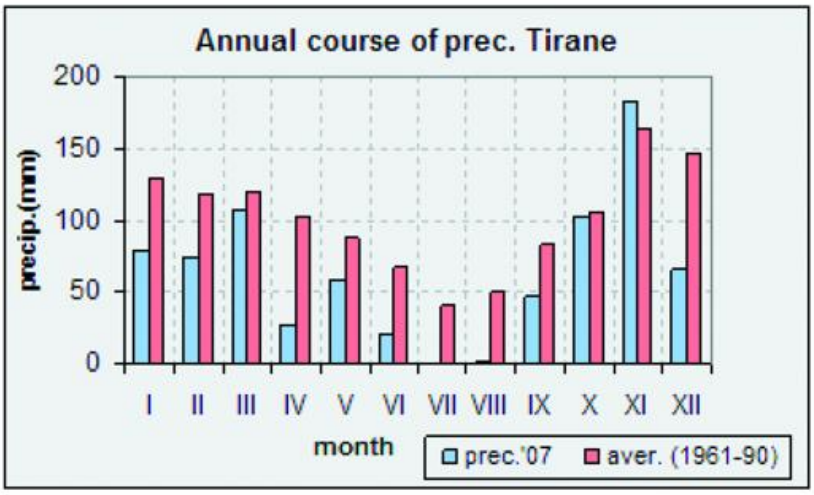

Fig. 0.21: *Monthly precipitation totals 2007 in Tirana (Albania) compared to the 1961-1990 normal. Source: Institute for Energy, Water and Environment, Polytechnic University, Albania*

(Fig. 0.21). Moldova had a dry period from May to July; only 45-140 mm, i.e. 18-56% of the normal total, were registered for these three months together. This was due to four longer episodes without any rainfall, just like in Romania. This led to the severest drought in Romania and Moldova for at least 60 years and caused high crop losses. Another extreme spring-summer drought (middle of May until middle of August) occurred in the southeastern Ukraine. In May it was already too dry for germination of some sowings. In the Middle East, the precipitation affected various seasons throughout the year, e.g. in Beirut (Lebanon, Fig. 0.22).

In the easternmost parts of the Region, the annual average precipitation was near normal, whereas the area was particularly wet in winter and spring. Hard drought conditions were reported from eastern and southern Georgia from the second half of July through to September.

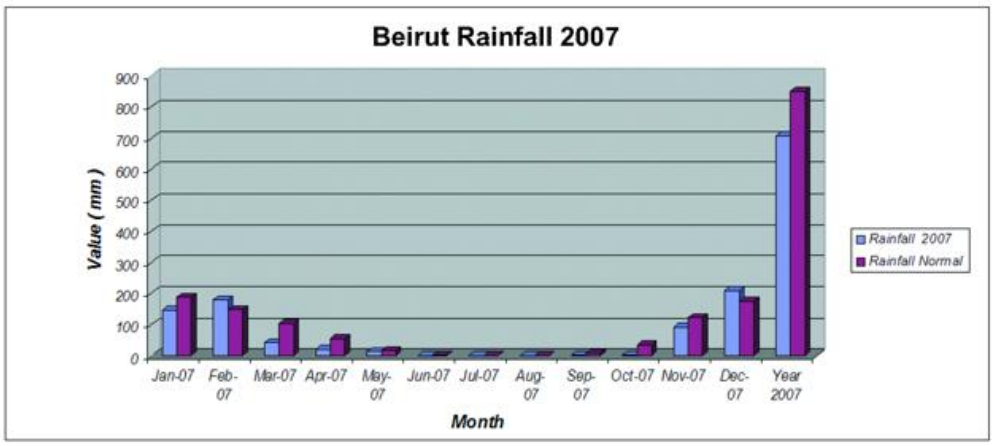

Fig. 0.22: *Monthly precipitation totals 2007 in Beirut (Lebanon) compared to 1961-1990 normal. Source: Ministry of Public Works and Transport, Climatological Service, Republic of Lebanon*

Snow

Snow was generally rare. At Luxemburg airport only 19 snow days were recorded. This is only a little more than half of the normal (36 days).

However, some periodically high snow depths were recorded in 2007. Heavy snowfall events in Switzerland at the end of autumn and beginning of winter 2007/08 brought an early snow cover in the Alps which resulted in significantly higher snow depths as compared with the long-term mean for that season.

In Iceland, except for a two-week period in January the snow cover in 2007 was very light compared to the normal 1961-1990.

Northeastern Europe had a persistent snow cover mainly only in February.

The high mountains of Lebanon received 30% less snowfall than normal. The number of snow days was also less than normal.

Sunshine duration

The majority of the Region was by far sunnier than normal, though, with a few exceptions not beyond 25% (Fig. 0.23). In some months, however, sunshine duration exceeded 150% of the normal in some places. The most outstanding month was April which was very sunny in large parts of western, central and eastern Europe, at many locations it was the sunniest April ever recorded (see also Fig. 4.7 on p. 57). Some locations in Ireland had their sunniest year since 1968.

Only a few larger areas experienced less sunshine than normal: eastern Iceland, northern Scotland, parts of Finland, northern Russia, Belarus, and most of the Middle East. Especially December was very dull in some of these areas, partly with less than 25% of normal sunshine duration.

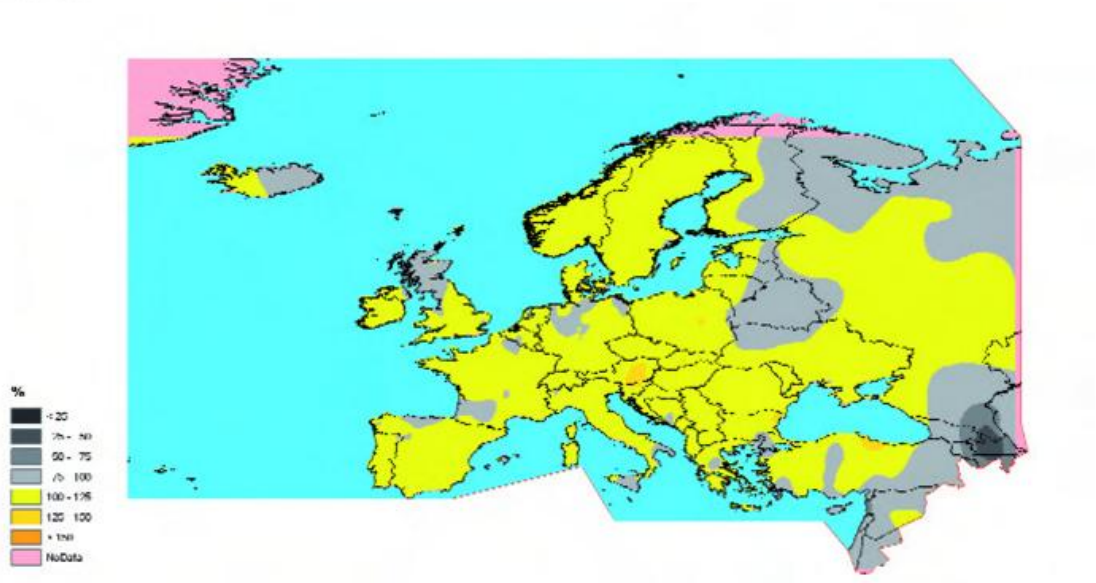

Fig. 0.23: *Mean annual sunshine duration 2007 in per cent of the 1961-1990 normal in WMO Region VI (interpolation of CLIMAT data).*
Source: Deutscher Wetterdienst, Germany

Wind

Many storms moved over northern central Europe, especially in January. The strongest storm, which crossed most parts of central Europe and caused extensive damage was winter storm Kyrill on 17-19 January.

In the east of the Region, wind gusts of over 150 km/h were reported from Armenia (particularly in the basin of Lake Sevan) and Azerbaijan during the period from January to March.

Summer storms affected the western and northern sectors of Iberia, especially in July and August. In late August, the eastern coast of Sweden was hit by a storm with winds as high as 125 km/h. This was the first heavy storm in August in Swedish coastal areas since 1975.

Another storm on 9 November caused high waves in the North Sea of up to 17-18 m and heavy flooding on the islands. December was very stormy in Iceland, causing interruptions in air and land communication on several occasions.

Mean annual wind speeds were exceptionally low in Ireland, with lowest values recorded at Rosslare station.

15 tropical storms developed over the Atlantic. Six of them became hurricanes. This number corresponds to the long-term average. None of these storms affected the Region.

Arctic sea ice

The mean extent of Arctic sea ice amounted to 4.28 million km² in September 2007. This was the smallest extent ever recorded since the start of satellite observations in 1979. At the end of the annual melting period the total Arctic sea ice area was 39% below the long-term mean of 1979-2000 and 23% below the previous record in 2005.

Seasonal Survey

Temperature

In most of Europe the seasonal averages were higher than normal in winter 2006/07, spring 2007 and summer 2007, wheras autumn 2007 was colder than normal over large parts of the continent.

Winter 2006/07 was very mild over most of Europe with significant anomalies exceeding +3°C particularly in central and eastern Europe and +5°C in some parts of the southeast. Around Svalbard, winter temperatures were up to +8°C above normal. In northeastern Europe, February was the only cold winter month, but it did not counterbalance the other two very mild months of the season.

It was the warmest winter on record in England, central and southeast Europe (Slovakia, Hungary, Romania, Croatia, Belgrade in Serbia, Slovenia) and Malta. The recurrence time of such a mild winter was calculated to be more than 50 years for most of central and southeastern Europe, partly even more than 100 years (Fig. 0.24). This was consistent with a strong positive phase of the winter North Atlantic Oscillation (NAO). Furthermore, the North Atlantic and the Mediterranean were warmer than normal, in some parts significantly warmer. A large area with considerable cold anomalies, however, was observed in most of the Middle East.

The mild winter in central Europe led to an early start of the growing season, but also caused some damage to agriculture due to an increased development of mouse population.

Spring 2007 was also significantly warm over most of Europe. Mean anomalies again exceeded +3°C in parts of western, central, southeastern and northeastern Europe, in Spitsbergen even +4°C. In many places there, this was the warmest or second warmest spring ever recorded,

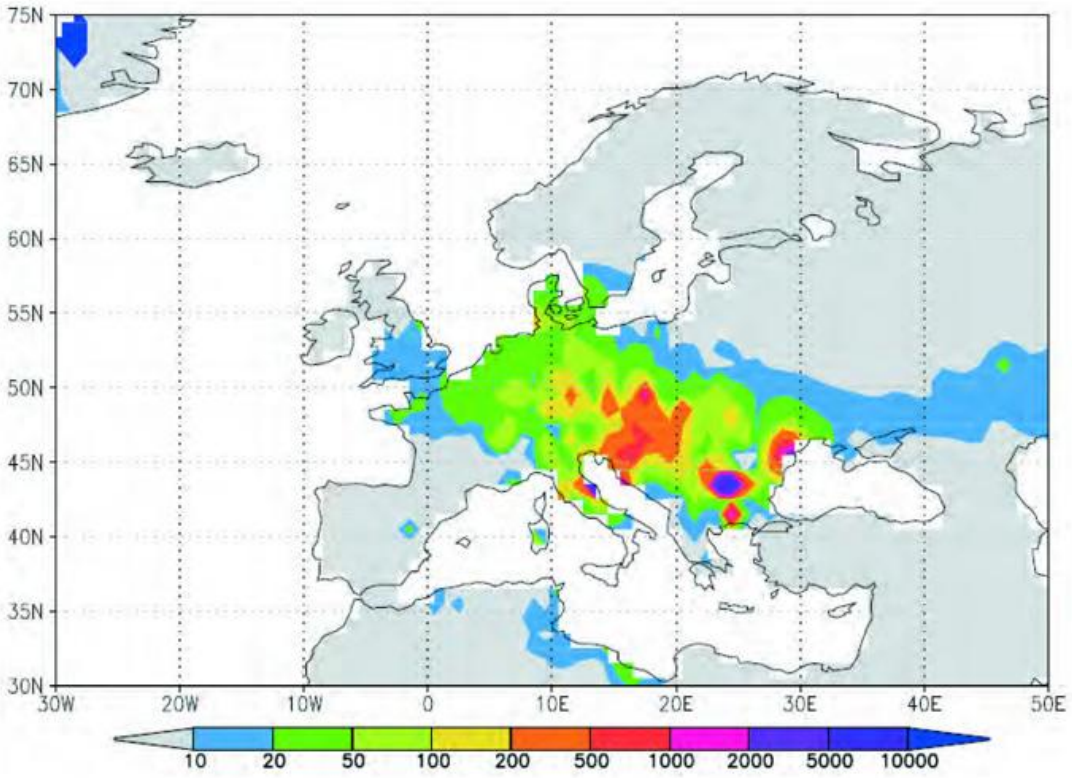

Fig. 0.24: *Recurrence time (in years) of winter 2006/07 temperatures in Europe, based on the HadCRUT3 data set of the Hadley Centre, United Kingdom, corrected for global warming. HadCRUT3 = Hadley Centre and Climate Research Unit temperature Version 3. Provided by KNMI, The Netherlands*

mainly due to the strong anomalies in April. It was the third successive season with a new record in central Europe. The North Atlantic, the Mediterranean and even most of the Middle East were also warmer than normal. Colder-than-normal anomalies occurred only locally.

Summer 2007 again was warmer than normal in nearly the whole Region with smaller but still mostly significant anomalies due to a cool July and August in western Europe.

At Svalbard airport, the summer mean temperature amounted to 6.4°C and was over +2°C higher than normal. This resulted in the warmest summer since the start of measurements in 1912. In Denmark and Sweden, summer started with a very warm and sunny spell in the first half of June, whereas the rest of the summer was dominated by unsettled weather. In contrast, Finland had unusually warm weather only in early August.

The highest anomalies (> +3°C) occurred in southeastern Europe (Bosnia and Herzegovina, Serbia, northeast Romania, Moldova, southern Ukraine) due to some extreme heat waves throughout all summer months. Especially in June and July, two outstanding heat waves occurred there with record daily maximum temperatures of 40-47°C, and also in August temperatures of > 40°C were measured. Several countries in southeastern Europe had their warmest summer since records began. Twice, and in some places even three times as many hot days than usual were recorded in Serbia. Forest fires devastated thousands of hectares of land particularly in Serbia, Croatia, Romania, Bulgaria and Greece. It was the second warmest summer in Romania since 1901, behind 1946, and also in Hungary (behind 2003). The two heat waves also affected the Middle East. Temperatures in Lebanon, Cyprus and most of Syria exceeded the 90th percentile during the summer months. Frequent forest fires occurred.

In contrast, there was no summer heat wave the in Portugal for the first time since 1997, and thus, the anomalies were only slightly positive there. The country recorded the lowest summer mean temperature since 1990.

Again, slight colder-than-normal anomalies occurred only locally, especially over the east Atlantic. Nevertheless, it was the coolest summer in Ireland since 2002, although summer mean temperatures were slightly higher than normal. Only two summer days (Tmax >= 25°C) were recorded in Ireland (10-11 June).

Autumn 2007 set an end to the series of long warmer-than-normal periods in large parts of central, southern, southeastern and also some of eastern Europe – it was the only season in 2007 in this area which was colder than normal, although the difference was slight. Even the eastern provinces of Spain were under the influence of cold air advection. However, only in some parts of eastern and southeastern Europe (e.g. the Baltic countries, Austria, Croatia) the seasonal mean anomalies were below -1°C and thus significant. It was the coldest autumn for nearly 20 years (since 1988) in Hungary.

On the other hand, autumn 2007 was significantly warm over the central North Atlantic with mean anomalies of up to +2°C (or more), and warm over most of northern, western and parts of eastern Europe, and in the Middle East. September and October were more than +2°C warmer than normal in Armenia, which can be put down to two strong heat waves on 4-9 September and 14-17 October.

Precipitation

Wet and dry periods changed frequently depending on the seasons. Whereas northern Europe was wet especially in winter and partly also in spring, western and central Europe had a very wet summer, and eastern and southeastern Europe a wet autumn.

Winter 2006/07 was very wet in the northern half of Europe and very dry in the southern half of the Region. It was the wettest ever recorded winter in Denmark and the second wettest in Latvia. Locally, seasonal totals exceeded 300% of the normal in Norway and 200% in some other parts, e.g. Poland. Less than 40% of the seasonal precipitation fell in parts of southern Spain, Greece and the Middle East.

Due to the mild and mostly dry winter in the Alps, snow was quite rare there (Fig. 0.25). Further southeast, there was not a single day with snow cover in some places in Serbia (Vojvodina); as opposed to a normal of 30 days. In Scandinavia, due to higher-than-normal winter temperatures, only the northern parts and the highlands had a persistent snow cover during the whole winter season and more snow than normal. In many parts of the southern half of northeastern Europe a persistent snow cover occurred only in February. Lower parts of southern Norway reported much less snow than normal.

Spring 2007 continued to be wet in most of Scandinavia and northern Russia, locally with over 200% of the normal seasonal precipitation; only central Sweden remained quite dry. Most of western and central Europe received a near-normal seasonal precipitation total: a very dry April was compensated by a very wet May. Most of eastern Europe, however, was very dry and also some areas south of the Alps and in the Middle East.

In the Netherlands, little or no precipitation fell during the period from 22 March to 6 May, making it the driest period in at least 100 years. In Uccle (Belgium), no rainfall occurred from 31 March to 7 May, which is there the longest ever recorded period without rainfall in spring.

In northeast Spain the seasonal totals were quite high due to heavy rain events from the end of March until the beginning of April. These heavy rainfalls, combined with snow melt caused flooding and severe damage to agriculture.

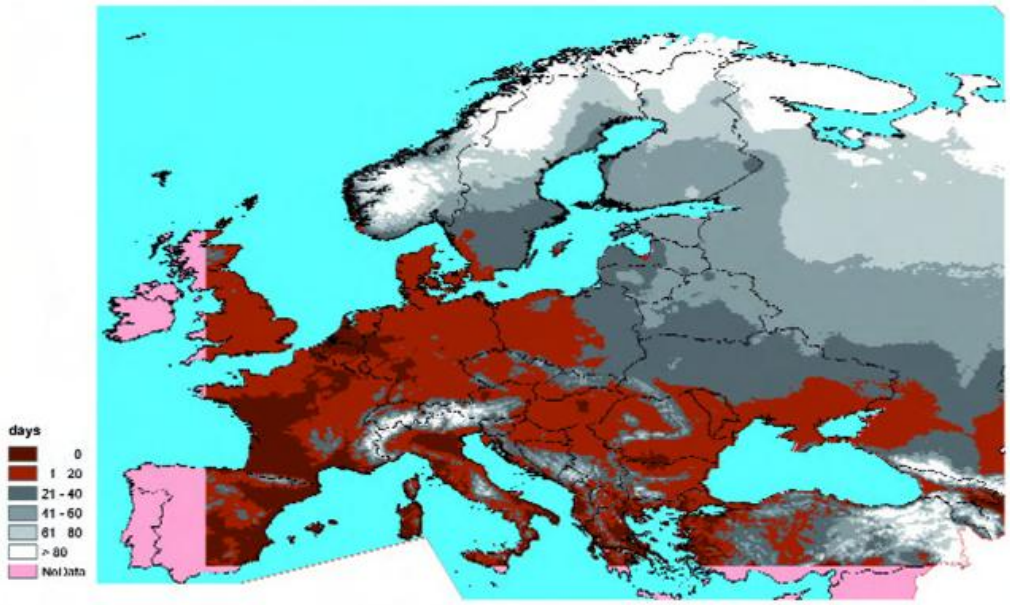

Fig. 0.25: *Number of snow days in Europe in winter 2006/07. NoData areas: no station observations available beyond the western and southern border lines for the whole winter. Source: Deutscher Wetterdienst, Germany*

Summer 2007 was very wet in most of western and central Europe with up to 200-300% of the seasonal precipitation in Ireland, parts of the United Kingdom and northern France. This was mostly due to thunderstorms and heavy rainfall, causing severe flooding. In Ireland, Kilkenny and Dublin Casement Aerodrome had their wettest summer since rainfall records began in the 1950s, while England and Wales had their wettest summer for over 90 years. 33 successive rain days (with at least 0.2 mm daily rainfall) were recorded in Dublin between 11 June and 29 July. Portugal saw its rainiest summer of the 21st century.

In northern Europe, there were wet as well as dry areas to be found. In Iceland, an extended period of warm and dry weather in June and July caused local water shortages, and the southeastern region of the country had its driest summer since 1873. This unusual dry spell was followed by an exceptional wet period beginning in the second half of August. Large regional precipitation occurred in Finland during the summer season, with some of the southeastern part of the country receiving precipitation amounts of 383 mm, which is 50% more than usual. Sweden was very dry in the north, but wet in the south. Several stations in southernmost Sweden recorded the rainiest summer ever. Parts of eastern Norway received 175-200% of the seasonal normal. Summer 2007 was the third rainiest summer in Denmark: only the first two weeks in June were dry, the rest of the summer was very wet with local floodings. It was also very wet around the southern Baltic Sea. Another zone of high precipitation can be found in northern Russia.

The Alpine region experienced unusually heavy thunderstorms with hailstones up to tennis ball size. Zurich (Switzerland) had its 4th wettest summer since measurements began in 1864. In some other parts of Switzerland this summer was the wettest ever recorded.

In contrast, it was drier than normal in southeastern Europe, around the Mediterranean and the Black Sea. Several sectors of eastern Iberia received less than 40% of the seasonal average. The southern Adriatic region was affected by severe drought in July and August with precipitation totals less than 60% of the normal. Only 15 mm of precipitation fell in Dubrovnik

(Croatia) during the whole summer season, making it the driest summer there since 1961. In the Middle East, parts of Syria, Lebanon and Cyprus received less than 50% of the normal rainfall. The Ukraine experienced the severest drought in summer for 100 years.

Autumn 2007 was very dry in western Europe, as opposed to the preceding summer. It was the driest autumn for more than 30 years in many places in Ireland and the driest autumn of the 21st century in Portugal. Southern Scandinavia and northern Russia were dry, too.

Central, southeastern and parts of eastern Europe, parts of the Mediterranean and southern Italy, however, had a large excess of precipitation. Autumn precipitation totals exceeded 200% of the normal e.g. in eastern Austria and parts of Serbia. Autumn floods were reported from many places in Romania.

Monthly Surveys

January

- **Mildest January on record in many European countries**
- **Eastern Europe extremely mild**
- **Wet in the north and east, dry in the south and west**
- **Heavy storms in the northern half of Europe**

Atmospheric circulation characteristics

Many Atlantic low pressure systems passed over the Region, most notably over northern, central and eastern Europe, within a strong westerly, very mild airflow, with some of them developing into heavy storms. In contrast, the southern and southwestern parts of the Region were under high pressure influence during most of the month. Only occasionally some low pressure systems moved further south over the eastern Mediterranean. Towards the end of the month, a strong high pressure system formed over the East Atlantic and colder air masses from the north reached Europe, causing frequent snowfall.

Temperature

The year 2007 started with a very mild January over of almost all Europe (Fig. 1.1). Especially the first 20 days of the month were very mild. The highest monthly anomalies were recorded in the east and reached over +10°C in parts of Russia and Kazakhstan (Fig. 1.2). The monthly mean temperature in Uralsk (western Kazakhstan), for example, was -11.7°C, compared to a normal of -22.4°C.

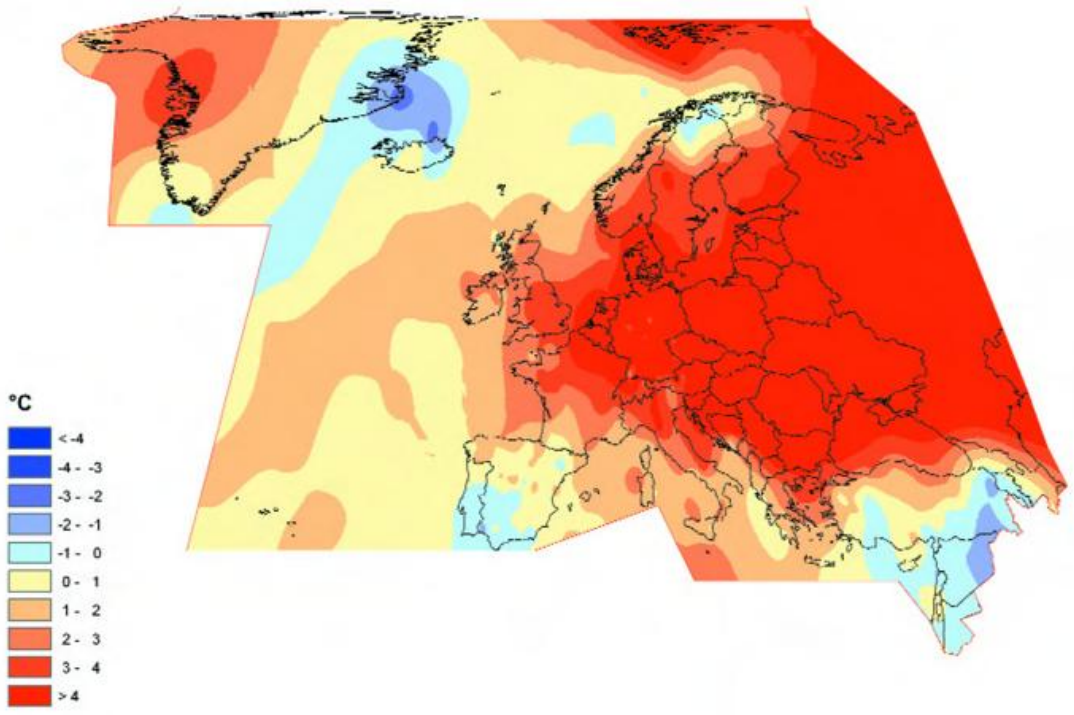

Fig. 1.1: *Monthly mean temperature anomalies in January 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

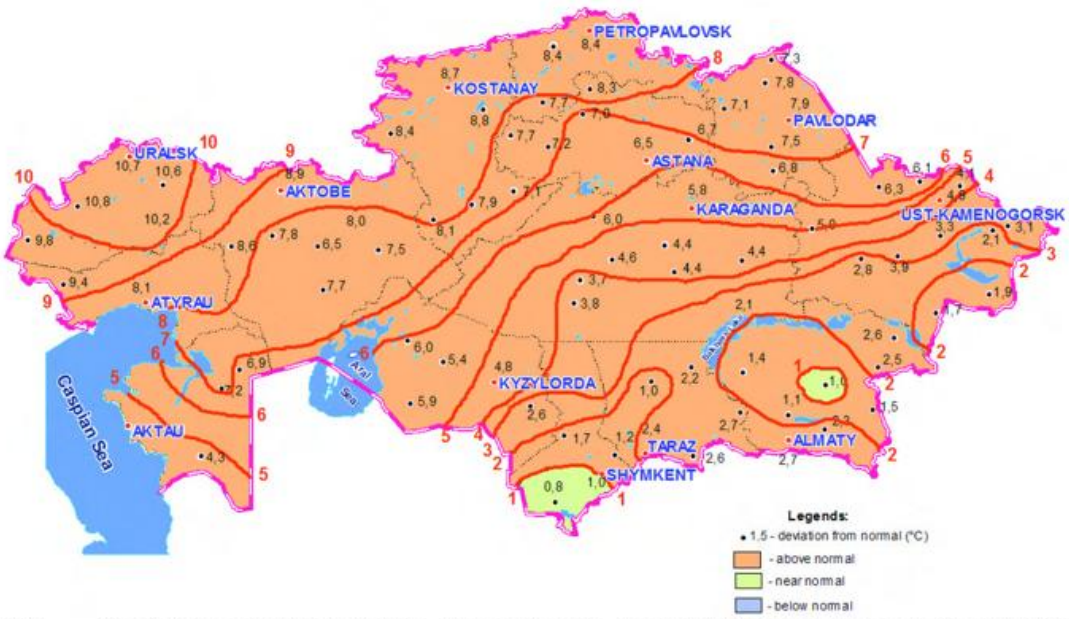

Fig. 1.2: *Monthly mean temperature anomalies in January 2007 (reference period 1961-1990) in Kazakhstan.*
Source: Kazhydromet, Kazakhstan

In central Europe, the month was around +5°C warmer than normal, in some parts of Italy partly around +4°C. Further to the east, the anomalies were, on average, +6-8°C e.g. in Lithuania, Poland, Belarus, eastern Austria and Slovenia, Hungary, north-eastern Croatia, northern Serbia, Romania (Fig. 1.3), Bulgaria, Ukraine and European Russia (Fig. 1.4). The period 7-24 January was the warmest period in Romania when daily deviations topped +10°C. Macedonia, experienced a similar period, but later in the month (19-26 January). The station Zavizan in the Velebit mountains in western Croatia (1594 m altitude) saw a monthly January mean above 0°C for the first time since 1954 (Fig. 1.5). Even the water surfaces were remarkably warm. Particularly the North Sea and the Baltic Sea were 3-4°C warmer than normal near the coasts of central Europe.

Source: Meteorological and Hydrological Service of Croatia

Many European countries had their mildest January on record on national average (on global average it was also the mildest ever recorded!) or at least at some stations, as e.g. in the Benelux region, France, Germany, Switzerland, Austria, Italy, Hungary, Serbia, Romania, Belarus, European Russia, Malta. The United Kingdom experienced the mildest January since 1916 (mean temperature 6.7°C, anomaly +3.4°C). Jan Mayen in the Arctic and some coastal stations in southern Norway registered new records for maximum temperature in January. No air frost occurred at most coastal stations of Ireland. The coastal station Hallands Väderö in Sweden reported the first frost of the season not until 22 January, which is the latest date ever reported by a Swedish station. German lowlands partly did not see any ice days (days with maximum temperature below 0°C). Moscow in European Russia reported with -1.6°C a new record of monthly mean January temperature in at least 130 years. Poland had a monthly maximum temperature of 15.8°C. Italian farmers were in alarm because of the early flowering of many species of fruit trees. Daily maximum temperatures above 20°C were recorded at several stations in Italy and also in Malta. People went swimming in the sea in southern Italy. A series of 22 consecutive days with maximum temperature anomalies over +5°C were registered in Serbia (Fig. 1.6).

Only the last week of January was characterised by a sudden drop of temperature in northeastern Europe and later also in parts of central Europe. On 23 January, the maximum and minimum temperatures in Estonia decreased by 10°C within two days. It was only towards the end of January that ice began to form in all sea areas around Scandinavia. In Germany, minimum temperatures dropped to less than -15°C on 26 January locally even in the lowlands.

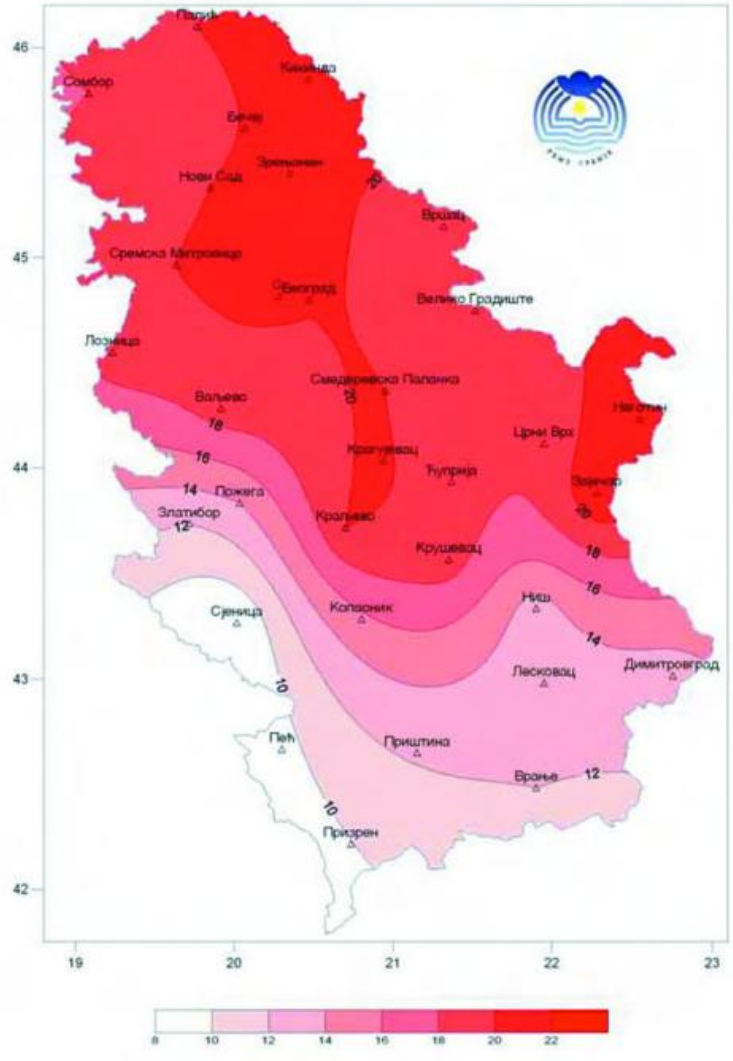

Fig. 1.6: *Highest number of consecutive days with monthly mean temperature anomalies above +5°C (reference period 1961-1990) in January 2007 in Serbia. Source: Republic Hydrometeorological Service of Serbia*

Some slightly negative monthly anomalies were recorded in parts of eastern Greenland, Iceland and its surroundings in the North Atlantic, northern continental Scandinavia, the southwestern Iberian Peninsula and the Middle East. Extremely cold conditions were reported from the Ararat Valley in Armenia where persistent below-normal temperatures were recorded throughout the whole month and the mean monthly temperature was 6-7°C below the 1961-1990 normal. Minimum temperatures reached -24 to -26°C in some parts of the valley, thus breaking the daily minimum records. In contrast, maximum temperatures up to +22°C were measured in the lowlands of Azerbaijan and Georgia, and also in the Lebanon.

Precipitation

Northern, central and eastern Europe were generally very wet, with the precipitation in many places amounting to 200-300% of the normal monthly totals, locally even more e.g. in Estonia, Poland, whereas western and particularly southern parts of the Region were very dry (Fig. 1.7). The areas of high precipitation partly report some heavy rainfall events due to several winter storms moving from the North Sea to eastern Europe. These heavy rainfalls also caused local flooding in the areas concerned.

At some locations, January 2007 was record breaking wet, e.g. in West Scotland (since 1993), at some stations in Norway and Denmark, and in Belarus. All Baltic countries received on average a monthly precipitation total of at least 100 mm. Latvia had its highest monthly average January total in the last 84 years. With such conditions in January, flash floods occurred, which is unusual for winter time. Latvian river levels rose by 1 to 3.6 m. The Daugava, Latvia's largest river by basin area, had the largest January runoff ever recorded.

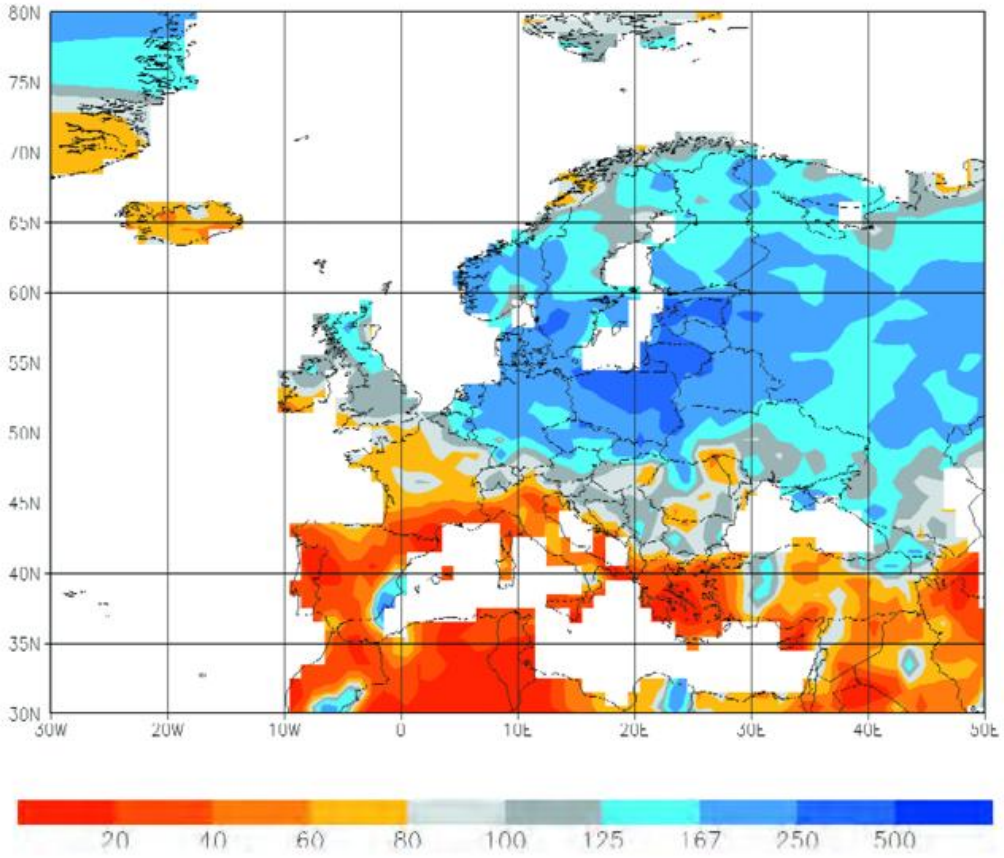

Fig. 1.7: *Monthly precipitation amounts for January 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

In contrast, the south and the west of the Region were generally dry. Some stations in Greece registered drought conditions with less than 10% of the normal precipitation. Malta saw its second driest January (behind 1983) in the past 84 years. With only five rain days and a mere total of 8.6 mm (long-term average is 95.5 mm), rainfall in Malta was in sharp contrast with last year's when January was the second wettest ever recorded.

In the Middle East, monthly rainfall totals were below normal in Israel and the Lebanon. However, several heavy local floodings were reported from the Lebanon after up to 73 mm rainfall within 12 hours.

Snow

Due to high precipitation, higher mountain areas in southern Norway and parts of northern Norway had considerably more snow than normal. As a result of the mild weather conditions, however, southern and central parts of Finland had no snow cover until mid-January. In German lowlands, a snow cover appeared only shortly if ever. In Austria, large amounts of fresh fallen snow were reported only from east Tyrol and upper Carinthia. Elsewhere in the country precipitation mostly fell as rain, or snow melted instantaneously. In most parts of southeastern countries, e.g. Slovenia and Serbia, particularly in the valleys, the number of days with snow cover was also considerably less than the normal average.

Significant weather events

January 01-06:	Heavy snowfall and avalanches in the high mountains in France (Alps), Switzerland, Liechtenstein, Austria, northern Italy
January 03:	Sea storm along the coasts of Italy with strong north-westerly winds up to 100 km/h and heavy rainfall over southern parts of the country. Later, storms and heavy rain were also reported from Turkey and the Ukraine.
January 09-10:	New January maximum temperature records for most of Latvia and Lithuania (9-13°C)
January 10:	Severe storm with heavy rain and flash floods in Russia (St. Petersburg)
January 11:	Daily maximum January temperature record in Moscow (8.6°C) in at least 130 years
January 11-12:	Storm in western, central and eastern Europe with gusts up to more than 180 km/h and torrential rain
January 14-16:	Storm in northern Europe (Norway, Sweden, Latvia, Lithuania, Belarus) with gusts up to 170 km/h
January 15:	Due to lack of snow over the Alps, water level of rivers in northern Italy reached historical low levels.
January 17-19:	Storm with gusts over 200 km/h in the mountains and over 140 km/h in the lowlands, heavy rain and widespread damage in western, central and eastern Europe and in the Alps (storm "Kyrill"). In Germany this was the strongest storm since Christmas 1999 (storm "Lothar"). Globally it ranks on place 13 of most expensive natural catastrophes since 1989 (MunichRe 2007). A daily precipitation total of 90 mm was measured on the Brocken (Harz, Germany) on 18 January.
January 19-21:	Record high maximum temperatures over 20°C in Austria, Switzerland and northern Italy resulted from a north foehn situation in the aftermath

of storm Kyrill on January 17-19. This had strong impact on skiing sites in northern Italy (Fig. 1.8). In eastern Austria, night temperatures up to 17-20°C during some hours

January 20: About 5,000 people had to be evacuated in northeast Israel due to a snowstorm.

January 20: Salt (central Jordan) recorded 68.2 mm of precipitation in 24 hours.

January 22-24: Rapidly increasing snow cover of 10-30 cm and more within some hours in France, southern and southeastern Germany and Switzerland after a short, but intense snow storm, combined with cold airflow from the north

January 24-30: Severe storms in Bulgaria and Turkey with heavy rain, thunder and hail. The ports of Burgas and Varna in Bulgaria were closed. Local disruption of electricity supply. On 28 January, widespread gusts up to about 90 km/h in Greece. Storm and heavy precipitation also in west Georgia

January 25: Daily maximum temperature of 22°C at Baku, capital of Azerbaijan

January 28: Snowfall in coastal and low latitude regions of Portugal for the second consecutive year. Such kind of phenomena is very rare in these places.

Fig. 1.8: *Ski slopes at Corno alle Scale (Italy, central part of the Apennines). Left: on a "normal" winter, right: on 19 January 2007 Source: ARPA-SIM, Emilia-Romagna, Italy*

February

- **Mostly mild, but very cold in northeastern Europe**
- **Mainly wet in western, central and eastern Europe, other areas partly very dry**

Atmospheric circulation characteristics

At the beginning of the month, an extended high pressure system persisted over northwestern and western Europe, leading cold air at its east flank to most of the continent, but only for a few days. Later, the cyclonic systems passed over western, central and eastern Europe, very frequently in a mainly mild airflow, whereas northern Europe and the Arctic region were often under high pressure influence. Some cold troughs moved over northeastern Europe, with forming a large cold high pressure system there, especially in the second half of the month. In the Mediterranean, low pressure systems were mostly quite weak und occurred only occasionally. Particularly the western Mediterranean was often under high pressure influence within a warm air mass, especially at the end of the month.

Temperature

February 2007 was again a very mild winter month in most of Europe (except the northeast), over the Atlantic, in the Arctic region and most parts of the Middle East (Fig. 2.1), despite a cold spell during the first decade in many parts of the Region. The highest monthly mean anomalies were recorded in western Greenland and Spitsbergen with over +6°C. Large areas of central Europe and parts of west Kazakhstan had anomalies of over +3°C, in some areas in southeastern Europe (e.g. northeast Croatia, western Romania) amounting to even around +5°C.

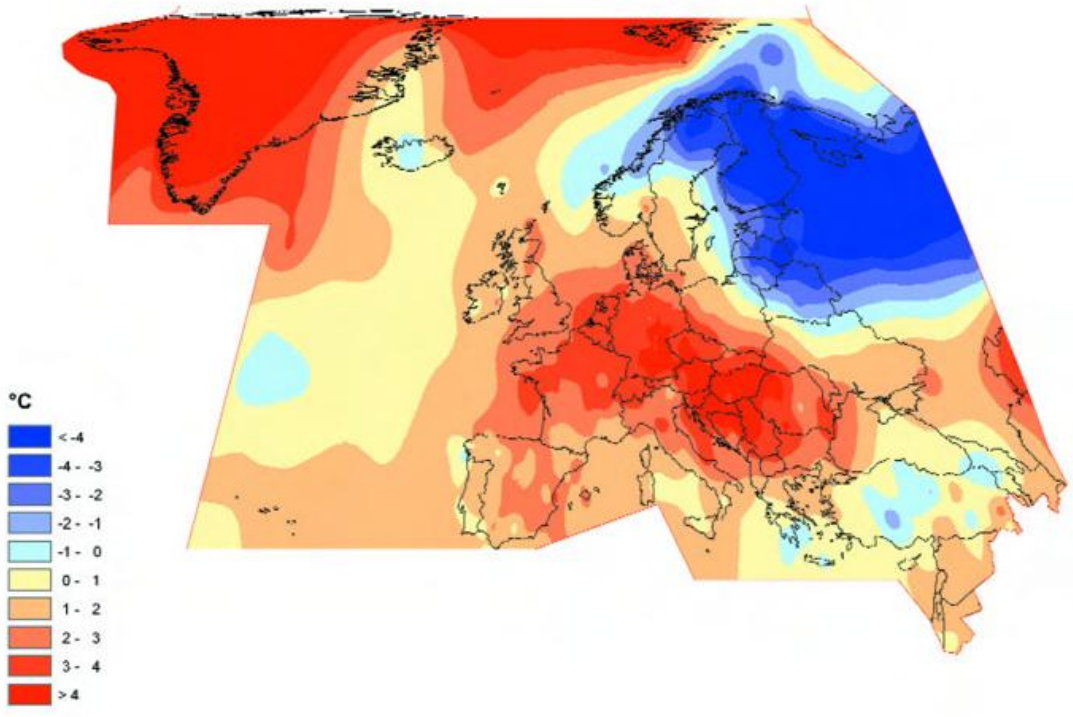

Fig. 2.1: *Monthly mean temperature anomalies in February 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Slovenia reported the warmest February ever at the coast and the second warmest in some other places inland. The frequency of frost in central Europe was low, with only 4 air frost days and no ice days having been counted at the airport in Luxemburg (the normal 1971-2000 is 18 frost days and 4 ice days). In the south, it was warm especially at the end of the month: temperatures of 20-25°C were measured in southern Italy and eastern Sardinia, and also near the eastern Mediterranean in Turkey and the Lebanon (normal maximum temperatures in February at the coast of the Lebanon are around 17°C). February in Malta had the highest average daytime temperature (16.8°C) in the past 9 years. The month was also particularly warm throughout Iberia, making it the 4th warmest February in Spain.

Armenia had slightly above-normal monthly mean temperatures, but two cold spells on 1-4 February and 26-29 February with minimum temperatures down to -30°C in the northwest of the country.

On the other hand, north-eastern Europe was very cold on the monthly average with monthly mean anomalies down to -8°C in northern European Russia and below -5°C in northern Norway and Sweden, parts of Finland and the Baltic countries. Following two very mild months, this was the first typical winter month in this season in that area. Especially the first part of February was cold. European Russia had a cold spell on 5-11 February with mean (!) daily temperatures below -30°C in the north of Karelia. The Finnish station Salla registered a minimum temperature of -39.9°C in early February. Northern Norway (especially the Finnmark region) recorded monthly mean anomalies below -5°C, with the lowest minimum temperature of -39.0°C having occurred on 13 February. The Baltic countries had monthly mean anomalies ranging from -1°C in the west to around -4°C in the east. Throughout the month there were two cold spells with minimum temperatures below -30°C in Latvia and northeastern Lithuania. Even in the Ukraine, minimum temperatures down to -26°C were reached. Monthly mean maximum temperatures were also low in northeastern Europe: in Estonia the average temperature was recorded at 4.3°C compared to a normal of 12.4°C.

Precipitation

With totals of more than twice the normal in many places, and even 300% of the normal over some smaller areas in the northern and southern parts (Fig. 2.2), western, central and eastern Europe were very wet. Southeastern and central southern England had the wettest February since 1990. In large areas of northeastern Europe, where it was cold, a persistent snow cover finally occurred after the mild winter months, whereas especially in central and southeastern Europe snow was rare or restricted to the mountains.

Other areas were quite dry, especially in various parts of northern Europe, the western Alps, southern Spain, Malta (less than a third of the long-term average), the Aegean, and around the Black Sea. In central parts of Armenia, only 25-40% of the normal precipitation were recorded. Other countries in the Middle East partly received heavy precipitation throughout the month, especially the areas near the eastern Mediterranean. Lebanon was very wet in its coastal and interior parts, but precipitation was below normal in the high mountains.

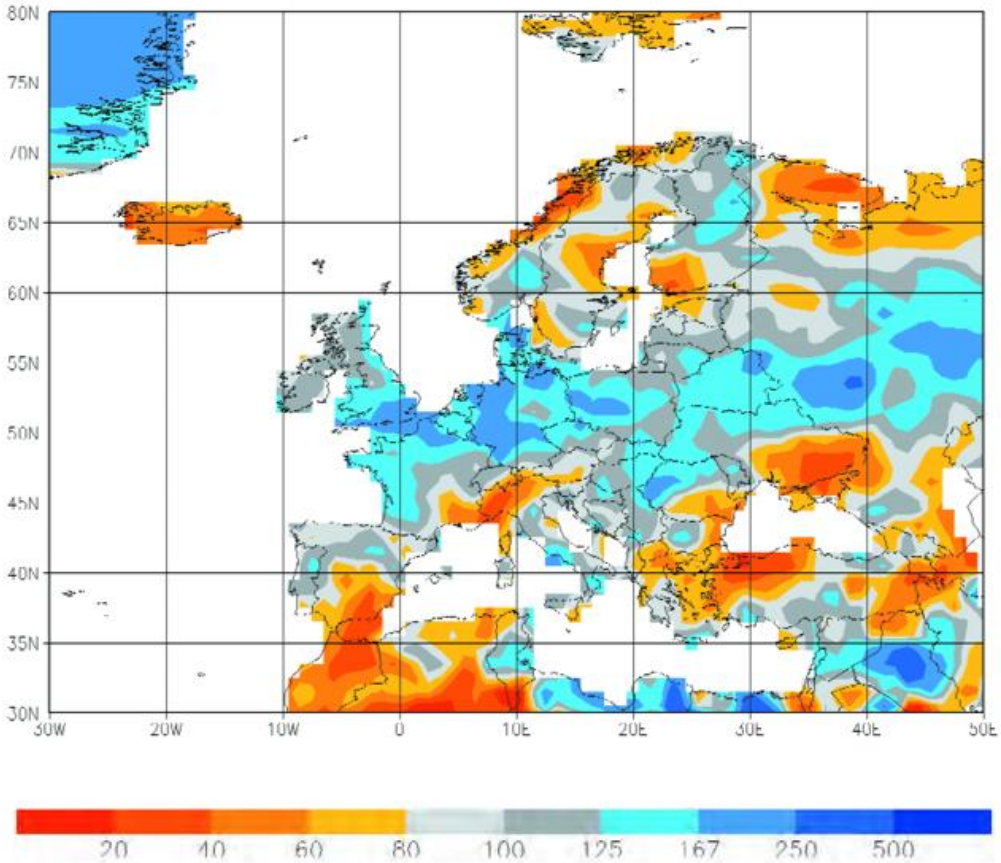

Fig. 2.2: *Monthly precipitation amounts for February 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

February 01-02:	Thunderstorm with heavy rain, flash floods, landslides in Switzerland
February 01:	Wind speeds up to 108 km/h in northern Bulgaria in a foehn situation
February 01-02:	Heavy snow and avalanches in Georgia
February 02-07:	Snowstorm in Turkey: up to 2 m snowfall, roads blocked, more than 1,000 villages cut off
February 03:	Storm in Greece with gusts up to 110 km/h
February 08-11:	Snowfall and freezing rain in Germany, numerous traffic disruptions
February 11:	Small tornado in eastern France (Lorraine, Vosges), roofs damaged, power supply cut off
February 13:	Heavy storm with gusts up to 115 km/h in Monaco in the early morning
February 21-24:	Snowstorm in northern Europe (southern Norway, southern Sweden, Denmark). Roof of supermarket, sport halls damaged, highway blocked. Freezing rain in northeastern Germany caused severe traffic problems.
February 22-25:	Severe storms caused by a cold front in east Romania (with snow), southeast Bulgaria, Georgia, Azerbaijan, western Kazakhstan, with gusts over 145 km/h, houses damaged
February 24:	Storm with strong gusts in Switzerland

March

- **Warm nearly everywhere, especially in the Arctic and eastern Europe**
- **Very irregular precipitation distribution**

Atmospheric circulation characteristics

A mild westerly airflow with frequent low pressure systems passing from the Atlantic to western and central Europe continued into the beginning of March 2007. In eastern Europe, a blocking high prevented further eastward propagation of these frontal systems. Instead, eastern Europe was influenced by a southerly flow of warm air at the west flank of this blocking high. At the beginning of the second decade of the month, the main frontal zone shifted northwards to northern Europe, and a large high pressure zone extended over western and central Europe. In the second half of the month, the large-scale circulation changed again considerably, this time from a zonal to a strong meridional pattern. A large trough extended from the north over central Europe to the south. At the end of the month, a large cut-off low formed over central Europe and the western Mediterranean, while a high pressure system set up over northern Europe, resulting in an easterly flow over central Europe.

The Arctic region remained frequently under low pressure influence.

The southern parts of the Region, especially the southwest, were most of the time under the influence of high pressure systems, except a few temporary cut-off lows affecting the western Mediterranean.

Temperature

March 2007 was warmer than normal nearly everywhere in the Region except for a few places over the North Atlantic, on the Iberian Peninsula, in France, eastern Turkey, northern Syria and Jordan (Fig. 3.1). The highest anomalies were recorded in the Arctic region and Russia, reaching more than +7°C, which is in sharp contrast to the preceding month of February in the latter area. In Finland, the Baltic countries, Belarus and the northern Ukraine, the monthly mean anomalies exceeded +5°C on areal average. Especially the last decade of the month was very warm, leading to a start of the vegetation period 20-25 days earlier than normal in these countries. Tartu in Estonia set a new monthly mean March temperature record of 4.5°C (normal: -2.1°C). In some countries March 2007 was the warmest ever recorded, e.g. in many parts of Norway (including Svalbard), Finland, Latvia, Belarus and European Russia. There were also new records for March maximum temperature in many places in this area, e.g. in Helsinki 17.5°C on 27 March.

In central Europe the anomalies ranged between +1°C and +4°C, with, however, a cold spell affecting particularly the areas around the Alps starting on 19 March (see significant weather events below).

The southern parts of the Region were only slightly warmer than normal, due to variable weather conditions throughout the month. In Georgia, Armenia and Azerbaijan, especially the first decade of the month was warm; the maximum temperature reached up to 21°C in the south of Armenia and 24°C in Georgia. However, very low temperatures were reported afterwards, with minima between -18 and -19°C in the high mountains of Armenia above 2000 m altitude on 20-21 March. Georgia had minimum temperatures below zero even in the lowlands and on the coast; this was also the minimum at the annual scale.

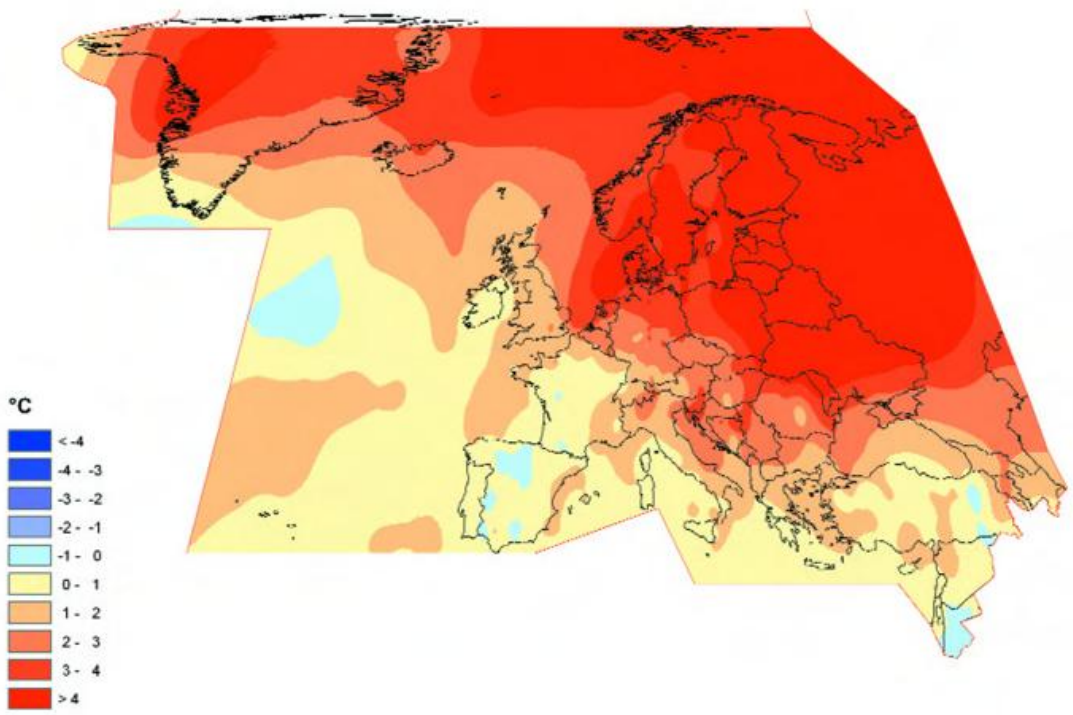

Fig. 3.1: *Monthly mean temperature anomalies in March 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Precipitation

As the circulation pattern changed several times over the month, wet and dry areas were distributed very irregularly throughout the Region (Fig. 3.2). It was considerably wetter than normal particularly in the Arctic region, the southern west coast of Norway, parts of northeastern Europe, large parts of eastern central Europe, some parts of Slovenia, Croatia and Serbia, near the Black Sea and over/near the western Mediterranean, partly with more than twice the normal precipitation. In some places in Italy (particularly in Sicily, e.g. Palermo), monthly totals of more than 200 mm were registered, and some historical records broken. Žabljak in northeastern Montenegro recorded its second highest monthly precipitation total (171 mm) and its highest ever measured daily total (83 mm) in March since 1958 (Fig. 3.3).

In the east of the Region, up to 17 rainy days were counted in west Georgia. Central parts of Armenia received almost twice the monthly normal precipitation.

Large dry areas were to be found over central Scandinavia, eastern Europe and west Kazakhstan (due to prevailing anticyclones in the second half of the month), the western Iberian Peninsula, southern France / northwestern Italy and the eastern Mediterranean.

Significant weather events

March 04-06: Severe storm, tornado, heavy rain and flooding in the southern and eastern United Kingdom, houses and roads damaged/flooded, train derailed

March 06-07: Severe storm and landslides in Turkey. Settlements damaged, trees broken

March 07-08: Severe storms in Spain, gusts up to 110 km/h, heavy rain, forest fires, roofs damaged

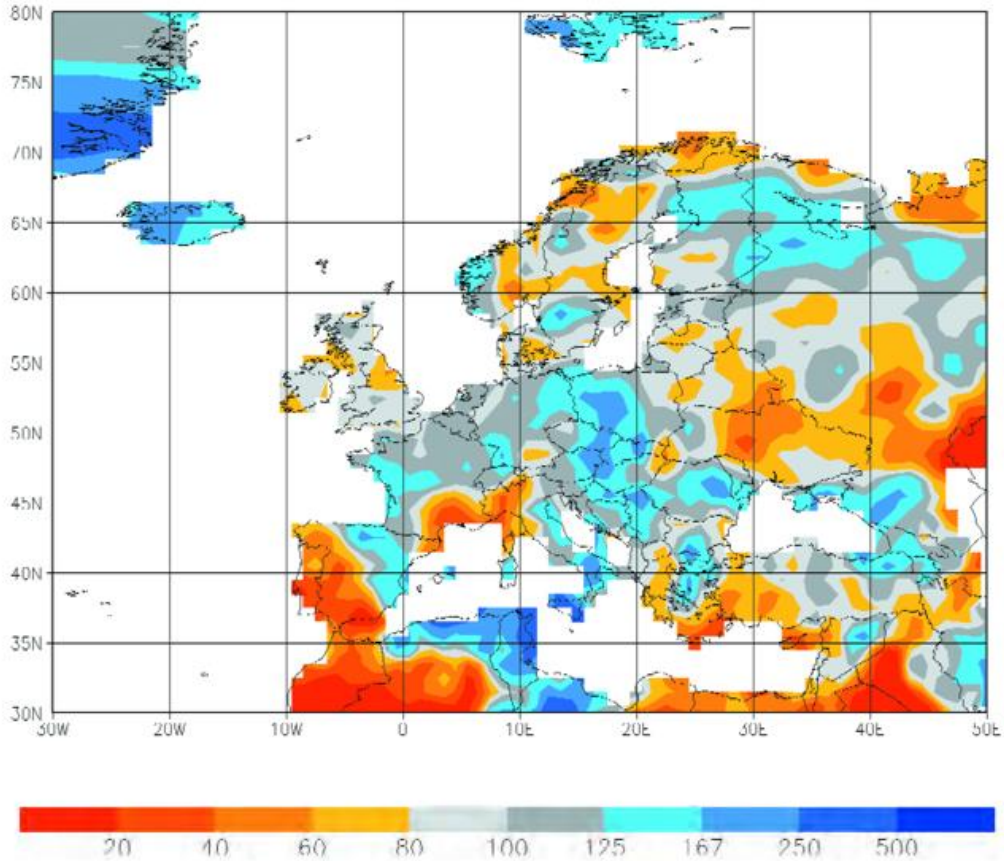

Fig. 3.2: *Monthly precipitation amounts for March 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

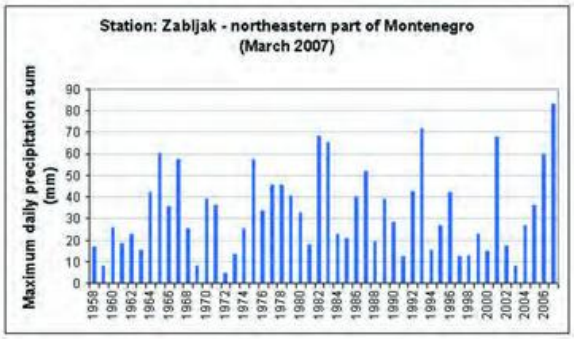

Fig. 3.3: *Maximum daily precipitation totals at the meteorological Station Žabljak (northeastern Montenegro) in March*
Source: Hydrometeorological Institute of Montenegro

March 12: Flash flood in Lithuania, Neman River burst its banks due to ice-drift, roads flooded, 130 people isolated

March 12: Low temperatures in south-central parts in Italy, snowfall in the mountains

March 13: A tornado and a severe hailstorm in Cyprus

March 15: Large amounts of rainfall in Israel with snowfall in the mountains

March 17: Floods in Latvia, ice jam, Daugava River burst its banks, houses flooded

March 18-19: Storm in northwestern Germany, snowfall, frost, high waves, camping grounds flooded, fish market in Hamburg flooded

March 19-21: Severe storm in England, hail and snow, high waves

March 19-24: Heavy snowfall in the Alpine region (Germany, Switzerland, Austria) due to the formation of a strong low over northern Italy. 50 cm of snow fell within a few hours in southern Austria, almost 30 cm in various towns of northern Switzerland; some areas of the northern Alps received 1 m. These days brought more snow to large parts of Austria than the whole preceding winter. Damage to trees and power lines. Strong snowfall also in northern and eastern parts of Germany. Even in the lowlands of Slovenia snow was falling. In Slovakia, highest ever measured snow depth of 402 cm on 24 March (and on 5 March as well)

March 20-25: Heavy rain, floods, strong gusts over >140 km/h in Romania, Bulgaria, Greece and Turkey. Houses, bridges, roads damaged. In Bulgaria, locally more than 80mm/24h of precipitation. In a ski resort in south Bulgaria, tourists were cut off due to fresh deep snow. In Turkey, roofs were damaged, a minaret of a mosque collapsed

March 23: In Armenia, heavy snowfall. Snow cover reached 80-90 cm in the high mountains at 2000-2500 m altitude

March 23: Sharav event (hot and dry weather spell) in Israel. Temperatures reached 27-28°C in the late evening at 21 UTC. It was the 3rd highest temperature at 21 UTC in Bet Dagan (coastal plain) since 1962 (Fig. 3.4).

March 25-31: Heavy rain and floods in Spain, Ebro River overflowed, losses to agriculture

March 26: Heavy hailstorm in Cyprus

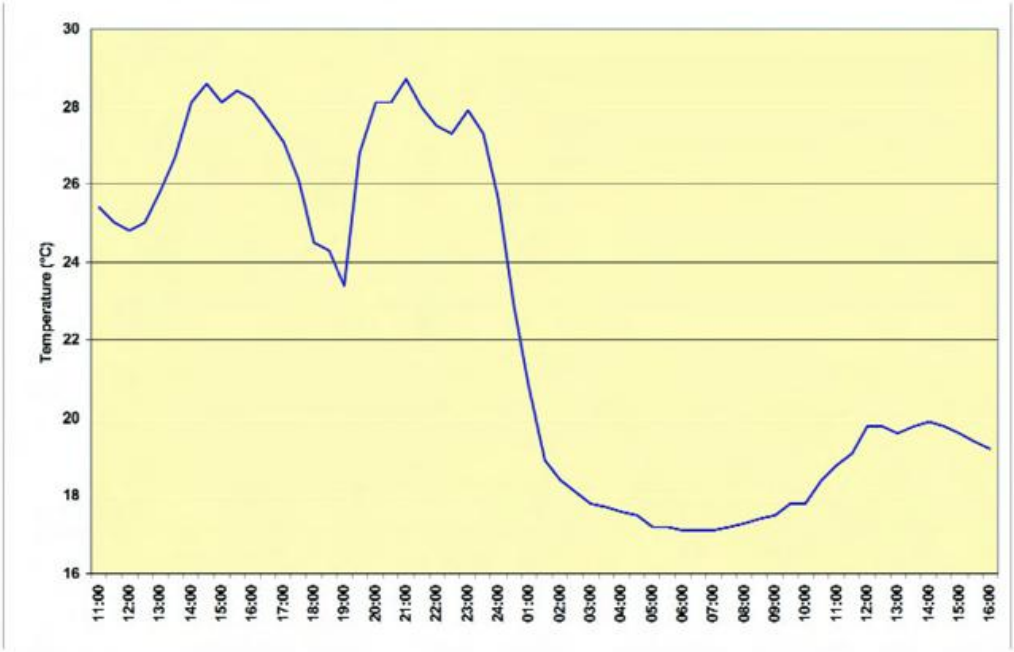

Fig. 3.4: *Temperature at Bet Dagan (central coastal plain in Israel) during and after a Sharav event on 23-24 March 2007*
Source: Israel Meteorological Service

April

- **Warmest, driest and sunniest April ever recorded in many countries in western and central Europe**
- **Cold in the Middle East**

Atmospheric circulation characteristics

The main frontal zone was located very far in the north, almost in the Arctic region at the beginning of the month. Some strong low pressure systems affected Iceland, Svalbard, the western and northern coasts of Scandinavia and occasionally also Russia. South of this frontal zone, a high pressure zone extended over northern Europe, while a low pressure zone resided in the south.

During the first decade of the month, the frontal zone moved southwards to central Scandinavia and the centre of the anticyclone to northwestern and later to central Europe where it remained almost stationary. The high pressure influence extended to eastern Europe and even to the southeast as far as the eastern Mediterranean.

The North Atlantic was mainly under low pressure conditions, though with a warm airflow from the south.

At the end of the month, an omega pattern set up with high pressure over northern, western and central Europe and with low pressure over the North Atlantic and the east. Cold air advanced to the Middle East.

Temperature

April 2007 again was considerably warmer than normal in most of the Region, this time especially in western and central Europe with anomalies of + 4-6°C in many places (Fig. 4.1), locally even more. These anomalies were comparable to those of June 2003 e.g. for Zurich, Switzerland (Fig. 4.2); they were in the upper tail of the frequency distribution and thus are expected to occur very rarely.

Many locations in western and central Europe, but also up to the south in northeastern Spain, Italy and Slovenia, had by far their warmest and sunniest April ever recorded (e.g. France, Fig. 4.3). With a monthly mean of 11.2°C it was even the warmest in the long 349-year Central England Temperature time series. In De Bilt (Netherlands), the monthly average amounted to 13.1°C, the highest value since 1706.

Especially the second decade was exceptionally warm in central Europe. On April 13 or 14, the first summer day (daily maximum at least 25°C) was recorded in many places (e.g. Netherlands, Luxemburg, Czech Republic). In the Netherlands this had not happened so early in the year since 1901. With 29.8°C, 15 April was the warmest April day in De Bilt in 100 years. Maximum temperature of 28.7°C in Uccle (Belgium) was the highest since the start of the time series in 1833. Luxemburg airport reported 7 summer days, but no frost days (normally, April is without any summer days but has 4-5 frost days at this station). Germany had 14 summer days on average.

Even Iceland recorded the highest temperature ever measured in April: 23.0°C at the station Ásbyrgi in the northeast of the country. Several stations in Norway and Sweden (e.g. Stockholm, Malmö) registered their warmest April, too. The high temperatures led to a very early development of the vegetation.

Source: Deutscher Wetterdienst, Germany

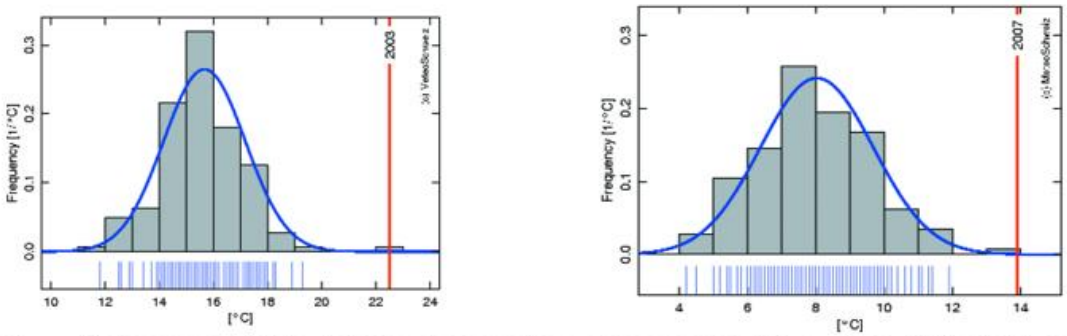

Fig. 4.2: *Comparison of the 2-meter temperature of record breaking June 2003 (left) and the extraordinary hot April 2007 (right), with the corresponding normal frequency distribution of April/June 1961-1990 in Zurich, Switzerland.*
Source: MeteoSwiss, Switzerland

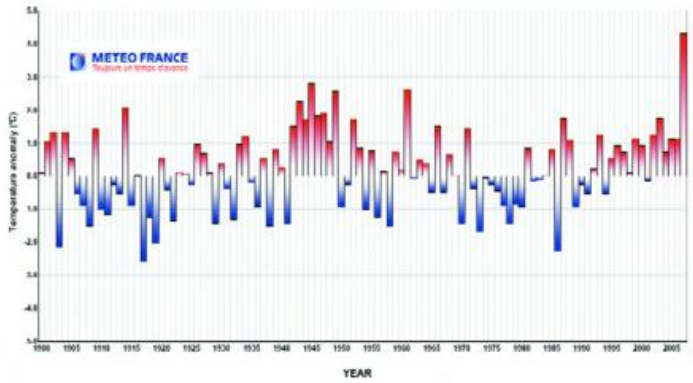

Fig. 4.3: *Monthly mean temperature anomalies in April 1900-2007 (reference period 1971-2000) in France.*
Source: Météo France, France

New records were also set for monthly mean April maximum temperatures. 20.5°C was the highest mean maximum in Belgium since 1901. 20-25°C were recorded in Lithuania at the end of the month. Also in Italy, monthly mean maximum temperatures of more than 20°C were reached in some places, e.g. in Verona, Trieste, Pisa and Rome, all breaking records since 1961. For Spain, a new national record for April maximum temperature was set at the station Oviedo in the north of the country (28.3°C).

On the other hand, it became considerably colder than normal in some eastern and south-eastern parts of the Region with anomalies down to -3°C in northern and eastern Turkey, Georgia and Azerbaijan. Frosts were reported from Armenia and Georgia during the first half of the month causing damage to plants, especially blooming trees. In Israel, however, April 2007 was characterised by a large number of Sharav events, the warmest on 7 April with temperatures reaching 35-37°C in the coastal plain and in the Negev.

In southern Greenland and a few places in southern Spain, the monthly mean temperature stayed slightly below the normal.

Precipitation

It was an unusually dry April in most of Europe. Especially large parts of central Europe and adjacent areas, even in southeastern Europe, received less than 20% of the normal precipitation (Fig. 4.4). Less than 3 mm fell during the whole month in many places, e.g. in southeast England, Luxemburg city, western Slovakia (Fig. 4.5), Hungary, Bosnia and Herzegovina, some locations in Greece, or even no precipitation at all (e.g. most of the Benelux region, some locations in northeast France, Germany, Switzerland, eastern Austria, Poland, Czech Republic and Serbia). These drought conditions were the reason for widespread significant soil moisture

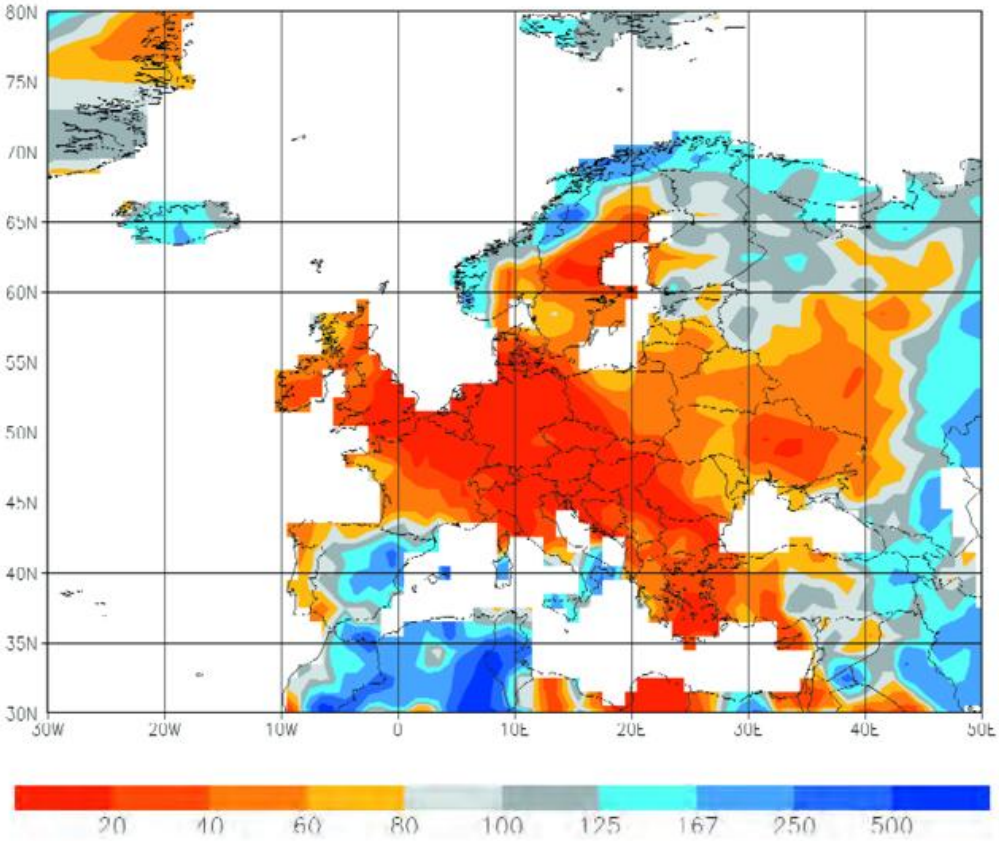

Fig. 4.4: *Monthly precipitation amounts for April 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

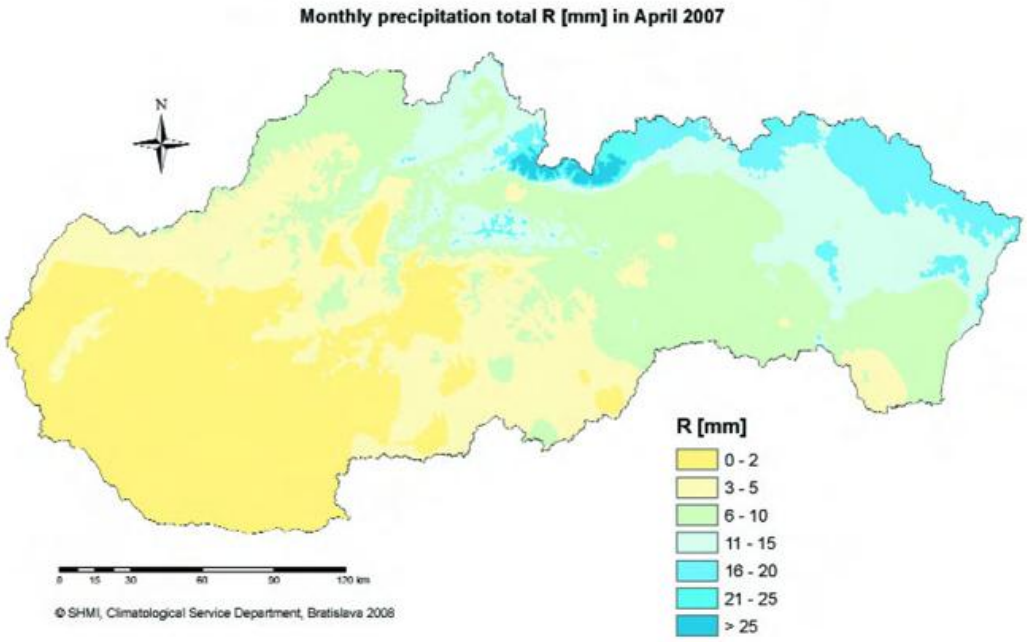

Fig. 4.5: *Monthly precipitation totals in April 2007 in Slovakia. Source: Slovak Hydrometeorological Institute*

deficits endangering winter and spring crops, and causing the outbreak of fires. In Ireland, only 2-6 wet days (daily precipitation total of at least 1 mm) were recorded, at Luxemburg airport even only 1 day with a local thunderstorm (normal is 11 days) occurred. Many other countries reported similar conditions.

Many stations in western, central and parts of southeastern Europe experienced their driest month on record. Germany had a monthly spatial average total of 4 mm (7% of the normal), making April 2007 the by far driest month in Germany since 1901 and in Hungary as well (Fig. 4.6). In Brussels (Uccle), such an April without rainfall had never occurred before (since 1833). 10 mm (15% of the 1961-1990 normal) of rainfall were recorded within the England-Wales precipitation series starting in 1766, making it the lowest April total since 1938.

Fig. 4.6: *Rank of years referring to the lowest monthly April precipitation totals in Hungary, period 1901-2007. April 2007 was by far the driest. Source: Hungarian Meteorological Service*

In most of northern and eastern Europe, April 2007 was not as dry as in western and central Europe, but even there the precipitation totals were only around 50% of the normal, or less, in many places.

Even Malta in the Mediterranean was very dry although, in contrast to central Europe, it was a very cloudy month there (Fig. 4.7, average sunshine duration 6 hours per day).

Wet areas were only recorded at the northern and western coasts in Scandinavia, in the easternmost parts of the Region and over/near the western Mediterranean, partly with more than twice the normal monthly precipitation total. Some stations in northern Norway received even 400% of their monthly total, thus even setting new monthly precipitation records in some cases. In west Georgia, only the first half of the month was rainy whereas the second half was dry.

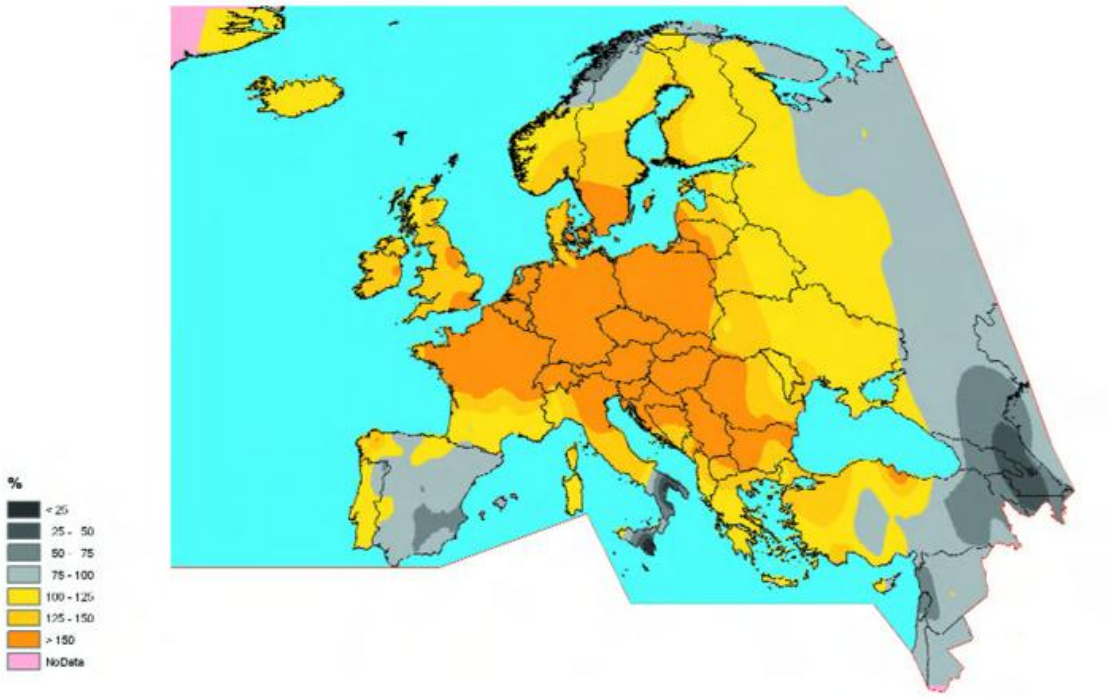

Fig. 4.7: *Mean monthly sunshine in April 2007 duration in per cent of the 1961-1990 normal in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Significant weather events

April 03-08: Heavy rain and flooding in northeast Spain

April 10-11: Gusts up to 103 km/h and high waves up to 13 m in the maritime Arctic (weather ship Polarfront)

April 13: Heavy rain in the central parts of the Negev desert in Israel and in Jordan. Highest rainfall amount in a 4-hour period since 1953 (38 mm) in Israel

April 15-25: Frequent frost events in various parts of Turkey. Flowers and fruits of trees damaged

April 16: Heavy rain (180 mm within a few hours) in Mallorca. Several houses, roads and parking lots flooded

April 23-25: Record high daily minimum temperatures at many stations in the United Kingdom, e.g. London (St. James Park) 14.5°C on 24/25 April

April 23: Water level of the Po River (northern Italy) reached its lowest record, causing problems for agriculture. Water level lowering of Lake Garda about 50 cm below normal

April 24-25: Heavy rainfall in Armenia (Yerevan and Ararat Valley), intensity up to 30mm/6h, flash flood of River Ksani in Georgia

April 28-29: Frost and snow in some places in Georgia

April 29-30: Heavy rain with hail particularly in central and eastern France. Roads, cars flooded, 300 evacuations

April 29-30: Heavy rain in Turkey and Syria

May

- **Warm in most of Europe and in the Middle East**
- **Very wet in northern, central and most of western Europe, dry in the east**

Atmospheric circulation characteristics

May 2007 began with a meridional circulation pattern over Europe with a large high pressure system over northern, western and central Europe, and low pressure west and east of it. However, the high pressure zone weakened rapidly and was replaced by a mainly westerly zonal airflow propagating from the Atlantic eastward. Thus, cyclonic activity with precipitation became frequent in western, central and northern Europe, while a blocking high persisted over European Russia. Towards the end of the month, some larger troughs moved from the Atlantic to Europe, sometimes extending to the Mediterranean.

In the south, the Iberian Peninsula and the western Mediterranean were temporarily under the influence of the Azores High, whereas the eastern half of the Mediterranean was mostly affected by some cyclonic activity.

Temperature

Mai 2007 was again quite a warm month in nearly the whole Region. The monthly mean anomalies were generally not as high as in April, but still reached +1-3°C in large areas of western, central, southern and eastern Europe and in the Middle East (Fig. 5.1), locally even more than +3°C.

Whereas the first decade of the month was quite cold in eastern Europe (frequent ground frosts in Poland and European Russia led to crop damage), it became especially hot at the end of the month in this area. In Russia, Belarus and the Baltic countries, heat waves at the end of the month led to daily maximum May temperatures above 30°C; historical records were nearly reached or exceeded. 3-8 days with such high temperatures were recorded in Belarus; this was very unusual for May in this country. Near the Black Sea in the lowlands of Georgia a

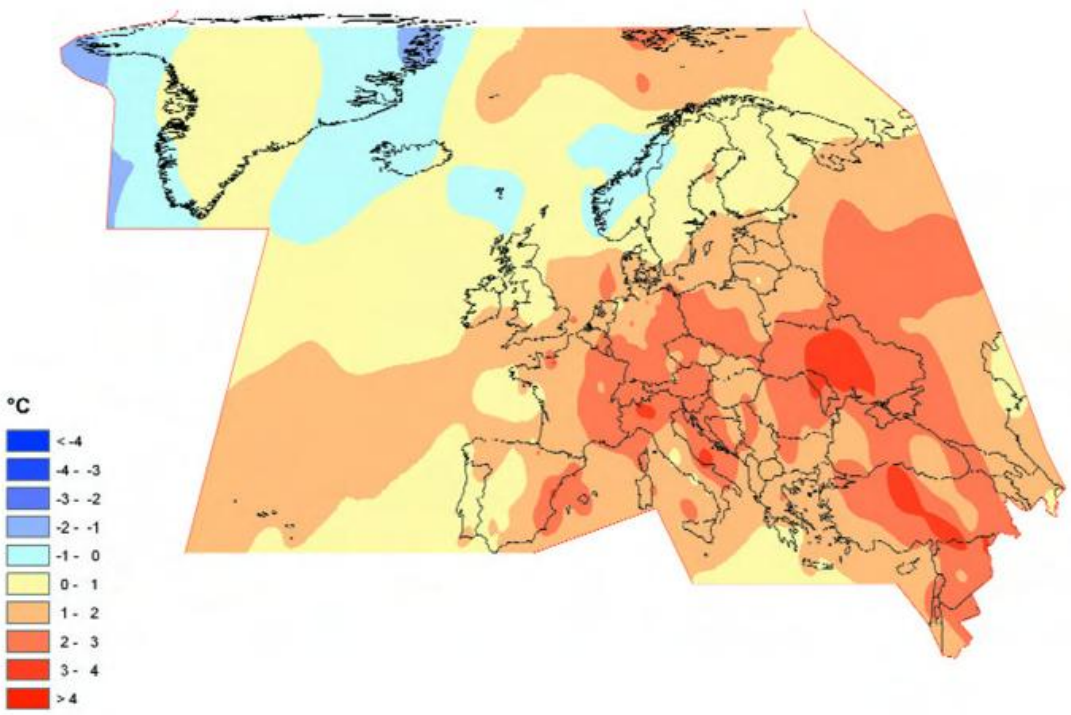

Fig. 5.1: *Monthly mean temperature anomalies in May 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

maximum of 34°C, in the southern parts of European Russia locally even up to 42°C were reached. Armenia, too, had record high maximum temperatures at the end of the month (23-27°C in the mountain regions, 33-35°C in the valleys). In the plains of Azerbaijan 34-39°C were reached, the highest May values in 100 years.

At the same time, a strong temperature decrease occurred over western and central Europe, although these areas had relatively high temperatures the weeks before. In southern Ireland, maxima above 25°C were reached on 17 May; the Czech Republic had its first tropical day in the year on 14 May.

May 2007 was also extremely hot in the entire Mediterranean coastal region, with several stations breaking monthly mean and maximum temperature records in Spain (e.g. Murcia, Alicante). Daily maxima of 30°C were also exceeded in several places in Italy (e.g. Verona 34.8°C, a new record), even on lower mountains (e.g. Monte Argentario, 632 m altitude).

Most of northern Europe was only slightly warmer than normal. Some places in the northwest (parts of Greenland, Iceland, some northern parts of the North Atlantic, west coast of Norway) were even colder than normal (anomalies down to -2°C).

Precipitation

It was very wet in large parts of northern, northeastern, western, central and southeastern Europe, and also in most parts around the Mediterranean, again with locally more than twice the normal total, in northern Scandinavia even three times (Fig. 5.2). May 2007 was the wettest on record in many places: Germany received 131 mm on spatial average (184% of the normal, making it the wettest May since 1901), De Bilt in the Netherlands 138 mm. This was really in sharp contrast to the preceding extremely dry April and filled up the soil water reservoirs in

central Europe which were dried out before. Many plants were thus saved from drought damage. But some of the high precipitation was due to various thunderstorms and hail events, particularly in the second half of the month, causing flooding events.

In contrast, most of the east of the Region was dry. Monthly precipitation totals in widespread parts of southern Ukraine, Georgia and Azerbaijan were below 40% of the normal, partly (e.g. in Romania around the Danube Delta) even below 25%. In the west, parts of Greenland, Iceland and Ireland as well as parts of the Iberian Peninsula experienced a notable precipitation deficit, too. Malta, too, was very dry – only 0.4 mm of precipitation (4% of the long-term average) fell at the international airport throughout the month.

Some countries in southern and southeastern Europe, i.e. most of central and southern Spain, Serbia and Bulgaria, were very wet particularly in the second half of the month due to frequent thunderstorms with heavy rain, partly with hail, which also caused damage to agricultural crops.

Some smaller areas with high precipitation were also to be found near the eastern Mediterranean, e.g. in Greece, Cyprus and Israel, due to an above-normal thunderstorm activity with heavy flood-causing rain events. Cyprus received 68 mm of precipitation on country average, which is nearly 350% of the normal for May. Monthly totals in Israel amounted to 20-50 mm in the inner parts of the country; this is a multiple of the long-term average of less than 5-10 mm for May. Israel and also Lebanon saw more than twice the normal number of rainfall days in many parts of the countries.

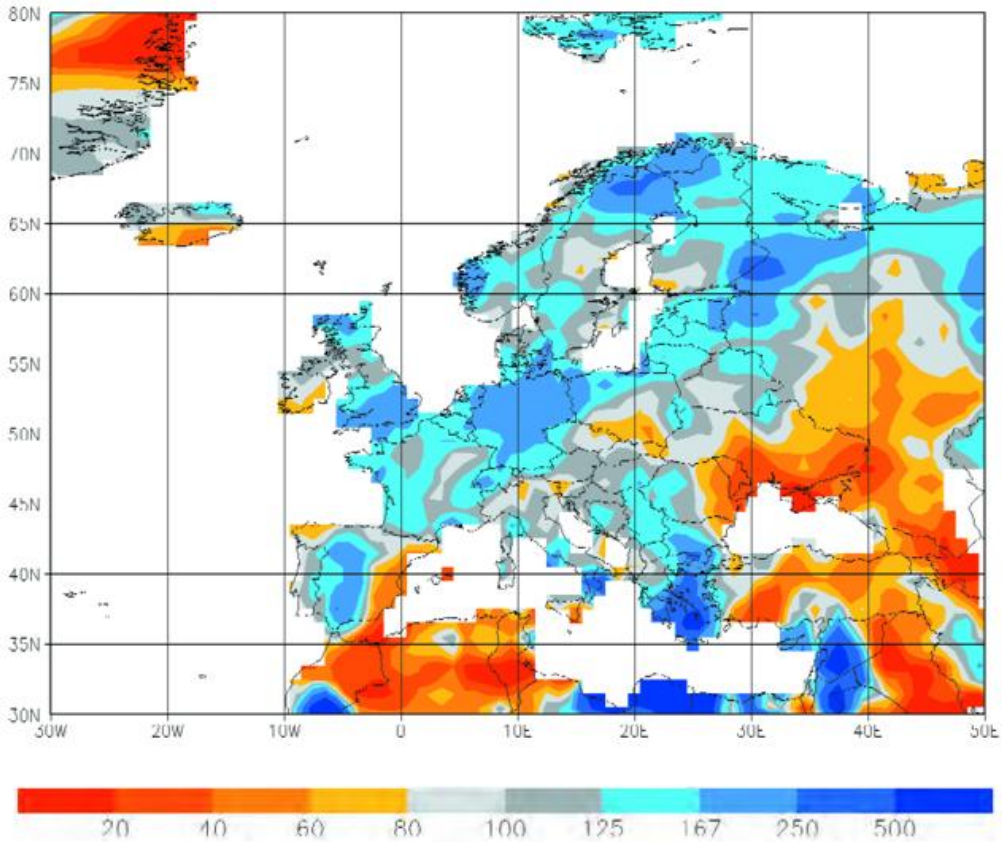

Fig. 5.2: *Monthly precipitation amounts for May 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Flooding due to snow melting

Although precipitation totals were low in Armenia, rapid increase of temperature caused very intensive melting of snow in the mountains. The result were numerous floodings across the country with high damage to agriculture, livestock and roads.

Significant weather events

May 02:	Strong cold front with frost below -6°C in some places in northern and north-eastern Hungary
May 03:	Heavy rain and flooding in western Azerbaijan (Gazakh region). Agstafa and Kyur River burst their banks, villages flooded
May 04:	Heavy rain, flash flood, landslide in southwestern France (Bayonne). Nivelle River burst its banks, houses flooded/damaged, 5 injured and 3 deaths
May 09:	Tornado in North Ireland (United Kingdom), houses and cars damaged, 1 injured
May 10-12:	Heavy rain and flooding in eastern Georgia. Rivers Mataniskhevi, Kobaskhevi burst their banks, 200 houses, farmland flooded, livestock killed
May 11:	Storm with gusts up to 120 km/h in many parts of Germany. Trees fell down, disruption of roads and electricity
May 11:	Severe storm and heavy rain in western and central Belarus. More than 200 houses and agricultural structures damaged, 290 settlements without electricity, 5 injured, 1 death
May 11:	Severe storm in southeastern Cyprus (Larnaca, Nicosia), tornado, heavy rain, hail. Roads flooded, trees and power lines downed, air traffic affected
May 12:	Heavy rain in Israel (Judean desert, northeast of the Dead Sea) caused flooding of the Kumeran River
May 13:	2 relatively long lasting tornadoes in northern and western Germany with tracks of 5 and 12 km. Roads blocked, trees downed
May 13:	Flash floods and heavy rain in Israel around the Dead Sea, 4 deaths
May 16:	25 mm of precipitation in 1 hour in central Jerusalem (Israel) in the early afternoon. Many streets were flooded.
May 17-22:	Thunderstorm and heavy rain in north Bulgaria with hail balls of egg size and tornadoes. 161 mm of precipitation accumulated over 4 days, Vladayska River near Sofia overflowed. In Greece (South Aegean), locally more than 55 mm of rain within 24 hours were reported on 19 May. Heavy hailstorm also in Cyprus on 17 May, in Turkey a few days later, causing damage to crops and fruit trees
May 21:	Severe thunderstorms, flash floods, landslides in central and western Switzerland (Berne, Lausanne). 50 houses damaged, cellars flooded, roads blocked
May 22-27:	Heavy thunderstorms caused by a cold front over Germany. Strong gusts, hail and heavy precipitation especially in western Germany (e.g. 17 mm within 30 minutes in Bonn, at other locations even more), flooding of buildings and roads, trees fell down
May 23-26:	Heavy rain in central and southern Spain. Streets were flooded in Madrid, widespread flooding of fields and vineyards, disruption of railroads, 400 evacuations
May 26-28:	Frequent thunderstorms, hail, flooding, landslides in Greece, east Turkey, Georgia, Azerbaijan

May 27: Rainfall total of 74.8 mm in 24 hours at St. Catherine's Point (Isle of Wight, UK)

May 28: 2nd lowest May maximum day-time temperature of 7.9°C at Heathrow (London, England) since 1949

May 28: Heavy snowfall/rain and storm in Corsica (France) after strong temperature decrease. Wind speeds up to 120 km/h, huge waves (3 meters)

May 28-29: Strong temperature dropdown in southwestern Germany by up to 20°C caused fresh snow cover of several cm in mountain regions even below 1000 m altitude. In lower altitudes, abundant rainfall (partly more than 70mm/24h) especially in eastern and southeastern Germany caused overflow of smaller rivers.

May 28: Highest temperature in May in Moscow since 1891: 32.9°C

June

- **Mostly warm, except northern Russia and a few other places**
- **Heat wave in southeastern Europe**
- **Very wet in western and central Europe, dry in most parts of the north and east**

Atmospheric circulation characteristics

Northern Europe was mainly under high pressure influence. The Arctic frontal zone with cold troughs mainly affected Svalbard and northern Russia.

Low pressure influence (sometimes with quite strong cyclonic systems) continued over the North Atlantic, western and central Europe, but warm air masses still remained. A blocking high persisted over eastern Europe and temporarily in the Middle East at the beginning of the month, but became weaker later in the month.

The Azores High also weakened compared to the previous month, and some low pressure systems reached the central Mediterranean.

In the last decade of the month, warm air from the Mediterranean moved to southeastern Europe, causing a further temperature increase and resulting in a heat wave with extremely high temperatures there.

Temperature

June 2007, too, was mostly warmer than normal (Fig. 6.1). Anomalies above +3°C were recorded especially in southeastern Europe, locally up to +5°C, e.g. in Greece. This was mainly caused by an extreme heat wave in the last decade of the month with daily maxima of 40-47°C, partly record-breaking and lasting several days, especially in the Balkan countries, Italy, Greece, Cyprus and Turkey, but also Israel and Jordan. In Israel, the temperatures were not record-breaking, but the long duration (one week) was unusual for June.

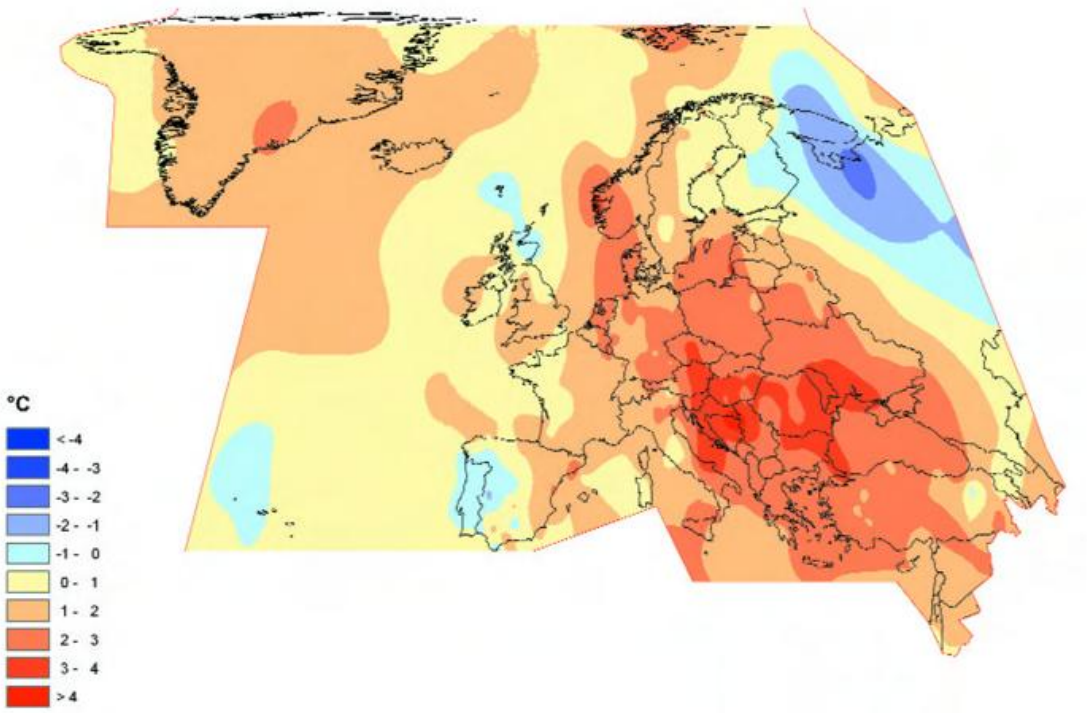

Fig. 6.1: *Monthly mean temperature anomalies in June 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Western Europe saw some temperature records, e.g. Belmullet in Ireland had a monthly mean temperature of 14.6°C, the highest mean June temperature on record since 1956. At several stations in eastern provinces of Spain, monthly records were broken.

In Sweden, there was a long heat wave during the first half of June, followed by cooler temperatures afterwards.

It was colder than normal in northern European Russia (anomalies down to below -2°C), parts of eastern Finland, and towards the west of the Region in Scotland, on the western Iberian Peninsula, and parts of the Azores Islands.

Precipitation

Notably most of western and central Europe was wet, with monthly totals partly more than 200% of the normal (Fig. 6.2). At Kilkenny (Ireland), it was the wettest June on record since 1957; the highest monthly total in Ireland was measured in Dublin at 171.5 mm. Also in eastern and northeastern England, June 2007 was the wettest on record in some areas: in the region of Yorkshire, the monthly total was over 300% of the normal, some stations reported even more than 500% (Fig. 6.3). Generally it was the wettest June in the United Kingdom since 1873 and also the wettest ever recorded June in Denmark. 11 thunderstorm days were recorded at Luxemburg airport, more than twice the normal. In Switzerland, especially the first 10 days of the month were characterised by many thunderstorms over the entire country, causing considerable damage. In the south, Messina in Sicily (Italy) registered 79 mm as the monthly total, breaking the previous record of 1977 by nearly 5 mm. It was the wettest June in 85 years at Malta Airport, mainly due to a heavy rainfall episode at the beginning of the month.

In most of northern and eastern Europe and partly in southern Europe and the Middle East, precipitation amounts were low or around normal. Large parts of western and central Norway received less than 25% of the normal, just like most parts of southeastern Europe, especially

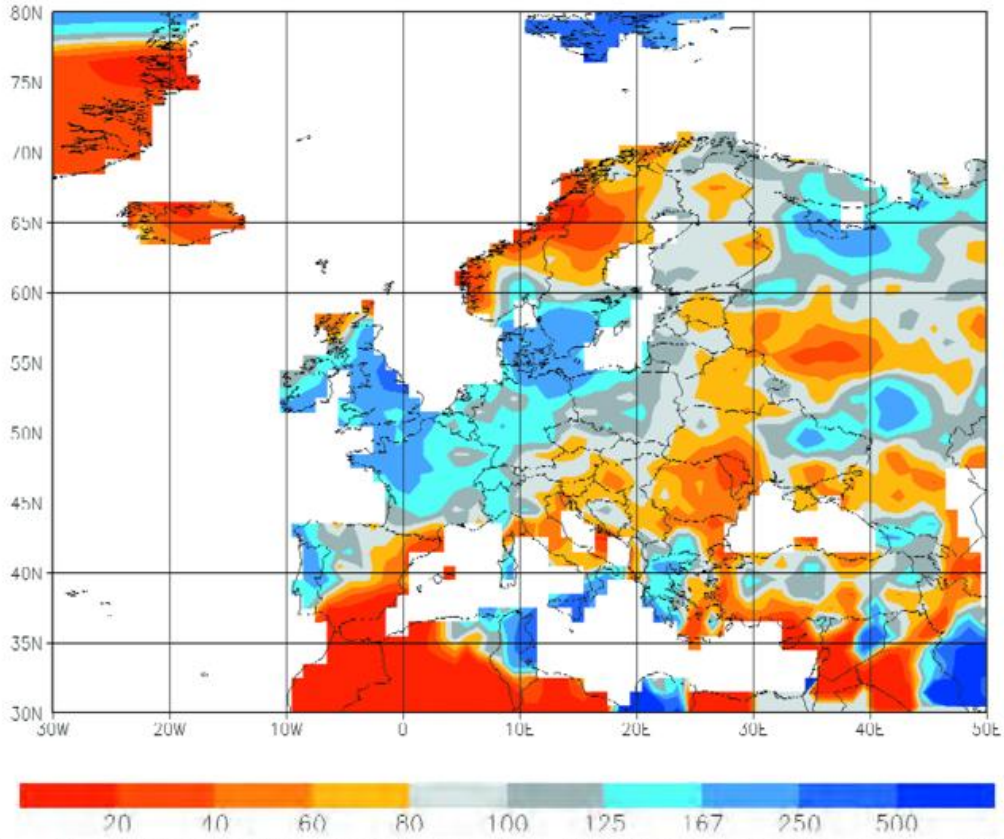

Fig. 6.2: *Monthly precipitation amounts for June 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

northeastern Romania and Moldavia. Some areas near the eastern Mediterranean were very dry, although storms with heavy rain, thundering and hail occurred frequently. The Baltic countries and European Russia experienced a very dry beginning of June, whereas the second half of the month was rainy with many thunderstorms and hail. West Georgia reported drought conditions for this month, but there were also several severe storms with flooding in some parts of the country.

Significant weather events

June 01-04: Severe storms with gusts up to 100 km/h in the Volga area of Russia. More than 270 buildings damaged, trees and power lines downed, 3 deaths, many injured

June 03: Flooding in Quba (Azerbaijan), causing losses of cattle, bridges destroyed, damage to agriculture. Flash flood at rivers in Georgia.

June 06-07: Heavy precipitation in Bulgaria: 279 mm (600% of the monthly normal) in the Pazardjik region. In Turkey, too, heavy rain and flooding

June 07: Hailstorm with hailstones of 25 mm diameter in central Armenia

June 08: 100 mm of rain within 1-2 hours in the evening in central Switzerland (Langeten catchment), locally probably a lot more. Langeten River took a new path passing a village, causing serious devastation

June 09-16: Heavy thunderstorms partly with hail (pigeon egg size) in western and southwestern Germany. Trees uprooted, rain up to 100 mm, streets flooded

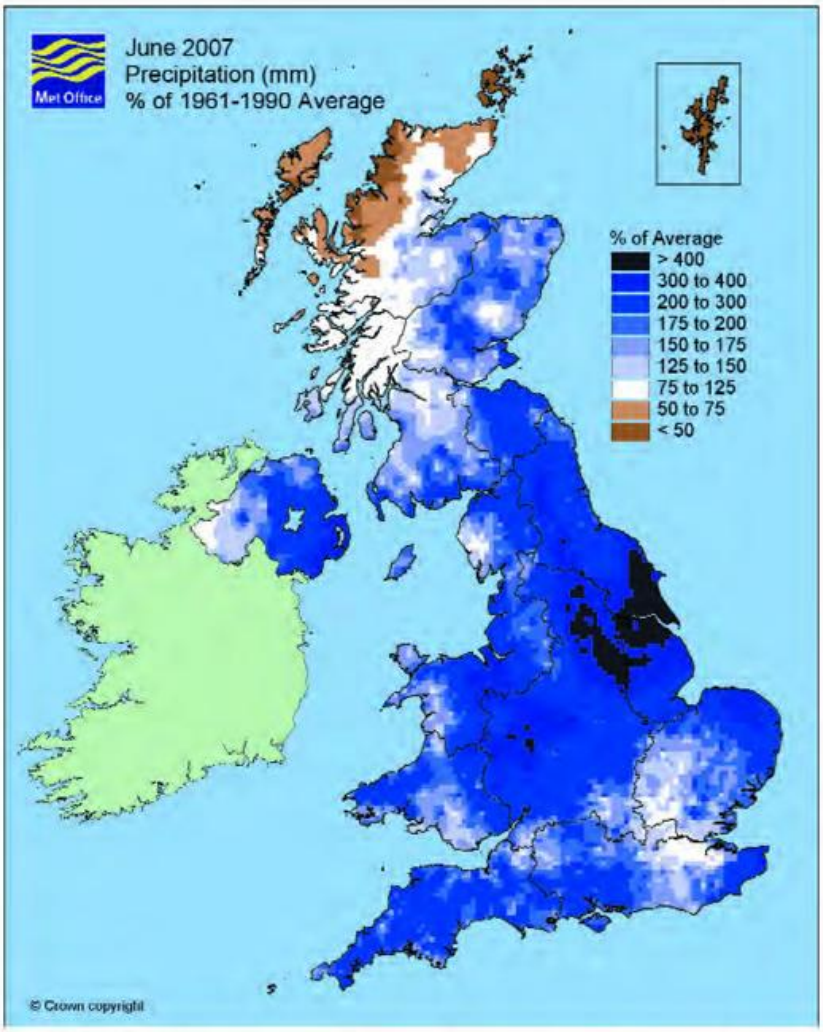

Fig. 6.3: *Monthly precipitation totals for June 2007 in per cent of the normal 1961-1990 in the United Kingdom*
Source: Met Office, United Kingdom

June 10-11: Severe thunderstorm with hail and heavy rain in southwest France (Gers). Houses flooded, vineyards damaged

June 10: Extreme Sharav event in Israel with temperatures reaching 40-42°C in the coastal plain, in the northern valleys and in the Negev

June 12-14: Heavy rainfall with flooding in northern Ireland, northern England and the midlands of the United Kingdom. Flash floods, rivers burst their banks, schools closed

June 14-16: Severe thunderstorms in southern and northeastern Germany, strong gusts, hail, heavy rain (50 mm / 24 h), flash floods, mudslides. Buildings damaged, trees and power lines downed, roads flooded

June 15: Severe storm over Venice (Italy), strong wind, heavy rain, hail. Power outage, bridge closed, concert cancelled

June 16-17: Severe storm in the Carpathian region, Ukraine. Heavy rain, hail, flash floods, mudslides, TV tower and bridges damaged, houses flooded, losses in agriculture

June 19-23: Heavy thunderstorms in Germany, Switzerland and Austria with supercell and hail. Gusts up to 135 km/h. During the evening of 20 June, 21 mm within 10 minutes in Chur (Switzerland), highest value at this location since 1981. Flooding in the city of Zurich on 21 June. Agricultural losses (vine, fruits, crops) in Austria over areas of several thousand hectares. Devastations by water and mud masses in the Alps. Gusts up to 120 km/h in Vienna. Several open air stages of the "Danube Island Festival" were destroyed.

June 23: Tornado in Frankfurt/Main (Germany), thunderstorm, heavy rain. Roads flooded, trees downed

June 23-29: Heat wave in southeastern Europe and the Middle East: 42-45°C in southern Italy with several fires, 39.5°C in Malta on 25 June, 41°C in Serbia, 45°C in Romania on 26 June, heavy storm one day later; 42°C in Bulgaria in many places, 46.4°C in Greece, 42-46°C in the Jordan Valley in Israel, 44°C in Deir Alla (Jordan)

July

- **Mostly warm with heat waves especially in the southeast**
- **Cool in western and parts of northern Europe**
- **Wet in most of the north, dry in the south**

Atmospheric circulation characteristics

Strong low pressure influence continued across northern and central Europe throughout July 2007. The main frontal zone first had a zonal pattern and extended from the North Atlantic to central Europe and later also to eastern Europe. In the middle of the month, the circulation pattern became more meridional. A trough formed over the North Atlantic, affecting western Europe with cold and wet air, whereas warm Mediterranean air masses flowed to southeastern Europe, causing two more heat waves in this area. This situation remained stationary for many days. Only at the end of the month, the large-scale circulation became zonal again.

The very northern Scandinavian areas remained under high pressure influence most of the month.

Southern Europe was affected by a strengthening and extending Azores High.

Temperature

Most of the Region was still warmer than normal (Fig. 7.1). In the Baltic countries, especially the first ten days were warm, with another heat spell in the middle of the month in Lithuania. Southeastern Europe and the Middle East were particularly warm, just as the preceding month, with monthly anomalies above +4°C, which was the result of two more extreme summer heat waves in the second half of the month.

Daily maxima of 40-47°C were measured in many places (in some cases new records were set), e.g. in Slovakia, Hungary, southern Italy, Croatia, Montenegro, Serbia, Romania, Moldova, the southern Ukraine, Bulgaria (Fig. 7.2), Macedonia, Greece, Cyprus, Turkey, Jordan and Israel. Even in eastern Germany, Austria and Malta, values above 38°C were recorded. It was the warmest July since 1901 in Romania. There were 8 consecutive days in July 2007 with a maximum temperature over or equal 40°C in Podgorica (Montenegro), and also in Romania the

number of maxima over or equal 40°C set a new record. The July average maximum temperature for Italy was 34.7°C, which makes it the warmest July in at least 30 years. Israel and Lebanon were also affected by the heat wave.

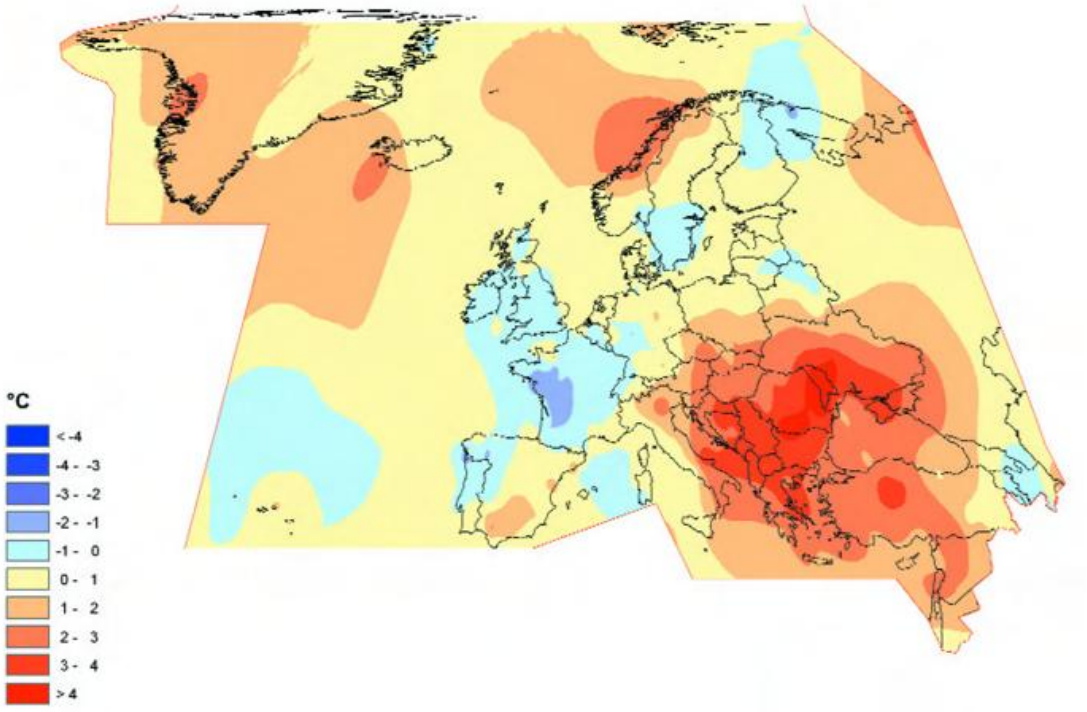

Fig. 7.1: *Monthly mean temperature anomalies in July 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

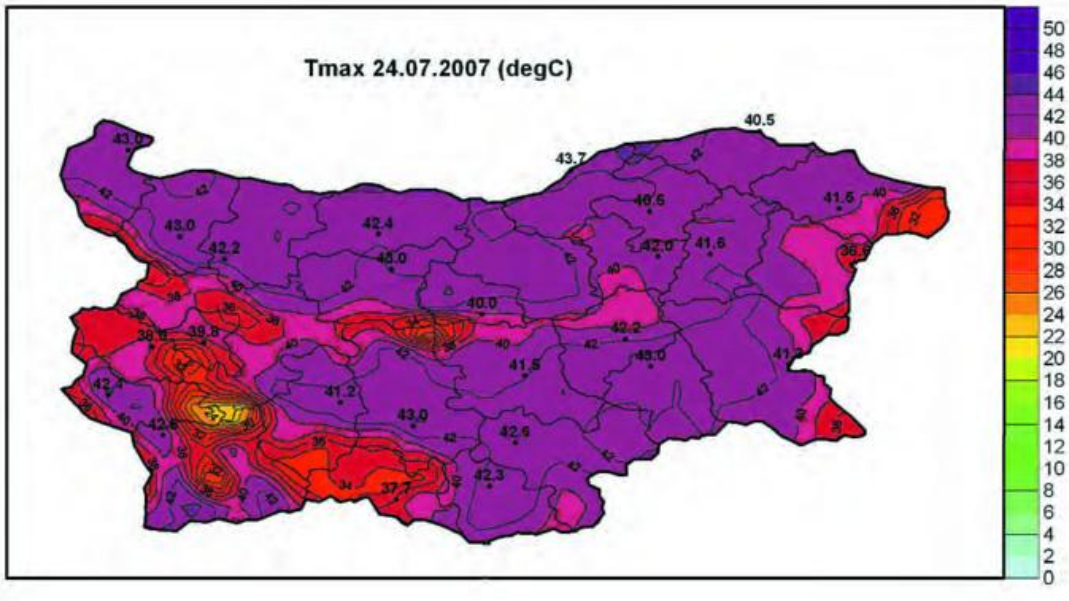

Fig. 7.2: *Maximum temperatures for the hottest day in July in Bulgaria*
Source: National Institute of Meteorology and Hydrology, Bulgaria

On the other hand, large areas of western and some parts of northern Europe as well as parts of the North Atlantic and the western Mediterranean were cooler than normal, for the first time in 2007. Notably in western France, the anomalies were below -1°C. Armenia was also slightly cooler than normal (-0.4°C).

Precipitation

It was wet in western, central, eastern and parts of northern Europe, except Greenland, Iceland, northern Norway and central Sweden (Fig. 7.3). Ireland, southern parts of the United Kingdom, northern parts of France and even parts of southern Norway saw more than 300% of the normal precipitation. Rainfall was even more extreme in western England and Wales. In many places, this was the wettest July in many years and the number of wet days was unusually high there (up to 25 days with monthly totals of at least 1 mm in Ireland, the normal being 9 to 14 days). For the Netherlands, this was the wettest July since 1942 (155 mm, 200% of the normal). Sweden registered a new record for the highest monthly July precipitation total at 334 mm. The Baltic countries and Belarus also had a very wet July, locally even record-breaking, with more than 200% of the normal rainfall in Lithuania. This was partly due to a heavy rainfall event at the beginning of the month when some places in Lithuania received 96-202 mm of precipitation within 5 to 8 days (Fig. 7.4).

Southern Europe was very dry. There was nearly no precipitation over parts of the Mediterranean region and near the west coast of the Black Sea. Bulgaria received only 12% of the normal precipitation, southern Serbia even only 5%. Wildfires were reported from Macedonia and Greece. The severest drought in 60 years was recorded in Moldova, as July

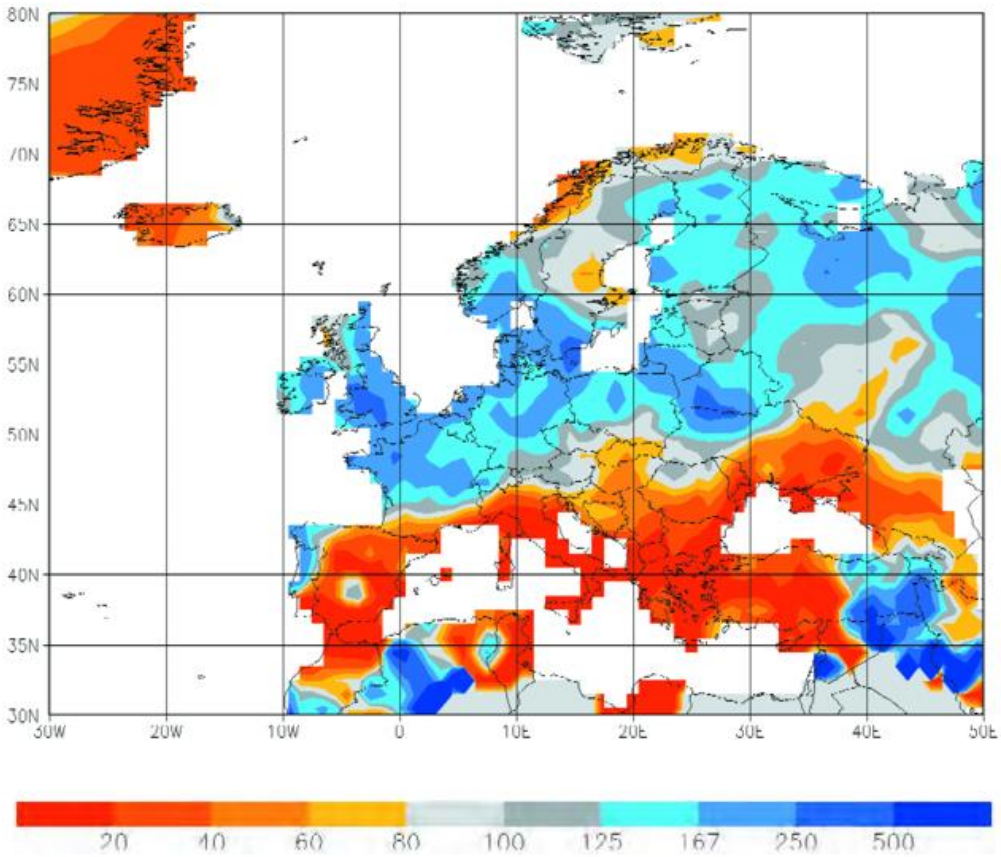

Fig. 7.3: *Monthly precipitation amounts for July 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

2007 was the third successive very dry month there, causing severe losses of agricultural crops (Fig. 7.5). Drought conditions and forest fires were also reported from northern parts of Montenegro where droughts normally are very rare in contrast to the southern parts of the country. In the Middle East, some high positive anomalies were to be found, but since the summer precipitation amounts are generally low there, the absolute totals were not very high. July in Armenia is one of the driest months normally, but July 2007 was unusually rainy with 150-300% of the normal due to some heavy showers.

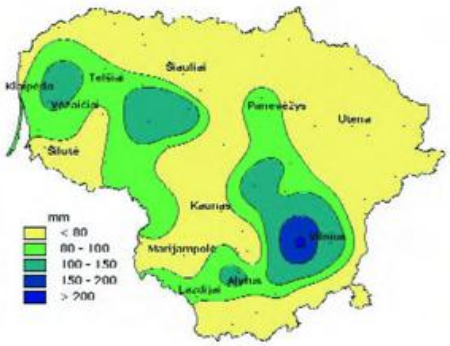

Fig. 7.4: *Precipitation totals after an extreme rainfall event over 5-8 days in the beginning of July 2007 in Lithuania*
Source: Lithuanian Hydrometeorological Service

Fig. 7.5: *Drought in Moldova in July 2007*
Source: State Hydrometeorological Service, Republic of Moldova

Significant weather events

July 01: Heavy rainfall with flooding of Pedieos River in Cyprus

July 03-04: Flash flood in northern Ireland. River burst its bank, houses, bridges, roads flooded, evacuations

July 04: Flash floods in Switzerland, landslides. Rivers burst their banks, buildings flooded

July 07: Heavy rain (85-86 mm / 12 h) during the night in Lithuania. The quadrennial Lithuanian Song and Dance Festival had to be disrupted.

July 11: Severe storm in Romania, heavy rain, hail, flash floods, landslide. More than 100 houses damaged, trees and power lines downed, crops destroyed

July 12: Hail in Horki (Belarus), average hailstone diameter 43 mm, some hailstones had 50-60 mm (Fig. 7.6). Such a hail event occurs there only once in 50 years on average.

July 15-22: Heat wave in many European countries with maxima around 40°C and more particularly in southeastern Europe. In Lithuania, maximum temperatures of 30-34°C on 17 July

July 18: Widespread strong thunderstorms with heavy rain showers and strong gusts near Tartu (Estonia). Hail caused heavy damage to crops.

July 19-20: Hailstorm in the Bernese Oberland (Switzerland). Golf or even tennis ball-sized hailstones

July 19: Tornado and hailstorm in the western and central Czech Republic. Houses damaged, trees and power lines downed

July 20-29: Up to 147 mm of rain in central England with extensive flooding on 20 July. On the following days, heavy rain in southern parts of the United Kingdom, causing the severest flooding in 60 years

July 21-22: Heavy thunderstorms with hail and heavy rain in southeastern Germany. Thunderstorm also in Switzerland (around Berne), flooding and landslides

July 21: Heavy precipitation in Georgia with daily amounts up to 101 mm

July 22: Tornado in southern Poland. 100 buildings damaged, power outages

July 22-29: Heat wave in southeastern Europe and parts of the Middle East: new temperature records in Serbia 44.9°C, in Romania 44.3°C and Bulgaria 44.8°C, maximum in Athens (Greece) 45.6°C, in the Jordan Valley (Israel) 43-45°C, in Jordan 42-47°C

August

- **Very warm in the east, but western Europe mostly cool**
- **Western, central and parts of southeastern Europe mainly wet**
- **Eastern Mediterranean and some of the easternmost parts of the Region very dry**

Atmospheric circulation characteristics

In August 2007 low pressure influence continued in western and central Europe. Shortly after the beginning of the month, some more large troughs affected western and, increasingly, central Europe with cold and humid air, whereas a high pressure system formed over southern Scandinavia, the Baltic countries and Belarus, and later over European Russia. High pressure influence was also dominating over Greenland and the Mediterranean area, in the second half of the month also over the North Atlantic. At the end of the month, a large low pressure system developed over Scandinavia.

Temperature

Most of the Region was warmer than normal with the highest anomalies in the east (Fig. 8.1, up to +5°C in the eastern Ukraine, southern European Russia and western Kazakhstan). It was the second warmest August in European Russia since 1972, in Belarus in 60 years (behind 1992). In Finland, the highest recorded temperature during the summer was measured unusually late in the middle of August at 30.7°C. In Lithuania, 32-33°C were reached.

Like in the preceding two summer months, record-breaking daily maxima of more than 40°C were also recorded in August in the southeast and south, especially in southern Italy, Bosnia and Herzegovina, Bulgaria, Greece, but also in the easternmost parts of the Region (southern Ukraine, European Russia, Azerbaijan). There were twice as many tropical days than normal in Serbia.

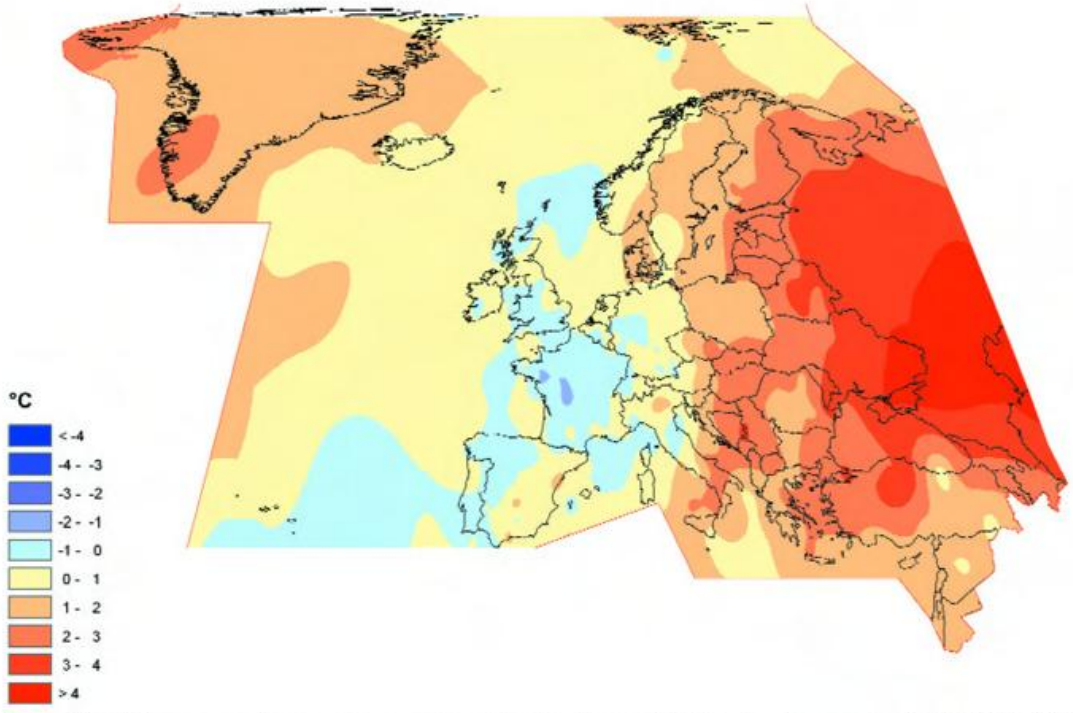

Fig. 8.1: *Monthly mean temperature anomalies in August 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

In contrast, most of western Europe was slightly cooler than normal; locally the anomalies were below -1°C in France and Spain. England had its coldest August since 1993.

In the Arctic region, Greenland and western Svalbard had monthly mean anomalies below +1°C this August. Due to glacier calving in Svalbard, a cruise ship was hit by a wave of ice and water.

Precipitation

Large parts of western, central and southeastern Europe were wet, also eastern Turkey and a few locations in the north of the Region, partly with more than 200% of the monthly total (Fig. 8.2). Zurich (Switzerland) recorded a monthly total of 260 mm, making it the second wettest August on record since 1864. In the first half of August, the highest daily rainfalls in Switzerland in more than 100 years were measured, especially in some regions in the midlands. During the last days of the month, exceptional thunderstorms hit several parts of Switzerland (the Lake District, Freibergen and Bernes Jura). Precipitation amounts within 72 hours locally reached or even exceeded the normal monthly totals, resulting in local land slides and floods. Other parts of Europe (Germany, northeast France, Austria, northern Italy, Romania and Bulgaria) were also affected by heavy rain with local flooding. Hailstones of tennis ball-size caused enormous damage to houses and fields in Austria several times. Southeastern Portugal received the highest August precipitation totals since 1976. Some stations in Romania had their highest ever registered August precipitation totals, up to nearly 300% of the normal.

Most of northern, eastern and southern Europe was dry. Near the central and eastern Mediterranean, and partly in the east of the Region (central European Russia, west Kazakhstan, Azerbaijan) less than 20% of the normal precipitation fell over a large area. In Italy (e.g. in central and southeastern Sicily) there was no precipitation to all.

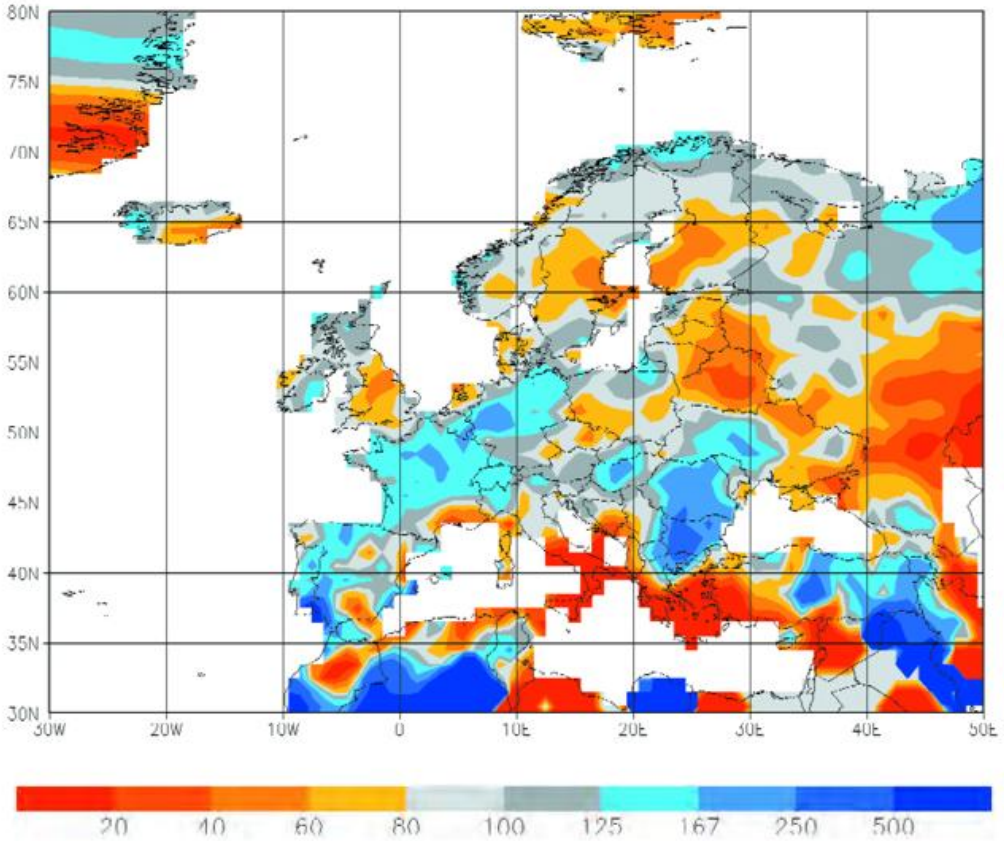

Fig. 8.2: *Monthly precipitation amounts for August 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

August 02-03:	Flooding in Austria (regions Tyrol and Salzburg), thunderstorms and hailstones of tennis ball-size. Flooding also in southern Germany
August 06-12:	Thunderstorms and heavy rain in Germany, Austria and Switzerland (daily totals over 100 mm) due to a low pressure system over northern Italy
August 05-07:	Heavy rain and thunderstorm in northeast Bulgaria: 291 mm in less than 24 hours. Flooding due to a broken water reservoir barrier in the region of Razgrad. Torrential rain up to 80 mm/h in Romania. Thunderstorms and heavy rain with flooding also in Greece (> 50 mm / 24 hours)
August 11-16:	Severe storms with flash floods in northern Germany. Torrential rain up to 176 mm / 24 h. Villages, towns inundated, roads closed, evacuations. Flash floods also in northern Ireland.
August 17:	Devastating storm in parts of Savinja Valley (Slovenia). Thunderstorm with heavy rain also in northern Italy (Piedmont)
August 19-20:	Hailstorms in Austria. Torrential rain, flash floods
August 21-22:	Heavy rain in western and northern Germany up to 91 mm in 24 hours, 50 mm within 3 hours. Towns and roads flooded. Severe storm (gusts up to 120 km/h) and heavy rain also in northeastern Poland
August 23:	New record of rainfall intensity of 70 mm / 6 hours in Kapan (southern Armenia)
August 23-25:	Heat wave: maximum temperatures of 40-45°C e.g. in Montenegro, Bulgaria and Greece. Forest fires resulting from the heat and additional strong winds in eastern and southern Greece.
August 28:	Storm at the Swedish east coast at 90 km/h, the first storm in August in Swedish coastal waters since 1975
August 30:	Snow depth of 2 cm in Kiruna, northernmost city of Sweden. First measurable snow depth in August at any Swedish station since 1994

September

- **Colder than normal in many parts of Europe**
- **Warm over the North Atlantic and in the Middle East**
- **Western Europe, eastern Mediterranean and Middle East very dry**
- **Central and eastern Europe mostly wet**

Atmospheric circulation characteristics

A high pressure area over the North Atlantic extended to western Europe and persisted there during a longer time. Central Europe was still under cyclonic influence. Cold air masses flowed at the east flank of the Atlantic high pressure system to western and central Europe and even further to southern parts. A large cut-off low developed over central Europe and moved to the southeast. Over eastern Europe, a warm air flow from the south was dominating, but mostly with cyclonic circulation. The eastern Mediterranean and the Middle East saw anticyclonic conditions most of the month.

In the middle of the month, central Europe became also increasingly anticyclonic and the main frontal zone moved northwards. A large quite stable low pressure system resided over northern Europe and led cold air especially to western parts of Scandinavia.

The circulation changed again at the end of the month. Another deep trough extended from the north to western and central Europe, whereas a high pressure area formed over eastern Europe.

Temperature

The area of colder-than-normal temperatures in western Europe extended further to the east. September was a cold month for many parts of continental Europe except the East (Fig. 9.1); the anomalies were below -1°C in many places, locally below -2°C (e.g. northwestern Austria).

It was still warmer than normal over most of the North Atlantic, large parts of northern and eastern Europe, parts of the Mediterranean and particularly the Middle East. High anomalies between +4 and +5°C and daily maximum temperatures up to 37°C were reached in Azerbaijan, up to 34°C in Georgia.

Precipitation

Most of western Europe was very dry, also some areas in northeastern Europe, particularly in Belarus and northern European Russia, in many places with less than half the normal precipitation total (Fig. 9.2). The eastern Mediterranean and the Middle East mostly had extremely low precipitation totals (less than 20% of the normal). Most of Armenia received only 1.7 mm precipitation on country average, which was 2-3% of the normal, and in some parts of the country there was even no precipitation at all. These extremely dry (and hot) conditions resulted in extensive drought in Armenia; several forest fires were reported. Cyprus, too, had no precipitation, and Moldova had also a severe drought.

In contrast, central and parts of southeastern and eastern Europe were very wet (partly 200-300% of the monthly total), just like a couple of other local areas in northern Europe, parts of Italy and on the southern Iberian Peninsula (due to thunderstorms with heavy rain). 300-500% of the normal monthly total fell in large parts of eastern Austria, record-breaking in many places. In some places along the Danube River, heavy rain caused the severest flooding in 20 years. September was the wettest month of 2007 in the Czech Republic, where normally June is the wettest month of the year.

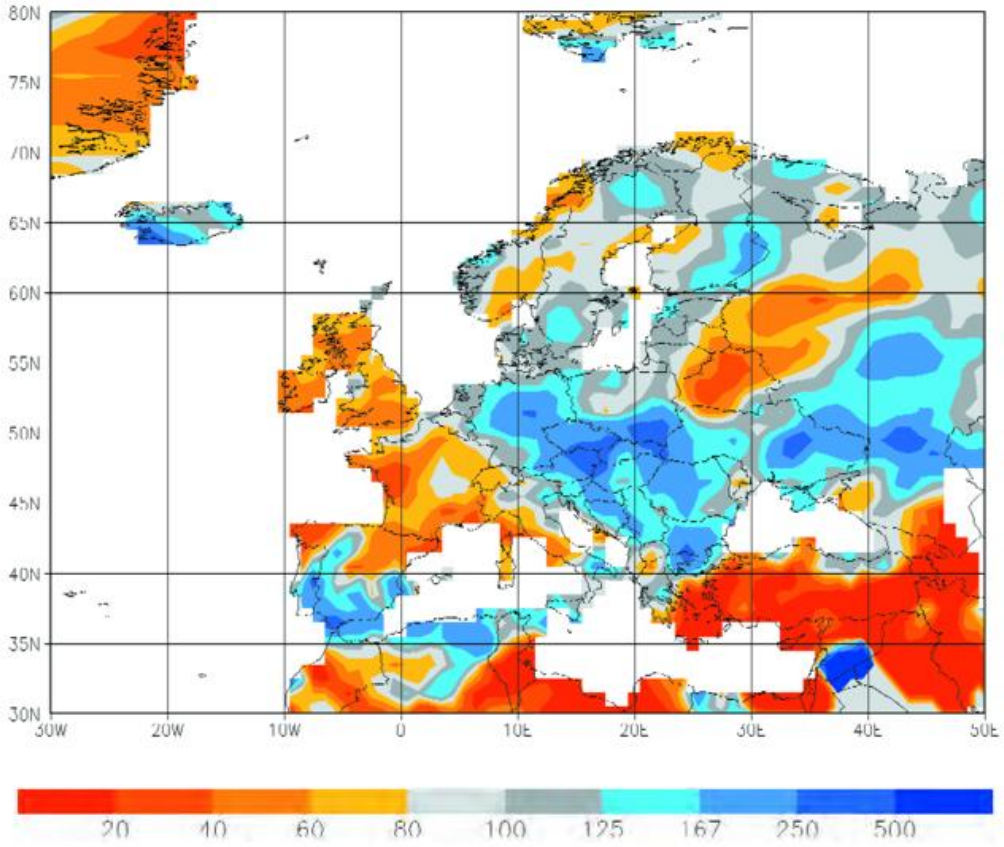

Fig. 9.2: *Monthly precipitation amounts for September 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

September 01-02:	Thunderstorms with hail (egg size), heavy rain, tornado and wind gusts >140 km/h in southern and central Bulgaria. Heavy rain also in north-eastern Greece
September 04-07:	Severe storm with flash floods in eastern and southern Romania. Gusts up to 100 km/h, more than 1300 houses flooded, 225 km of roads/bridges damaged/destroyed, train service disrupted, 1400 evacuations. Heavy rain and flooding also in Poland, Czech Republic, Austria
September 04-09:	Heat wave in Armenia: new September records with maximum temperatures at 32-40°C.
September 05-08:	Heavy rains in Austria along the main ridge of the Alps caused flooding. Rainfall rates up to 245 mm in 72 hours, snow down to 1000 m altitude. Heavy rain and floods also in the Czech Republic and southern Poland (Carpathians). In Italy, foehn storm with losses to agriculture
September 13:	Severe storm in southern Spain with hail and heavy rain
September 17:	Tornado north of Stuttgart (southern Germany). Damage: € 100 000
September 18-19:	Abundant rain within a cold front over Slovenia causing flooding and land slides, particularly in Železniki (Fig. 9.3)
September 21-23:	Thunderstorms with severe hail and rainfall in Andalucía (southern Spain) leading to floods and crop damage
September 23:	Heavy rain in Turkey, flooding of several towns.
September 24:	Thunderstorms, series of small tornadoes in southern and central England. Houses, vehicles damaged, trees downed
September 27-30:	Heavy rain with regional flooding in western and northern Germany
September 27:	160 mm of daily precipitation over the Venetian Lagoon (Italy) with flooding. Many crops destroyed

Fig. 9.3: *Flooding a day after exceptionally heavy precipitation in Železniki, Slovenia. Source: Environmental Agency of the Republic of Slovenia*

October

- **Cold in many parts of Europe**
- **Warm in the north, the east and over the North Atlantic**
- **Very dry in most of the Region, very wet in parts of eastern and southeastern Europe**

Atmospheric circulation characteristics

The main frontal zone extended from the North Atlantic to the northeast across Iceland and Svalbard, with mild air and cyclonic systems moving into these areas.

High pressure influence was dominating over large parts of Europe, even in southern Scandinavia. Most of that area, however, was in a cold air mass. Only the eastern parts of the Region were often within a warm southerly air flow. A strong stable cyclonic system developed over the Baltic countries, persisted there during some days and moved northwards.

In the middle of the month, Arctic air masses moved southwards to southeastern Europe and cold fronts passed over these areas, bringing frequent showers with them. Towards the end of the month, a strong cut-off low formed over the central Mediterranean.

Temperature

Like the preceding month, October was also colder than normal in many parts of Europe, partly with deviations from the long-term mean of less than -1°C (Fig. 10.1). Only the first weeks were mild, e.g. in Switzerland, with maximum temperatures up to 22°C, whereas in the second half of the month the temperatures went down.

However, it was remarkably warmer than normal in northern and, again, in eastern Europe as well as in the Middle East, over the North Atlantic and in northwestern Europe. Monthly mean anomalies exceeded +6°C in northeastern European Russia. The active vegetation period in Lithuania ended ten days later than normal.

Precipitation

In most of the Region, October 2007 was a dry month, especially in western, central and northern Europe as well as the Middle East (Fig. 10.2), partly with monthly totals less than 50% of the normal. It was the driest October of this 21st century in Portugal. In many areas of Israel, there was no rainfall at all or less than 5 mm in the whole month (normal monthly total is 25-40 mm).

In contrast, parts of eastern and southeastern Europe were very wet with totals above 350% of the normal in Romania. Southeastern Spain saw thunderstorms around Alicante and Valencia, with partly 100 mm of precipitation during one hour. There was also abundant precipitation over Corse in the Mediterranean. In the east of the Region, the coastal zone of Georgia received 140% of the normal precipitation, whereas the other parts of the country were dry or around normal.

Snow

Within a cold air flow at the beginning of the last third of the month, the snow line dropped to quite low altitudes in Slovenia.

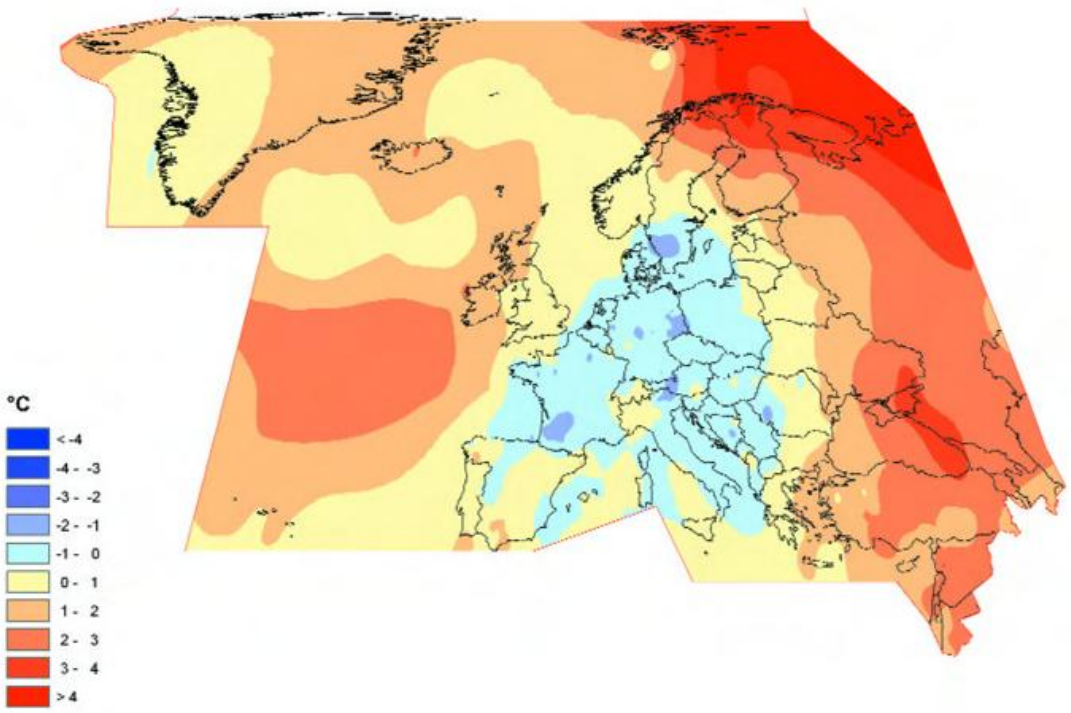

Fig. 10.1: *Monthly mean temperature anomalies in October 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

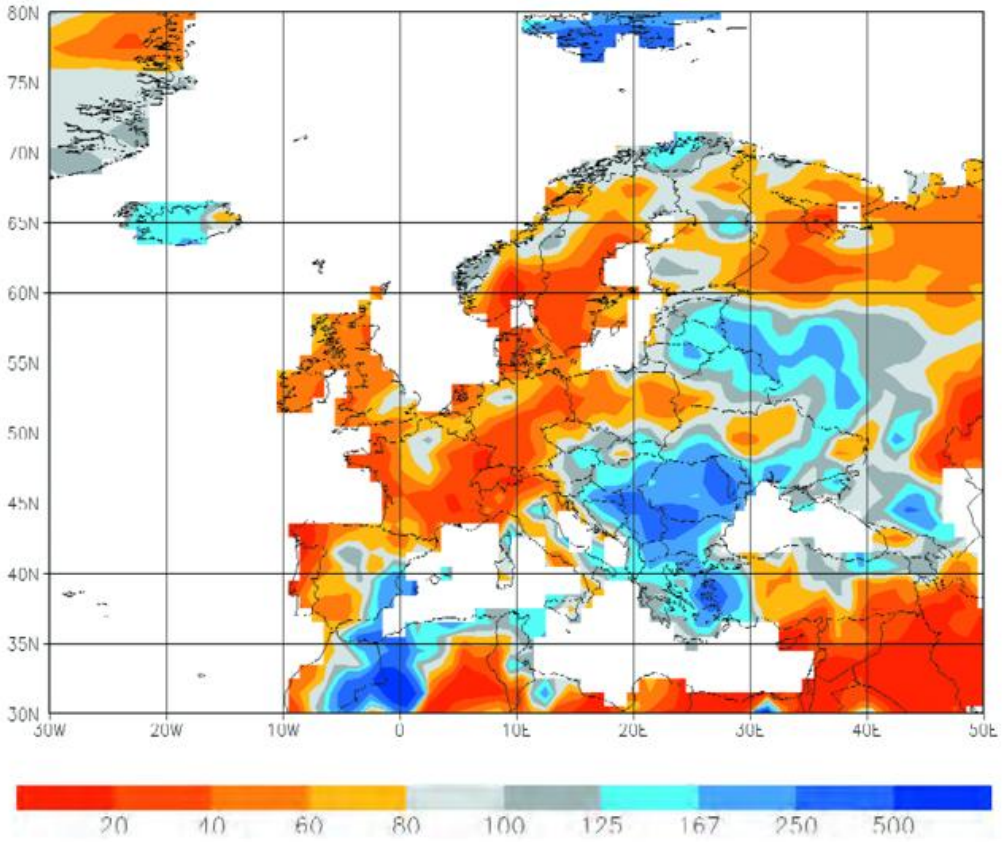

Fig. 10.2: *Monthly precipitation amounts for October 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

October 04:	Violent storm over Mallorca Island in the evening moving from SSW to NNE, with central axis over Palma – Inca – Puerto de Alcudia. Probably several tornadoes on a path of 15-20 km length
October 06:	Severe thunderstorm in southern Italy. Heavy rain, flash floods, roads, tunnels flooded
October 11-12:	Torrential rainfall around Valencia (eastern Spain). Two-day precipitation totals exceeded 400 mm in the mountainous regions of the Alicante province (Fig. 10.3), more than 50% of the annual normal. In Valencia, 170 mm was registered on 11 October alone, making this the second wettest day since records began. 87 mm fell within one hour at Alcalalí in the Marina Alta region of Alicante.
October 14:	Heavy snowfall in Moscow, Russia. More than 40 000 people without electricity
October 14-17:	Heat wave in Armenia, the second one this autumn. Maximum temperatures up to 32°C in the valleys. This heat wave was followed by a rapid decrease of temperature of 10-12°C. In the Ararat Valley, minimum temperature fell down to 0-2°C.
October 17-18:	Severe thunderstorm and flash flood in eastern Spain (Costa Blanca, Mallorca). Vehicles swept away, power failure, evacuations
October 20:	Snowfall in some areas of the lowlands in Switzerland
October 20:	Tornado near Nicosia (Cyprus), causing damage to properties
October 20-23:	Heavy precipitation in southern Romania and Bulgaria: up to 129 mm in 24 hours

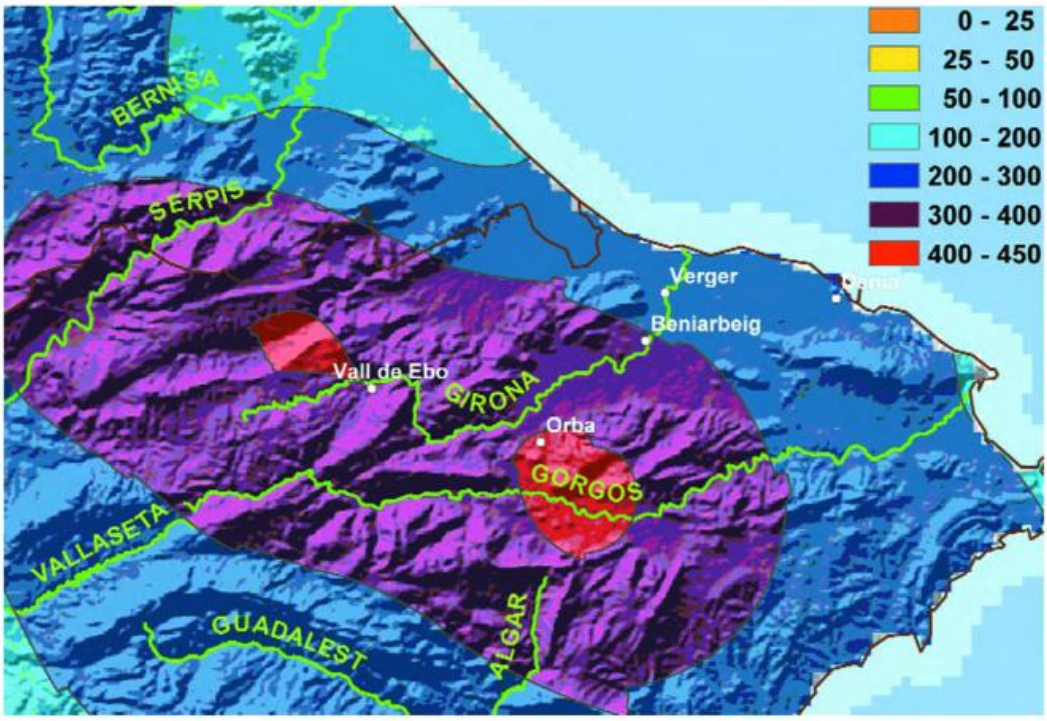

Fig. 10.3: *2-day rainfall totals in mm on 11-12 October 2007 in the Marina Alta region, Alicante, eastern Spain*
Source: National Meteorological Institute Spain

November

- **Cold in most of Europe**
- **Mild in the Arctic and over the North Atlantic**
- **Dry in western Europe, wet in central and eastern Europe**

Atmospheric circulation characteristics

The eastern North Atlantic and western Europe were again under unusually strong high pressure influence most of the month. A cold air mass was still lying over most of Europe, now extending further to the east. Cyclonic activity was concentrated to the eastern parts of the Region with cold fronts passing frequently over the Black Sea. Temporarily, it became also cyclonic over central Europe and the central and eastern Mediterranean.

Mild air masses passed over the North Atlantic from the south to the Arctic region, reaching as far as Greenland and Spitsbergen.

Temperature

The third autumn month of 2007, too, was cold in many parts of Europe, this time, however, also in the eastern parts (Fig. 11.1). In some places, the anomalies were below -2°C, locally even below -3°C, e.g. in Romania. In northeastern Europe, the weather cooled down markedly in the middle of the month when minimum temperatures fell to values between -6 and -13°C in Lithuania. There was frost during the whole month in Serbia. Only the Arctic region, most of the North Atlantic, northwestern and northern Europe as well as parts of the eastern Mediterranean and the neighbouring countries remained considerably warmer than normal. In Svalbard, the anomalies exceeded +4°C, over the North Atlantic partly +3°C.

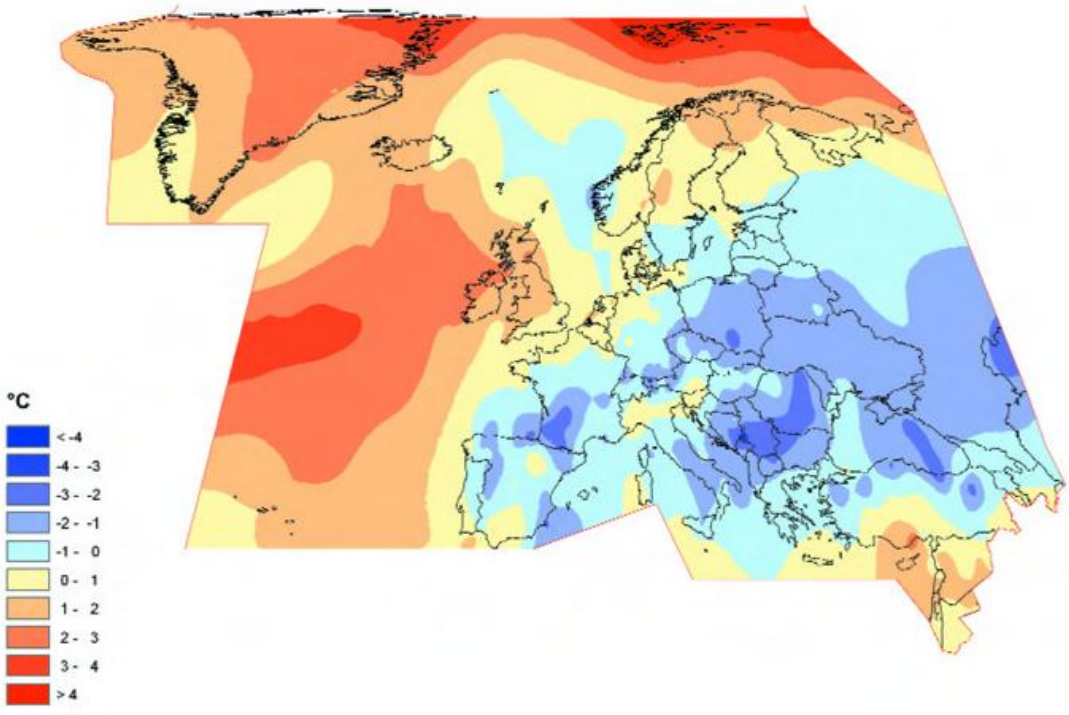

Fig. 11.1: *Monthly mean temperature anomalies in November 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Precipitation

November again was dry in western Europe especially (Fig. 11.2). Southwestern France (Pyrenees) and eastern Spain received less than 20% of the normal monthly total. Other parts of the Region, particularly northern Italy, Slovenia and the respective Adriatic coasts were very dry, just like southern Scandinavia and parts of European Russia.

Central and parts of eastern and southeastern Europe, some areas of northern Europe and a large area around the Black Sea were wet, partly with more than twice the monthly total (e.g. Bulgaria). Flooding of houses occurred in Serbia, Montenegro, and at the end of the month also in Greece. East of the Black Sea, in the coastal zone of Adjara (Georgia) the monthly total was 534 mm due to some daily totals up to 100 mm. Local high rainfall amounts up to 79 mm in 13 hours were registered in Lebanon.

Heavy snowfall was recorded in Austria and Switzerland as early as in the first half of the month, causing snow depths of more than 1 m even in the lowlands. It was the heaviest snowfall in Switzerland since 1955. In Davos, 62 cm of snow fell in 24 hours, setting a new record. Some regions in the Alps received snow depths up to 150 cm; winter resorts could never open so early in the season. A snow cover of 100 cm and more occurred also in the highlands in Romania during the second decade of the month, and Serbia had more snow days than normal at that time of the year.

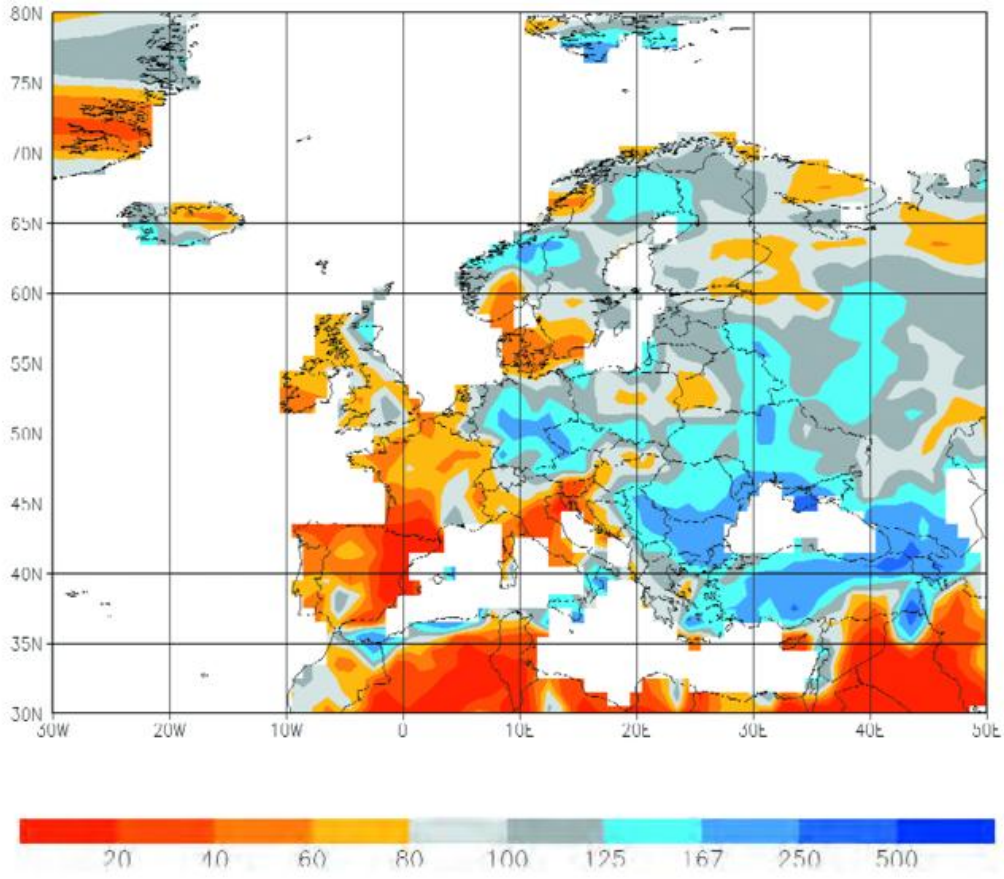

Fig. 11.2: *Monthly precipitation amounts for November 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

November 05-06:	Sharav event in Israel: 33-35°C in the coastal plain and the northern Negev. In the last 45 years, there were only 2-3 days on which temperatures in November were similar or higher.
November 08-09:	Storm over the North Sea with heavy flooding on the islands and waves up to 17-18 m. One of the highest storm surges on the East Anglian coast (United Kingdom) since 1953. In Germany, beaches flooded, parts of Hamburg City flooded, gusts up to 140 km/h on the islands
November 09-10:	Heavy snowfall particularly in southeastern Germany up to 70 cm
November 10:	Storm with gusts up to 120 km/h in Greece (north, east, south) and Turkey. Damage to infrastructure and agriculture
November 11:	Storm with gusts of hurricane force in the Rostov region of southern European Russia, the Ukraine and over the Black Sea. Waves up to 6 m. Ships sank, oil tanker broke into two, nearly 5 million litres of oil spilled, gas pipeline damaged, ports closed, roads blocked
November 15:	Intensive snowfall (40 cm within 4 hours) in eastern Austria in the late afternoon. Highway southwest of Vienna blocked
November 16:	Hailstorm in northwest Malta, gusts up to 90 km/h, heavy rain, crops destroyed
November 16-19:	Heavy rain and gusts over 140 km/h in Bulgaria. Heavy rain in Greece and Turkey with flooding. Hundreds of buildings damaged, traffic paralysed, power outages, water supply affected, thousands of evacuations
November 17:	70 cm snow depth in the region of Javorina (Slovakia). Earliest occurrence of such snow depths in this place since, at least, 1951
November 18:	New record for the lowest all-time daily minimum temperature in Mirandela (Portugal): -10.9°C
November 18:	Severe hailstorm in Cyprus, in some villages damage to properties and crops
November 19:	Storm with gusts up to 122 km/h in Novorossiisk (southwestern European Russia, at the Black Sea)
November 19-21:	200 mm of precipitation in 3 days at one station in the Carmel region (northwest Israel). Highest 3-day total since the beginning of measurements in 1953
November 20:	Severe storm in southern Spain (Andalucía). Gusts up to 90 km/h, heavy rain, landslides. Roofs of buildings damaged, trees downed
November 26-28:	Heavy rain and snowfall in southwestern Serbia and Montenegro. Rivers burst their banks, part of dam broken. 145 houses damaged/flooded, bridges damaged/destroyed, roads blocked

December

- **Very mild in the north, colder than normal in the south**
- **In northern Europe mainly wet, rest of the Region mainly dry**

Atmospheric circulation characteristics

At the beginning of the month there was a more or less zonal air flow from the Atlantic to Europe with frequent cyclonic activity. However, during the second decade of the month, a high pressure area developed over most of Europe with cold air persisting over the southern half of the continent. At the northwest flank of the large anticyclone, mild Atlantic air moved to northern and northeastern Europe. Towards the end of the year, anticyclonic conditions became weaker there.

The Mediterranean was mainly under low pressure influence during most of the month.

Temperature

The winter season 2007/08 started with a very mild December in northern Europe (Fig. 12.1). Monthly mean anomalies exceeded +4°C over a large area in the northeast and reached up to +9°C in eastern Lapland and between +6 and +8°C in northern European Russia. Temperatures in Finland were well above zero during nearly the whole month; values as high as 7.4°C were reached even in the most northern corner of Lapland. In the northernmost part of Sweden, December 2007 was the warmest December in more than 70 years. In parts of northern Norway, it was the warmest December on record.

In contrast, it was still colder than normal in most of the southern half of Europe (like the preceding month), and also over the northern parts of the North Atlantic. Monthly mean anomalies were mostly below -1°C, in southeastern Europe partly below -2°C, in Romania and west Kazakhstan locally even as low as around -4°C or less. The number of ice days was two or three times higher than usual in Serbia. An unusually long period of 10 ice days (Tmax <= 0°C) also occurred in the northwest mainland of Greece. In Armenia, a minimum temperature of -32°C was reported from the north of the country. Daily minimum temperatures in the lowlands of Israel were around 0°C at the end of the year, in Jordan even below.

In central Europe as well as in Italy and parts of southeastern Europe, December 2007 had a mild start, but was followed by a quite cold second half of the month. Some new daily minimum temperature records at -5°C or less were recorded in Italy.

Precipitation

December 2007 was a dry month in most of the Region (Fig. 12.2). The Iberian Peninsula, northern Italy, eastern Europe and parts of the Middle East were the driest areas, frequently with less than 40% of the monthly total. Parts of Portugal and Spain received less than 20% of the normal precipitation, as well as in the Middle East, the lowlands of Armenia and the Ararat Valley. Rainfall totals in Israel were also low (70% of the normal), but distributed to quite a large number of 14-16 rainfall days. Local heavy rainfall up to 75 mm in 11 hours was reported from Lebanon.

It was wet especially in the Arctic region and most of Scandinavia. Only the southern and central parts of the west coast of Norway were considerably drier than normal.

Towards the end of the year, prolonged freezing rain lasting up to 6-7 days occurred in some places in Lithuania. Icing caused considerable damage to electric cable networks.

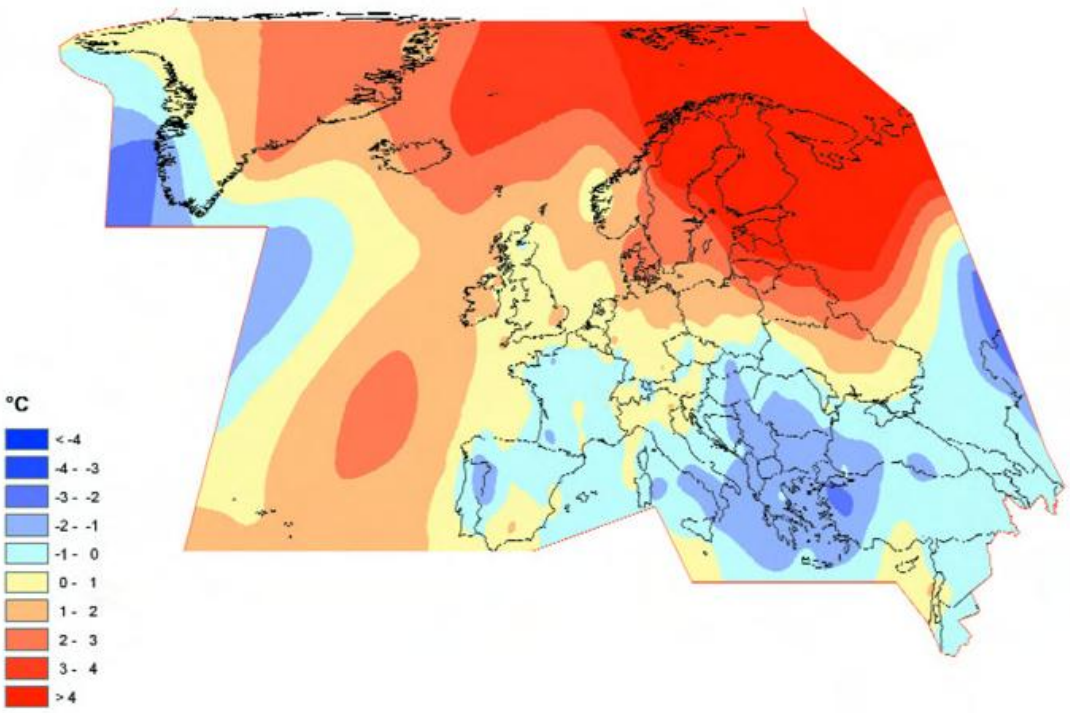

Fig. 12.1: *Monthly mean temperature anomalies in December 2007 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

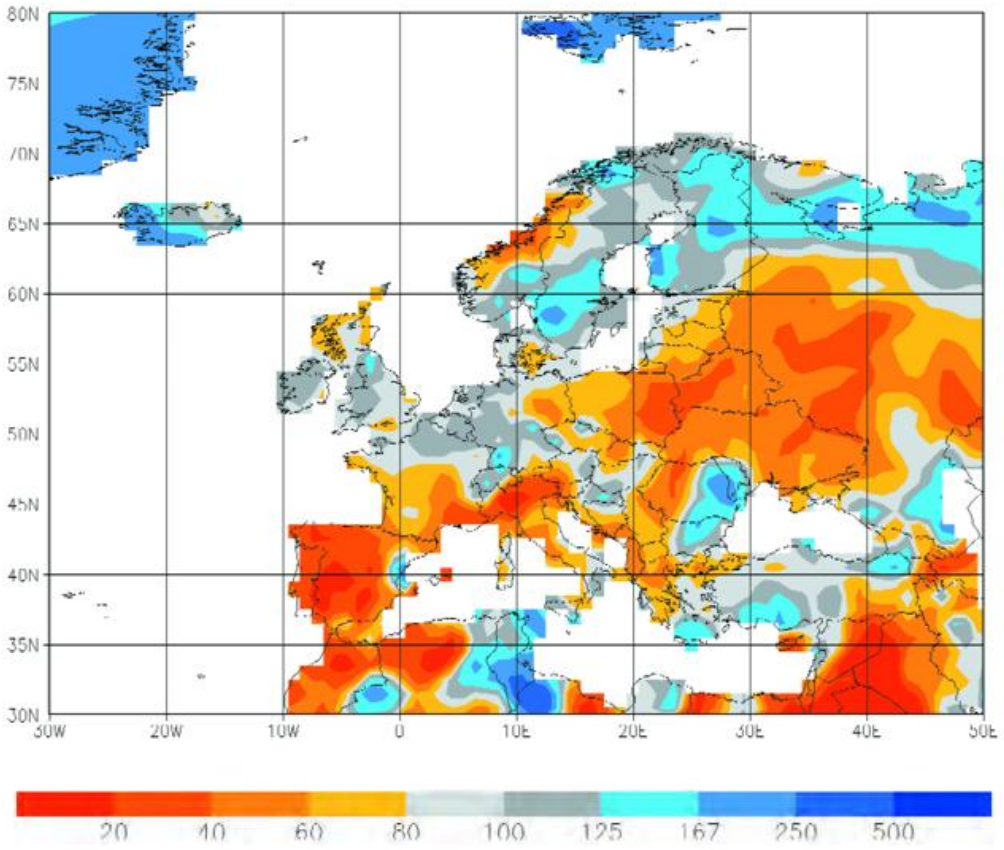

Fig. 12.2: *Monthly precipitation amounts for December 2007 in per cent of the normal 1961-1990 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Rainfall totals across the United Kingdom were generally close to average, with some stations in northwest England, though, having recorded over 150% of their normal rainfall.

In central and southeastern Europe, Dezember 2007 had very different periods in terms of precipitation. In Brussels (Belgium), the first decade was the wettest since 1901 with 82 mm, the second decade the driest with 0.9 mm. In Bulgaria, too, a wet first half of the month was followed by a dry second half.

West of the Black Sea, it was very wet with monthly totals up to twice the normal in northeastern Romania. Malta also received about 200% of the normal, which makes a monthly total of over 200 mm.

Snow

During the second decade, snowfall occurred over the south-central Adriatic regions in Italy, even at sea level. Several harbours at the south-central Adriatic Sea were affected by snowfall, which is quite rare (Fig. 12.3).

An intensive snowfall period on 9-12 December occurred in Switzerland resulting in snow depths far above the long-term mean for this time of the year. Ski areas experienced a perfect start into the season 2007/08.

In the lowlands of Germany, only some smaller areas had a snow cover for a few days, mostly in the last decade of the month. In Poland, the number of days with snow cover ranged from 0 in the west up to 20 in the southern region. The snow cover, though, was thin (<10 cm). Romania had a snow cover in most regions, with up to more than 150 cm in high mountains above 2000 m altitude. It was snowing every day in Serbia in the second half of the month.

In contrast, especially northeastern Europe saw less snow than usual. At the end of the year, no snow was left on the ground in southern Finland. A white Christmas was only to be celebrated in the north and the easternmost parts of the country. In some other northeastern areas, e.g. in Lithuania, there was no chance for a persistent snow cover throughout nearly the whole month.

Fig. 12.3: *Snow blowing over Bari Harbour (Italy) in December 2007*
Source: National Weather Service CNMCA, Italy

Significant weather events

December 02-03:	Storm in Germany and Switzerland with gusts up to 160 km/h in the mountains. Trees fell down, disruption of power lines. Heavy rain up to 51 mm in 24 hours, flooding of streets, Christmas markets closed
December 04-06:	Heavy rainfall with transport disruptions in Bulgaria and flooding in Turkey and Cyprus
December 07-09:	Slow-moving depression (966 hPa central pressure) brought stormy conditions and an exceptionally high wave of over 17 m to the west coast of Ireland (Fig. 12.4). Highest wave ever measured by the Irish buoy network. Storms also over Belgium and Germany
December 15-25:	Unusually long period of ice days in Florina in the northwest mainland of Greece, altitude 689 m
December 17-18:	Heavy snowfall over south-central Italy. Traffic blocked. More than 1 m of snow at Fonni (Sardinia, Italy, altitude 1029 m)
December 18:	11°C in Nikkaluokta in northernmost Sweden, the highest ever recorded December temperature in this part of the country
December 21:	137 mm of daily precipitation at Sundsfjord, Norway
December 25:	Daily minimum of -9.2°C in Shoubak (Jordan)
December 28:	Heavy rain and landslide in southern European Russia (Dagestan)
December 29-30:	Thunderstorms and heavy rain (100 mm / 24 h) in northwest Malta. Roads flooded, telephone lines cut off

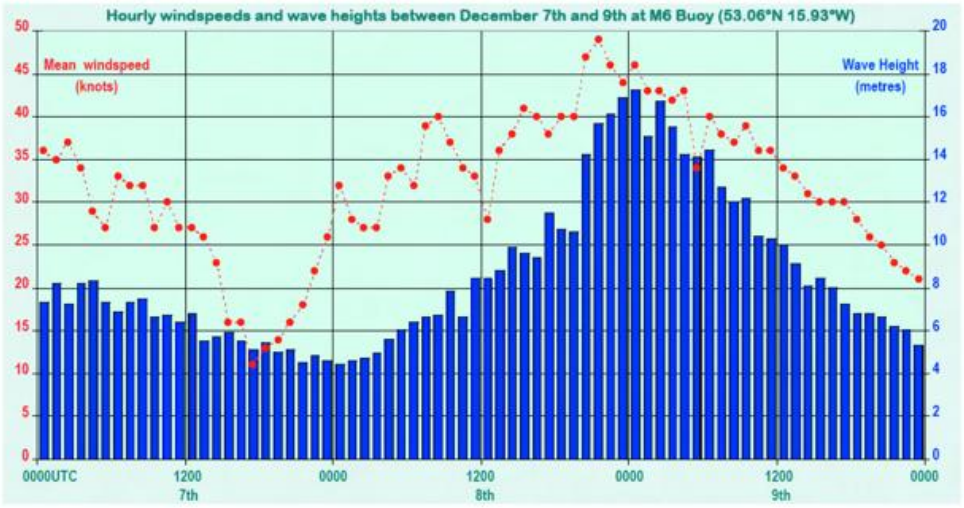

Fig. 12.4: *Hourly wind speeds and wave heights on 07-09 December at M6 Buoy (53.06°N, 15.93°W). Highest wave of 17 m near the west coast of Ireland in the night of 08-09 December 2007 Source: Met Eireann, Ireland*

ECSN Activities Report 2007

Responsible member: KNMI; Programme Manager: Aryan van Engelen

The objective of the optional programme ECSN – the European Climate Support Network – is to strengthen the (now 24) members' capabilities and resources in their climate practices (Fig. 13.1) predominantly by jointly carrying out projects and initiatives that have a European coverage and focus on tangible deliverables addressing the user community.

Fig. 13.1: *Per 31 December 2007, all 24 EUMETNET members participate in the Optional Programme ECSN.*
Source: ECSN

In 2007, ECSN intensified its active collaboration and involvement outside the strict ECSN community, which was materialized by participation in the EU projects ENSEMBLES and MILLENNIUM, by appointing a rapporteur on ECSN in the WMO Working Group on Climate related Matters of RA VI (Europe) and by inviting non ECSN members to attend major ECSN conferences: the Data Management Workshop and the biennial European Conferences on Applied Meteorology and Climatology (ECAM resp. ECAC, in collaboration with EMS, the European Meteorological Society). The enhanced activity of ECSN is expressed by the nomination of the results of two major ECSN projects (EuCLIS and ECA&D) as platforms of WMO Regional Climate Centres.

For showcase **EUROGRID** (**S-EUROGRID**, SMHI, Christer Persson) the main ambition is to illustrate the importance of the full-scale EUROGRID, which is intended to be a future European central resource for gridded climate, meteorological, hydrological and environmental products and data, in line with overarching European and Global initiatives such as Inspire and GEOSS.

In 2007, S-EUROGRID focussed on demonstrating how existing shared gridded datasets from European NMHSs can be used for high standard products and services (Fig. 13.2). Nine gridded datasets have been incorporated: amongst them are two European datasets, ERAMESAN (SMHI) and ENSEMBLES (MeteoSwiss and KNMI). A web designed S-EUROGRID demo system has been realised (www.e-grid.eu).

Outlook: the reputation of S-EUROGRID is obvious from an increasing number of NMHSs expressing their ambition to become partners. Also, it is recognised that a high resolution grid, based on the high quality observational networks of the European NMHSs, should be their core business in the light of the increasing need for derived products that support the society's adaptation to the changing European climate.

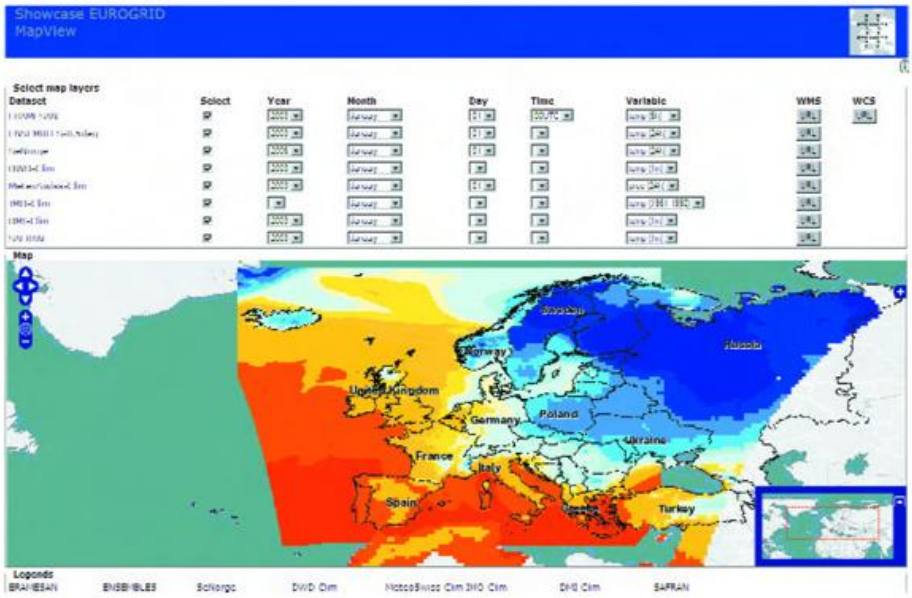

Fig. 13.2: *S-EUROGRID screenshot: demo Map View of data sets. Source: www.e-grid.eu*

HRT-GAR (ZAMG, Ingeborg Auer) aims at the preparation of a High Resolution Temperature Climatology for the Greater Alpine Region with a high temporal and spatial resolution. It envisages to supplement the coarse resolution of temperature information provided by the ECSN Climate Atlas of Europe and to provide an optimal basis for further applications. In 2007, the modelling of temperature data from approximately 1700 stations was performed.

Outlook: together with the final report the results will be accessible on an open website and be submitted to a peer reviewed journal.

The **European Climate Information System** (**EuCLIS**, DWD, Peter Bissolli) is the successor of the Generate Climate Monitoring Products (**GCMP**), an ECSN project which was completed in 2004. GCMP is a Web Platform allowing access to national and European climate monitoring products in the form of thematic maps, descriptive texts, significant weather events and the RAVI Bulletin, provided by 21 participating NMHSs (Fig. 13.3). GCMP will be maintained until the development of EuCLIS has been completed. Based on modern Web-technology, EuCLIS provides a significant extension of the GCMP functionalities, e.g. handling of a higher number of contributing institutions, restricted and public user access, descriptions according to the WMO metadata standard etc.

Outlook: EuCLIS is nominated (like ECA&D) as a candidate platform for a future WMO-RAVI Regional Climate Centre. Links will be made with monitoring products arising from the ECSN projects EUROGRID and ECA&D.

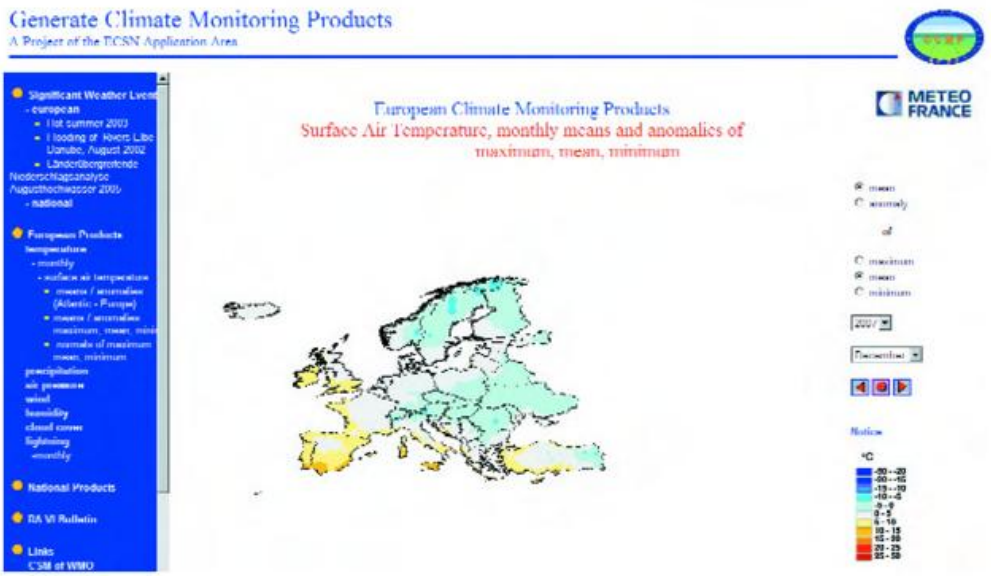

Fig. 13.3: *GCMP screenshot: mean temperature December 2007 for Europe. Source: www.gcmp.dwd.de*

The **European Climate Assessment and Data set** (**ECA&D**, KNMI, Aryan van Engelen) project was initiated in 1998 by ECSN (http://eca.knmi.nl). Today, in its fourth phase, the aims are unchanged: to create and maintain a European data set of daily high quality observational series and, on the basis of derived indices, to produce assessments of European climate. ECA&D co-operates with 53 partners (European NMHSs predominantly) and offers some 6600 climate time series (temperature, precipitation, air pressure, snow depth, relative humidity, cloud cover and sunshine duration), including a set of 40 standardized indices, observed in a network of more than 2000 stations (Fig. 13.4). In April 2007, the EUMETNET council agreed to the proposal to continue ECA&D as a EUMETNET project for a period of 4 years.

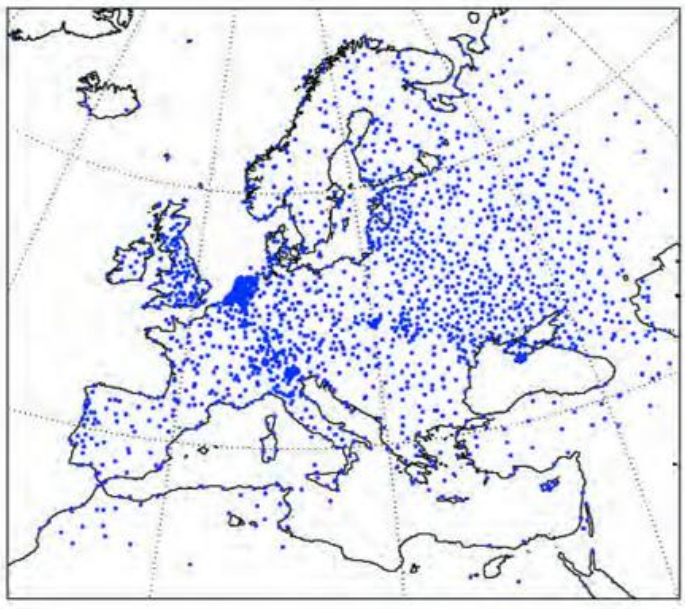

Fig. 13.4: *Station density ECA&D per December 2007. Source: ECSN*

Outlook: ECA&D is aiming to fulfil, like GCMP/EuCLIS, a role as a platform of an RCC. For this purpose the soft- and hardware is put through a major overhaul (completion planned for spring 2008), necessary for the aimed transition from project environment to operations.

In the EU-FP6 **ENSEMBLES** project Wp5.1, MeteoSwiss (Christoph Appenzeller) and KNMI (Albert Klein Tank) collaborate since 2004 with the objective of producing daily gridded datasets (1960-2000) for surface climate variables (max/min/mean temperature, precipitation, surface air pressure and snow cover) covering Europe, for the greater part with a resolution (~50 km) high enough to identify extreme weather events and with attached information on data uncertainty. The work has been completed in November 2007 and the gridded data set has been made publicly available through the ECA&D website.

The aim of the EU-FP6 project **MILLENNIUM** (KNMI, Aryan van Engelen) is to determine with quantifiable precision whether the magnitude and rate of the 20th Century climate change exceeds the natural variability of European climate over the last millennium. ECA&D forms the baseline platform for the Millennium instrumental data. Especially for the Millennium community (www.millenniumproject.net) datasets of monthly aggregated data of all ECA&D indices and all stations have been constructed, accessible via web pages with a dedicated design.

The **6th ECSN Data Management Workshop** (20-22 November 2007, Vienna, ZAMG, Ingeborg Auer) was a real success. About 80 participants from 23 countries were updated on the actual state of climate data management in Europe by 43 oral and 8 poster presentations in 5 sessions: “Data Recovery, rescue and very long series“, „New Tools for Data Quality Control”, “Homogenisation” “Gridding” and “Data Services and Products”.

The Ozone Layer over Central Europe in 2007

Wolfgang Steinbrecht, Hans Claude, and Ulf Köhler - Deutscher Wetterdienst

In 2007, the recent overall tendency towards higher ozone values has continued. As shown in Fig 14.1, annual mean total ozone columns were very similar in the last 5 years, and about 2% below the long-term average at Hohenpeissenberg. This is 2% higher than the decadal mean during the 1990s. However, total ozone is still substantially lower than in the 1970s and 1980s. By no means has ozone fully recovered from the large chemical losses in the previous millennium. Nevertheless, ozone levels in 2007 are consistent with the general levelling seen in recent years. This is expected, since major influence factors (chlorine loading, aerosol loading, solar flux) have not undergone any major changes in 2007. If the very low total ozone columns of 1992 and 1993, after the Pinatubo volcanic eruption, are disregarded, measurements at Hohenpeissenberg (and other European stations) indicate a turn-around of ozone some time after 1995. This is consistent with stratospheric chlorine loading, which has also turned around between 1997 and 2000. Chlorine is expected to keep decreasing slowly in the future.

The largest contribution to the total column comes from ozone in the lower stratosphere, between 15 and 30 km altitude. Ozone variations in this altitude region are shown in the middle panel of Fig. 14.1. They are the main force for total ozone variations. The lowest annual means at 20 km occurred after volcanic eruptions in 1983, 1985, 1992 and 1993. In the last 10 years, ozone near 20 km height has also increased. In 2007, annual mean ozone above the long-term average was registered for the first time since 1994. Given the usual ups and downs, ozone in the lower stratosphere shows signs of recovery. However, a good part of this (e.g. the high values in 1998, 2004, and 2007) is not due to the slow and smooth decline of chlorine, it is rather due to the specific meteorological conditions in these years.

In the free troposphere (5 km), ozone develops quite differently. From the late 1960s to the late 1980s, tropospheric ozone at Hohenpeissenberg (and other stations) has increased tremendously. After 1987, this increase has not continued, instead ozone decreased sharply until about 1991. Since then, tropospheric ozone values above Hohenpeissenberg have gone down

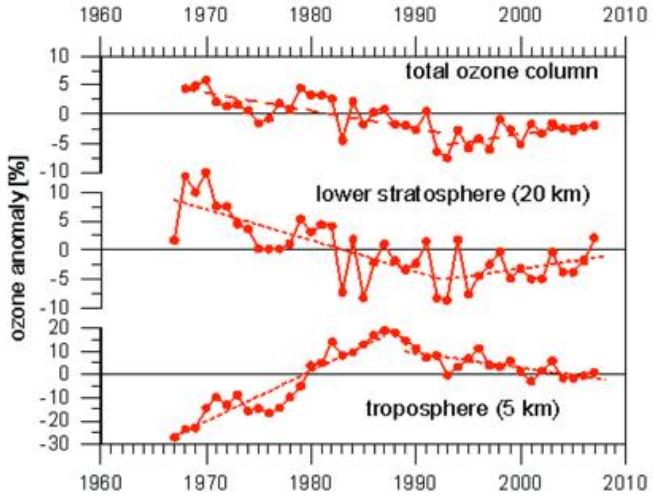

Fig. 14.1: *Annual mean anomalies of total ozone column (top panel), ozone partial pressure in the lower stratosphere (middle), and ozone partial pressure in the free troposphere (bottom), all at Hohenpeissenberg. Trend-lines are given for the main periods with ozone decrease and increase.*
Source: Deutscher Wetterdienst, Germany

slightly. A similar behaviour has been observed at the ozone sounding stations in Uccle (Belgium) and, to a lesser degree, in Payerne (Switzerland). It must be noted, however, that ozone measurements near the ground at many stations, including Hohenpeissenberg (988m) and Zugspitze mountain (2965m), show a more or less continuous ozone increase since the late 1980s and not the steady decline registered by sonde data in the free troposphere (DWD Ozone Bulletin No. 116, http://www.dwd.de/ozonbulletin). The cause for this major discrepancy is currently not understood.

Although stratospheric ozone shows signs of improvement, the ozone layer is still thinner than in the late 1970s before substantial ozone destruction by man-made chlorine set in. The reduced thickness of the ozone layer, combined with its substantial natural variation from day to day (sometimes exceeding 30%), means that very low ozone columns are possible at any time. Especially on clear days this can result in substantially enhanced solar UV-radiation, and pose substantial sun-burn risk. Fig. 14.2 demonstrates this risk by giving the weekly maxima of the UV Index at Hohenpeissenberg in 2006 and 2007. Results are based on the regular spectral UV measurements at Hohenpeissenberg, which started in 1990 (DWD Ozone Bulletin No. 117, http://www.dwd.de/ozonbulletin). Due to high position of the sun in the sky, the highest UV values occur in summer and at noon. UV is also enhanced when total ozone is low and when the sky is clear. Clouds usually result in a substantial UV reduction, but sometimes they can reflect light and increase UV irradiation. Despite the general levelling of total ozone, very high UV Index values were measured at several occasions in recent years, e.g. in March and June 2006, or in May, June and July 2007. UV Indices higher than 7 imply a significant risk of sun-burn (unless precautions are taken) and can occur at Hohenpeissenberg from the end of April until August. To help reduce this risk, the Deutscher Wetterdienst, within in the ESA PROMOTE project, provides a global forecast of the expected UV Index values, available at http://www.uv-index.de.

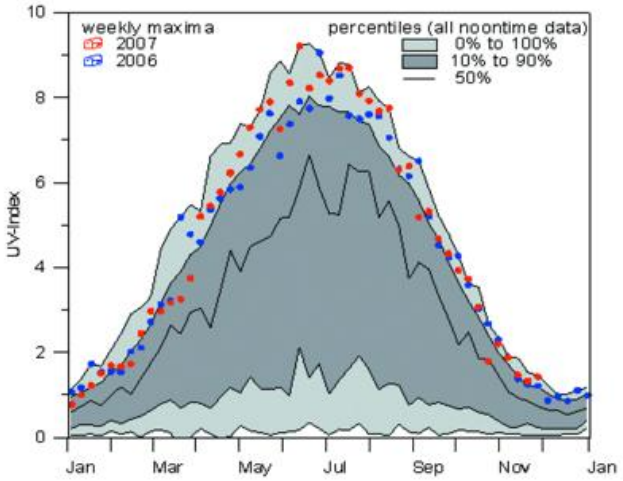

Fig. 14.2: *Annual course of weekly maxima of the UV Index in the years 2006 (blue) and 2007 (red) from UV B measurements at Hohenpeissenberg. The background shading gives the probability of exceeding a certain UV index, calculated on the basis of all measurements at local noon ± 1 hour (not just weekly maxima) at Hohenpeissenberg since 1993. At the beginning of May, for example, 100% of (all) UV Indices measured near local noon are less than 7.4, 90% are less than 6.5, 50% less than 3.9 and 10% less than 1.1.*

Foreword

"Better climate information for a better future" – this is the theme of the WMO's World Climate Conference 3 in August/September 2009.

Nowadays, a large amount of climate information is available, provided by National Meteorological and Hydrological Services and climate research centres: climate data from various data sources, climate analyses, assessments and predictions as well as impact studies. We all know their main message: climate change is still ongoing, even faster than in the past, and consequently, mitigation and adaptation to future climate continue to be important topics over the next years. Climate variability, however, shows a wide variety, both spatially and temporally. Policymakers, on their part, need to know details of climate change and its consequences to take the right measures at the right time and at the right place.

This Annual Bulletin on the Climate – it is the 15th issue now – is one of the main contributions to the provision of climate information especially devoted to our Region VI as it combines valuable national information into one summarising, but nevertheless comprehensive report. Its significance also becomes particularly apparent with regard to the future Regional Climate Centre on Climate Monitoring whose pilot phase started in June 2009. The Annual Bulletin gives an overview of climate variability in 2008 in our Region and also contains many noteworthy details about climate events in the various countries. To show what has happened and what can happen in a world where the climate is changing is indispensably needed to assess what the future will bring and whether this will be more frequent than today.

The year 2008 has taught us another lesson about how contrasting climate variability can be in our Region which doubtlessly shows a very heterogeneous climate. The winter of 2007/08 was very mild particularly in northeast Europe but unusually cold in the Middle East. Some places in northern and northwestern Europe experienced their wettest year on record whereas Spain suffered from a long-lasting winter-spring drought. These contrasts are the result of the interaction of various circulation mechanisms which influence our regional climate and which are also embedded in the general global climate change manifesting itself in our Region. 2008 was once more one of the warmest years in at least more than 150 years on European average.

This presentation of the whole climate information would not have been possible without the numerous national contributions from our Members, the National Meteorological and Hydrological Services. Once again, nearly all Members of the Region (48 out of 50 countries) have sent very interesting articles and figures to our editors at the German Meteorological Service (Deutscher Wetterdienst, DWD). I would like to express my sincere thanks to all contributors and also to the editorial team of DWD, namely to Peter Bissolli, Peer Hechler, Volker Zins and all internal reviewers, for compiling and writing the texts and doing all the editorial and technical work. Congratulations to the colleagues from DWD for their voluntary dedication to all 15 issues of this publication in all these years.

Daniel Keuerleber-Burk
President of WMO Regional Association VI

Outstanding Events and Anomalies in 2008

Temperature

- Mild winter 2007/08 particularly in northeast Europe
- Cold January in the Middle East
- Several heat waves in southeastern Europe in summer

Precipitation

- Wettest year on record in some places in northern Europe
- Long winter-spring drought in Spain

Sunshine

- Sunny February and May in many parts of Europe

Annual Survey

1. Atmospheric circulation

Europe commenced the year under a strong zonal (positive) North Atlantic Circulation (NAO) pattern, which continued until March, when a blocking pattern developed over Russia resulting in a strong meridional pattern during April. May saw high pressure dominate northern and central Europe, followed by cyclonic conditions with frequent thunderstorms across central Europe during the summer. A negative phase of the Arctic Oscillation (AO) brought cold Arctic air into northeastern and at times also central and southern Europe from April to September. Conversely, south-westerly flow during the summer across southeastern Europe resulted in several heat waves. In October, a blocking pattern established over Russia and remained there for most of the rest of the year, producing mild conditions over eastern Europe and colder air masses over western Europe. In November, a deep trough extended from Scandinavia to Iberia. The year ended with very cold air flowing from the high latitudes to southeastern Europe and the Middle East on the eastern flank of a central European high pressure system.

In contrast to the North Atlantic-European pattern, Greenland, especially its western part, was affected by cold air masses at the beginning of the year. Starting in February/March, however, it was then included in the general Arctic warmth, particularly at the end of the year.

The Southern Oscillation Index (SOI), which is a measure of the strength of the El Niño Southern Oscillation phenomenon (ENSO) and is described by the pressure difference between Tahiti (tropical Pacific) and Darwin (Australia), was positive throughout the whole year except a slight negative value in May. Highest values occurred from January to March and again from September to December, while ENSO was weak in late spring and summer. High positive SOI values indicate La Niña conditions. It can be assumed that the La Niña conditions from January to March were related to the parallel positive NAO/AO phase due to the general strengthening of the NAO during La Niña winters. Also, the northward shift of the frontal zone during winter 2007/08 is congruent with La Niña conditions. In November, the La Niña cooling of the East Pacific could have inversely affected the NAO due to a smaller thermal difference on the thermal planetary frontal zone and thus causing weaker west winds also over the North Atlantic. Normally, the ENSO impact on Europe is highest in spring, but as the SOI decreased considerably in spring 2008, there was probably only little impact on spring climate in 2008.

The zonal index over central Europe (20°W-40°E, data from DWD) was very high in January-March and again in October-November, with values being considerably higher than normal. April, May and September had negative and below normal values. This reflects the positive NAO/AO mode in January-March and the sudden switch to a strong meridional pattern in April. The high October-November zonality over Europe is in accordance with the AO, but not with the NAO, which suggests that the shift of the Icelandic Low to the central Arctic region nevertheless caused a zonal circulation over Europe.

In central Europe, cyclonic weather types dominated throughout the year; anticyclonic types were in majority only in May and October. The total number of days with cyclonic types was considerably higher than normal especially in spring and summer, but also, though to a lesser extent, in other seasons. However, the high number of cyclonic types did not have any major effect on the annual precipitation totals in central Europe.

2. Temperature

Overview

Warmer-than-average[1] conditions extended across most of Europe in 2008. The mean land surface temperature for the European region (35°N-75°N, 10°W-30°E), as derived from the CRUTEM3 dataset (Climate Research Unit Temperature Version 3, land air temperature anomalies on a 5°x5° grid box basis, http://www.cru.uea.ac.uk/cru/data/temperature/), was 1.16±0.17°C above the 1961-90 mean. This made 2008, along with 2006, the 4th warmest year in Europe since 1850. With the northern latitudes not taken into account (35-65°N, 10°W-30°E), it was even the second warmest since 1901. Anomalies ranged from around zero in southwest Europe up to more than +2°C in the northeast of the Region (Fig. 0.1). The high anomalies in the northeast were mainly due to exceptionally high temperatures during the winter of 2007/08 (Fig. 0.2 Finland). January and February were very mild not only in these areas, but also in most of Europe except the southeast. 2008 did not set so many new weather records as the previous two years, but this year has once more confirmed the general warming trend on the global as well as the regional level.

Only a few places in southwestern Europe and in some parts of Turkey reported a cooler-than-average annual temperature in 2008. In many countries across central and southeastern Europe, September was the only colder-than-normal month, whereas all the other months were warmer than normal (Fig. 0.3 Poland).

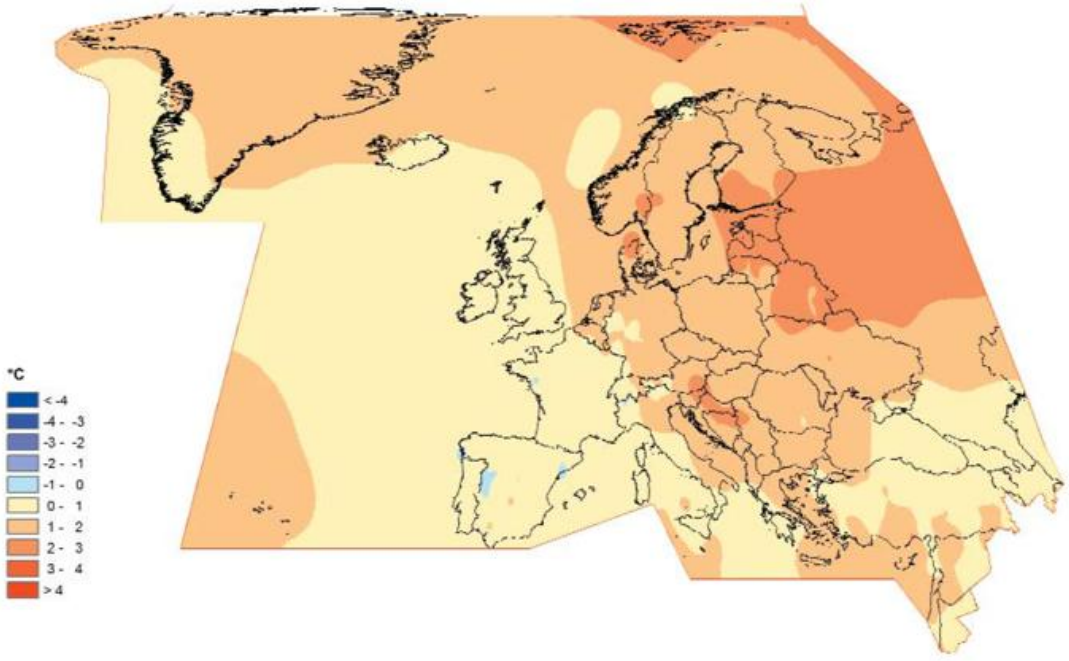

Fig. 0.1: *Mean annual temperature anomalies in 2008 (reference period 1961-1990) in WMO Region VI (interpolation of CLIMAT data).*
Source: Deutscher Wetterdienst, Germany

[1] The standard reference period used in this publication for European averages is 1961-1990 for temperature, and 1951-2000 for precipitation, unless otherwise expressly specified.

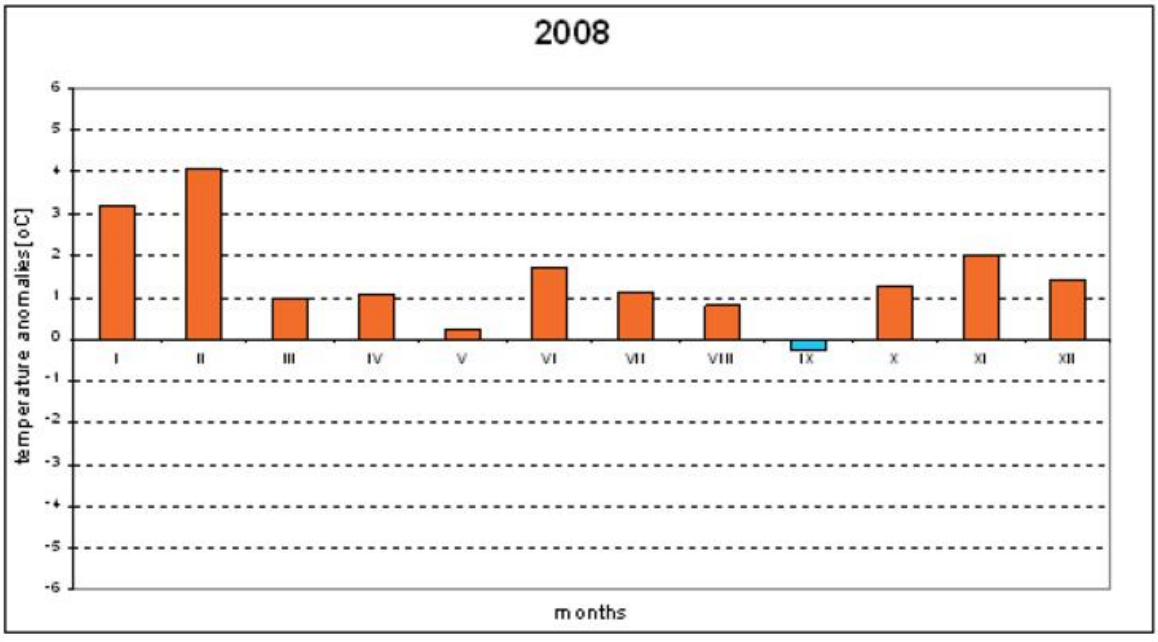

Fig. 0.3: *Mean monthly temperature anomalies 2008 (reference period 1971-2000) in Poland (averaged over 20 stations).*
Source: Institute of Meteorology and Water Management, Meteorology Centre, Poland

Northern Europe and Arctic region

Widespread anomalous warmth was present over the European Arctic in 2008. The island of Hopen, in the Svalbard archipelago, experienced a temperature anomaly of +2.7°C (annual mean temperature -3.7°C). The island of Jan Mayen (northeast of Iceland) had an annual average temperature of 0.7°C, 2.1°C above normal. Greenland and the Faroe Islands also were warmer than usual (Nuuk in Greenland +0.3°C, Tórshavn, Faroe Islands +0.6°C).

2008 was the 13th consecutive warmer-than-average year in Iceland. The Icelandic capital Réykjavik reported an annual temperature anomaly of +1.0°C, with similar records coming from many other Icelandic stations. Temperatures during May to September were unusually high in parts of the country (Fig. 0.4) and the period from May to July has never been so warm in Réykjavik since 1941. October was the only colder-than-normal month in the country as a whole.

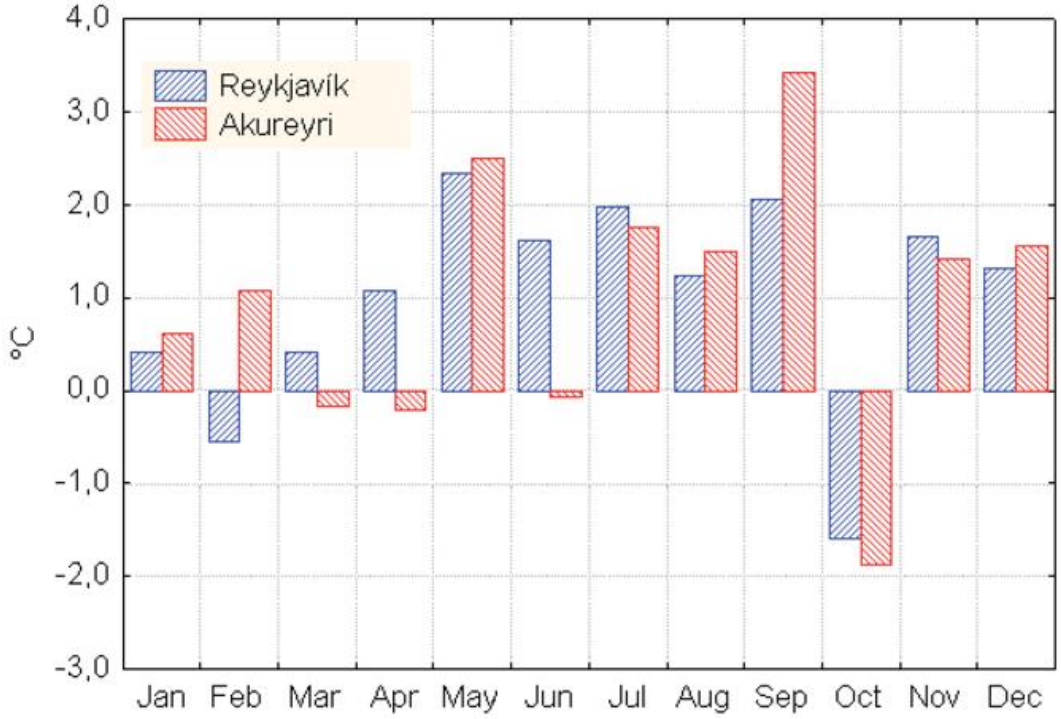

Fig. 0.4: *Mean monthly temperature anomalies 2008 (reference period 1961-1990) in Réykjavik and Akureyri, Iceland.*
Source: Icelandic Meteorological Office

In Norway, Sweden, Finland and Denmark, annual mean temperatures were well above normal (Norway: +1.4°C, locally above +2°C (Fig. 0.5); Sweden: +1°C to +2.5°C). It was the second warmest year in Denmark (along with 2006 and behind 2007), with an annual mean temperature of 9.4°C, which is +1.7°C above normal. Thus, the last three years were the warmest ever recorded in Denmark since 1873 (Fig. 0.6). There were no new temperature records in Denmark for 2008, but it was consistently warm throughout the year. 2008 was the warmest year at some southeastern stations in Sweden (Fig. 0.7). Stockholm and Uppsala both noted their warmest year (in Stockholm together with the year 2000) since the start of their long time series in the middle of the 18th century (mean annual temperature 8.5°C in Stockholm, 7.8°C in Uppsala).

Southwestern and most of southern Finland experienced the warmest year since 1961 . Annual anomalies in Finland reached up to around +2.5°C above normal in the south of the country.

It was the warmest year since 1961 in Lithuania, where the annual mean air temperature rose to 8.2°C. Latvia reported its second warmest year over the last 85 years (7.6°C country mean). With an annual countrywide mean of 7.4°C, 2008 was the warmest year in Estonia since 1989, when the same value was reached. In the long-term time series of Tartu, the year 2008 shows the highest annual mean since 1866 at 7.2°C. Anomalies in all Baltic countries were around +2°C.

North Atlantic

The North Atlantic was around +1°C warmer than normal, in the North and near the Azores somewhat more, near western Europe less, but still above zero. It is assumed that warmer-than-normal sea surface temperatures have also contributed to positive anomalies over land.

Central and western Europe and the Alpine region

Central Europe was warmer than normal, but not so warm as 2007. Anomalies ranged from near zero in southwestern and western Germany up to +2°C in Poland. At various stations in Slovakia, 2008 was the warmest year since records began in 1871, but as there were no extreme heat waves in summer, the absolute maximum did not exceed 35°C in that country. Belgium did not have any ice days (maximum temperatures below 0°C) in 2008, which was quite a very exceptional situation.

Over western Europe, annual temperature anomalies were generally lower than in central regions. Despite temperatures mostly of 0.4-0.7°C above normal, 2008 was one of the coldest years in the last decade in France, the UK and Ireland. The Netherlands recorded an anomaly of +0.8°C (annual mean temperature 10.6°C) with particularly warm months in January and May. Similarly, Belgium had outstanding warm months in January, February and May while the other months were closer to the long-term average (Fig. 0.8).

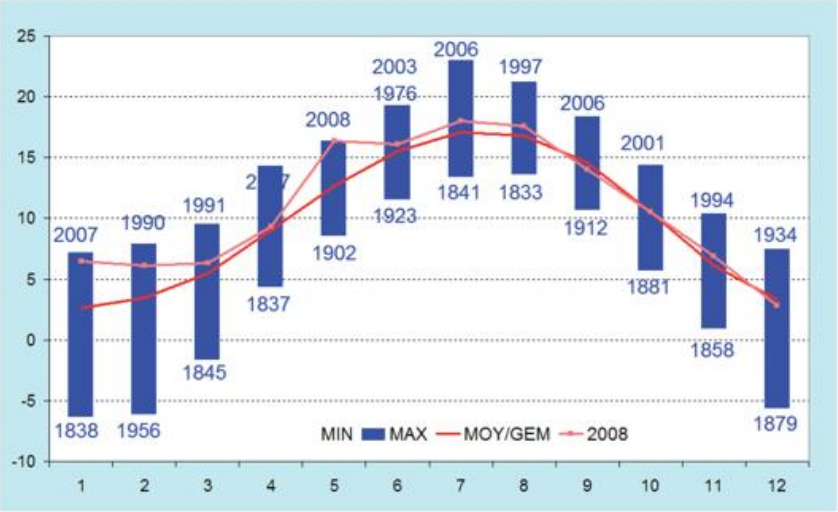

Fig. 0.8: *Monthly averaged mean temperature (°C) in Uccle, Belgium in 2008 (pink) and on long-term average 1901-2000 (red). Blue bars indicate maximum and minimum mean temperatures and the corresponding years.*
Source: Royal Meteorological Institute, Belgium

The weather conditions in Switzerland during the first half of the year were determined by frequent foehn events and generally high temperatures, followed by a second half with more alternating warm and cold spells. Anomalies in Switzerland were about +1°C, making 2008 as another warm year, though clearly colder than the recent 5 warmest years on record (Fig. 0.9). Anomalies in Austria were in the range from +0.6 to +1.5°C. Due to frequent southerly foehn events, valleys in the northern Alpine region experienced temperature anomalies above +1.3°C.

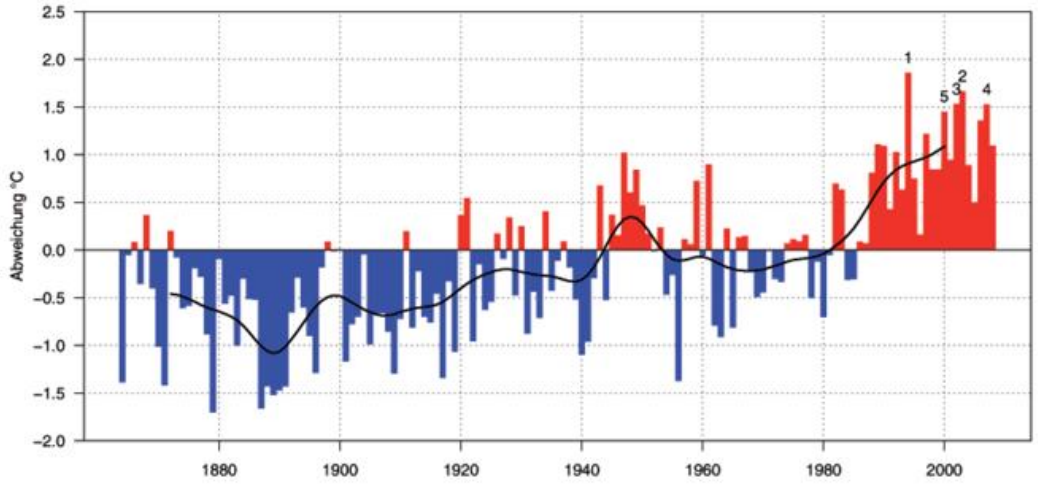

Fig. 0.9: *Mean annual temperature anomalies 1864-2008 (°C; reference period 1961-1990) in Switzerland (averaged over 12 stations). Red (blue) bars indicate positive (negative) anomalies. Black curve: 20-year Gaussian low pass filtered data.*
Source: MeteoSwiss, Switzerland

Iberia

While western Iberia registered negative anomalies throughout the year (except at the beginning of the year), the eastern and southern parts were characterised by consistent positive anomalies (except autumn). Although annual temperatures in Spain were slightly above average, it was the coldest year since 1996 (Fig. 0.10). The country mean of mainland Portugal was 0.2°C lower than the 1971-2000 average. Here, it was the coldest year since 1993, and for the first time since then the annual mean maximum temperature was below normal. Especially the second half of the year was colder than normal in Portugal.

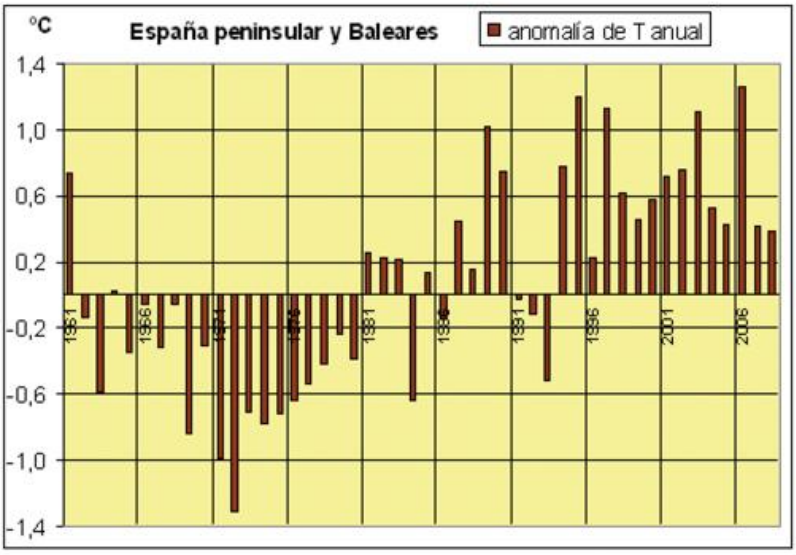

Fig. 0.10: *Mean annual temperature anomalies 1961-2008 (reference period 1971-2000) in Peninsular Spain and Balearic Islands.*
Source: National Meteorological Institute Spain

Mediterranean, eastern and southeastern Europe

The year 2008 was 1° to 2°C warmer than normal across most of eastern and southeastern Europe (Fig. 0.11 showing Bosnia and Herzegovina as an example). In Belarus, most of northern European Russia and parts of the southeastern Ukraine, anomalies exceeded +2°C, while anomalies in southern Greece, Sicily and parts of the Italian Peninsula were below +1°C. In Hungary, it was the third warmest year on record since 1901; all months except September were warmer than normal and two short, but severe heat waves occurred in August and September. On more than 40 days, maximum temperature was 30°C or more in southern Hungary (Fig. 0.12). In Belarus, 2008 was the warmest year on record, along with 1989 (Fig. 0.13). All months were warmer than normal except May; February was especially mild. Behind 1995 and together with 2007, 2008 was the second warmest year in European Russia in a 100-year record. In the Ukraine, especially February and March were considerably warmer than normal, but also summer and late autumn (Fig. 0.14).

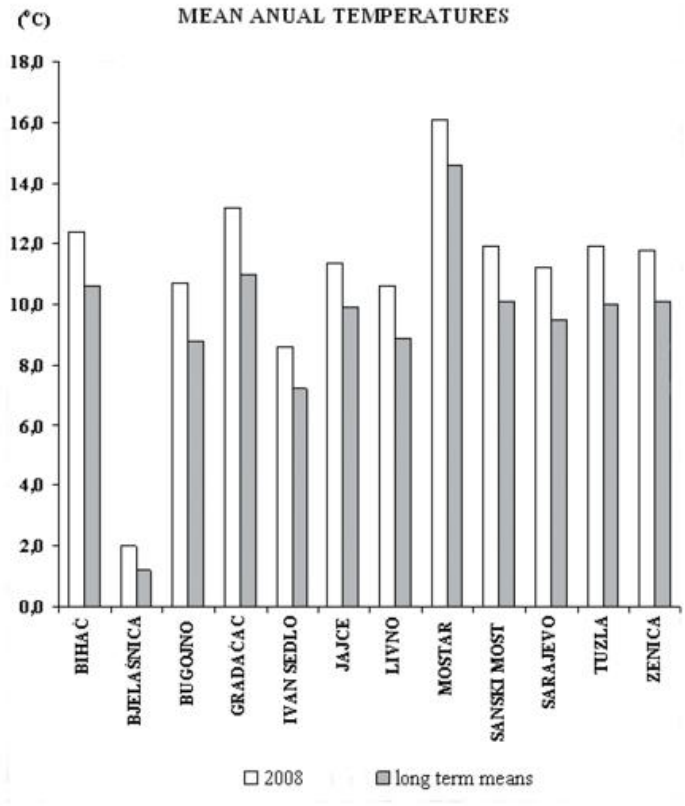

Fig. 0.11: *Mean annual temperatures in 2008 and for the reference period 1961-1990 at stations in Bosnia and Herzegovina.*
Source: Federal Hydrometeorological Institute, Bosnia and Herzegovina

On the Balkan Peninsula, the highest deviation from normal was observed in Bosnia and Herzegovina and in northern parts of Croatia. Across most of Croatia, temperatures exceeded the 98th percentile of the 1961-90 distribution. With 13.4°C, 2008 was the third warmest year in Zagreb, ranking behind 2000 and 2007 (beginning of records in 1862). New absolute maximum records were reached in Serbia in February, May and September at several locations throughout the country. Serbia also recorded heat waves from 26 May to 3 June and from 20 to 27 June while in August, the number of tropical days (>=30ºC) was twice the long-term average. Bulgaria experienced its 3rd warmest year on record since 1901, behind 2007 and 1994. Albania had annual mean maximum temperatures up to +2.6°C above normal and minima up to +3.4°C above normal, especially in the coastal zone.

Middle East and South Caucasus region

Annual temperatures across the Middle East were generally 0° to 1°C above normal, although anomalies in Cyprus, southern Turkey and parts of Syria, Lebanon, Israel and the mountain regions of Azerbaijan (above 1000m altitude) exceeded +1°C. Positive anomalies in the Caucasus countries (e.g. in Azerbaijan), but also in Turkey were mainly due to warm months in March and April (Fig. 0.15). Although 2008 was generally a warm year in Turkey, it was slightly colder than the preceding 3 years (2005-2007). In particular the annual mean minimum temperatures were higher than normal in Turkey while the maxima were lower. Jordan had frost for a couple of days on several occasions in February-April in hilly regions in southern and eastern parts of the country. Severe frost damage mainly affected fruits (zucchini, bananas), but also vegetables and crops.

3. Precipitation

Overview

In 2008, rainfall in Europe was unevenly distributed both, spatially and temporally (Fig. 0.16), and the year was characterized by several major storm events with extremely intense and heavy precipitation. Annual precipitation was mostly above the long-term average (1951-2000) in northern and western parts of Europe and below average in southern Europe. Less than 80% of normal precipitation was observed in Bulgaria, Greece and the Middle East, in parts of the eastern Mediterranean even less than 60%. Some areas, particularly in northern Europe and the Arctic, received more than 125% of normal precipitation.

Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst , Germany

Northern Europe

Precipitation in 2008 was mostly above the long-term average in the Nordic countries. Highest anomalies occurred in southeastern and southwestern Finland, where precipitation was 150%-200% of the 1961-1990 normal. Kemiö recorded 1064 mm of precipitation, the second highest total recorded in Finland in the last hundred years.

In Sweden, precipitation totals locally reached 175% of normal, which was partly due to the wet winter. The Swedish station Mollsjönäs (near Gothenburg) reported an annual total of 1866 mm and thus set a new Swedish record for highest annual precipitation beating the previous one of 2007. Denmark received 109% of normal precipitation with a very dry May partly compensating for wet conditions in January, March, August and October. Denmark's annual rainfall has risen by about 100 mm since 1870. Annual precipitation was close to normal in Norway, although some southern parts received 50% more than normal.

Parts of the European Arctic experienced well-above-average precipitation. Ny-Ålesund on Svalbard reported 128% of average precipitation. On Iceland, precipitation was close to normal in the north and east but in the southwest of the island, 2008 was a wet year (Reykjavik 117%), though not as wet as 2007. The year 2008 began with heavy precipitation in Iceland, whereas the first part of the summer was very dry. Tórshavn on the Faroe Islands received 115% of the 1961-90 normal annual precipitation, Nuuk in western Greenland 139%.

In the Baltic countries, Tartu in Estonia saw its second wettest year since 1866 with 873 mm of precipitation (144% of the 608 mm normal). Latvia had an annual precipitation total of 744 mm (113% of normal) with August and October having been particularly wet. Lithuania noted near-

normal annual precipitation: a wet start of the year (especially in January to March) was compensated by some drier-than-normal months during the summer half year (May-September, Fig. 0.17).

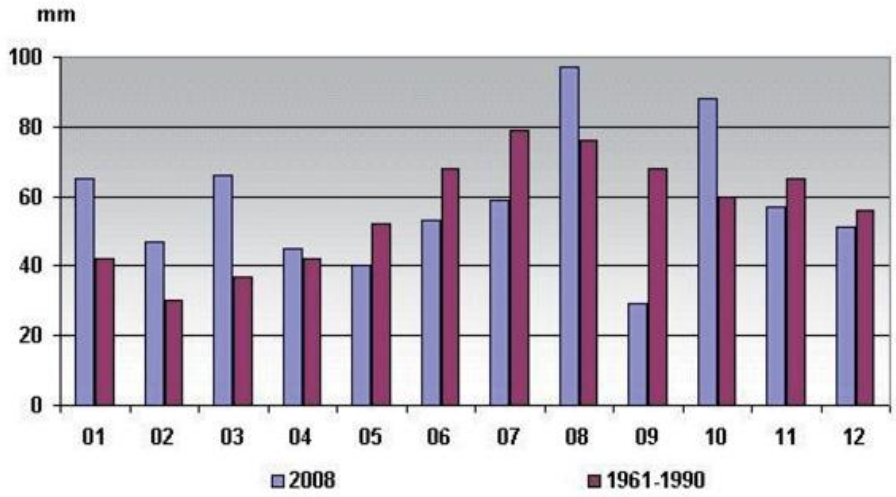

Fig. 0.17: *Precipitation totals in 2008 and the 1961-1990 average in Lithuania. Source: Lithuanian Hydrometeorological Service*

Western and central Europe

With 118% of the 1961-1990 mean annual rainfall the United Kingdom experienced its third wettest year in a national rainfall series that begins in 1914. The annual totals partly exceeded 135%, particularly in northeast England and southeast Scotland (Fig. 0.18). Rainfall totals in Ireland were also well above average, especially due to high summer rainfall, but also to a 10-20% higher-than-normal number of wetdays (days with 1 mm or more rainfall). It was the wettest year on record in places of Ireland (Fig. 0.19): e.g. Shannon Airport recorded its highest annual precipitation total (1268 mm) since observations began in 1945. In most of France, precipitation was only slightly higher than normal with only some areas in the southeast reporting annual totals up to 150% of the 1971-2000 normal which were close to records in some places.

In central Europe, precipitation was close to or slightly below average, with the exception of eastern Austria (> 110%), the southern alpine region (120%-140% due to some heavy rain and snowfalls resulting from depressions over northern Italy), and Slovakia (115%). Between May and September, a large number of strong thunderstorms with heavy rain, tornadoes and hailstorms were observed in central Europe, causing some casualities and significant damage. Long dry periods as in 2007 did not occur in 2008 in central Europe.

Iberia

The Iberian Peninsula generally experienced below-average rainfall in 2008, with the largest anomalies of more than 20% below the long-term mean over Portugal. There have now been 4 very dry years in the recent past in Portugal (2004, 2005, 2007, 2008; Fig. 0.20). In the north-eastern regions of Spain, annual precipitation was slightly above average. The 2008 accumulated precipitation over the Iberian Peninsula was slightly less (around 5%) than the 1961-1990 average, but averaged only over Peninsular Spain and the Balearic Islands, it was

rainier than usual. The annual total of 630 mm at La Rioja exceeded by 8% the previous year's record in a series of almost 60 years. Spain also broke new records for daily precipitation during spring and autumn, with the highest being 155 mm in Cádiz.

The year was generally characterized by periods of drought interspersed with local heavy rainfalls. Drought conditions prevailed in Spain from the beginning of the year until mid-April, making it the worst drought in this country for over half a century. From the beginning of the year until mid-March in Spain, only 2.8 mm of precipitation fell on spatial average which is around 40% of the winter half year precipitation from October 2007 to March 2008. The following seasons show a very different pattern, with most of Iberia recording above-average spring rainfall on the one hand and below- (above)-normal values over western (eastern) Iberia in summer and autumn on the other hand. The southernmost coast of Iberia was (as compared with the normal) much drier than the rest of Iberia in spring and much wetter in autumn.

From April to June and September to November, heavy rainfalls were recorded frequently in Spain. Each month, at least one Spanish station set a new daily precipitation record. Despite locally heavy rainfalls, however, it was generally very dry in Portugal between October and December. The Azores Islands were also dry at that time of the year.

Mediterranean, eastern and southeastern Europe

In 2008, rainfall deficits were observed in some areas of the Italian and Balkan Peninsulas and in the eastern Ukraine while precipitation was above average in parts of central European Russia, Slovenia and Romania. Belarus and Hungary had near-normal annual precipitation. However, the precipitation anomalies were distributed very irregularly over the year: e.g. Hungary had a very dry February which was followed, though, by a very wet March; in the Ukraine, February and August were very dry, April, July and September, on the contrary, very wet.

Corsica in the western Mediterranean was wet in 2008 reaching the highest annual rainfall totals for over 40 years. Northern Italy experienced two very intense rain periods in May and June. Croatia had a deficit in annual rainfall, especially in northern parts and southern coastal areas. Precipitation in Dubrovnik was below the 10th percentile (1961-90 base period). It was also dry in most parts of Serbia, where the annual total as well as the number of rain and snow days was low. Macedonia, too, was dry most of the year, but September and December were very wet months. The annual total rainfall in Athens in Greece was 87% of the 1961-90 average.

Middle East and South Caucasus region

Drier-than-average conditions affected most of the Middle East region in 2008. Precipitation anomalies ranged between 40% and 60% of normal in Cyprus and in parts of Jordan and Syria. Averaged over the whole country of Cyprus, the hydrological year October 2007 to September 2008 was the second driest since 1902 with an annual precipitation of 272 mm (Fig. 0.21). The country now suffers its 3rd consecutive year of drought and, as a result thereof, severe water shortages.

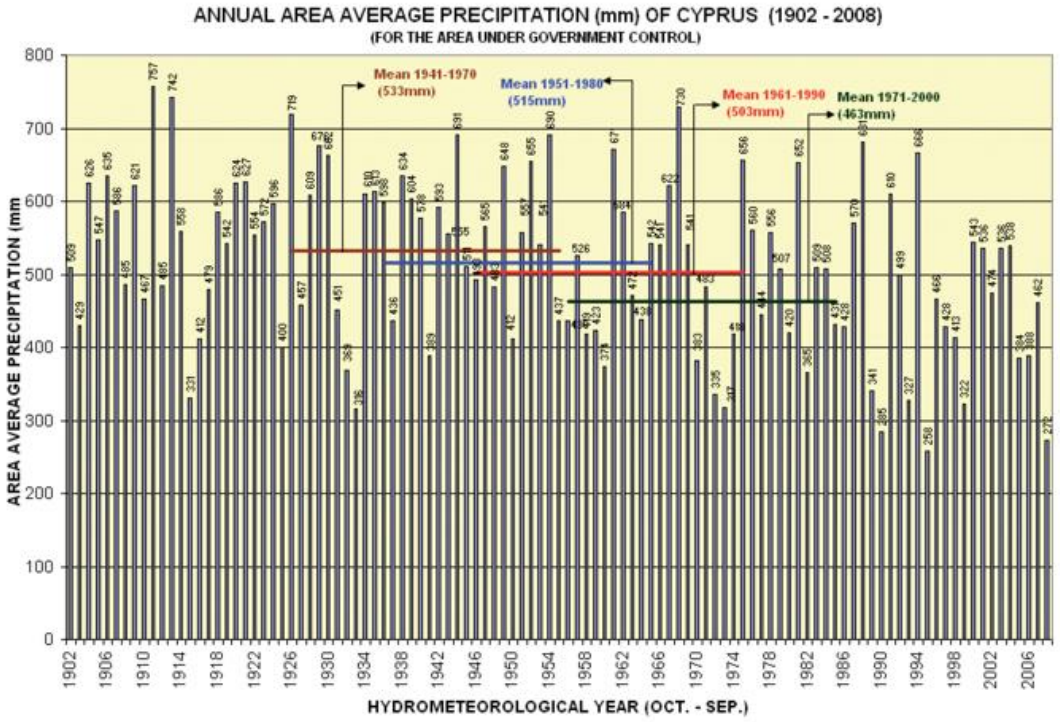

Fig. 0.21: *Annual area-averaged precipitation totals 1901/02-2007/08 (hydrological years October-September) in Cyprus, compared to various climatological means. Source: Meteorological Service, Cyprus*

Annual rainfall was 60-80% of average in Lebanon, Israel and parts of Turkey. Heavy rain in the Lebanon was reported particularly in January, February and October. Less rain than normal occurred in the other months of the winter half year. Precipitation deficits in Jordan amounted to more than 100 mm in several places (Fig. 0.22). In Turkey, the deficits were mainly due to low winter and spring precipitation. Only September was a wet month (Fig. 0.23). In other areas of Turkey and in the Caucasus region, annual precipitation generally was close to the long-term mean, although shortage of precipitation throughout the year was recorded in Armenia which also reported, however, frequent hailstorms and heavy rains from May to September. In Azerbaijan, February to March were dry whereas the summer half year (May-October) was quite wet except August.

4. Snow

In Iceland, snowfall in 2008 was slightly more frequent than in the previous eight years, but it barely reached the average totals of the preceding decades. There were 64 days with snow cover in Réykjavik, which is 9 days more than the 1961-90 average. On the other hand, the snow season from autumn 2007 to spring 2008 had its lowest number of snow days averaged over northern Europe in more than 25 years (Fig. 0.24).

Lithuania experienced its first snowfall of the 2008/09 season as late as in the second half of November and a short period of heavy snowfall (>30 mm / 12 h) at the seaside at the end of that month, though fortunately followed soon by fast snowmelt. In European Russia, a lower-than-usual snow cover was recorded in western and southwestern parts, whereas snow persisted longer than usual in the other areas.

After a winter season 2007/08 with generally very little snow, central Europe had snow in March. Basel and Geneva registered their first snowfall of the year at the end of March, the latest arrival of snow since measurements began in 1931. Many areas over central Europe experienced a white Easter. In the following snow season, during the last weeks of autumn, the Alpine region received an early snow cover even at lower altitudes. Due to continuous southern flows, considerable snow amounts were also recorded at the alpine south side. At the end of November and in December, the snow cover was unusually deep in the western part of the Julian Alps.

In the last week of October and in November, snow affected large areas of Iberia. From 28 November to 3 December, a cold spell brought snow to areas above 600m in Portugal.

The annual number of days with snow cover was generally low this year on the Balkan Peninsula. In most parts of Serbia, for example, there were around 20 snow days less, locally even around 30 days less (Fig. 0.25). The Lebanon in the Middle East had 30% less snow than normal (only 380 cm on average on high mountains) and 35% less snow days.

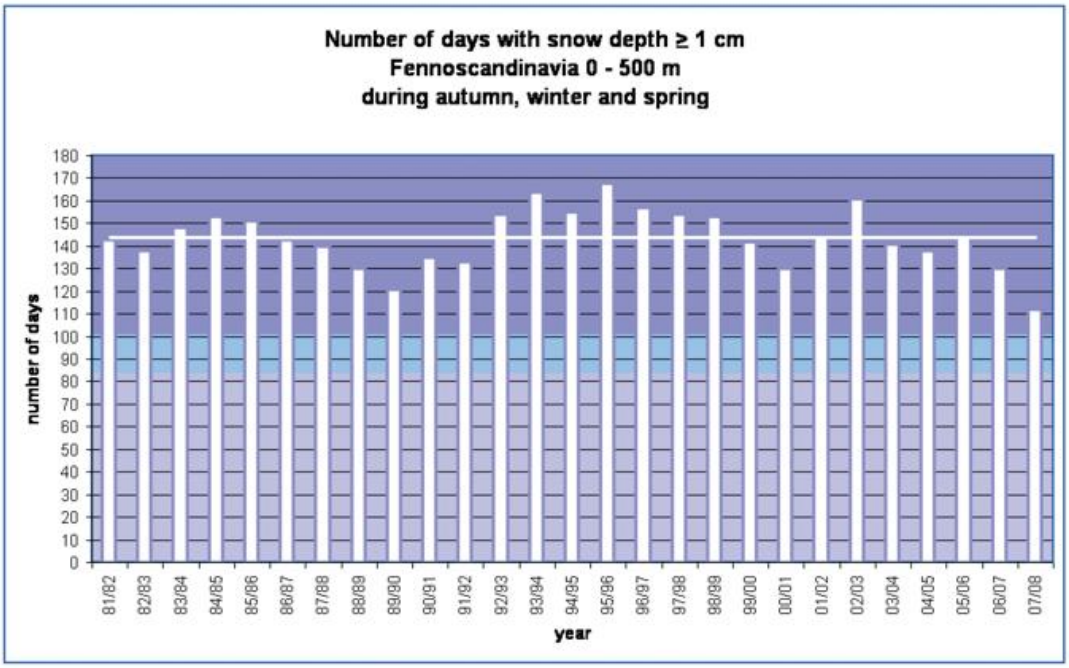

Fig. 0.24: *Number of snow days in Fennoscandinavia during September 2007 – May 2008 (grid point average over Norway, Sweden, Finland, Denmark, and the Baltic countries, based on interpolation of SYNOP data, only elevations 0-500 m considered). Source: Deutscher Wetterdienst, Germany*

5. Sunshine duration

Most places in northern, central and southeastern Europe were sunnier than normal in 2008, whereas most of eastern and parts of western Europe, but also the Middle East received less sunshine than normal (Fig. 0.26).

In the north, Tórshavn on the Faroe Islands registered an annual total of 1003 hours of sunshine (normal 840 hours). Réykjavik in Iceland also experienced a very sunny year with more than 1400 hours of bright sunshine, 195 hours more than on average, whereas the rest of Iceland was quite dull. Denmark had a surplus of 22% of sunshine duration as compared with the climate normal. This corresponds to almost one additional sunshine hour per day.

In central Europe, it was a very sunny year in the Netherlands (1794 hours, almost 250 hours more than normal) and in Poland. In Germany, however, the year was only 7% sunnier than normal. Sunshine duration in France was also near to normal.

On a seasonal level, winter 2007/08 was the sunniest winter in France since 1950, particularly in the northern two thirds of the country, the sunniest winter in Germany since 1951 (Fig. 0.27) and the 2nd sunniest winter in the United Kingdom since 1929. Large parts of western and central Europe, including the United Kingdom, France, Germany, the Netherlands, Switzerland and Austria, also had an exceptionally sunny February with some areas recording over twice

their monthly average sunshine duration. In Slovenia, it was also one of the sunniest February months ever recorded in some places. On the other hand, February, and also the whole winter of 2007/08, had less sunny days than average in southern and central Finland, making it a very dark season for the country.

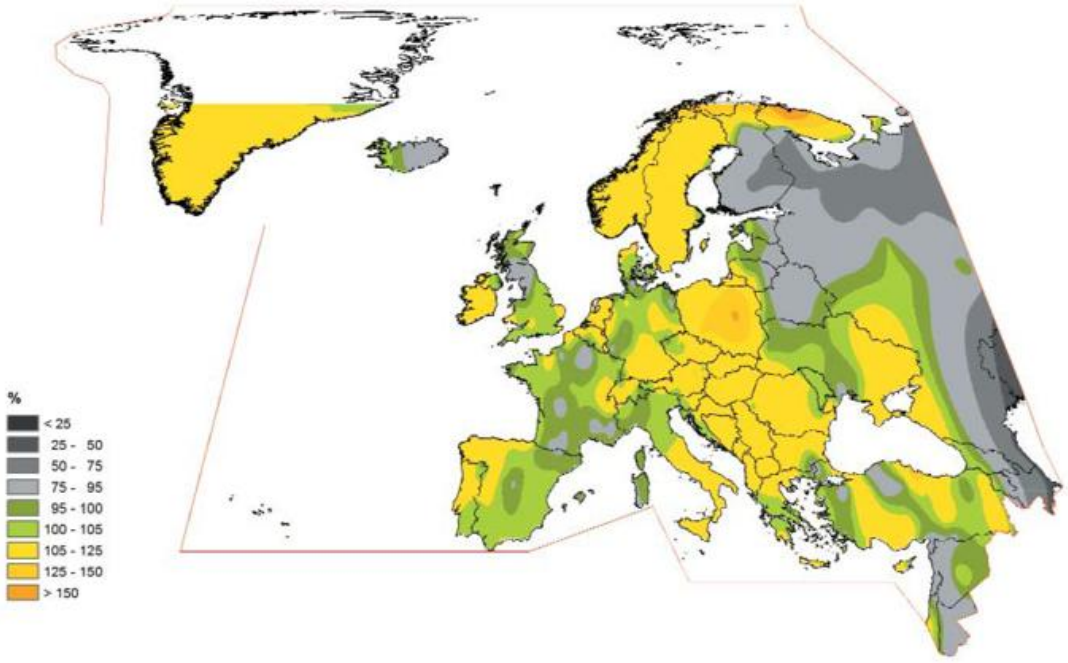

Fig. 0.26: *Mean annual sunshine duration in 2008 in per cent of the 1961-1990 normal in WMO Region VI (interpolation of CLIMAT data).*
Source: Deutscher Wetterdienst, Germany

May was exceptionally sunny in many parts of central and southeastern Europe, but also in southern Scandinavia. It was the sunniest spring (663 hours) and May (347 hours) ever recorded in Denmark. In the Netherlands, the first decade of May was the sunniest on record for that time of year in over a century. Germany, too, had a very sunny May (the third sunniest since 1901) with up to around 400 hours of sunshine (12.5 hours a day on average) at the Baltic coast.

Summer was not very sunny in Finland: less than half of the usual sunshine durations were measured in many places in eastern and northern parts of the country due to a wet season. Lithuania, however, had a very sunny June, recording 360-370 hours of sunshine in some places, which is 95 hours more than normal. Eastern Europe in general experienced a very sunny summer with up to around 200 hours more sunshine than normal.

In many places in Ireland, August was the dullest on record with only around 60% of normal. In other parts of western and northern Europe and in the Middle East, August was rather gloomy whereas it was a very sunny month in southeastern Europe.

September was a dull month in most of Europe, but exceptionally sunny in Hungary where the sunshine duration amounted to more than 300 hours (normal around 250).

December was sunny in western and central Europe, with partly more than 150% of normal. Some places in the northwest of Germany had up to 80 hours of sunshine.

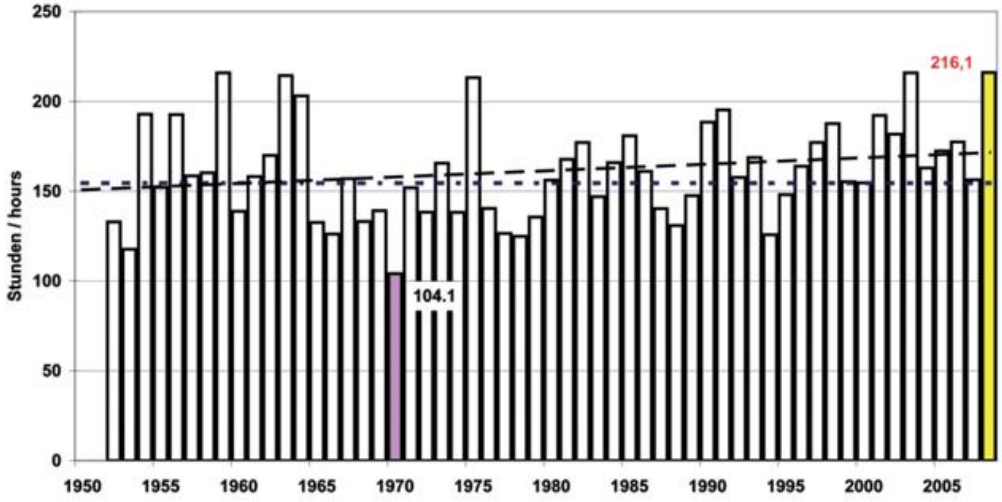

Fig. 0.27: *Mean sunshine duration averaged over Germany in winter 1951/52 – 2007/08. Source: Deutscher Wetterdienst, Germany*

6. Wind

The highest wind speed measured in 2008 at Norwegian maritime stations was 107 km/h (on the 26th of October on the Heidrun field outside the county of Trøndelag).

In 2008, Norway's capital Oslo also was affected by several heavy storms.

There were no severe storms in Denmark in 2008, but it was quite windy for several days between the end of January (25th) and the 1st of March, on midsummer night and on the 21st of December.

Mean annual wind speeds in Ireland amounted to 13-22 km/h. They were above normal everywhere in the country and thus the highest annual values for 6 to 9 years.

Central Europe was affected by some severe winter storms between January and March, and a large number of strong thunderstorms occasionally accompanied by tornadoes between May and September. October was quite stormy over the northern coastal areas, locally with up to hurricane force. However, parts of central Europe had an abnormally low wind speed on annual average, e.g. Belgium, although it was a little bit higher than during the past years in this country.

Thunderstorm activity was very high in Bulgaria.

The annual mean surface wind speed in the Lebanon was 30% lower than normal in the lowlands of the country, but around normal in mountainous regions.

7. Sea ice

The maximum sea ice extent of 2008 in the Baltic Sea was reached on the 24th March, covering as little as 49.000 km². This is less than 12% of the whole Baltic Sea area. In a typical winter, the sea ice covers an area of about 218.000 km² (52% of the total sea area). This was due to the warmer-than-normal sea water in late autumn 2007, relatively high air temperatures in December 2007 and the absence of cold spells in the winter of 2007/08, preventing longer lasting formation of sea ice.

On 14th of September 2008, the extent of the Arctic sea-ice-covered area was recorded to be 4.52 million km², which is the second smallest in 30 years behind 2007. This confirms once again the present negative trend of Arctic sea ice cover in summer. The Greenland Sea (east of Greenland) had even less sea ice than 2007.

Seasonal Survey

Temperature

All seasons were mostly warmer than normal, though not everywhere in the Region. The mild winter especially in northeastern Europe was outstanding. It was colder than normal in the Middle East in winter, in northeastern Europe in summer and in western Europe in autumn.

Winter 2007/08 was mild in most of Europe and extremely mild during all three winter months especially in northeastern Europe. In the southeast of the Region, however, it was in general colder than normal.

Mean temperature anomalies in the far north exceeded the 98th percentile. They ranged between +3° and +4°C in southern Scandinavia and exceeded +4°C in northern and eastern Norway and Sweden as well as in most parts of Finland and the Baltic States. Finland recorded temperatures 4° to 6.5°C above the 1971-2000 average, i.e. temperatures that were around 1°C higher than the previous record set in 1925. The number of winter days (daily mean temperature below 0°C) was 20-30 in southern and 45-55 in central Finland, which is significantly less than the normal for these parts of the country (typically the mean temperature during winter is below 0°C in all of Finland). Even Lapland had about 10 winter days less than usual. Svalbard reported monthly temperature anomalies of +7 to +8°C in January and February.

There was hardly any ice cover in the Baltic Sea and no permanent snow cover in most of southern Finland. Average winter temperatures in Latvia and Lithuania were 5°C above the long-term mean and even +6°C in Estonia (station Tartu). Seasonal anomalies exceeded +2°C in northern parts of the Ukraine and +3°C in Belarus and in northern Russia.

In many parts of Norway, Sweden, Finland and the Baltic States, winter 2007/2008 was the warmest in recorded history. The same is confirmed by various other long time series, e.g. the Helsinki and Stockholm series (since 1829 and 1756, respectively). In Stockholm and Uppsala, this winter was at least +0.5°C warmer than any other winter on record. In Norway, it was the third warmest winter on record for the country as a whole. Denmark had only 18 frost days on an areal average as compared with a normal of 53 days. Sea ice measurements in the Baltic Sea indicated that this winter had the lowest sea ice extent since 1720, and thus was probably the mildest winter over the Baltic Sea in at least nearly 300 years. It was also the warmest winter on record in Tartu (Estonia) since 1865 and the second warmest winter in Latvia (slightly behind the winter 1924/25). In Belarus, this winter was also exceptionally warm.

The very mild winter in the northeast was mainly due to a dominant southwesterly flow, in conjunction with anomalously high sea surface temperatures in the North Atlantic. This pattern was consistent with an ongoing positive phase of the winter North Atlantic Oscillation (standardised NAO-Index = +1.37 for December 2007 – March 2008). Very probably, global warming also has its effect on the increasing temperatures like, for example, the winter temperatures in Finland which have risen by over +1°C in more than a century. Since 1990, more than two out of three winters have been warmer than the 1971-2000 average in this country. In northeastern Europe, especially minimum temperatures were high in 2008 due to reduced radiative cooling whereas maximum temperatures were closer to the normal.

Western and central Europe were mostly 1-3°C warmer than normal. In Germany, winter 2007/2008 was the sixth warmest on record. This was partly due to the high sunshine duration as this winter was the sunniest winter in Germany in more than 50 years. The winter in the United Kingdom (and other countries) was cooler than in 2006/07 despite the relatively high temperature anomaly of +1.6°C. France as a whole was about +1°C warmer than normal.

Winter 2007/08 was also much warmer than average in Iberia (around +1°C), with Seville experiencing its warmest winter since 1951. Temperatures across Italy and the Balkan Peninsula were closer to the long-term mean, especially towards the south. Winter in Serbia, for example, was characterised by a succession of extremely warm and extremely cold periods. The total number of freezing days for the whole winter was nevertheless well above normal in many parts of Serbia, which was mainly due to a cold spell in the second half of December 2007.

In contrast to other parts of the Region, the winter was characterized by unusually cold conditions across the eastern half of the Mediterranean, the Middle East, most of the Black Sea, the Caucasus countries, southern European Russia and west Kazakhstan, locally with anomalies even below -2°C. Especially January was very cold in these areas, but the other two winter months were also colder than normal. Particularly eastern Turkey was significantly colder. Armenia had the third coldest winter in the last 50 years. Even parts of southeastern Europe experienced several cold spells with daily minima below -10°C in the lowlands, e.g. in Bosnia and Herzegovina.

The southwestern coast of Greenland and the adjacent ocean areas were colder than normal during the whole winter (seasonal anomalies mostly between -1 and -2°C).

Spring 2008 was warmer than normal nearly everywhere in Europe and the Middle East and significantly warmer in the southeast of the Region, over the eastern North Atlantic and in central Europe between northern Italy and Denmark. Anomalies ranged between +1 and +2°C over most of the land areas. Around the Caspian Sea, temperatures were higher than ever recorded. In Belarus, such a warm spring statistically occurs only once in 7 years. Locally, seasonal anomalies exceeded +3°C in the east of the Region due to warm March and April months (in spite of a cool May). On the contrary, a warm May (especially a heat wave in the last days of May) mainly contributed to a warmer-than-average spring season in western and central Europe, whereas a wintry spell came over large parts of Europe at the end of March and the beginning of April.

Over most of the sea areas and in parts of northern, western and southern Europe, anomalies were less than +1°C but still positive. Spring was relatively warm (+0.44ºC) over Iberia. In Portugal, it was the 15th consecutive spring with temperature anomalies above the 1971-2000 average.

Spring temperatures in Montenegro were in the upper decile of the 1961-90 distribution in coastal areas and northeastern parts, and in Croatia. Israel had two long Sharav events in early spring with record breaking temperatures.

Only a few areas in the far north were slightly colder than normal.

Summer 2008 again was warmer than normal almost everywhere in the Region. Anomalies were highest in east Greenland and in the southeast, locally exceeding +2°C or even +3°C (e.g. in Bosnia and Herzegovina). Some places in Greenland were record-breaking warm (e.g. Upernavik in northwest Greenland, Danmarkshavn in northeast Greenland). Over most of the other areas in the Region, anomalies ranged between 0 and +2°C.

Summer was especially warm in parts of the northern Balkan Peninsula during all three summer months, with several strong heat waves. Mean temperature anomalies in Croatia, Serbia, Bosnia and Herzegovina as well as in Montenegro exceeded the 98th or 99th percentile in most parts. The highest summer temperatures in Serbia were close to 40°C (Valjevo 39.1°C on 15 August) and the number of hot days (maxima of 30°C or higher) was above average in the whole country, in August even twice the normal. Summer temperatures were also well above average in Greece due to several heat waves during all three summer months, with highest deviations in August. Temperatures exceeding 40°C affected Cyprus in the second half of July and during the last week of August.

On the other hand, it was a colder-than-normal summer in northeastern Europe, particularly in eastern Lapland, almost the whole of Finland (except the most southwestern part) and northwestern European Russia, partly with anomalies < -1°C. In eastern and northern Finland, there were hardly any temperatures above 25°C, and even in the southwest of the country, this threshold was exceeded on 5-11 days only, which is just half of the usual.

Over western Europe, summer 2008 was one of the coldest since the turn of the century. On a national average, Ireland experienced fewer than 10 days with maximum temperatures exceeding 20°C. However, seasonal mean temperatures were still above average throughout most of central and western Europe, with anomalies generally around +1°C, which was chiefly due to warmer than normal nights. Only some smaller parts in western Europe (e.g. western France, Spain) were slightly cooler than normal. No heat waves were recorded in Portugal this summer. Daytime temperatures in the United Kingdom were in general below normal, which gave the impression that the summer was unusually cool.

Autumn 2008 was warmer than normal in the Arctic region, most of the North Atlantic, northern, central and eastern Europe and the Middle East. Anomalies exceeded +2°C over parts of the Arctic and European Russia, in some areas exceeding the 90th percentile. In Russia, it was the warmest autumn in the Moscow region in more than 100 years. The warm autumn in eastern Europe is mostly due to the temperatures recorded in November. In eastern central Europe, the seasonal anomaly amounted to around +1°C.

It was a cold autumn in most of western Europe, particularly in Ireland, Portugal, Spain, France, Belgium and the western parts of Germany, in Switzerland, Austria and Italy, mainly due to a cold September. Locally, seasonal anomalies were below -1°C. It was the coldest autumn at many stations in Ireland in ten years and in the United Kingdom in 15 years. Having been largely dominated by an extremely cold November, particularly in the later days of the month, the minimum temperatures in Portugal were the third coolest since 1931. Spain experienced its coldest autumn since 1993. Parts of southeastern Europe were slightly colder than normal (e.g. Bosnia and Herzegovina in all three autumn months) despite a long warm spell from 28 October to 8 November (e.g. in the major part of Serbia).

Below normal temperatures in the Adriatic were due to below normal sea surface temperatures in that region.

Precipitation

The distribution of wet and dry seasons was very heterogeneous. Northern Europe, for example, was wet in winter and summer, the middle latitudes were wet in spring, and the Mediterranean region was particularly dry in winter.

Winter 2007/08 proved to be much wetter than normal across the Nordic countries. Norway experienced over 145% of the 1951-2000 normal, parts of the country over 200%. Denmark and the United Kingdom both received 125% of the 1961-1990 normal on country average. In many parts of Finland, annual total precipitation was well above the 1971-2000 normal (the annual total was 150-200% of the normal). Lithuania recorded more than 150% of the normal monthly total (1961-90) in both, January and February. Latvia, too, was clearly wetter than normal in both months and periodic melting of snow together with rain produced several winter floods.

On the contrary, it was a very dry season in the southern half of Europe, particularly in Iberia, the Mediterranean region and north of the Black Sea. The seasonal precipitation total was less than 80% over most of these areas and in many places even less than 60%. At some locations in Montenegro and Croatia, seasonal rainfall was only 40% of the average. Long dry spells in Cyprus during the winter caused a decrease in crop production. Portugal suffered its most severe winter drought since 1917. These conditions were related to positive mean sea level pressure anomalies over western Europe and northern Africa, which along with 500 hPa

geopotential height anomalies, suggested that the northern European blocking pattern was shifted slightly southwards, a feature that limits the natural progression of Atlantic low pressure systems bound for southern Europe. Even most of the Alpine region was dry, seasonal precipitation was below 40% of the normal in southern Austria.

Snow was quite rare (20 snow days or less) in the lowlands of western, central and southern Europe. Due to mild weather, the southern parts of northern Europe, especially around the Baltic Sea, rarely received snow and if so, only little amounts (Fig. 0.28). No ice was recorded in the Latvian sector of the Baltic Sea or in the Gulf of Riga this winter. Only 20-30 snow days were recorded in southern and southwestern Finland, which is well below the normal (more than 70 days). In Germany, there was almost no snow cover during the winter months. No snowfall at all was measured during all three winter months at most locations in the central and western lowland parts of Switzerland. Austria also received little snow, as little as 10-30% of the winter average and the Pyrenees had a deficit in snow, too. However, the northern parts of Scandinavia, most of European Russia and the high mountains had their usual snow during the whole winter. In Cyprus, snow fell in areas above 100m at several occasions in January and February.

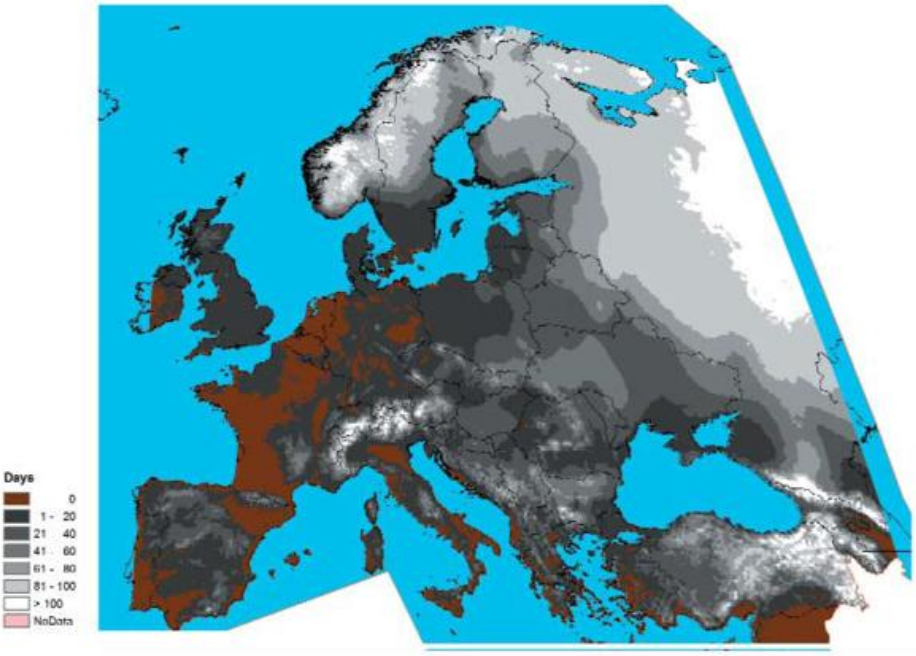

Fig. 0.28: *Number of snow days (number of days with at least 1 cm of snow cover on the ground) in Europe in winter 2007/08.*

Spring 2008 was wet over large parts of western Europe, especially southern England, France, Spain and Portugal, and over most of eastern Europe with seasonal totals of more than 150% of the normal in many places. Parts of eastern Norway received up to 200% of the spring normal. The northern part of the Netherlands was an exception: local totals of only 30 mm were reported during the months of April and May.

It was particularly dry in Svalbard (partly less than 30 mm or less than 40% of the seasonal total) and unusually dry in western Iceland.

Spring precipitation was near normal in central Europe where a very dry May compensated wet March and April months. Some of the precipitation in March and April fell as snow due to a late wintry spell.

In the south, it was near normal or wetter than normal in the western half of the Mediterranean, but dry in the eastern half and especially in the Middle East with very little precipitation (around 60% of the seasonal total or less) during the whole season. Iberia experienced a very dry March (except northeastern Spain). A very wet period, however, started there in April. Spring rainfall exceeded 125% of the normal over most parts of Iberia, with several new monthly precipitation records. The records set in March, though, were largely confined to the Basque country stations of Bilbao (215 mm) and San Sebastián (238 mm). In the following months, however, several new all-time records of accumulated monthly precipitation were observed over a wider area of southern (April) and coastal (May) Mediterranean provinces, including stations with more than 100 years of data (e.g. Tortosa). In general, it was the wettest spring in Spain since 1971 (which remains the wettest on record).

Summer 2008 was wetter than normal over the higher mid-latitudes, especially in Ireland, the United Kingdom (parts of northern Ireland and eastern Scotland had around twice their seasonal normal), southern Sweden and northeastern Europe (parts of the Baltic countries, Finland and northern Russia). Summer precipitation reached more than 200% of the 1961-90 normal in eastern Ireland. Eastern and southern parts of the country, including Dublin Airport, experienced their wettest summer in 50 years. Summer 2007 had already been wet, nearly as wet as summer 2008 in eastern Ireland. In the England and Wales precipitation series, the summers of 2007 and 2008 together were the wettest consecutive summers since 1879/1880. In the UK-wide time series started in 1914, this is also true for the United Kingdom as a whole where, however, summer 2007 had been wetter than summer 2008.

Central and western Europe (except Ireland and the United Kingdom) mostly had a summer of near normal precipitation, but high spatial and temporal variations. The Netherlands, however, reported 111 mm of rainfall in July (70 mm average) and 110 mm in August (62 mm average). In general, the summer season was characterised by often and quickly changing weather situations in the mid-latitudes due to frequent disturbances in a southwesterly air flow, partly with quite intense thunderstorms. Agricultural soil irrigation was not necessary in Slovakia this summer.

Parts of eastern Austria measured their wettest summer on record. Anomalies reached 120-160% of the 1961-90 normal. A new seasonal record was set at Eisenstadt (Burgenland, eastern Austria) with 479 mm of precipitation, which is almost 250% of the normal. Unusually heavy thunderstorms with hail occurred in Austria in all three summer months, causing flooding and large agricultural losses. In Hungary, too, summer 2008 was abundant in showers, especially in June and July.

In the Arctic region, there was in general very little precipitation, less than 80% of the seasonal total in many places, in northern coastal areas of Norway partly only 30-50%.

Summer was dry also in the southern parts of Europe, particularly over western Iberia and the Mediterranean except Sicily, and in the southeastern parts of the Region in southern Serbia, Bulgaria, Greece and Turkey. Southern Portugal received less than 10 mm of precipitation, which is less than 20% of the normal average. On the contrary, parts of eastern Iberia were characterized by above average summer precipitation totals, and this despite the fact that Iberia is typically extremely dry in summer.

An extended period of flooding occurred in Moldova from the end of July until the middle of August as a consequence of heavy precipitation at the end of July (see July section for more details).

Autumn 2008 had near normal precipitation in most of the Region. There were some places with considerably higher than normal precipitation (150% of the normal or more) in the north (e.g. southern Iceland, Svalbard, southern Finland, northern Russia, northeast and midlands of England) and locally over and near the Mediterranean and around the Black Sea.

Northern England recorded the wettest autumn since 2000. Some intense rainfalls occurred in western and southern Europe, especially in France, Spain and Italy. Seasonal totals in Corsica were up to twice as high as the 1971-2000 normal. 350 mm of precipitation fell over northern Italy near Bologna between 28 October and 1 November. Between 31 October and 2 November, France was locally affected by flooding after up to around 500 mm of precipitation had fallen in the regions west of the Rhône River in the southeast of the country.

It was dry in some other parts of the Region, in Lapland, in central Sweden, Russia, some parts of the Middle East and particularly in Portugal and western Spain (less than 60% of the normal). However, Portugal locally also experienced some very heavy rainfalls. An extremely wet period also occurred over Gibraltar.

Monthly Surveys

January

- **Very mild in most of Europe, cold in Greenland and the Middle East**
- **Wet in the north, dry in the south**

Atmospheric circulation characteristics

Due to both, an unusually strong Icelandic low and Azores high, mild Atlantic air masses passed Europe within a southwesterly flow and were accelerated even up to the northernmost sea areas. A colder Arctic air mass remained stagnant over Greenland.

A number of Atlantic low pressure systems passed across northern and northern central Europe, causing high amounts of precipitation. A few heavy storms occurred too.

Most of the time, the southern half of the Region was under high pressure influence, except a few local low pressure systems. Especially the Middle East was affected by an unusually strong Siberian high and cold continental arctic air masses, some of which extended far southwards.

Temperature

January 2008 was very mild over nearly the whole of Europe. Temperature anomalies exceeded +4°C in the northern, eastern and central parts of the continent (Fig. 1.1), +6°C in Sweden, Finland and northern Russia and amounted to nearly +8°C in Svalbard and up to almost +10°C at the northeastern-most coast of the Region.

Daily temperatures showed large variations in northeastern Europe. The first third of the month was cold (e.g. minima down to -18°C in Lithuania) whereas it was very mild at the end.

Mean temperatures were more than +3°C above normal in parts of the United Kingdom (in the Midlands and East Anglia). A local maximum temperature of 15.2°C was recorded on 20 January at a station in Herefordshire (Preston Wynne).

Central Europe was also very mild. With a mean temperature of 6.5°C (+3.7°C anomaly), January 2008 was the second mildest January (behind 2007) in the Netherlands since the start of regular temperature measurements at the station De Bilt in 1706. Monthly averages in France were up to +4°C warmer than normal in the northeast (same as in Germany). In the middle of the month, maximum temperatures of more than 10°C were recorded on several days for large parts of central Europe, with record values of up to 15°C near the Rhine River. Sea surface temperatures in the German North Sea reached 5-6°C, in the German Baltic Sea 4-5°C. Poland was up to +3°C warmer than normal in the west of the country.

The northern Alpine region profited from high temperatures due to several south foehn events. Southern upper and lower Austria recorded highest monthly mean anomalies of up to +4.5°C. Only the first 5 days of the month were very cold, then it was mild for the rest of the month.

January was also a particularly warm month throughout Iberia. In Portugal, the anomaly amounted to +1.5°C making January 2008 the second warmest January since 1931. Averaged over continental Spain, January mean temperatures were 1.7°C above the 1971-2000 average. Southern Spain reached temperatures of about 22-23°C around 20 January. Italy had monthly anomalies which mainly ranged between +1.5 and +2.5°C, in some northwestern parts even up to +4.5°C due to a warm spell in the last week of the month.

January was also unusually mild in eastern and some parts of southeastern Europe. Anomalies exceeded +4°C in northern Slovenia and the northern and central parts of Croatia. An exceptionally low number of freezing days was recorded in the mountainous areas of Serbia. It was cold in Macedonia at the beginning of the year, but the second half of January became mild with maximum temperatures exceeding 10°C and minima frequently above the freezing point. Russia recorded its mildest January in Moscow in 130 years.

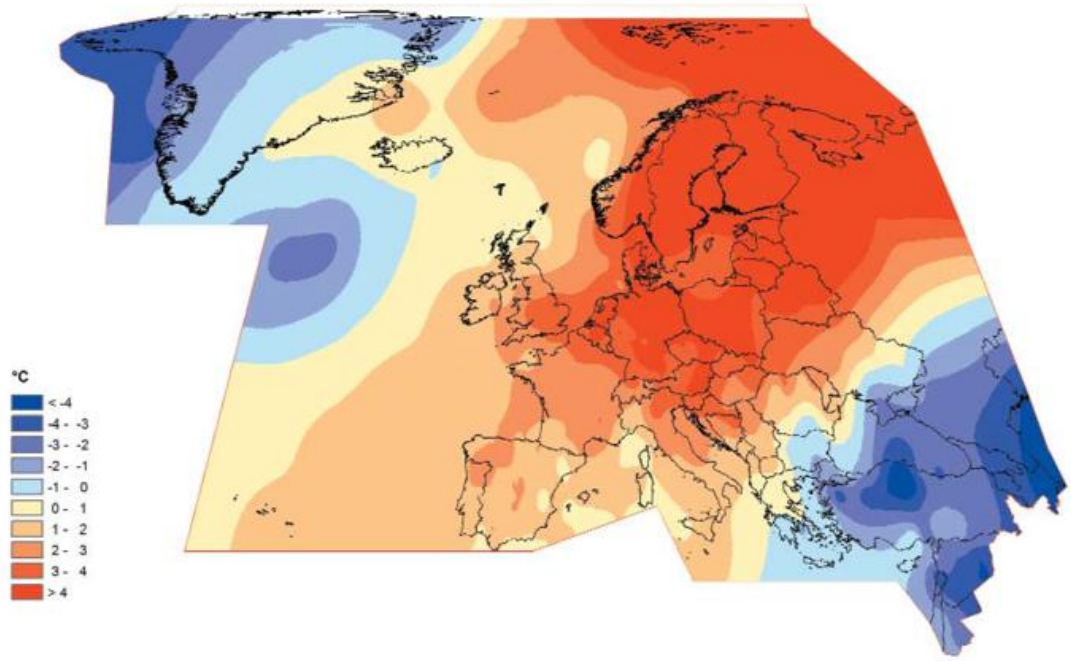

Fig. 1.1: *Monthly mean temperature anomalies in January 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

There were only two large areas where the temperatures were colder than normal: Greenland with the central Atlantic and the Middle East. Especially western Greenland and the nearby Atlantic areas were very cold. On early morning of 29 January, the station Eismitte in Greenland (3207 m altitude) recorded -54°C.

The whole Middle East and some southeastern parts of Europe also experienced a cold start of the year with monthly mean anomalies locally going down to -4°C and even down to -8° or -10°C in parts of Turkey, Armenia and Azerbaijan. Minimum temperatures below -24°C were measured in the interior parts of Bulgaria. Greece also recorded unusually low minimum temperatures in many places during a cold spell from 03-05 January. Turkey had frost at the end of the month in Izmir, causing damage to vegetables. Some places in Turkey experienced their coldest January nights in nearly 50 years; night temperatures dropped down to -34°C in eastern Turkey. Monthly mean temperatures across Cyprus were around 1°C below normal, with widespread ground frost during the first half of the month causing damage to crops. Severe frost was also reported from southern Israel and Jordan; temperatures dropped below 0°C even in the coastal plain. The frost period lasted 4-6 days; it was the longest since at least 1964 and caused extensive damage to agriculture, especially vegetable crops in many places in Israel. In most parts of the country, it was the coldest winter month since 1992. In Syria's capital Damascus (station 611 m above sea level) night-time temperatures fell below -10°C in mid-January, and Jordan recorded its lowest 2008 minimum temperature at -10°C on 10 January. Further east, parts of Georgia also experienced one of their coldest nights in 10 years, again with temperatures dropping to -10°C in the capital Tbilisi and to -25°C in mountainous areas.

An unprecedented prolonged cold spell was reported on 08-24 January all over Armenia with extremely low temperatures due to the invasion of an arctic cold air mass from the northeast. With -33.6°C on 13 January, the town Tashir in the north of Armenia set a new monthly minimum record. The surface of Lake Sevan was completely covered with ice (Fig. 1.2) by 14 January which is the earliest date of freezing of the lake water ever reported. The extremely low temperatures also caused freezing of fruit trees in the Ararat Valley. In Azerbaijan, Baku registered its lowest temperature in 100 years on January 7-8. January was also very cold in west Kazakhstan (monthly mean temperatures between -8 and -11°C, anomalies between -3 and -5°C) and southern European Russia. Daily minimum temperatures between -25 and -28°C were measured in the south Russian region between the Caucasus Mountains and Volgograd.

Fig. 1.2: *The entire surface of Lake Sevan (Armenia) became completely covered with ice by 14 January 2008.*
Source: Armstatehydromet, Armenia

Precipitation

January 2008 was wetter than normal in almost all parts of northern and northern central Europe, with locally more than twice the normal amounts (Fig. 1.3). The southwestern Norwegian coastal areas received monthly totals above 300 mm, the western parts of the United Kingdom and Ireland totals of more than 200 mm. In parts of northern England and southern Scotland, monthly precipitation exceeded the normal average by 150%. It was the wettest January in eastern Scotland and the second wettest in Northern Ireland since 1914. Poland was also exceptionally wet with monthly totals of over 300% in eastern and central parts of the country. The northern Norwegian coast, on the contrary, received by far less precipitation than normal.

On various occasions, there was also freezing rain in central Europe, causing hundreds of traffic accidents e.g. in Germany.

Most of the southern half of Europe was quite dry. Less than 60% of the normal precipitation was registered in many parts of this area. Southeastern Austria recorded less than 25% of normal January precipitation. Some parts of northern Croatia, including Zagreb, received less

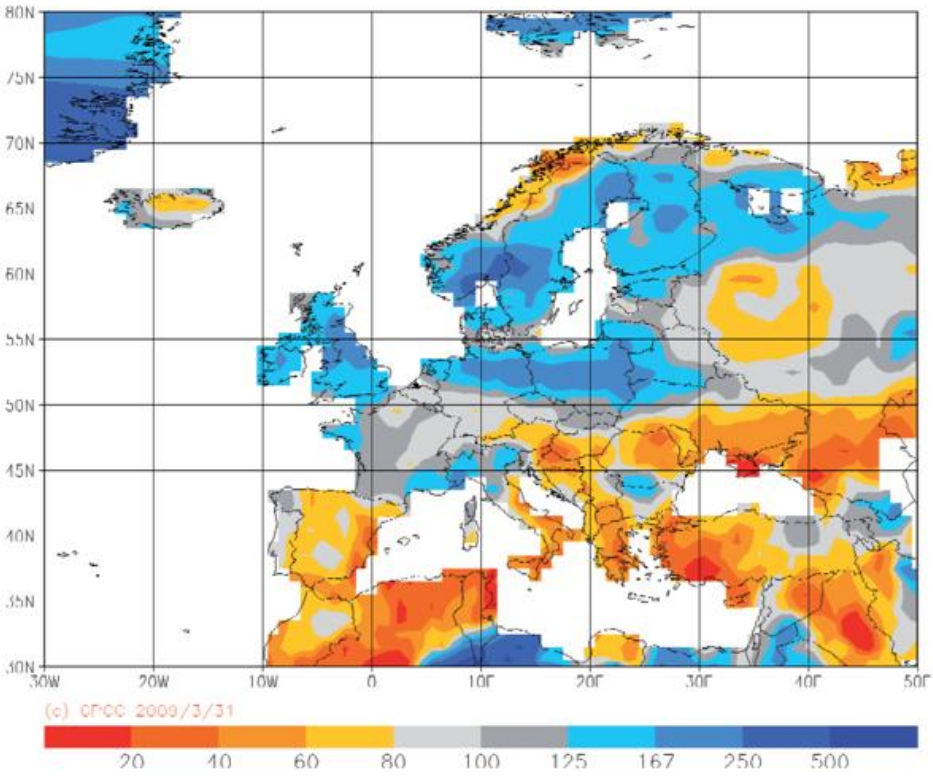

Fig. 1.3: *Monthly precipitation amounts for January 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

than 20% of normal. Locally, the monthly total was less than 10 mm in some southern countries, e.g. at the southeastern coast of Spain, Greece, western Kazakhstan and the plains of eastern Georgia.

A few areas in the south, e.g. in the western Alps and southeastern France, however, recorded high precipitation due to a Genoa low on 11-12 January. In these parts, monthly precipitation totals exceeded 100 mm, mostly caused by the said event. Parts of northern Italy also received high rainfall amounts, e.g. Pisa 152 mm (203% of the 1961-1990 normal). Jordan reported a local monthly total of 141.9 mm in Rass Munef.

Snow

Generally, snow was rare over most of Europe due to the prevailing mild weather. In the north, Iceland did not have much snow although communication was often disrupted due to snowstorms and slippery roads. Parts of northern Russia, the Baltic countries, central and southern Sweden, which normally are completely snow-covered in January, were without snow in the middle of the month. Western Europe had hardly any snow in the lowlands during the whole January, and almost everywhere in Germany, there was no snowfall at all in January. Very small amounts of snow fell in the alpine parts of Austria but there was no snow in the eastern lowlands of the country.

On the other hand, some remarkable snow events occurred in the southern and eastern parts of the Region. So, southern France, parts of Italy, and southeast Europe recorded heavy snowfall at the beginning of the month. The alpine south side had several snowfall events due to south foehn events. Poland also had snow, being snow-covered at the beginning of January

with more snowfall events throughout the month. In Serbia, the mountainous areas were snow-covered during the whole month, other areas only during the first half of the month. Due to a snowstorm on 2-3 January, eastern and southeastern Romania was very soon covered by snow up to a depth of 143 cm in the mountains. Another snowstorm affected the mountains in Romania at the end of the month (26-28 January).

The southeast of the Region, which was very cold in January, saw some unusual snowfalls. Heavy snowfall was recorded on 29-30 January in Greece, Turkey and in Cyprus, even at lower altitudes above 100 m. Armenia also received snow well above normal, particularly in the mountain regions. The snow cover on the Aragats Mountain had reached 181 cm by the end of the month. In Georgia, snow fell at the beginning and once more at the end of the month, with a snow depth of up to 50-100 cm in the east Georgian mountain areas and 2.5-4 m in the high mountain regions of the country. Snowfalls even occurred during the last decade of the month in Israel, Syria and Jordan. A snow depth of 65 cm was measured in Jordan and up to 20 cm in Jerusalem. Altogether, snow is very rare in this part of the Region at this time of the year.

Significant weather events

January 02-03:	Southeastern Europe (especially Romania, eastern Bulgaria, southern European Russia) was hit by an intense storm with heavy snowfall. Black Sea harbours and main airports of Romania closed. Strong gusts (Bora) in Novorrossisk, European Russia (Black Sea coast) of over 120 km/h.
January 03-05:	An exceptionally strong and sustaining foehn storm swept over the Alps from the south. Wind gusts exceeded 130 km/h, the temperature rose up to 12°C in typical foehn valleys in Switzerland. The alpine south side experienced snowfalls down to low altitudes.
January 05-07:	Freezing rain caused widespread traffic accidents in Germany.
January 08:	Traffic in Georgia was severely disrupted after the temperature fell to its lowest level in 15 years. Temperature dropped to -10°C in Tbilisi and to -28°C in mountainous areas. Roads were left impassable in some areas due to snowfall.
January 09:	On the morning, a storm developed over Scotland with a central pressure below 965 hPa. Gusts of hurricane force were recorded in southern Scotland and northern Ireland. Malin Head in Ireland recorded the highest gust (168 km/h) of all stations in the country since December 1998.
January 11-12:	Storm due to a Genoa low affected Corsica Island with gusts around 110 km/h and high precipitation amounts in the western Alps and southeastern France.
January 12-13:	Strong snowfalls in the Alps in Switzerland, avalanches in northern Italy.
January 14:	Strong winds up to 100 km/h at the northwestern Atlantic coast of Iberia, causing a shipwreck with five victims. During the following days, the storm extended to the northern half of Spain.
January 16:	Storm in northern France, trees fell down, shopping centre evacuated.

January 18-22: Heavy rain in northern Germany caused flooding of rivers. Up to 200 mm in 5 days fell on the Harz Mountains. Hail up to 1 cm diameter was found in northeastern Germany.

January 19: Storm in Norway and Sweden up to 117 km/h over sea and 88 km/h at the Swedish west coast. Power disruptions, trees fell down and blocked roads.

January 22-24: Sea storm with strong winds over southern Italy and Sicily up to around 115 km/h. Highway and trains were blocked for several hours in Calabria.

January 22: Fruits and vegetables destroyed in the Jordan Valley due to frost.

January 24-29: 2 storms over the Aegean Sea with snow and gusts up to 117 km/h. Heavy storm also in Turkey on 28-29 January.

January 25-28: Storm in central Europe (with gusts of up to 115 km/h in northern Germany, up to 165 km/h in Austria) following a cold front passage caused power blackout and massive forestry losses. Strong winds >70 km/h also in Poland on 26-27 January.

January 27-29: Heavy rain in the Lebanon and Jordan. 57.4 mm in 10 hours fell in Beirut on 27 January. 49.6 mm in 24 hours were recorded in Rass Munef, Jordan, on 29 January.

January 30-31: During a storm, Jerusalem was covered by snow with a recorded depth of 20 cm. Likewise, Jordan's capital Amman received 30 cm of snow, while Lebanon, Syria and even Cyprus were affected by severe cold conditions. Armenia had a severe snowstorm on 31 January with a precipitation intensity of 31 mm / 12 hours, particularly severe on the Poushkin pass in the north of the country and across the western shore of the Lake Sevan.

January 31: Storm in Denmark and northern Germany, trees uprooted, roofs untiled. Storm with high waves over sea also in the United Kingdom.

February

- **Again very mild in most of Europe, cold in southern Greenland and the southeast**
- **Wet in the north, dry in the south**

Atmospheric circulation characteristics

The main circulation patterns were very similar to January: a mild Atlantic air flow and an ongoing passage of a large number of Atlantic low pressure systems over most of the northern half of the Region and dominating high pressure influence in the southern half. However, in contrast to January, even the northeast of Greenland was affected by the mild air mass.

Again, like in January, temporarily cold air masses advanced far to the south in the eastern parts of the Region, even down to the eastern Mediterranean. Over the northwest Atlantic, cold Arctic air masses moved from Canada southwards and affected the south of Greenland.

Temperature

February 2008 was warmer than normal in nearly the whole Region. Anomalies exceeded +4°C in northern, eastern central and eastern Europe (Fig. 2.1) and +7°C in parts of Finland, Estonia, northwest Russia and the Arctic area. Coastal waters near northern Germany were around +1°C warmer than normal and without ice.

February 2008 was the warmest February in southwestern Finland since 1990 and the second warmest on record on country average in Norway. Especially the last third of the month was extremely mild there. On 24 February, 9.2°C were recorded in Jomala on the Åland Islands. With 16.5°C, a new local record for the highest maximum in February was set in Belarus.

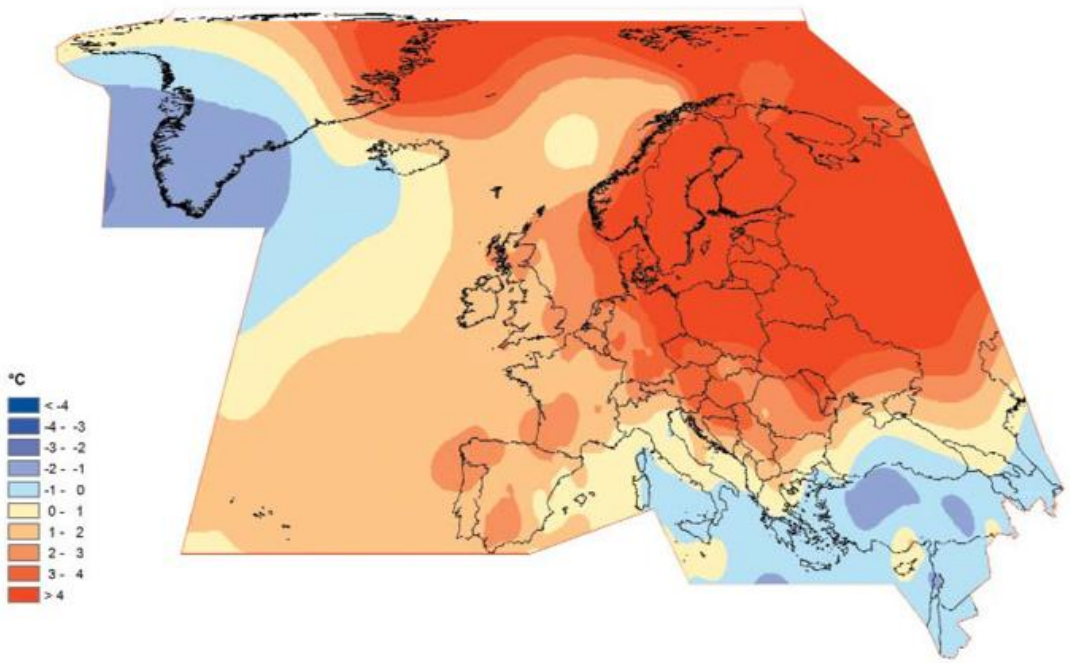

Fig. 2.1: *Monthly mean temperature anomalies in February 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Southern parts of western and central Europe also experienced a mild period towards the end of the month. Again on 24 February, local daily record maxima of over 20°C due to foehn were measured on a sunny day in southern Germany (Munich, Stuttgart), Austria (Salzburg, Innsbruck) and eastern Switzerland (and a few days earlier also in southwestern France). Averaged over the whole month, monthly mean temperature anomalies ranged from around +1 to +3°C in western Europe and from +2 to +5°C in central Europe.

February was also extremely mild in the southern Spanish cities of Seville, Cordoba and Cadiz as well as at the north-western (Galicia) stations of Santiago and La Coruña, which measured new monthly records with regard to their time series longer than 60 years.

With up to around +3°C, southeastern Europe was warmer than normal only in its northern parts. New records of absolute February maximum temperatures were set on 25-27 February at 22 stations across Romania and in the northeast mountainous region of Montenegro (up to 24°C above 600 m altitude). Serbia and Bulgaria were also unusually warm around that date. Earlier that month, already on 5 February, some stations in Serbia had, with maximum

temperatures exceeding 25°C, reported new records for this time of year. The absolute maximum temperatures recorded in many places in Slovenia were also among the highest ever recorded February maxima.

Like in January, in February only two areas were colder than normal: over and around southern Greenland and the southeast of the Region, but now extending further over the Mediterranean. Italy, Greece and Turkey had frost during several days even in the lowlands, especially in the middle of the month. Monthly mean anomalies in the Middle East mostly dropped down to -1°C, in Turkey locally even below -6°C.

Precipitation

The precipitation anomalies were also similar to the values reported in January: February 2008 was mostly wetter than normal in the north of the Region, but unusually dry for this time of the year in the southern half, except a few local wet areas (Fig. 2.2).

In the Nordic countries, parts of western Norway received more than 300% of the precipitation normal. Bergen at the west coast of Norway had a precipitation total of 329 mm, which is more than twice the normal. Some areas in Estonia received a monthly total of 290% of the 1961-90 normal precipitation. Various places in European Russia also saw more than twice the normal.

Rainfall was also well above normal across northwestern Scotland, with some stations recording over 200% of their normal rainfall (1961-90). However, precipitation was lower than normal in most of the other parts of the United Kingdom and France, particularly in southwestern France. In the England-Wales precipitation time series, only 38 mm or 58% of the 1961-90 normal was recorded for the whole month.

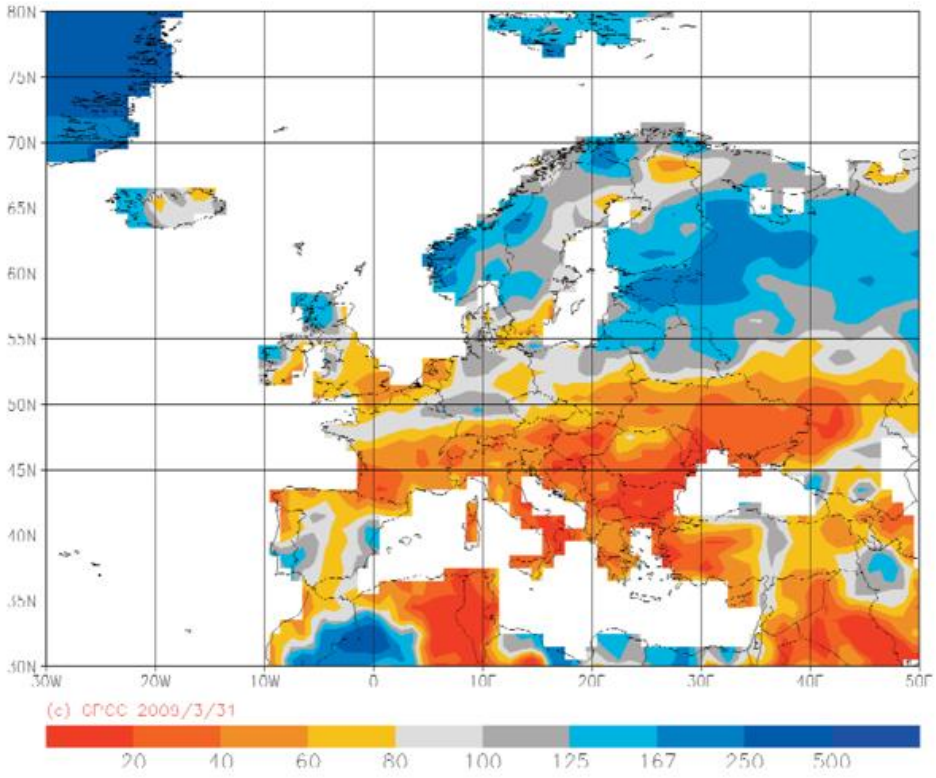

Fig. 2.2: *Monthly precipitation amounts for February 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

February was especially dry in Hungary (only 19% of the 1971-2000 normal), eastern Austria and southeastern Germany (both locally < 25% of the 1961-90 mean), parts of Switzerland and southern France as well as southwestern Poland (around 50% or less).

In February, most of Iberia was particularly affected by severe drought conditions. The month was also exceptionally dry in most of Romania and parts of Moldova, the Ukraine, Bulgaria, Greece, Serbia, Croatia and Hungary, where in many places less than 10 mm of precipitation fell, which is less than 20% of the normal. Sofia (Bulgaria) and Budapest (Hungary) both recorded a monthly total of only 1 mm. Monthly precipitation in Athens was about 25% of the normal. Further to the east of the Region it was 20-50% in Armenia and 20% in western Georgia. Damascus in Syria only received 7 mm of precipitation which is less than 30% of the normal.

Snow

The southeastern parts of the Region were still widely affected by snow. Frequent snow was reported from Greece and Turkey around the middle of the month, also at the southern coast of Turkey. Many villages were cut off. Also in Cyprus, snow fell in areas above 100 m. Snow was even recorded in Lebanon, Israel and Jordan. In Georgia, the snow depth amounted to 60 cm in the mountain areas and 2-2.5 m on high mountains, locally even more than 4 m. The lowlands of western Georgia also reported a snow cover of 30 cm. The northern Balkan Peninsula had less snow. In Serbia, only the mountains were persistently covered by snow throughout the whole month whereas other areas temporarily had snow around the middle of the month. Romania had a continuous, but in the lowlands light snow cover the whole month.

In the north, Iceland had more snow than normal. In contrast, the snow cover was thin in western and southern Finland at the end of the month with a completely bare ground in some southern and southwestern parts of the country. In some places in northern Finland, however, the snow cover was even thicker than usual.

In western and central Europe snow was rare in the lowlands and the lower mountains. Like in January, Germany again was widely without snow. A continuous snow cover was observed in southern Poland, whereas the rest of the country saw snow covers only temporarily.

Significant weather events

February 01:	Snowstorm forced Oslo's airport to be closed for several hours.
February 02:	Thunderstorm in western Estonia.
February 08-09:	Storm over Iceland with damage caused by both, wind and local snowmelt.
February 10:	Hail in Antalya, Turkey; settlements damaged.
February 11:	Persisting fog caused around 100 flight cancellations at the airport of Frankfurt, Germany.
February 11:	Tornado in Cyprus, west of Nicosia, caused damage to agriculture.
February 13-14:	Strong wind at about 110 km/h around Murmansk, northern European Russia.
February 17-18:	Heavy precipitation with flooding in Lisbon (Portugal). 18 February was Lisbon's rainiest day on record since 1877 with a daily total at 118 mm.
February 17-19:	Storm and heavy snowfall in southeastern Europe and the Middle East. Ports of Varna and Burgas (Bulgaria) closed because of storm and high

sea. Temperatures dropped rapidly and roads were blocked due to strong icing. More than 25 villages in Greece and some more thousands in Turkey were cut off by heavy snowfall, and Athens was covered by several centimetres of snow. The Acropolis had to be closed for visitors. On 18 February, the storm reached Israel, bringing snow, hail, rain and strong winds. Five centimetres of snow were reported in Jerusalem. Thunderstorms with hail affected southern Lebanon.

February 22: Storm of hurricane force hit Gothenburg (Sweden), causing numerous power blackouts. The severe storm also reached Denmark, northern Germany, the coast of Lithuania and northwest Poland with local wind speeds of more than 100 km/h.

February 22-26: Persistent dense mists and fogbanks over eastern Po Valley, Italy.

February 23: Thunderstorm in Belarus, a rare event at that time of the year which occurs in that country in winter only every 20-50 years.

February 24-25: Storm over Azerbaijan, gusts up to 100 km/h.

February 25: Flooding of the David River (Israel) due to local large rainfall amounts.

March

- **Mostly warm, especially in the east, cold over the polar Atlantic areas**
- **Mostly wet, a few dry areas in the north and the south**
- **White Easter in central Europe**

Atmospheric circulation characteristics

A strong zonal circulation with frequent cyclonic activity continued to persist over the Atlantic and Europe. The circulation extended over nearly the whole continent except the Arctic, even down to the Mediterranean, and moved north-eastwards over its eastern parts. Thus, particularly the Middle East and southern parts of eastern Europe were dominated by a southwesterly flow of warm air.

Temperature

March 2008 was also mostly warmer than normal in the Region, but the spatial distribution of anomalies was quite different from the preceding winter months. The highest monthly anomalies, exceeding +4°C, were to be found over the southeast of the Region (Fig. 3.1) where the winter had been cold. In the eastern Ukraine, southern European Russia, Kazakhstan, Armenia, Azerbaijan and Jordan, March was more than +5°C warmer than normal. The month was up to +8°C warmer than normal in west Kazakhstan at the eastern border of the Region (anomalies were even higher in other parts of the country not being part of the Region, Fig. 3.2). The central North Atlantic and also most of Greenland (except the northeast) were more than +2°C warmer than normal.

The Arctic Region and the high latitude Atlantic areas east of Greenland had monthly mean anomalies below normal, dropping down to -2°C in northeast Greenland and locally in Lapland and northern European Russia. Minimum temperatures below -40°C were recorded in Greenland (e.g. Danmarkshavn on 6 March) and Lapland (station Nikkaluokta in northern Sweden on 23 March). The Summit Camp of Greenland (elevation 3000m) saw a lowest daily minimum temperature of -59°C at least.

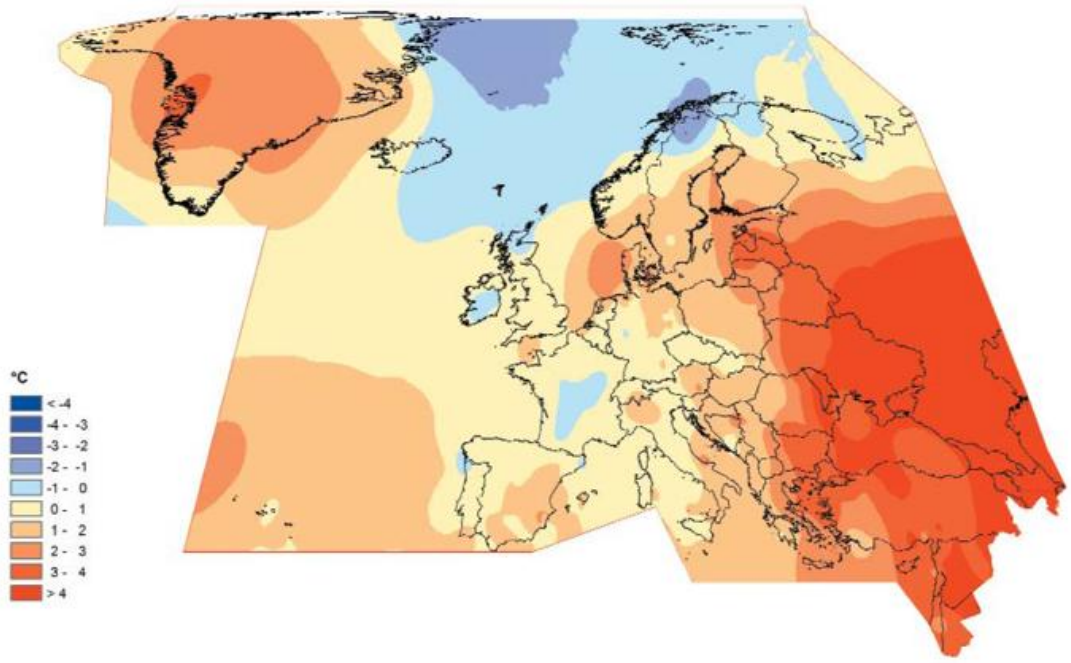

Fig. 3.1: *Monthly mean temperature anomalies in March 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Fig. 3.2: *Monthly mean temperature anomalies in March 2008 (reference period 1961-1990) in Kazakhstan.*
Source: Kazhydromet, Kazakhstan

In central Europe, the anomalies were still mostly positive, but by far lower than in February (below or around +1°C). Only locally were they negative. Thus, March was colder than February, e.g. in some places in eastern and southern Germany. Anomalies were higher for the North Sea and the Baltic Sea compared to the land areas in central and western Europe due to the warming during the preceding mild winter. With the daily minimum of -20.6°C, the lowest temperature in Austria in 2008 (except high mountains) was measured in Seefeld (Tyrol, Austria) on 6 March.

A very cold episode occurred around Easter (23-24 March) in central and western Europe. In many places in Germany it was the coldest Easter holiday since the beginning of measurements. Minimum temperatures went below -5°C, locally even below -7°C (e.g. Frankfurt/Main) on Easter Monday; the maximum temperature on Easter Sunday was only around or below 0°C at various sites in the German and Swiss lowlands. The cold air mass extended from northern Europe southwards. In central Sweden, minimum temperatures of -26°C were measured on 21 March. With -9.6°C, Denmark experienced its lowest temperature of the year on 23 March. The sea ice extent over the Baltic Sea (where hardly any sea ice had formed due to the mild winter) peaked as late as 24 March following the arrival of cold Arctic air and the consequential freezing of the Bay of Bothnia. Still, the maximum sea ice extent in that winter was the smallest in almost 300 years.

Even in the south, northern Italy experienced three frost days in the lowlands of Emiglia-Romagna during the last decade of the month, causing a substantial loss of fruit. In Slovenia, it was also colder than normal in the third decade of the month after the two preceding decades of the month had been warmer than normal.

At the same time, a tropical air mass and foehn effects caused night (!) temperatures of 30°C on the Black Sea coast of Turkey. The same temperature was reached during daytime in southern Russia north of the Caucasus Mountains. The heat wave even hit Armenia with daily maxima of 30-32°C in the southernmost part of the country. The vegetation period in Armenia started 15-20 days earlier than usual; apricot and peach blossomed already in the third decade of March. In Baku, Azerbaijan, a maximum temperature of 31°C on 26 March set a new record for the place.

In the area of the eastern Mediterranean, Tel Aviv (Israel) recorded 38°C on 24 March during a Sharav event. In some parts of the Negev, temperatures even rose as high as 39-40°C. At most stations in Israel, these were the highest March temperatures ever recorded since the beginning of measurements (Fig. 3.3) and the event was also record-breaking in terms of duration (5 days from 21 to 25 March) since 1964 at least. Jordan reported two heat waves, one from 5 to 10 March, the second from 17 to 26 March with a maximum temperature of 39.4°C in Deir Alla on 23 March. In Cyprus, temperatures reached 33°C at the end of the month, in Greece they rose up to 30.8°C.

Other parts in the south of the Region also experienced high temperatures. On 2 March, very high maximum temperatures (25-28°C) were recorded in northern Italy (e.g. Milan, Verona, Bologna, Ferrara) caused by a strong foehn situation, thus setting new records for March. Later, on 15 March, maxima up to 25°C were measured in some places of central and southern France (e.g. Vichy 23°C). At the end of the month (29 March) the temperature climbed up to 28°C in southern Spain (e.g. Seville).

Precipitation

March 2008 was wetter than normal nearly all over Europe (Fig. 3.4). At various places in Europe, precipitation totals reached about twice the normal, e.g. in the Baltic countries, northeastern Poland, European Russia (mid-Volga region), Germany, parts of upper Austria, Slovenia, Croatia, Montenegro (Fig. 3.5) and Albania. New records of monthly precipitation

were measured at the two stations Nikšić (413 mm) and Kolašin (427 mm), and also of the number of precipitation days (23 and 24 days, respectively). At other places, the precipitation totals even amounted to around 300% and up to 350% of the normal in Estonia and near the eastern border of the Region in west Kazakhstan, respectively. Some locations in Albania recorded the second wettest March ever. Some places in Bosnia and Herzegovina received nearly 200 mm even in the lowlands. Georgia in the Caucasus region recorded 130-140 mm (110-130% of normal). In the northeast, Latvia saw its wettest March in 85 years although Latvia's central and western rivers were spared from extreme spring floods. In northwestern Europe, England and Scotland experienced its wettest March since 1981 and 1994, respectively. Uccle in Belgium recorded its wettest March since 1833.

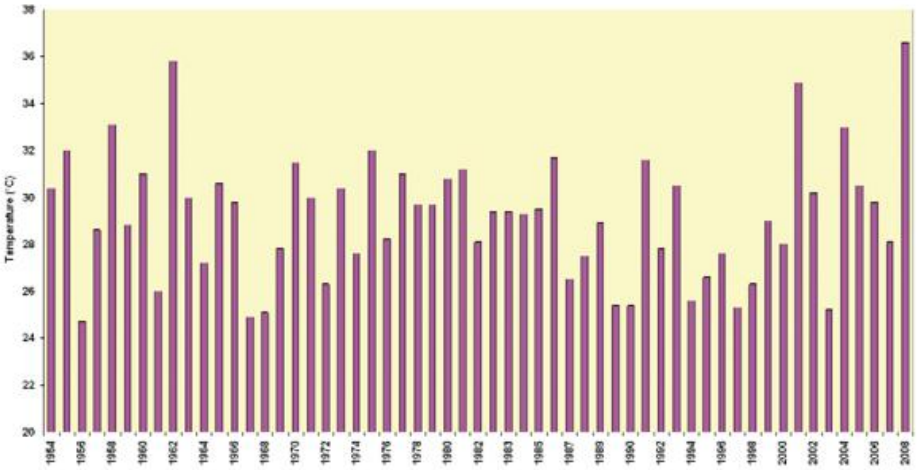

Fig. 3.3: *Absolute maximum temperature in March at Kefar Blum (Hula Valley, Israel) 1954-2008.*
Source: Israel Meteorological Service

In contrast, a few areas in the northernmost and southernmost parts of the Region which lay outside of the frontal zone received very little precipitation. Svalbard in the north and parts of Spain, southern Romania, Greece and the southern Middle East recorded monthly totals below 10 mm, which is far less than normal. Larnaca on Cyprus received a monthly total of only 3 mm (less than 10% of the normal) with the result that all months of that year's winter rain time (October 2007 until March 2008) were much too dry, which caused a severe drought in Cyprus. In central and southern Israel, there was virtually no rain and these places had seen only 3 more years in the last 70 years, in which they had received no rain in March. Damascus in Syria also received no measurable precipitation throughout the month. Armenia registered only 45% of the normal March precipitation on spatial average while the values in Azerbaijan were less than 40%.

Most of Italy was wet compared to the rest of the Mediterranean countries due to a persistent low pressure system residing there during the first decade and bringing frequent rainfall.

Snow

Snow in March 2008 did not only cover higher latitudes and high mountains, but also occurred especially in large parts of central and eastern Europe. An Arctic trough extending to northern and central Europe caused snow showers and a temporary snow cover in the lowlands of Germany and Switzerland on 4-5 March and around Easter (23-24 March). So, quite large amounts of snow arrived in central Europe late in the season after a winter with very little snow. Brocken mountain station (Germany) recorded a snow cover of 1 metre, a depth which had not

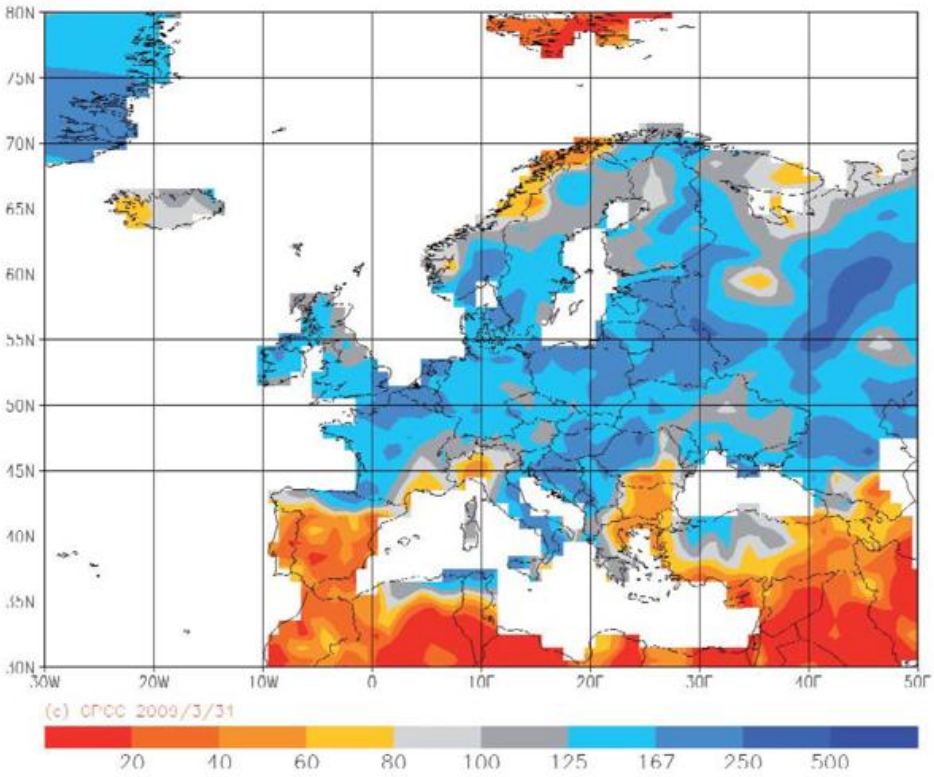

Fig. 3.4: *Monthly precipitation amounts for March 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

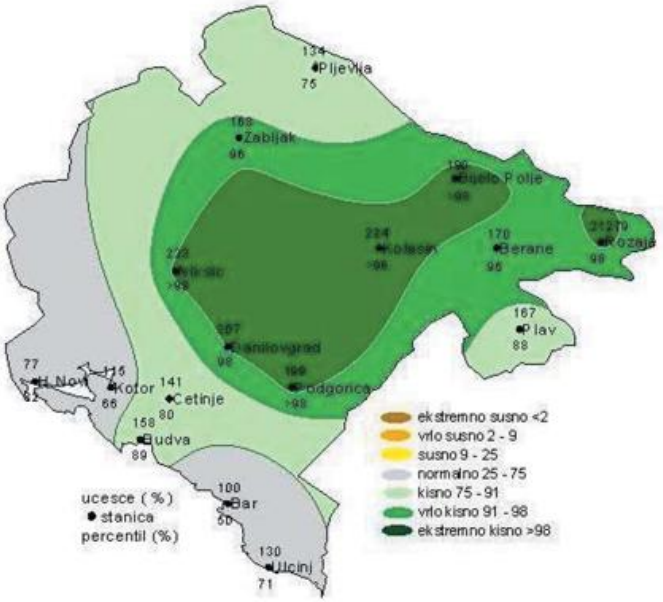

Fig. 3.5: *Monthly precipitation amounts for March 2008 in per cent of the normal 1961-1990 in Montenegro (upper numbers) and in percentiles (lower numbers).*
Source: Hydrometeorological Institute of Montenegro

been seen there during the whole winter. 15 cm were recorded in the northernmost parts of Germany (Schleswig station) while the Zugspitze, Germany's highest mountain (almost 3000 m altitude), reported 340 cm. In Austria, March brought more snow than any of the preceding winter months. Even in Italy, snow fell in many places above 400 m altitude, and various places in Slovenia also experienced snowy Easter holidays.

Snow even fell in the more maritime areas of the western half of Europe, e.g. with around 5 cm in the southern Netherlands, which then received the largest amount of this snow season. Snow also fell in Luxembourg, and some eastern areas of England received a snow cover of 5-10 cm on the morning of Easter Sunday (23 March). Iceland, too, was slightly snowier than usual this month.

Only a few days later than in central Europe, a snow event arrived in northeastern Europe. Intensive snowfall was recorded on 26 March along the west flank of a low pressure system in Belarus, Estonia and southern Finland causing a fresh snow cover of about 30 cm in some places.

Snow also covered parts of Romania during the last decade of the month. In Serbia, snow fell only on the mountains and temporarily in western and southeastern lower areas of the country. Eastern Georgia received snow at the end of the 2nd decade, with snow depths of up to 80 cm in lower mountain areas and 5 m on high mountains.

Significant weather events

March 01-02: A heavy storm (“Emma”) moved from the Norwegian Sea over central Europe to the east. Gusts of hurricane force were recorded even in the lowlands (e.g. up to 140 km/h at Salzburg, Austria) and up to over 220 km/h in mountainous areas. The storm was accompanied by heavy thundery precipitation and hail with local flooding. Infrastructure and electricity disruptions, forest damage and at least 14 fatalities were reported. Strong wind and hail was also reported from Romania.

March 04-07: Storm with heavy rainfall, snowfall and strong winds initially affected northern Italy, later the whole country. Gusts of up to 120 km/h occurred in Trieste on 06 March, Venetian harbour had to close, boat connections to the islands were interrupted.

March 09-13: A severe storm with flooding hit the UK, Belgium, France and Germany. A mean sea level pressure of 950.1 hPa was recorded in southwest Ireland (Shannon Airport) on 10 March at 6 UTC, the lowest March value on record in Ireland. 2-day rainfalls of up to 50 mm were measured in the south of the country. In certain places of France, strong winds lasted more than 12 hours. Gusts exceeded 130 km/h at the coasts of northwestern France, locally even reaching a speed of 155 km/h and causing flooding due to storm surges. Inland areas of northern France saw gusts often amount to 80-100 km/h. At sea, a buoy off the southwest coast of Ireland recorded a wave of 13.4 m on 10 March at 11 UTC, the highest wave on record there for March. The Black Forest in Germany received almost 100 mm of precipitation in 5 days. Another storm hit parts of the United Kingdom on 12 March.

March 14: Strong winds affected Cyprus, causing damage to property in Nicosia and uprooting trees in the southern coastal area.

March 18: A rather small, but quite active cyclone brought abundant snowfall to Lithuania with a snow cover of up to 10 cm that persisted over a week in

northern regions.

March 20: Hail at the Costa del Sol in southern Spain, flooding of roads. It was one of the rare precipitation events during a several-months-long drought period in Spain.

March 20-26: Coldest Easter on record in Germany with frequent snow; at the coasts of northern Germany also strong wind and flooding. Italy also had bad Easter weather: wind and rain with heavy sea storms over central-southern Tyrrhenian regions and damage and flooding in Rome.

March 24-25: Strong southern winds in Romania and Bulgaria with foehn effect at the northern slopes of the mountains. Gusts of up to 144 km/h on the Danube River. Heavy storm also in Turkey.

April

- **Mostly warm, some local cold areas in Scandinavia and western Europe**
- **Mostly wet, Arctic and most of the Mediterranean very dry**

Atmospheric circulation characteristics

The western Arctic areas still profited from warm air, high pressure influence and mild sea surface temperatures, whereas Lapland was in a cold northeasterly air flow at several times.

Western and central Europe occasionally lay in a northwesterly cold air flow. During the first half of the month, frequent passages of low pressure systems occurred. In the second half of the month, high pressure influence extended from the north to central Europe.

Eastern Europe and the Middle East were affected by a southwesterly flow of tropical air. Due to a blocking high over Russia, the easternmost parts of the Region were spared from the large rainfall area west of it. High pressure also dominated in the western Mediterranean.

Temperature

April was again mainly a quite warm month throughout the Region. The highest monthly anomalies (> +3°C) occurred in the Middle East, western Greenland, southeastern Norway and parts of eastern Europe, including the Baltic countries (Fig. 4.1). In some places in Syria, the anomalies were more than +4°C.

By the end of the month, mean daily temperatures reached 10°C in Lithuania and the active vegetation period started 1-2 weeks earlier than normal. Maxima of more than 20°C were recorded in Russia near Volga River on 4 April and in Moscow one week later. Very warm weather was also recorded in the second half of April in central European Russia, exceeding normal values by 4-5°C.

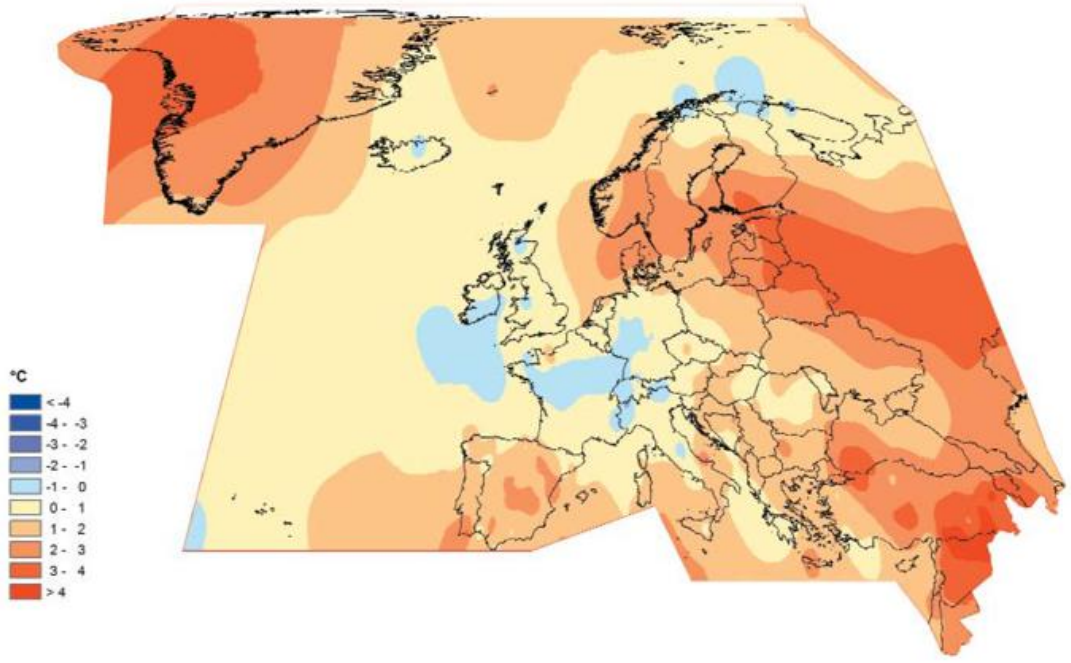

Fig. 4.1: *Monthly mean temperature anomalies in April 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Monthly mean anomalies in April were around +1°C in most of Austria, Hungary and Poland, up to +2°C in northeast Poland, mostly less than +1°C in Slovenia and only 0.3°C in Germany where the first two cold decades of the month were compensated by a warm decade at the end of the month. The North Atlantic temperatures were mostly around normal, in some areas in the north and the south about +1°C warmer.

Spain and Portugal were very warm at the beginning of the month (daily maxima up to 31°C on 3 April in Cordoba, southern Spain), with a monthly average of around +2°C above normal.

In April, several heat waves occurred in southeastern Europe and the Middle East. On 13-15 April, advection of Sahara air caused the maximum temperature to rise up to 30-36°C in Greece, Cyprus, Turkey and Israel. One week later (22 April), the station Heraklion on Crete (Greece) recorded 37.4°C which is the highest temperature ever measured in April in this place. In Israel, the month was characterized by a large number of Sharav events. Tel Aviv had 41°C on 23 April. With temperatures of 42-45°C, the Jordan Valley recorded its highest April temperatures over the last 40-50 years. Exceptionally high temperatures were also measured on 24-29 April in Armenia due to the invasion of hot and dry air from the deserts of the Arabian Peninsula; a maximum at 35.6°C was reached in Meghri in the south of the country. Never before had such a high temperature been recorded in Armenia in April. Azerbaijan also reported high temperatures on 24 April.

Only a few areas in Lapland and western Europe were slightly colder than normal. Temperatures in Lapland remained below 0°C in the first half of the month with minima below -20°C. The northern part of the Baltic Sea was frozen. In western Europe, frequent rain showers and cloudiness as well as occasional cold air flows especially in the first two thirds of the month were the main reasons for low monthly mean temperatures. England, Wales and the United Kingdom as a whole had their coldest April since 2001, although temperatures were close to normal. Sometimes, temperatures showed a large day-to-day variability. In England, 18°C were

measured in London on 4 April whereas the next day saw a strong cold snap from the northwest causing the temperature in southern England to drop down to near-zero values during the night of 5-6 April.

Precipitation

Most parts of the Region were clearly wetter than normal, especially most of western, central and parts of eastern Europe (above all the Ukraine), but also most parts of Iberia, Bulgaria, Greece and parts of Scandinavia (Fig. 4.2). More than twice the monthly normal was reached in some places, even in the southern half of Europe, e.g. Switzerland (Geneva, 144 mm), parts of Austria, Portugal (e.g. Lisbon, 151 mm), Greece (Athens, 69 mm) and the Ukraine (Kiev, 123 mm).

In the United Kingdom, rainfall totals were well above normal in parts of eastern Scotland and northeastern England. Central Europe was especially wet in the first half of the month. Although the second half of the month was drier in central Europe this did not compensate the high rainfalls at the beginning of the month. In Estonia, only the last third of the month was very dry: for 9 days there had been no rain at all. This led to drought conditions and forest fires. It was the same in Georgia in the Caucasus region: the first half of April was rainy, the second half dry.

The higher latitudes including most of eastern Greenland, Svalbard, Iceland and the northwest coast of Norway were considerably drier than normal. Parts of Greenland received less than 25% of their normal monthly precipitation. Stykkishólmur in Iceland experienced its driest April since 1951. It was also dry in Ireland, on the North Sea coast of central Europe, in southern Sweden and large parts of European Russia, in the Middle East and most of the Balkan Peninsula and the Mediterranean.

Eastern Spain continued to suffer from the ongoing winter-spring drought although it was already wet over in the other parts of Iberia. In the whole month, the Balearic Islands received a precipitation total of only 2-4 mm, i.e. about 10% of the normal. Malta Airport recorded a monthly total of only 3.6 mm and thus one of the driest Aprils over the past 84 years with monthly totals of only about one third of normal. Various places in Turkey received less than 40% of their monthly normal, Cyprus a monthly total of only 2.3 mm which is 8% of the 1961-1990 normal. Israel had no rainfall at all in April as opposed to the small amounts it receives normally. Out of the last 70 years, there had been only 2 or 3 years that were completely rainless in northern Israel. Large parts of Syria and Jordan were also rainless.

In Armenia, the monthly total precipitation was only 30-50% of normal, locally even less, thus causing problems for irrigation. Azerbaijan also received only around half the normal precipitation on country average, which made April 2008 the third successive dry month in this country.

Snow

Due to high precipitation, the snow depth on the peaks of the northern Alps increased in April up to 7 metres. In the first half of the month, snow came even down to the lowlands in northwestern and central Europe. On 6 April, a marked cold snap caused snowfall in southern England and one day later also in central Europe. As late as on 17 April, southern Germany measured a snow cover of a few cm.

Significant events

April 03: Thunderstorm with hail and tornado in Zakynthos (island in Ionian Sea, Greece, Fig. 4.3)

April 06-07: An area of sleet and snow moved across much of the Midlands of the United Kingdom and southeastern England with 5-10 cm reported fairly widely, causing Heathrow airport to close for a time.

April 17-19: Funnel cloud over Rome causing damage to trees, antennas etc. on 17-18 April. A tornado was seen in Romania on 19 April.

April 22-27: Heavy thunderstorm in lower Austria and southeastern Europe. Tornado in northeastern Bulgaria, hailstorm with hail stones as big as eggs. 220 houses and electricity network damaged, trees uprooted. Port and airport in Varna (Bulgaria) temporarily closed due to strong foehn winds.

April 28: Hail up to 50-70 mm in diameter near Krasnodar, southern European Russia.

May

- **Warm in the west, cold in the east**
- **Heat wave in central, southern and southeastern Europe at the end of the month**
- **Most of the Region dry, southwestern and eastern Europe wet**

Atmospheric circulation characteristics

High pressure influence was dominating over northern and central Europe and over the eastern Mediterranean and the Middle East.

The Azores high was weaker than usual this month and shifted to the south. At its north flank, Atlantic low pressure systems with moist air and frequent precipitation moved slowly over western Europe, Iberia and the western Mediterranean. Another centre of frequent cyclonic activity occurred over eastern Europe except the north.

At the end of the month, especially the central Mediterranean and central Europe were within a strong flow of very warm air, leading to a short, but intense heat wave over large areas of the continent.

Temperature

It was a warm May especially over western, central and southeastern Europe, the North Atlantic and most of the Arctic (Fig. 5.1). Anomalies over Europe were highest in western Ireland, northern France, Belgium, the Netherlands and western Germany, but also in Bulgaria in the southeast with more than +3° and in northwest France and Luxemburg with locally more than +4°C. The western German Baltic Sea also was around +3°C warmer than normal, whereas the German North Sea recorded +1.7°C more than normal and thus the second warmest May since 1971.

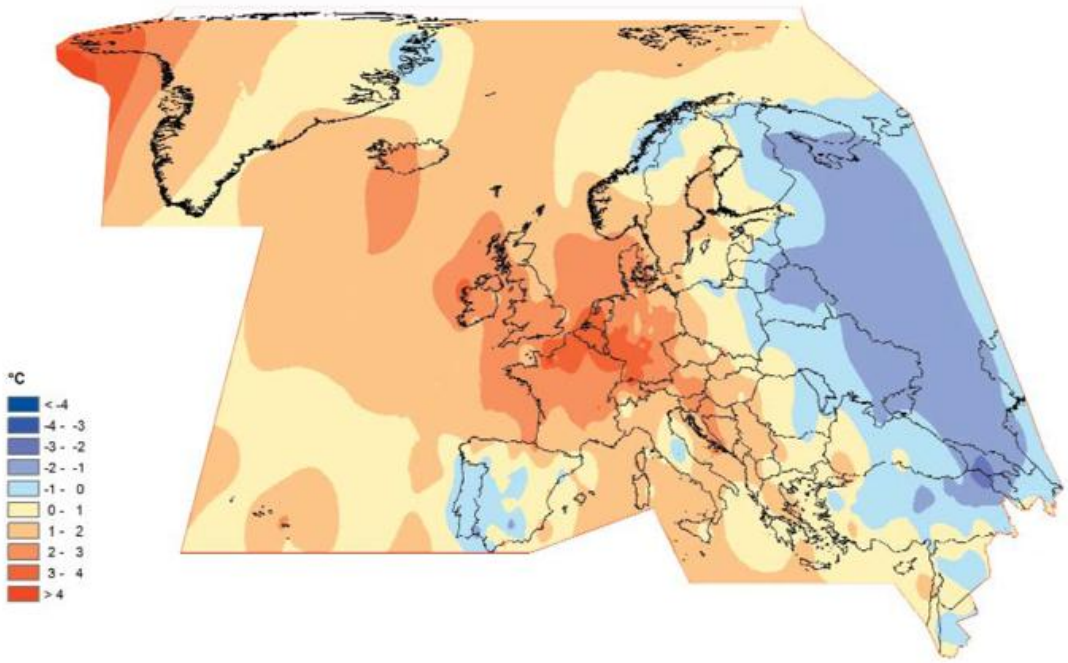

Fig. 5.1: *Monthly mean temperature anomalies in May 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

It was the warmest May on record in the United Kingdom, at most stations in Ireland and in many places of the Low Countries, e.g. in Uccle (Belgium). The high anomalies were caused to a considerable part by high maximum temperatures due to long sunshine durations over large parts of Europe. London-Heathrow recorded a maximum temperature of 25.0°C on 08 May. A temperature of more than 27°C was measured in the Champagne in northern France. The North Atlantic also continued to be warmer than normal, mostly more than +1°C. May also was exceptionally warm across the Netherlands – it was the warmest May in De Bilt in more than a century. It also was the third warmest May on record in Germany. Eastern and southern Germany had monthly maxima of more than 30°C at many stations and night frost in Germany occurred only at very few locations in the north and in the Alps. Most of Austria and Slovenia were 1-2°C warmer than normal.

At the end of May, warm Saharan air caused particularly high temperatures in southern, southeastern and parts of central Europe. Palermo, Sicily experienced 38.9°C, and 37-38°C were measured in Greece. Maximum temperatures in western Turkey reached 32-37°C. Chirpan, Bulgaria, recorded 36.2°C. Temperatures surpassed 35°C on 28 May in places in Serbia. The absolute maximum temperature for this May exceeded 33°C for the first time and thus was the warmest on record in many places of Croatia in the long time series of Zagreb Grič starting in 1881 (Fig. 5.2). New temperature records up to 34°C also were recorded in Montenegro. At some places at the coast of Slovenia as well, absolute maxima were the highest

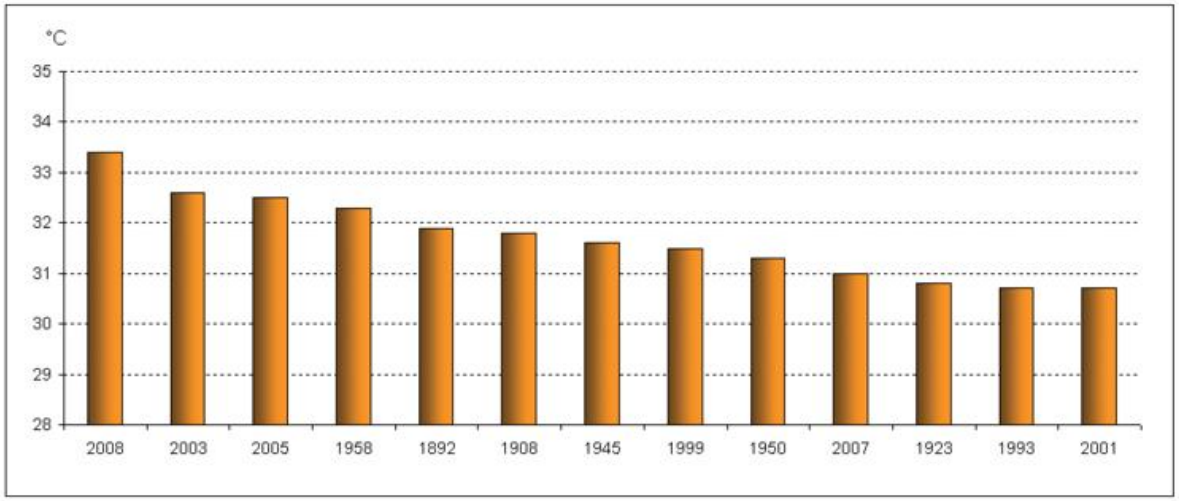

Fig. 5.2: *Years with highest absolute maximum air temperature for May in Zagreb Grič, Croatia (time series 1881-2008).*
Source: Meteorological and Hydrological Service, Croatia

ever measured in May. In Ljubljana, it was the third highest maximum. Austria also had a short heat wave in the last days of May, which brought new record May temperatures in many places, e.g. 34.9°C on 28 May in Graz. With 30°C on 27-29 May some stations in Switzerland set a new monthly temperature record due to foehn. Poland reported a monthly maximum of 29.1°C.

In the north, it was exceptionally warmer than normal in western Greenland (up to +3°C). On Iceland, it was the warmest May in Reykjavik since 1960 and the second warmest behind May 1935 in the whole time series of Stykkishólmur starting in 1845. Sweden reported new records of May maximum temperatures, again due to the heat wave in late May (and early June). In the northeast, monthly mean temperatures were around normal, but the weather was very variable with rapid changes between cold and warm spells.

Eastern Europe, parts of the Middle East as well as southwestern Iberia were 1-2°C colder than normal. Particularly the first decade of the month was colder than normal in Armenia by more than 3°C, and severe frost was to be found in Turkey that time.

Precipitation

May was a significantly dry month namely in most of the Nordic region, especially Denmark, southern Finland and the Baltic States (Fig. 5.3). Denmark had only 13 mm of monthly precipitation averaged over the country (normal 48 mm). Some areas in Estonia received only 9% of the normal May precipitation, which was the reason for many forest fires. Places in Lithuania received around 5 mm or less than 15% of the normal precipitation. The month also was exceptionally dry in Ireland, most of the UK except the south and most of central Europe including the Alpine region. It was the driest May in Germany since 1919: only around 25% of the monthly normal fell on country average, at some eastern German stations even less than 10 mm during the whole month. In Maribor, Slovenia, it was the second driest May since observations started with monthly precipitation totals of up to 37% of the 1961-1990 normal.

On the contrary, large parts of western and southwestern Europe (southern United Kingdom, western and southern France, Iberia, even northern Italy) were very wet, partly with twice the normal monthly total, over eastern Spain and the western Mediterranean even up to 3-6 times the normal: 237 mm fell in Ajaccio, Corsica, as compared to a normal of 40 mm. May was the wettest in Spain since at least 1971 due to both high rainfall amounts and a high number of rainy

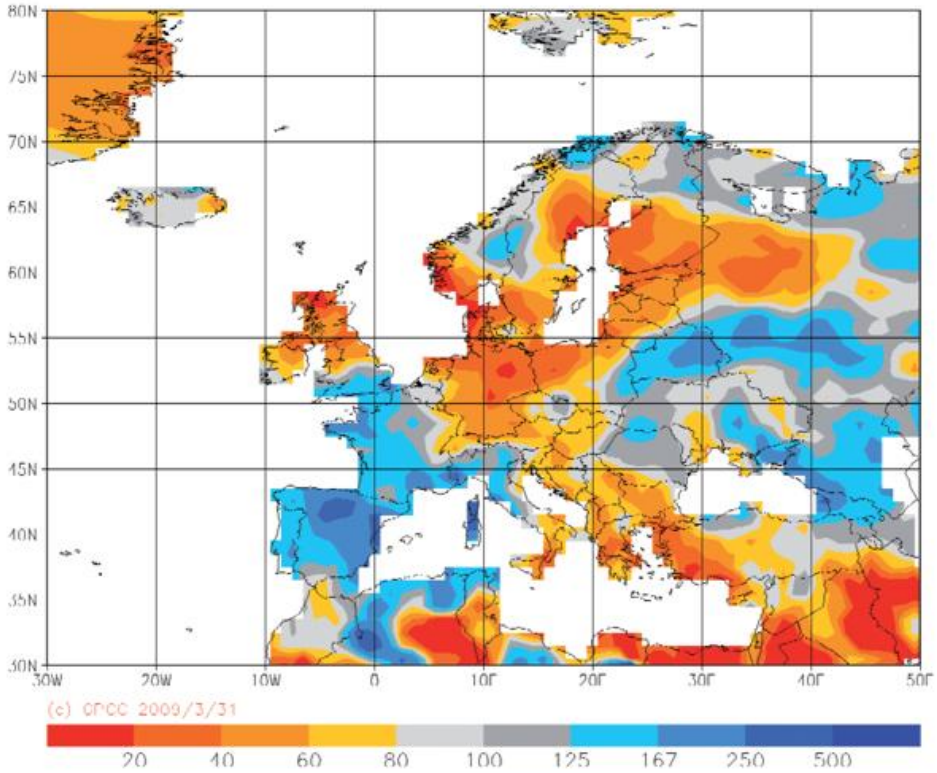

Fig. 5.3: *Monthly precipitation amounts for May 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

days, the latter especially in the northwest and southeast of the country. Particularly high amounts of more than 200 mm of the monthly precipitation were measured in northeast Spain, causing flooding in this area at the end of the month, and in the western Alps.

Another large area of higher-than-normal precipitation was to be found in eastern Europe. Particularly high amounts of more than 300 mm (more than 150% of the normal) fell along the southern slope of the western Caucasus Mountains. Azerbaijan also had a wet May due to partly intensive rainfalls after three preceding, very dry months. West of the Black Sea, torrential rainfall with frequent hail fell in Romania during the last decade of the month.

In contrast, large parts of southeastern Europe, the eastern Mediterranean and the Middle East were very dry. Even in southern Italy, a couple of places in Sicily recorded as little as a few mm on only 1 or 2 days during the whole month. Stations in Macedonia received a monthly total of less than 10 mm (10% of the normal precipitation). In Greece, stations in Athens recorded totals of 2-4 mm of precipitation for the whole month, which fell on just one day. The same was recorded for Antalya at the Turkish south coast (normal is 28 mm). Turkey as a whole experienced a dry period at the beginning of the month, causing a delay of seed germination. Syria, Lebanon, Israel and Jordan had hardly any precipitation, even in those places which normally are not rainless. Beirut, Lebanon recorded just 1 mm this month, compared to a 20 mm normal.

Snow

Snow cover continued to persist in Lapland (20-50 cm depth) at the beginning of the month, whereas the snow in southern and central Finland had completely melted by then.

A snow depth of 13 cm accumulated in Archangelsk, northern Russia, until 18 May. At the end of the month, a depth of 35 cm was still measured on the Canin Peninsula in northern Russia.

Significant weather events

May 08: Heavy rainfall and thunderstorms accompanied by heavy hail affected Cyprus (the area of Nicosia and Larnaca), bringing floods to the area.

May 09-10: Heavy rain over Mallorca and northern Spain, up to more than 40 mm in 12 hours on 10 May in the afternoon, 76 mm in 6 hours in Barcelona. (Winter and early spring months before were very dry in Spain!)

May 19-20: Very intense rain between Bologna and Modena, northern Italy. Local maxima of 60 mm in 1 hour, 83 mm in three hours, 140 mm over two days. Highest total rainfall in over 70 years with a return period for such rain intensity of more than 200 years. Heavy rain also over Corsica and Sicily.

May 20: Large hail up to 30-35 mm in diameter in Dagestan, eastern Caucasus, European Russia.

May 21-22: Strong thunderstorms in Romania and Bulgaria, partly with hail, hailstones as big as eggs, intense rain causing local flooding on Danube River (Fig. 5.4), land slides, electricity breakdowns.

May 24-27: 121.4 mm of precipitation fell in 4 days at a station in southeast England.

May 27-28: Severe foehn storm in Switzerland. Highest gust ever measured in May since 1981 at Gütsch above Andermatt (2287m altitude) at 180 km/h on 27 May. Large amounts of Saharan dust were transported to Switzerland.

May 27: Tornado at the Tarragona coast (near Barcelona, Spain).

May 29-30: Flooding in Piedmont region in northern Italy (Piedmont, Lombardy, Veneto), landslides. Heavy rain also in Corsica, 133 mm in 24 hours in Ajaccio at the west coast of the island, the heaviest rainfall for nearly 60 years.

May 29-31: Heavy thunderstorms with local flooding and tennis-ball sized hail (8 cm) in western Germany. Daily precipitation of 64.4 mm fell at station Asselborn, northern Luxembourg on 29 May. Heavy rain also in eastern France.

May 31: Heavy rain in northern Spain (89 mm in 24 hours in Bilbao) and western France (85 mm in 24 hours in Le Mans).

Fig. 5.4: *Flash flood on 21-22 May 2008 in Nikopol town on the Danube River, Bulgaria. Photo by A. Tonev.*

June

- **Mostly warm, cold in the east**
- **Heat waves in southeastern Europe**
- **Mostly dry, but some heavy thunderstorms, wet in parts of northern and southern Europe**

Atmospheric circulation characteristics

At the beginning of June, an omega pattern developed during the first decade, with warm air particularly over central and southeastern Europe and also western Scandinavia, whereas especially Russia, but temporarily also parts of western Europe including Iberia were within colder air.

At the end of the first decade, the Azores high extended to the north and also to the east over the middle latitudes of Europe, whereas a strong low pressure system persisted particularly over northern Europe.

In the second decade, the circulation changed to a more zonal pattern over the middle latitudes with not too strong frontal systems. However, low pressure and cold air in higher atmospheric levels extended temporarily from the north far to the south, even to southern Europe and the central and western Mediterranean, leading to frequent thunderstorms over these areas.

Strong high pressure influence persisted over Greenland and its surroundings, including Iceland and Svalbard. High pressure influence was also dominating over the eastern Mediterranean and the Middle East.

Temperature

June was another warm month in most of the Region including the whole North Atlantic (Fig. 6.1). The centre of the highest anomalies in Europe (> +3°C) was over southeastern Europe, another one in Greenland.

Angmagssalik at the southeast coast of Greenland saw a maximum temperature of 18°C on 14 June and still 15°C in the following night due to foehn. In southeastern Europe, Serbia had two quite long extreme heat waves, one from the beginning of June until 3 June, the other one from 21-27 June with a maximum of 38°C on the 25th. The latter heat wave reached even Romania, Bulgaria and western Turkey with maxima of 39°C, around 37°C and 40-41°C, respectively. The water temperature of the Black Sea reached 25°C. There were two short heat waves (18-19 June and 25-26 June) over the mainland of Greece with maximum temperatures of 38-40°C. Cyprus also recorded temperatures around 40°C. In Israel, it was one of the warmest June months in the last 40-50 years with mean monthly anomalies of 1.5-2.0°C above normal. This was due to some extreme Sharav events with temperatures reaching up to 40-41°C in the northern valleys and the Negev.

Southern Iberia was another centre of high positive mean temperature anomalies. Prevailing high temperatures culminated to values above 40°C particularly in southern Spain. In the Mediterranean, the monthly mean sea surface temperature near Malta was 22.1°C, slightly more than +1°C above the June average since 1978. Italy also was hit by a heat wave in the second half of the month with temperatures up to 38°C at several stations. Vienna in Austria reached 35°C on 22 June.

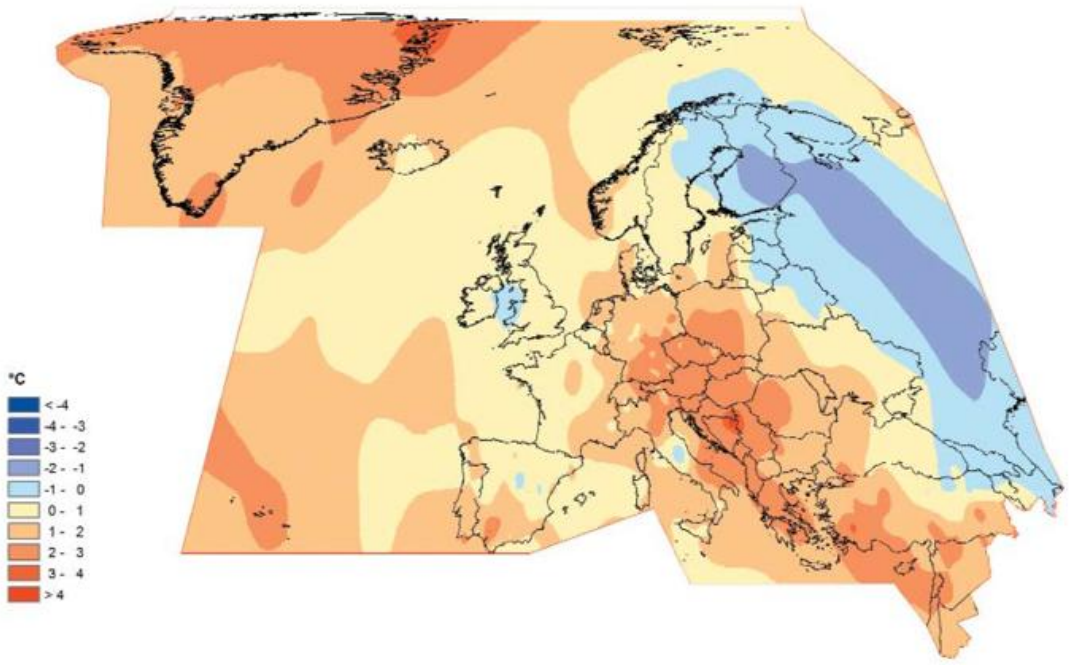

Fig. 6.1: *Monthly mean temperature anomalies in June 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

In western Europe, monthly anomalies amounted to +1°C in France. In the United Kingdom, June temperatures were generally close to or just above normal, but it was the coolest June since 2001. Temperatures were well above normal in southwestern and western Iceland.

Central Europe had anomalies around +2°C. Germany was 1.6°C warmer than normal on country average, with only one cool period around the middle of the month, Austria saw monthly mean temperatures around +2°C, partly up to +3°C above normal. The monthly mean temperature anomalies in Poland reached up to 2.5°C, with the warmest parts in western and central parts where maximum temperatures exceeded 32°C. Hungary was +1.9°C warmer than normal (1971-2000 reference), Romania +1.8°C.

It was still colder than normal in eastern and northeastern Europe. Anomalies below -1°C were recorded in Russia and southeastern Finland as well as in mountainous regions of Georgia. Minimum temperatures in some regions of Georgia dropped below 10°C even in the lowlands on 8 June. The first ten days in Estonia were also colder than normal, whereas southern parts of Norway and Sweden experienced high temperature maxima above 30°C at the same time. In European Russia, ground and air frosts were recorded everywhere in that decade except the south; in the northwestern part of the country, soil surface temperatures dropped to -6°C.

Precipitation

It was mainly dry in most of the Region, especially in the Arctic, in the middle latitudes, over the eastern Mediterranean and southwestern Iberia (Fig. 6.2). June was exceptionally dry in western and southwestern Iceland, e.g. in Iceland's capital Réykjavik (30% of normal), and drought affected some farming areas. Western Greenland was also exceptionally dry; only 3 mm fell in Nuuk at the west coast during the whole month as compared with the normal of 54 mm.

Some places in central and eastern Europe received less than 40% of the normal precipitation due to the fact that rainfall was especially rare during the first decade of the month. However, several local thunderstorms with heavy rain occurred in central Europe throughout the whole month.

A monthly total of 1.4 mm only was recorded in Malta. Although this location is generally dry in summer, the June total was less than half the normal of 3.2 mm. No measurable precipitation fell in Lisbon, Portugal, and only 3 mm (14% of the 1961-90 normal) in Istanbul, Turkey. Places in southern Spain and Gibraltar and in the Mediterranean on Sicily in Italy, on Crete in Greece and at the south coast of Turkey (e.g. Antalya) also had zero precipitation. Persisting drought on Cyprus caused numerous forest fires.

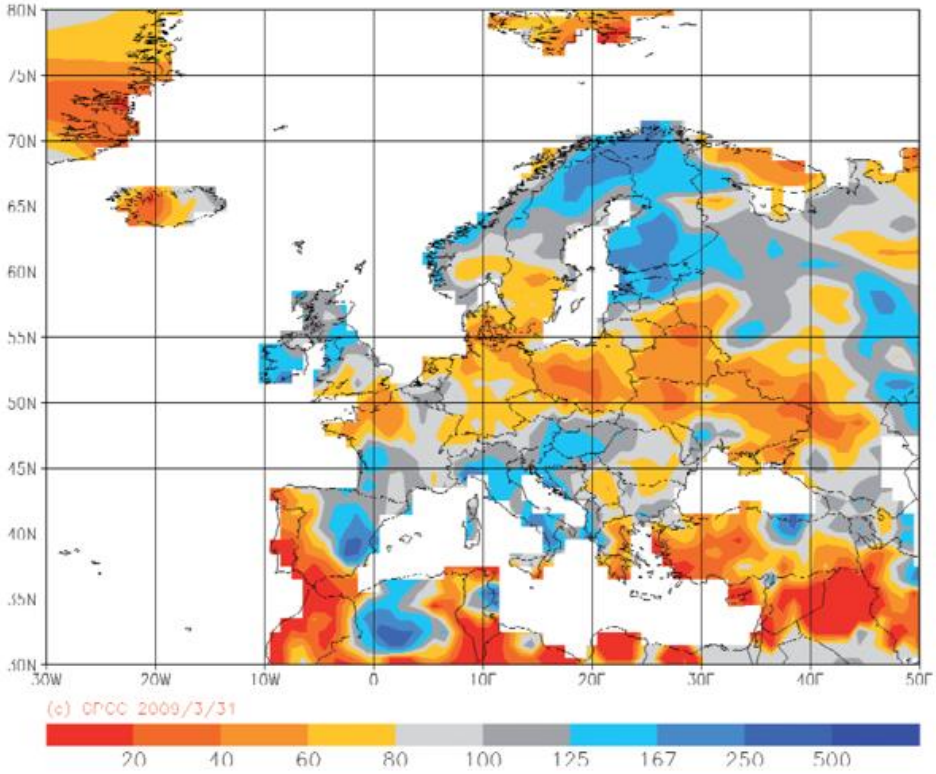

Fig. 6.2: *Monthly precipitation amounts for June 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Nevertheless, some places within the Region were very wet, especially Finland and northern Scandinavia, parts of Ireland and the United Kingdom, eastern Spain and southwestern France, parts of eastern Austria, Hungary, Italy and the western Mediterranean, the northern Balkan peninsula and parts of European Russia, partly with more than 200% of the normal monthly total. This was very often due to heavy thunderstorms. In northeastern Europe, the rainy period started on June 12 and continued until the end of the month. Latvia saw some extremely heavy rains, partly accompanied by hail with hailstones of several cm in diameter. During showers in southern European Russia (e.g. northern Caucasia), a precipitation total of 75-96 mm fell in 1-3 hours and hailstones of 25-40 mm in diameter were detected.

Hungary recorded 27 days with showers, i.e. nearly the whole month. Up to 300% of the 1961-1990 normal precipitation fell in Austria (south of Vienna) and in Albania. The highest monthly total in Albania was registered in Koplik with 157.1 mm which is the second highest June record ever. Such values are rather typical for a winter month in Albania, but not in summer which is normally much drier.

Armenia reported heavy rainfalls and thunderstorms in the second half of the month.

Significant weather events

June 02-03: At first, severe thunderstorms and heavy rain in southwestern and western Germany, later also in eastern Germany, partly with more than 50 mm in 1-3 hours.

June 06: Large hail up to 35-40 mm in diameter in Dagestan, eastern Caucasus, European Russia.

June 12-16: Heavy showers in various regions of the Ukraine and northern Caucasus, European Russia; 50-96 mm of precipitation within 3 hours or less.

June 14: Very intense rain close to Ferrara, Italy, along the Adriatic coast. Intensity locally 80 mm/h and totals for the whole event greater than 180 mm. Maximum total in more than 70 years, return period more than 200 years. Causing mildew in vineyards and fungi diseases in wheat.

June 17-19: 98.4 mm of rain due to an intense low pressure wave in North Wales (United Kingdom) within a 48-hour period ending 21 UTC on 19 June.

June 22-26: Thundery showers on 22 June with strong gusts and hailstones of approximately 5 cm diameter caused much damage in the eastern Netherlands. A large hailstorm was reported in Kaunas, Lithuania, with hailstones up to 28 mm in diameter. A heavy thunderstorm on 25 June occurred in central Germany with hail in the city of Mainz and on vineyards around. In Austria, heavy thunder and hailstorms with high precipitation also caused serious damage in the county Carinthia in the southeast; the cities of Spittal and St. Veit an der Glan partly flooded, agricultural losses (vine, fruits, crops). The TV transmission of the semi-final match of the European Soccer Championship in Austria was interrupted due to a heavy thunderstorm front passing over Vienna that time. Intense storm activity and precipitation also over the whole Czech Republic with gusts over 108 km/h and in Slovakia (daily precipitation of 70 mm in Kosice, east Slovakia, due to an isolated cumulonimbus cluster). In Hungary, 114 mm of precipitation fell within a few hours on 26 June.

June 28: A daily precipitation of 87.6 mm fell in eastern Latvia, more than the whole monthly normal precipitation. On average, such heavy precipitation occurs once every 4 years.

July

- **Mostly warm, cold in northeast and southwest Europe**
- **Middle latitudes, northeastern and eastern Europe mostly wet, western Scandinavia and Mediterranean mostly dry**

Atmospheric circulation characteristics

At the beginning of the month, a large low pressure system extended over northwestern, western and central Europe. In the second decade of the month, the low pressure centre moved to the North Sea, and central and eastern Europe were within a southwesterly air flow with warm air masses, causing heat waves particularly in southeastern Europe.

A high pressure system established over western Scandinavia and later extended to Iceland and Greenland, whereas frequent cold Arctic low pressure systems moved over northeastern Europe. Temporarily, in the second half of the month, a new cyclone with Arctic air masses developed over Scandinavia, and later moved to central and southeastern Europe under intensification.

Towards the end of the month, a new omega pattern built up with high pressure over northern and central Europe and low pressure over the Atlantic and eastern Europe.

Iberia and the Mediterranean remained mainly under high pressure influence.

Temperature

July was also warm in most of the Region. Anomalies exceeded +1°C in many parts of the area, especially in the northwest (e.g. Greenland, Iceland, Scotland, western Nordic countries) and in the southeast, locally even +2°C (Fig. 7.1).

Réykjavik in Iceland reported a new all-time record of daily maximum temperature since 1870 reaching 25.7°C on 30 July and an automatic station near Réykjavik even 29.7°C. It was the warmest July in Stykkishólmur since 1933. Another local record for July was set in southeastern Norway (county of Hedmark): 33.8°C on 26 July. Denmark also experienced a heat wave at the end of the month. Again, most of the North Atlantic was warmer than normal, too.

Central Europe was quite hot at the beginning of the month. Maxima up to 36°C were measured in southwestern Germany. Further maxima above 35°C were rare in Germany. With 33°C, the German North Sea island Norderney saw the highest temperature in the first decade of July since 1947. After the first hot days in July, however, the weather character changed to cooler and more variable conditions. And still, especially eastern parts of central Europe had another warm period at the end of the month. Berlin in Germany recorded a period of 8 days with a daily maximum of 30°C or more as compared to normally only 2.5 days.

Spain, Greece and Cyprus were hit by several heat waves with maximum temperatures locally exceeding 40°C. On the Adriatic coast in Italy, maxima of 35-40°C were recorded at the beginning of the month, whereas in Malta, the temperatures did not go beyond 35°C. In Bulgaria, 35°C were exceeded in many places on 18-22 July, causing wild fires. In the southeast of the Region, maximum temperatures reached up to 41°C in Azerbaijan and up to 44.5°C in Jordan.

Some areas of northeastern, western and southwestern Europe were slightly colder than normal. In parts of Finland, there were monthly mean anomalies below -1°C, mainly due to the first week of July which was the coldest since 1993, and minimum temperatures were falling as low as -2.7°C in the west of the country. Iberia was still warm in the south and east, but colder than normal in the northwest.

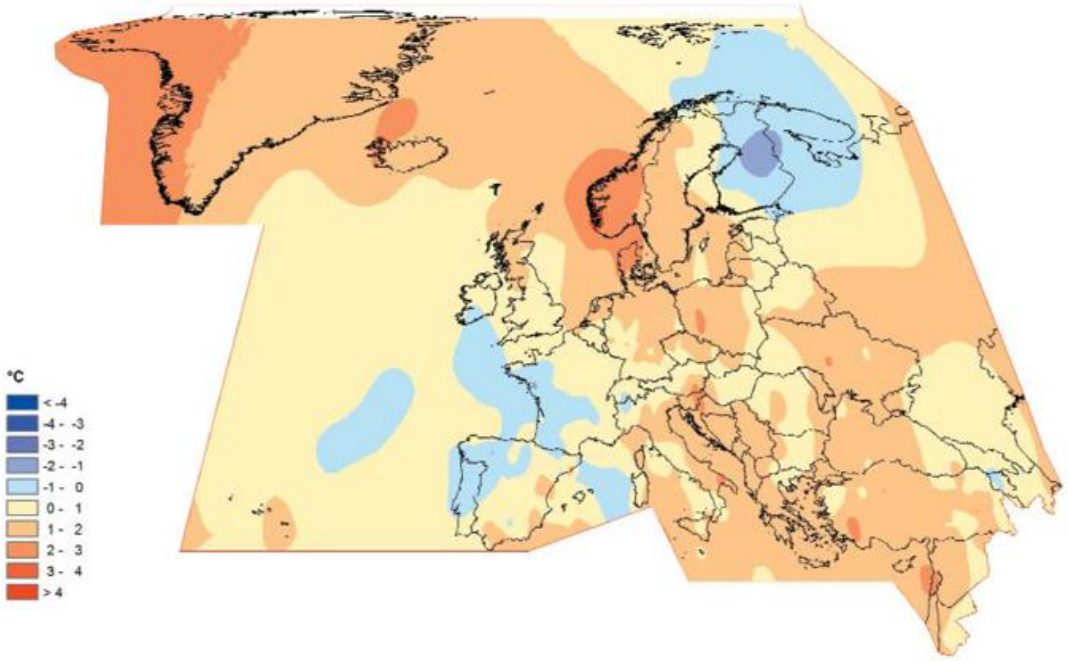

Fig. 7.1: *Monthly mean temperature anomalies in July 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Precipitation

The middle latitudes, the Alps, eastern and northeastern Europe were mostly wet (Fig. 7.2). In many places more than 150-200% of the normal monthly total was recorded, in parts of eastern Austria and European Russia even more than 250%, in Slovakia more than 300%. 430 mm was the monthly total recorded by a Slovak station at the north side of the High Tatras, the second highest on record since 1951 behind July 2001. In Lugano, Switzerland, it was the second wettest July since 1864 (359 mm) due to consecutive heavy thunderstorms, and also Germany had some severe thunderstorm events although July precipitation totals exceeded the normal only by 10% on country average. In parts of the United Kingdom, rainfall was also well above normal. The England-Wales precipitation time series recorded 104 mm for July 2008, which is168% of the 1961-90 normal.

In eastern Europe, precipitation was characterised by a high spatial variability, ranging from a monthly precipitation of 30 mm in the western part of Estonia to 130 mm in the southern part of the country. Like in June, again heavy thunderstorms with large hail of 20-30 mm in diameter occurred locally in the north Caucasian region in southern European Russia. Azerbaijan south of the Caucasus Mountains also experienced heavy weather with hail. With over 180 mm of precipitation, it was the second wettest July in Moscow in more than 100 years. In Chertkovo (near the Russian border to the Ukraine), it was the wettest July at least since 1961 (Fig. 7.3).

Large parts of Scandinavia received very little precipitation, especially in central Norway and Sweden. Monthly totals were lower than 50 mm (less than 60%) over large areas and locally even below 30%.

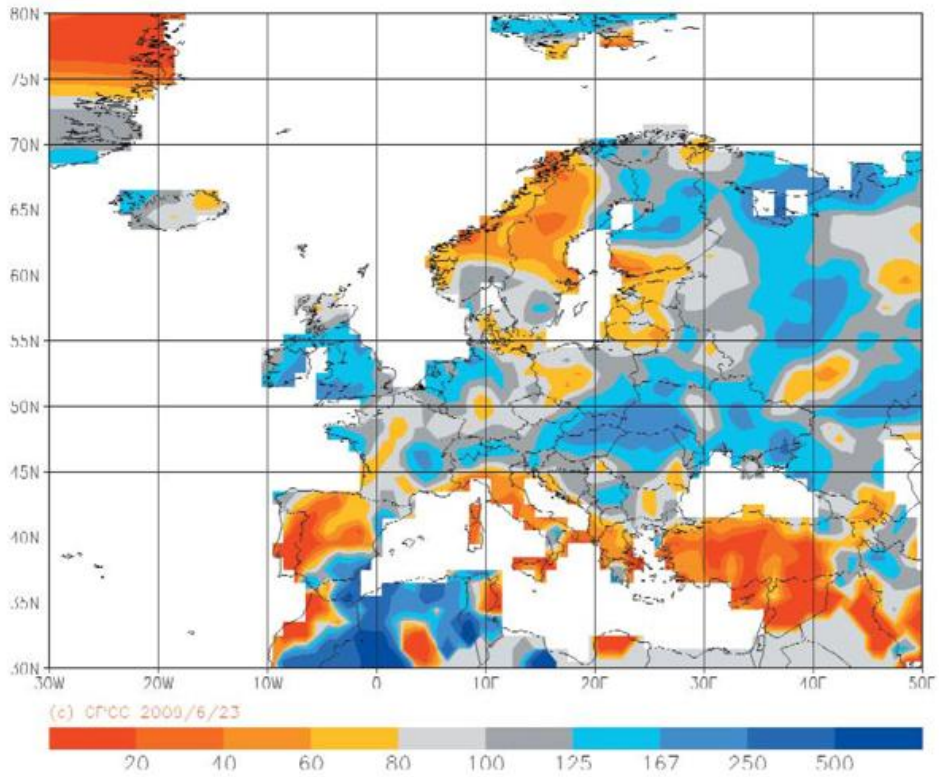

Fig. 7.2: *Monthly precipitation amounts for July 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

It was also very dry over most of the Mediterranean region and Iberia, except some smaller areas (due to local showers) especially in eastern Spain and the western Mediterranean. Monthly precipitation totals were less than 20% of the normal. Several locations (e.g. Lisbon in Portugal, Pisa in Italy, Athens in Greece) did not receive any measurable rainfall that month.

Snow

A stationary cold front in the middle of the month caused up to 1 m of fresh snow in the Alps in Switzerland. Snowfall was seen down to 1700 m. Montenegro recorded a snow cover in the highlands above 2000 m.

Significant weather events

July 02: 67 mm of precipitation in the afternoon in central-western Sicily (Italy). Heavy thunderstorms occurred also in central France (daily precipitation of more than 70 mm).

July 04: Eisenstadt, the capital of county Burgenland in Austria, was covered by hailstones up to 15 cm within a few minutes.

July 05: Oslo was affected by an intense thunderstorm, causing heavy rainfall and flooding. Gusts up to more than 95 km/h were reported.

July 06: Heavy shower with 72 mm of precipitation in one hour and ten minutes near Krasnodar, southern European Russia.

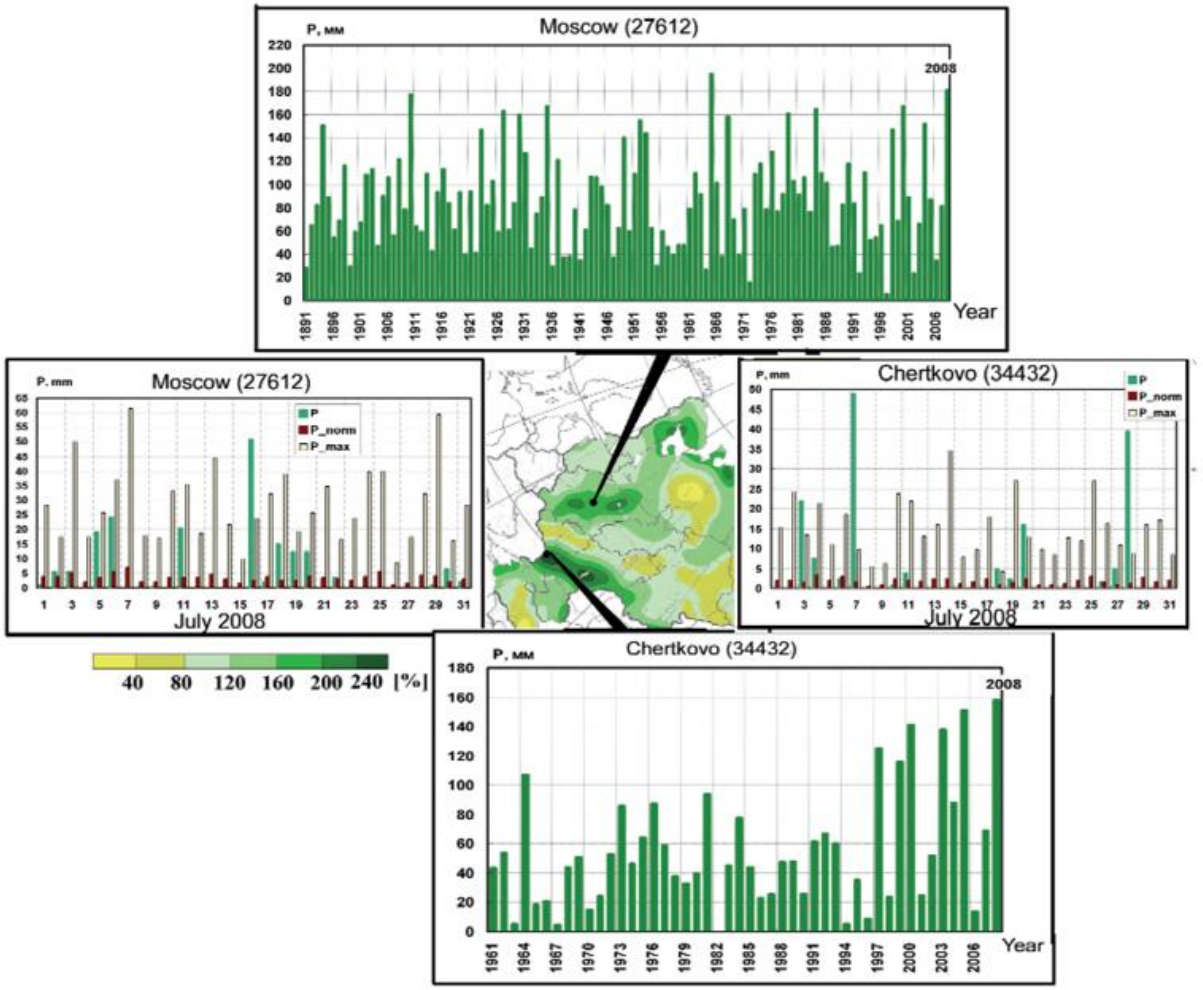

Fig. 7.3: *Precipitation totals in July 2008 in per cent of the normal 1961-1990 in European Russia. Insets show time series of monthly and daily precipitation at two meteorological stations (Moscow and Chertkovo, Russia).*
Source: Roshydromet, Russia

July 06: Heavy thunderstorms in northern Italy. Hail up to tennis ball size in the South Tyrol region and near Lake Garda.

July 08: 131.9 mm of daily precipitation fell near Kristiansand (south coast of Norway).

July 08: Thunderstorm caused damage in southwestern Bulgaria, tornado, hail stones as big as nuts.

July 08-09: Flooding in the Dashkesan region in Azerbaijan.

July 12-14: Heavy hailstorm along intense cold front affected upper Austria, Slovenia and northeastern Italy, particularly Venice. Crop losses in upper Austria over an area of 6,000 hectares; local heavy rain caused flooding of houses, the ground was covered by rocks, rubble and mud masses up to 3 m high, 750 inhabitants had to be evacuated for several weeks. Parts of forests in Slovenia were severely damaged (Fig. 7.4). Heavy rain and flooding also occurred in southern Switzerland (Ticino, 117 mm in 12 hours in Lugano).

July 15: Heavy rain in Võru (Estonia): 70 mm in 3.5 hours followed by hail causing damage to agriculture.

July 20: Heavy rain caused landslides in Austria (Upper Styria). Hail, strong gusts and flooding in other parts of Austria and southeastern Germany.

July 21: Ex-hurricane Bertha moved into the Region over the North Atlantic and Iceland, but weakened quickly.

July 21: Thunderstorm with tornado in northwestern Germany (west of Münster). Roofs untiled, but no fatalities.

July 21: Strong hailstorm in northern Italy with heavy rainfall.

July 21-29: Torrential rainfall due to a slow moving cyclone affected parts of the Ukraine (Carpathians), Moldova and Romania. Precipitation totals of up to 100 mm were measured in Romania (Moldavia region), in some places more than 200 mm (Fig. 7.5) and more than 350 mm in the Ukraine. At least 50,000 houses were affected by flooding and several ten thousand hectares of farmland were destroyed. 34 fatalities were reported. Dniester and Prut Rivers in Moldova saw a water level increase of 3-9 m until the middle of August (Fig. 7.6). In eastern Slovakia, heavy rains with flooding occurred on 20-25 July (Fig. 7.7). With 199 mm, a new 2-day precipitation record since at least 1951 was set on 22-23 July. Heavy rain and stormy gusts also occurred in eastern Austria.

July 22-28: Due to strong heat and drought over several weeks over the eastern Mediterranean, extensive forest fires occurred over Rhodes Island in Greece.

July 26: Heavy rainfall and strong hail in western Germany along a convergence line; up to 200 mm of precipitation within 5 hours in Dortmund, causing widespread flooding of the city of up to more than 1 m.

July 28-31: Slow moving depressions centred near the southwest of Ireland brought bands of heavy rain across Ireland and England. 28.8 mm of rain fell in one hour from 28 July 23 UTC to 29 July 00 UTC in central England. On 31 July, widespread rainfalls with 20-40 mm in 24 hours, locally even up to 90 mm, were measured in Ireland, most of which fell between 18 UTC and midnight. Such a 24-hour precipitation total has a return period of about 250 years and the 6-hour precipitation total was one of the highest values ever recorded in Ireland. River Arra (Ireland) overflowed its banks, many buildings flooded to a depth of over one metre.

August

- **Mostly warm, cold in northeast and southwest Europe**
- **Wet in most of the north, dry in the south**

Atmospheric circulation characteristics

A strong low pressure system persisted over the central North Atlantic at the beginning of the month. The frontal zone with cyclonic activity extended soon over most of northern and central northern Europe. Only the Arctic region remained mostly under high pressure influence. However, several strong Arctic cyclones over the Barents Sea led cold air to northeastern Europe.

The Mediterranean and also eastern Europe around the Black Sea were mostly under high pressure influence. By the middle of the month, a trough extended temporarily far southwards to the western Mediterranean, causing once again a strong southwesterly flow with warm air over southeastern and eastern Europe and heat waves in these parts.

Temperature

The distribution of temperature anomalies was almost the same as in July. It was warmer than normal in most of the Region, except northeastern Europe and some places in western and southwestern Europe (Fig. 8.1). Most of the North Atlantic continued to be warmer than normal, except some areas west of Europe. The monthly mean sea surface temperature in the Mediterranean near Malta was 27.3°C, which is +1.5°C warmer than normal.

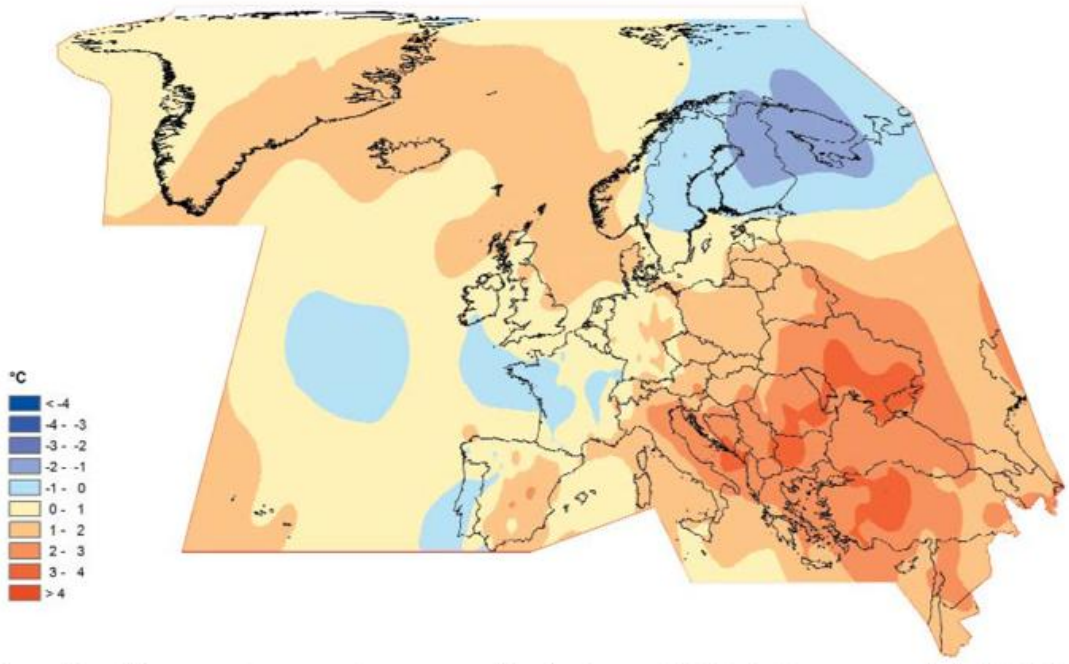

Fig. 8.1: *Monthly mean temperature anomalies in August 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

The highest anomalies were observed in the southeastern parts of the Region, exceeding +3°C in many places and +4°C locally in Turkey. Monthly mean maximum temperatures reached even more than +5°C as compared with the normal, e.g. in many parts of Albania, where various new August records were set.

Maxima in southeastern Europe exceeded 40°C in some places, reaching e.g. 41.1°C in Mostar (Bosnia and Herzegovina). Some places in Greece and Cyprus reached 40°C during the several heat waves. August was also particularly hot in Hungary, Serbia, the Ukraine, Romania and Bulgaria, with daily maxima above 35°C particularly on 12-17 August and partly also on 20-24 August leading to extended wild fires especially in southeastern Bulgaria. Macedonia also saw a warm month and monthly mean temperatures exceeded 25°C in several places (Fig. 8.2). Southern European Russia also experienced very hot weather especially in the second half of the month when maximum temperatures rose to 35-40°C and caused extreme fire risk. Azerbaijan reached similar temperatures (38-41°C).

Locally, temperatures were also quite high at night. Belgrade in Serbia, for example, recorded 10 tropical nights as compared with the August normal of 2.8 nights. The Ukraine saw local daily minimum temperatures above 25°C. With 21.8°C, the monthly mean minimum temperature in Tirana, Albania, set a new local record.

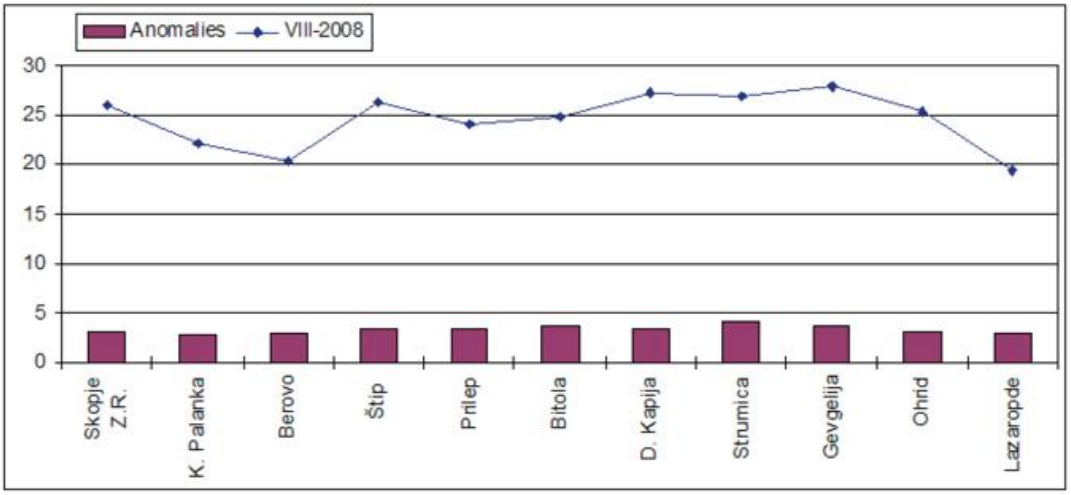

Fig. 8.2: *Monthly mean air temperature and anomalies (reference period 1961-1990) in August 2008 at stations in Macedonia.*
Source: Hydrometeorological Service of Republic of Macedonia

In the central Mediterranean, 40.2°C were measured on Sardinia on 6 August. Spain was also warmer than usual on monthly average: maximum temperatures reached 37-40°C in the south of the country at the beginning of the month, with similar values recorded at several later occasions. Portugal had a monthly mean around normal, but maxima climbed up to 38°C on 4 August.

Monthly mean temperatures in central Europe were less above average than in the southeast. Monthly mean anomalies mainly ranged between +0.5 in parts of Germany and +2°C in Slovenia. Poland's highest monthly maximum temperature of 33.7°C was measured on 1 August already and was the highest of the whole year. Germany recorded highest monthly maxima of up to 35°C in the northeast of the country on the first day of the month shortly before the heat wave ended.

Heat waves extended even to the northern parts of eastern Europe. Lithuania had a warm spell in the middle of the month when the maximum temperature locally climbed up to 29-32°C. The warm spell also affected Belarus bringing it a high mean temperature of 20.7°C in the second decade of the month (16 August was the warmest day). Most of Belarus has seen such a warm decade for the first time on record.

In the United Kingdom, only the monthly mean minimum temperatures were well above normal (+1 to +2°C), while the mean maxima were close to normal on average.

In August 2008, only the far northeast of Europe was remarkably colder than normal. Anomalies below -1°C were again recorded in Finland and northern Russia as in the preceding summer months. Northern Sweden and Finland saw slight frost at the beginning of this August.

Precipitation

August 2008 was very wet in most of northern and northern central Europe (Fig. 8.3). Monthly precipitation totals were higher than 100 mm (150% of the normal, locally more than 200%) in many places of Ireland und the United Kingdom, western France, the northern coastal areas of

Germany and Poland, southern Scandinavia, the Baltic countries and northern Russia. In Ireland, it was the wettest August since records began in 1837 and in Northern Ireland since at least 1914. By mid-month, several heavy rainfall events had destructed crops and severely affected harvesting over southern and eastern Ireland. Widespread flooding also occurred in Northern Ireland and parts of eastern Scotland. In the Netherlands, a monthly precipitation of 267 mm fell on Ameland island. In Denmark, it was the wettest August in 40 years. Some parts of Estonia received more than 300% of the 1961-90 normal (Fig. 8.4), making it the wettest August since 1950.

Some high monthly precipitation totals were recorded even in southern central Europe. Austria received monthly totals of up to 175% of the normal due to several hailstorms which caused enormous damage to houses and fields in several parts of the country. Severe thunderstorms with hail and heavy precipitation were also frequent in Slovenia, causing widespread damage to crops, buildings and cars.

The higher northern latitudes (parts of Greenland, Iceland, Svalbard, Lapland) were dry with some locations with less than 60% and locally even less than 30% of the normal precipitation.

The southern half of the Region was also mostly very dry. Especially during the second decade, there was no measurable precipitation in most places in Serbia. In many parts across and around the Mediterranean and the Black Sea, just a few mm or less than 20% of the normal precipitation fell throughout the whole month. Athens in Greece received a monthly total of 2 mm. Some parts of the Mediterranean, e.g. Malta, recorded no rain at all in this month as compared to a small normal average of at least 5.3 mm. Madrid, Lisbon and Istanbul were also without any measurable precipitation. Even in some mountain regions in Georgia, as little as 30-40% of the normal (30-40 mm) were registered. Only a few locations in the southeast of the Region received high amounts of shower precipitation. After a first rainy decade of the month, Azerbaijan was without any rain at all during the second and third decades.

Significant weather events

August 03: In the evening, a tornado was observed in northern France within a rainy front. Its path was longer than 15 km and had a width of 100-200 m, damaging, or completely destroying around one thousand houses (Fig. 8.5). The intensity level was estimated F3 or F4 on the Fujita scale. On the same day, another tornado devastated numerous farms in the northeastern Netherlands.

August 03-12: Many thunderstorms in Germany with heavy rain, strong gusts causing damage to buildings (due to a thunderstorm downburst or possibly a small tornado) on 04 August in the hills (Odenwald); roads flooded in northern Germany. In eastern Austria (Burgenland), flooding of vineyards on the same day. Several tornadoes in various parts of Germany.

August 04: Summer storm in southernmost Sweden, wind gust of hurricane force at 3 coastal stations. Most intense summer storm since 1985. Heavy rain, e.g. 58 mm in 24 hours in Gothenburg. Storm with hurricane force also over the southern Baltic Sea.

August 06-09: Highest-ever hourly rainfall (38 mm per hour) at Shannon Airport (Ireland) during a thunderstorm on 06 August (return period of over 100 years); almost 30 mm were recorded within a 30-minute spell. Another severe rainfall event with flooding followed on 09 August: 76.2 mm at Dublin Airport was the second highest daily total ever recorded in the station's 67-year history.

August 07: Heavy thunderstorms in northern Germany with heavy rains and strong winds. A tornado was observed, too.

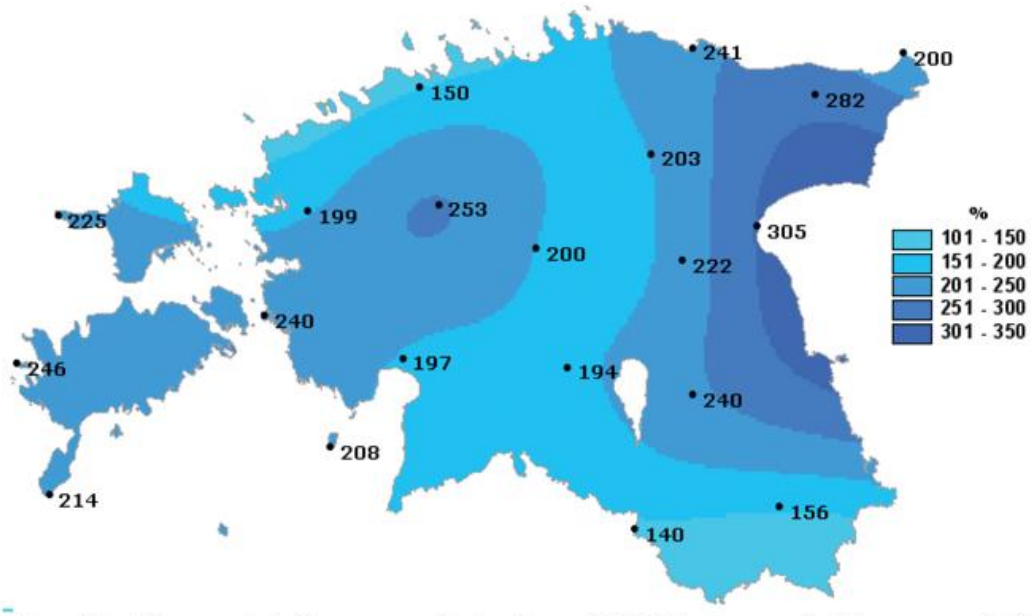

Fig. 8.4: *Monthly precipitation amounts for August 2008 in per cent of the normal 1961-2000 in Estonia.*
Source: Estonian Meteorological and Hydrological Institute

August 09: Strong thunderstorms in mountainous regions in Bulgaria with egg-sized hail stones. Heavy thunderstorms also in Slovakia and the western Ukraine.

August 12: Heavy thunderstorms in western and central Germany. 2 tornadoes damaged several houses and forests.

August 15: Hailstorms in eastern Austria (Burgenland again), damage over an area of 3,000 hectares. High daily precipitation of more than 100 mm fell at mountain stations in southern Austria. Heavy storms also in northern Italy, Slovakia and Poland.

August 16: Fair Isle (United Kingdom) recorded a daily precipitation total of 101.2 mm, thus setting a new record with an estimated return period of over 200 years.

August 16: Tornado affected Cyprus over the area south of Nicosia, causing damage to properties.

August 16: Rainfall in northeastern Israel – a most unusual event during the dry summer months.

August 26: Torrential rain in Jõhvi (Estonia) with a daily total of 116 mm.

August 31: Heavy rain and thunderstorm in east Thessalia and the Sporades (Greece). Flooding in the greater area of the city of Volos; daily rainfall total of 80.8 mm.

Fig. 8.5: *Track of a tornado on 03 August 2008 over Hautmont, northern France. One house was completely destroyed after the tornado had passed.*
Source: Météo France

September

- **Cold nearly all over Europe, warm in the Arctic and the Middle East**
- **Dry in most of Scandinavia, wet in the southeast**

Atmospheric circulation characteristics

In the first decade of the month, low pressure systems over the Atlantic transferred humid and only moderately warm air to northwestern and western Europe, whereas southeastern Europe and the Middle East were still in a warm air flow. Subsequently, a strong high pressure system with very dry air established over Scandinavia, leading cold air from the northeast to central Europe. In the second half of the month, a large low pressure complex moved cooler air masses also to southeastern parts of the continent.

In general, the Arctic region and Iceland experienced a very mild and humid air flow, particularly triggered by the ex-hurricane Ike which moved up north towards the south coast of Greenland in the middle of the month.

Temperature

September 2008 was colder than normal nearly all over Europe and the eastern central North Atlantic (Fig. 9.1). Most countries in western and central Europe were about 1°C cooler than average. In some places in France, Germany and Switzerland, the anomalies were below -2°C, in southeastern Europe between -0.5 and -1°C, in European Russia -0.4°C on average (due to alternation between intensive heat and cold waves).

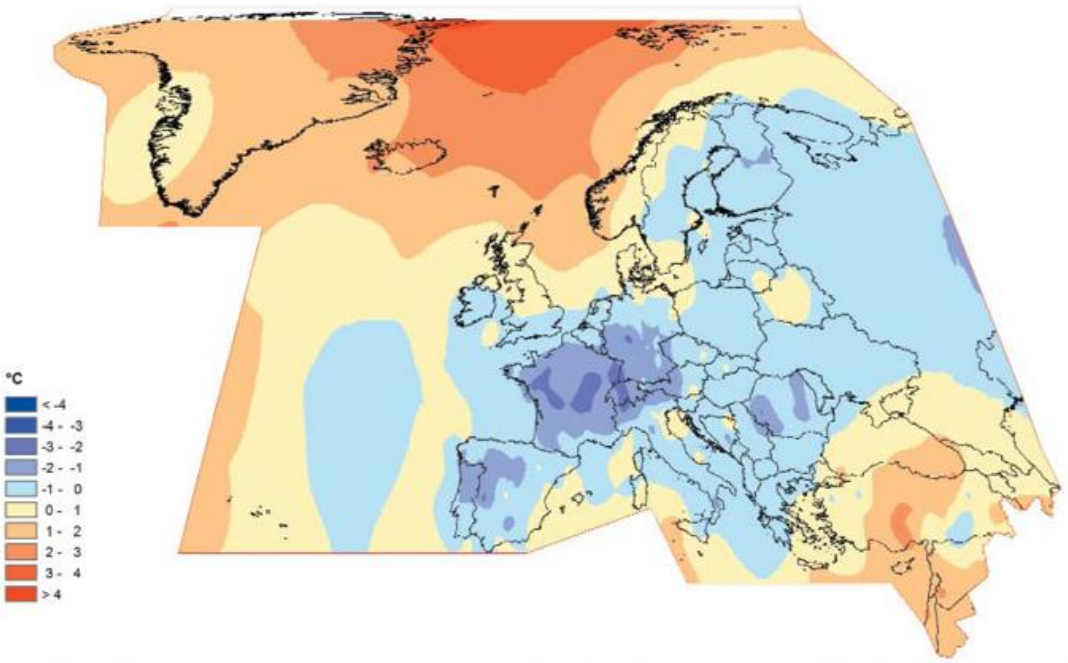

Fig. 9.1: *Monthly mean temperature anomalies in September 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

In Germany, Switzerland, Austria, Poland, the Czech Republic, Hungary, Croatia, Serbia and Romania, September was the only month of 2008 in which temperatures below the country average were recorded. In the middle of the month, widespread night frost occurred in central

Europe. New low maximum temperature records were set in Hungary with maximum values at around 5°C and thus the lowest maximum ever recorded since the beginning of measurements in this country. In Lithuania, mean daily temperature fell below 10°C by the middle of the month, bringing active vegetation to an end about 10 days earlier than normal. Across the United Kingdom, September mean temperatures were generally close to normal, while Wales and Northern Ireland had their coolest September since 1994.

In some countries, the cooling arrived some time later in the month. Hungary, Serbia, Montenegro, Romania and Bulgaria as well as the Mediterranean region (e.g. Greece, Malta) experienced a heat wave at the beginning of September with widespread maximum monthly temperatures of up to 35-40°C, whereas cooler conditions prevailed there in the second half of the month. Montenegro experienced its hottest 7-day period ever recorded; the average maximum temperature in that period was 34.3°C compared to the climatological mean of 28.6°C. Central and eastern Europe (e.g. southeastern Germany, Austria, Poland, Belarus, Ukraine) also recorded high maxima at the beginning of September, although the temperatures were somewhat lower than in southeastern Europe (30-35°C).

Averaged over the whole month, the Middle East was also characterized by warmer-than-normal conditions, but again this was mainly due to heat waves at the beginning of the month. Anomalies higher than +2°C were recorded in various places in the Middle East. Jordan experienced a heat wave on 1-7 September, with the highest maximum temperature measured at 43.4°C in Rwaished on 5 September. In Georgia, only the beginning of the month was warm with maximum temperatures up to 34°C in the coastal zone. The second half, however, was notably colder with first autumn frost in mountain regions. Armenia recorded 35-38°C in the lowlands.

It was also warmer than normal in the Arctic and the northern North Atlantic with monthly mean anomalies up to +4°C in northeast Greenland. Réykjavik in Iceland was +2°C warmer than the normal monthly average, other parts of Iceland more than +3°C (e.g. Akureyri). Temperatures above 20°C were recorded in Iceland on 17 September. Norway as a whole was +0.6°C above the normal monthly average, mainly due to high maxima during high pressure influence. Temperatures in Lapland reached up to 14°C.

Precipitation

Much of northern Europe was very dry. Less than 25 mm (or 40% of the normal) fell over large areas in Sweden and other parts of the north (Fig. 9.2). Latvia and Lithuania also saw less than half its normal September precipitation (1961-90). Various parts of western and central Europe including parts of the Alpine region, northern Iberia, central Italy and the Adriatic coasts were also dry despite various local heavy thunderstorms. In Ljubljana, Slovenia, it was the second driest September ever, together with September 1966.

Wet areas, on the contrary, were to be seen in the Arctic and in Iceland. It was a very wet month for Réykjavik (>250% of the normal), and Stykkishólmur on the west coast of Iceland recorded its wettest September since 1856. More than 200% of monthly precipitation was also reported from eastern Greenland. The midlands and the northeast of England, too, experienced a wet month, with some stations recording around 300% of their normal monthly rainfall (1961-90).

In other parts of the western half of Europe, there were also a few areas of high precipitation. Luxembourg Airport reported 162% of average September precipitation (1971-2000) and set new records for hourly and daily rainfall totals. Geneva had a monthly total of 215 mm, which is more than 250% of the normal. Italy received high monthly totals in its northern regions, particularly near the central Alps (up to 200-300 mm) and in the south (Puglia region). Most of the Mediterranean (except Corsica and Sardinia) was also wetter than normal. A monthly total

of 88 mm fell at Luqa Airport in Malta, far above normal. Most of this rain fell at the end of the month when 41.8 mm, alone, were measured on the last day of the month during a thunderstorm.

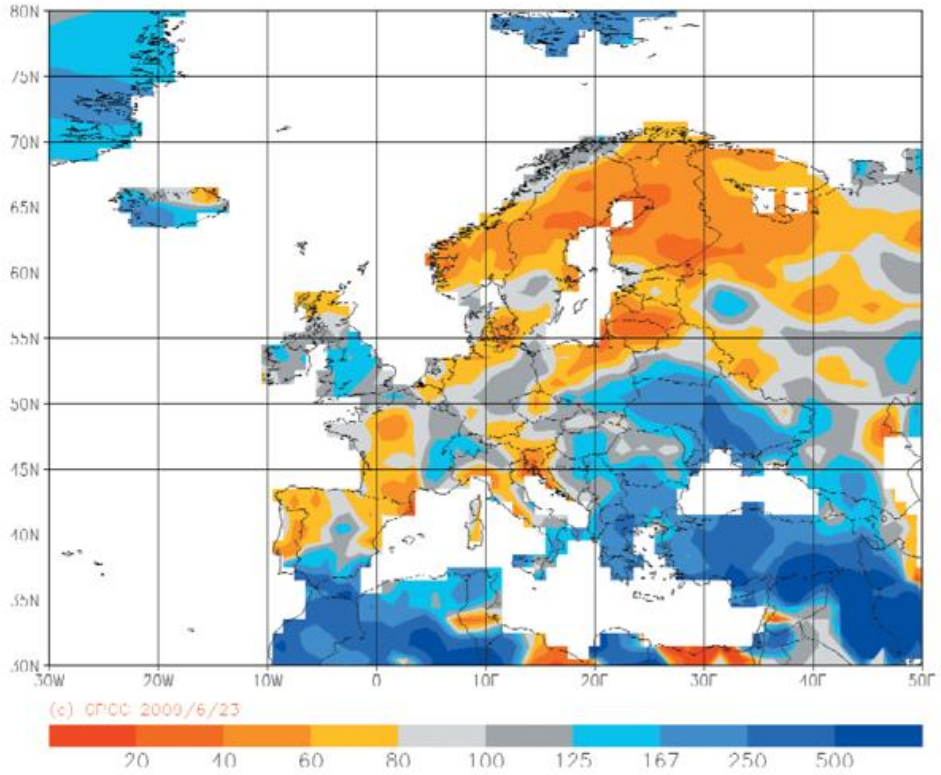

Fig. 9.2: *Monthly precipitation amounts for September 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Faro on the southern Atlantic coast of Iberia set a new record with 80.4 mm in 24 hours from 28 to 29 September and recorded a monthly total of 147.3 mm, its highest September total since the beginning of the measurements in 1965. At the end of September, the heaviest rainfall in 30 years occurred in eastern Spain and caused local flooding. Valencia recorded an hourly rainfall total of 144 mm and a 24-hour rainfall total of 390 mm. New monthly records were also set for southern Spain (e.g. Cadiz).

Many southeastern areas of the Region also received much precipitation, mainly due to some heavy rain events in the second half of the month especially around the Black Sea and the central and eastern Mediterranean. Along the southern and eastern coasts of the Black Sea, monthly totals amounted to more than 150 mm. It was exceptionally wet (around 200%, locally even 300% of the normal) in the Ukraine, Bulgaria, eastern Croatia, Macedonia and parts of Greece. Athens and southeast Albania received 350% of the September normal, marking a new September record since 1961 with monthly totals of close to 200 mm. Cyprus received a monthly precipitation of 22.4 mm, 5 times its normal. Turkey also experienced an exceptionally wet month with frequent heavy rain and flooding and monthly totals of 2 to 5 times the normal. In Israel, 5-10 mm of rain were measured at the end of the month. Some areas (mountains and the southern coastal plain) recorded even 15-30 mm and thus the highest monthly totals ever measured in September. Rainfall in Israel in September is not unusual, but in general the amounts remain below 1 mm. With heavy showers in several locations, it was also unusually

rainy in Armenia throughout the whole month. Armenia's capital Yerevan received more than 500% of its normal precipitation. Azerbaijan also had a wet month with some intense thunderstorms, and Georgia reported several flooding events.

Snow

Due to the widespread cooling in September 2008, snow fell on mountains above 1800 m in the northern Alps (e.g. on Wendelstein in Germany) in the middle of the month.

In the second half of the month, precipitation fell as snow in Romania in the mountains above 1500 m.

Significant weather events

September 05-06:	Flooding of buildings and transport disruption in the United Kingdom (Wales and England). Local 48-hour rainfall totals of more than 150 mm, estimated return period of over 200 years.
September 08:	Heavy rain in the morning in Riga, Latvia. Streets were flooded for several hours (Fig. 9.3). Heavy rain also in Estonia.
September 11-12:	Heavy rain and flooding in western Germany in the evening of 11 September. On the following day, thunderstorms with heavy rain also in other parts of Germany.
September 13:	Daily precipitation of 263 mm at the airport of Torino Caselle, Italy, caused by an intense low pressure area over the gulf of Genoa. About 50 flights cancelled, temperatures fallen by about 10°C particularly in the northwestern parts of the country, flooding, hailstorms, strong gusts, violent electrical discharges.
September 13:	8 hours of heavy rain near Krasnodar, southern European Russia, amounting to a total of 132 mm in that time.
September 15:	Torrential rainfalls up to a daily total of 100 mm in northern Dobrudja, Romania, during a thunderstorm. Heavy rain and temperature decrease up to 15°C in Montenegro; 125 mm of daily precipitation in the north-west part of the coastal area.
September 17:	Daily precipitation of around 200 mm in various places in southwestern Iceland.
September 23:	Heavy rain in eastern Spain (south of Valencia), up to 340 mm in 24 hours, heaviest precipitation in 30 years.
September 26:	Heavy, but short (less than 30 minutes) storm in Istanbul, Turkey; minaret crashed down on a restaurant. Gusts up to 104 km/h.

Fig. 9.3: *Flooded streets in Riga, Latvia after heavy rain on 8 September 2008. Source: Latvian Hydrometeorological Agency*

October

- **Cold in western Europe, warm in the east**
- **Wet in most of northern and western Europe, mostly dry in the east and south**
- **Early snow in northwestern and central Europe**

Atmospheric circulation characteristics

A large low pressure complex extended over northern and northern central Europe. Cold air masses moved over Iceland, northwestern and western Europe, reaching as far as Iberia. On the other hand, eastern Europe, particularly Russia, remained in a southwesterly warm air flow, partly anticyclonic. This situation occurred at the beginning of the month and once more at the end of October.

In the second decade of the month, a large high pressure area established over central Europe while northwestern and northern Europe were lying within the main frontal zone. The high pressure zone extended also to the central Mediterranean, whereas two low pressure systems affected the western and the eastern Mediterranean for several days.

Temperature

In the western parts of Europe, the cold conditions continued into October. Anomalies below -1°C were registered in many places (Fig. 10.1).

On Iceland, October was the only colder-than-average month in 2008. During the last week of October (28-29 October), some stations in the United Kingdom set new October records for low maximum temperatures since 1960. Northern Ireland had its coldest October since 1993. Even Spain and southern France were colder than normal despite a summery period with

temperature maxima above 25°C in the middle of the month. Malta in the Mediterranean also saw a colder-than-normal October with 0.4°C below the monthly normal. Especially the mean maximum temperature was lower than normal.

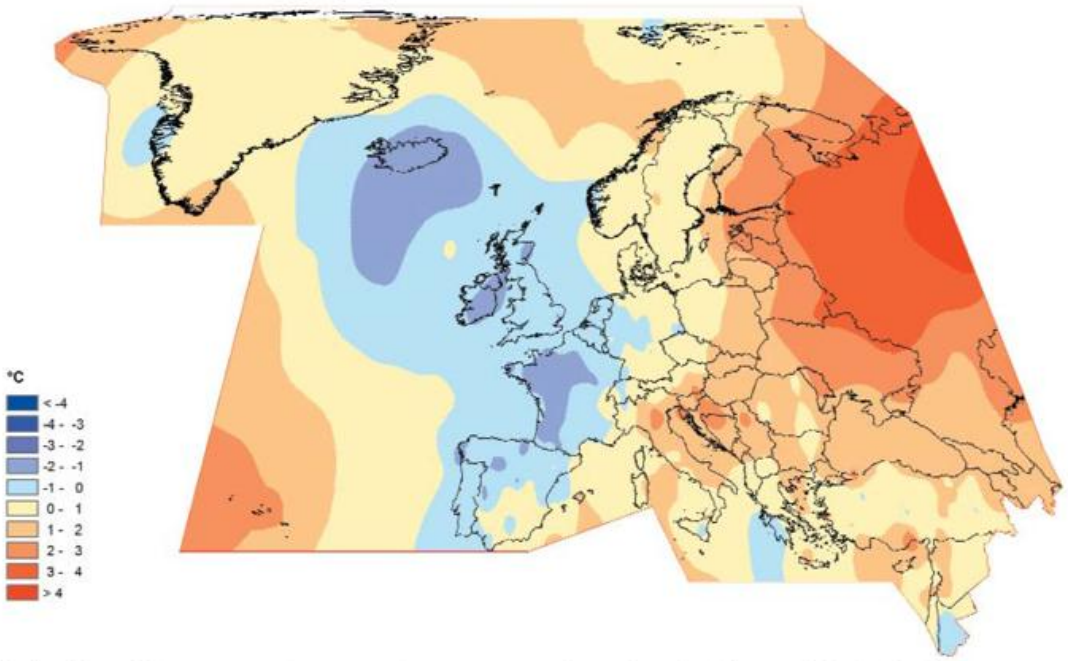

Fig. 10.1: *Monthly mean temperature anomalies in October 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

The North Atlantic was colder than normal over areas around Iceland and western Europe, but warmer elsewhere. Over the Azores Islands and the central North Atlantic, the anomalies were above +2°C.

In central Europe, Germany recorded at many places daily maxima above 20°C, at some places in the southeast even above 25°C, but a monthly average near normal (+0.1°C anomaly). In Switzerland, daily maximum temperatures rose to 20°C in the plains on both, the north and south sides of the Alps, and up to 15°C at an altitude of 1500 m.

The remaining areas of the Region were, in general, warmer than normal, most of the eastern half of Europe by more than +1°C. It was particularly warm in the easternmost parts of the Region with anomalies above +4°C over eastern European Russia. Lithuania was warm especially at the end of the month with maximum temperatures of 15-18°C. Poland even measured temperatures up to 21°C (Lodz) and Croatia up to 27°C. Frost was very rare in Serbia. Bulgaria saw temperature maxima up to 29°C at the beginning of the month, but afterwards experienced an abrupt temperature decrease.

Precipitation

It was mostly wet in the western and northern parts of Europe (Fig. 10.2). Some areas near the west coasts of Ireland, Scotland and England received monthly totals of more than 200 mm which in some places was more than 200% of the 1961-90 normal.

Scotland experienced its wettest October since 1954. Northernmost areas of Germany received more than 100 mm of precipitation during the first 5 days of the month which partly was more than the normal monthly total. With 181 mm, the German North Sea island Helgoland set a new monthly record for October causing the monthly total for the whole of Germany to rise to more than 130%.

Exceptionally high rainfalls also occurred at various places in Spain, along the Norwegian west coast and in a large area extending from southern Finland to northern Russia and the Baltic countries. More than 200% of the normal precipitation fell in Madrid and in Helsinki. The country average in Estonia was 154% of the 1961-90 normal precipitation. Western Greenland was also wet: Egedesminde at the Disko Bay received a monthly total of 79 mm, which is more than 300% of the normal.

Austria saw two episodes of heavy rain on 3 and 29 October in the southeast of the country, whereas northern and eastern Austria were rather dry with precipitation totals less than 75% of normal.

Coastal zones in Georgia received more than 100 mm (i.e. 140% of normal precipitation).

It was dry over most of eastern Europe and eastern parts around the Mediterranean, partly with monthly totals of less than 40% of the normal. In some places in Greece, only a few mm of precipitation fell during the whole month. In other places, there was no precipitation at all, which is very unusual for the place and month. However, October in Israel was rainy, with extreme rainfalls most of which occurred almost every day between 22 and 29 October. Haifa received 80 mm in just one hour, the highest 1-hour total ever measured in Israel.

Portugal, particularly the Azores Islands, was dry, the latter with locally less than 15% of the normal monthly precipitation.

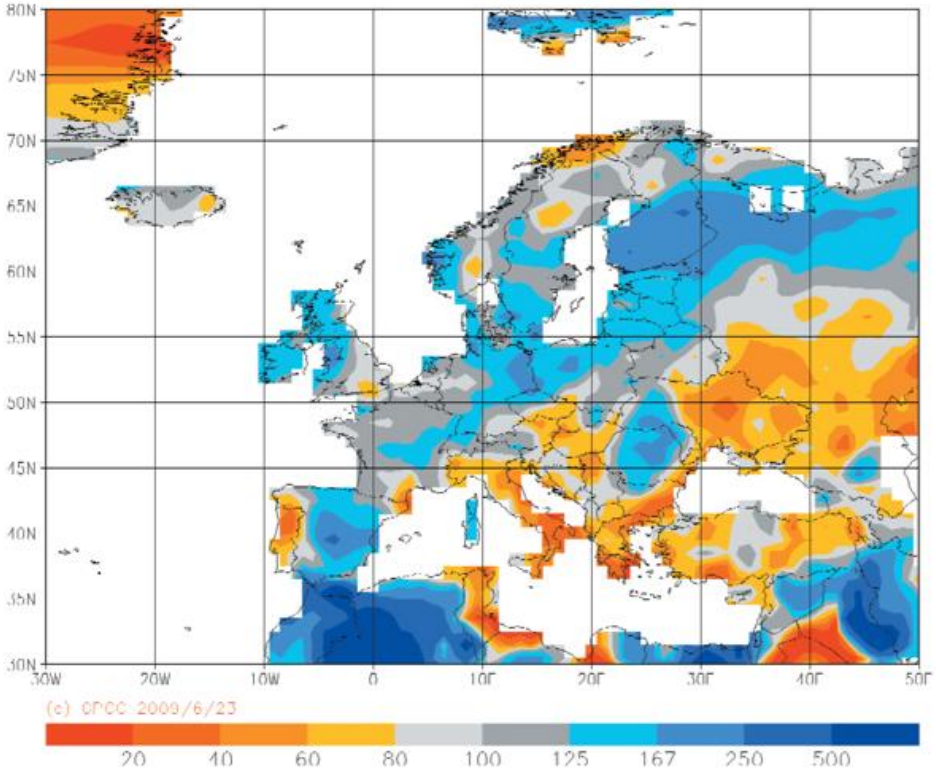

Fig. 10.2: *Monthly precipitation amounts for October 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Snow

Many mountainous regions received an early autumnal snow cover in the first days of the month. In the northern Alps, snow fell down to an altitude of 1000 m in parts of Switzerland and Austria. Some northern slopes received up to 15 cm of fresh snow. In the United Kingdom, Scotland also saw the first snow of the new season.

During a cold spell at the end of October, snow was observed in many places. London received October snow for the first time since 1934. New fresh snow records for October were set at many places in Switzerland on 30 October, particularly on the plains north of the Alps and in the Alps. October snow events normally are extremely rare in the lowlands of Switzerland. 20 cm of fresh snow in Zurich beat the October record of 1931 (14 cm). Snow even fell in the lowlands of eastern and southern Germany and in the Black Forest (up to 30 cm), where the heavy and wet consistence of the snow caused widespread damage to forests.

There was also more snow than usual at this time of the year on Iceland.

Significant weather events

October 01:	94.2 mm of precipitation fell in Höglekardalen, central Sweden, highest official daily total in 2008.
October 01-04:	In the northern Alps, a cold snap brought winter conditions to altitudes above 1000 m in parts of Switzerland and Austria. Several high roads and passes were closed to traffic.
October 02-03:	Flooding in Lenkoran and Quba, Azerbaijan.
October 05:	Heavy thunderstorms in many places across Bulgaria with daily precipitation totals of around 80 mm. Widespread damage to houses, trees uprooted, electricity and phone lines cut. Storm also in Turkey.
October 09-10:	Heavy precipitation and flooding at the eastern coast of Spain. Tornado in southeast Spain on 10 October.
October 12:	Large hailstones caused damage to fruit trees and potatoes in Cyprus. Floods caused damage to property in Nicosia.
October 19:	Intense precipitation above 50 mm in 24 hours in various places of the United Kingdom, particularly Scotland and north Wales. Locally, gusts with hurricane force in the Scottish highlands during the night 19-20 October.
October 22-23:	Supercell affected southern Sardinia, Italy. 276.4 mm of precipitation in 6 hours on southern Sardinia, Italy, most of which fell in the morning hours. Some areas of Cagliari were left without electricity for several hours. Corsica also received more than 200 mm of precipitation.
October 22-23:	Intensive rainfall in Cyprus accompanied by hail, strong winds and thunderstorms causing floods in the cities of Larnaca and Limassol.
October 30:	Torrential hailstorm in the southwest of the United Kingdom (east Devon) with an estimated rainfall/hail total of 160 mm in 3 hours in the morning, causing major flooding.

November

- **Mostly warm, cold in Iberia**
- **Mostly dry, wet in Scandinavia and the western Mediterranean**
- **Wintry spell with much snow in many parts of Europe**

Atmospheric circulation characteristics

A cold trough extended from Scandinavia to the southwest until Iberia. A cut-off low developed over Iberia early in the month, moving then to western Europe. As a result, Iberia was affected by a very cold air flow from the north. Iberia was also quite frequently influenced by high pressure with cold nights. The Azores high was strong and shifted to the north, whereas the mean position of the Icelandic low shifted towards northern Europe.

The central Mediterranean experienced much cyclonic activity with frequent rain and thunderstorms.

The rest of Europe mostly lay in a southerly or southwesterly air flow with warm air reaching even Russia or often was under high pressure influence. In the second half of the month, most of Europe was temporarily affected by a large cold trough, western and southwestern Europe once again at the end of the month.

Some cold Arctic troughs with cyclonic activity passed over Scandinavia, whereas the Arctic region was mainly in a mild air flow.

Temperature

In general, November 2008 was mild in most of the Region, particularly in the Arctic and in eastern Europe. The highest anomalies were more than +4°C in northeast Greenland and European Russia (Fig. 11.1) and up to about +6°C at the eastern border of the Region. Some stations in European Russia recorded their highest mean November temperature ever. All the other countries in the eastern half of Europe were mostly 1-2°C warmer than normal. A vast warm air mass from the south reached Lithuania, rising maximum temperatures to 8-15°C by 11 November. The daily temperature records were exceeded in many places.

Particularly the beginning of the month was very mild especially in central and southeastern Europe. November maximum temperature records were broken at numerous stations in Germany, with temperatures exceeding 22°C in the southeast of the country due to foehn. Parts of eastern central Europe (e.g. southern Poland, eastern Austria, parts of the Balkan Peninsula) locally also saw temperatures above 20°C during the first days of the month. In Slovenia, the absolute maximum temperature in Ljubljana and at the coast was the second highest since observations began. New temperature records also were measured in Montenegro in the coastal area and the northeast mountainous region. Unusually high temperatures of around 29°C were measured in Serbia on 1 November, 30°C in southern Greece on 2 November and up to 32°C at the southern coast of Turkey.

Averaged over the month, it was colder than normal in southwest Europe, particularly in Iberia. Monthly mean anomalies below -2°C were recorded in some places of Spain and Portugal. The North Atlantic had temperatures mainly around normal. Only west of the Azores Islands the temperatures were around +2°C higher.

November ended with a cold spell across western and central Europe. On 30 November, Northern Ireland recorded its lowest November maximum temperature on an areal average since records began in 1960. In Iberia and in Italy, minimum temperatures were below 0°C in many places.

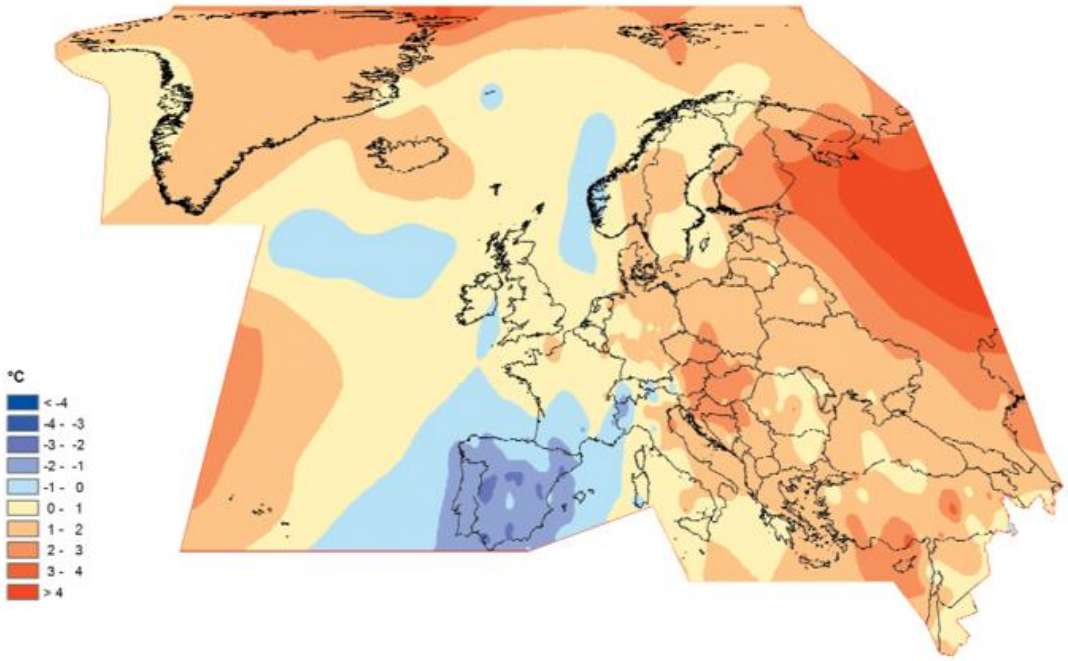

Fig. 11.1: *Monthly mean temperature anomalies in November 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

Precipitation

Most of the Region was drier than normal, particularly in the mid-latitudes, in Iberia, around the Black Sea and in the Middle East (Fig. 11.2). Southern Poland and some places in southeastern Europe and the Middle East received less than 50% of its normal precipitation, some locations in southwestern Germany even less than 30%. Parts of central Spain as well as central and southern Israel received only 20% of the normal. In the central coastal plain of Israel and the Judean Mountains, it was one of the 5-6th driest November months in the last 60-65 years. Cyprus received 40% of its normal precipitation, Damascus in Syria around 30% (7 mm). 20-30% of the monthly normal was recorded in Armenia, even less in Georgia. These dry conditions were unfavourable for winter wheat so that additional irrigation was required.

Only some areas in northern Europe (especially Scandinavia and northern Russia) as well as Italy and the areas around and across the western Mediterranean (including the southern Adriatic coast of Croatia) were very wet, partly reaching more than three times the monthly average. Already in the first decade of the month, rainfall totals up to 200 mm were measured at the southern slope of the Alps and in northwestern Italy. Southeastern France experienced a very intense rainy episode and flooding at the beginning of the month. In Belgium, it was not the intensity, but the number of 26 precipitation days which was exceptionally high. Around 150% of the monthly 1961-1990 normal was recorded in parts of central and eastern England. Monthly precipitation totals in southern Norway and in Estonia reached more than 200% of the 1961-90 normal.

Snow

On 15 November, a cyclone brought heavy snowfall (66 mm in 12 hours) and snowstorms to Lithuania, and here especially to the Baltic seaside. In some places, the snow cover rapidly reached a depth of 45 cm. On 23 November, the Baltic countries were again affected by a snowstorm with the snow depth reaching 56 cm in the central part of Estonia.

A wintry spell spreading from the north to the south arrived in Germany and Switzerland on 21 November. Snowfall was recorded especially in the hills and the Alps with fresh snow depths of around 35-40 cm and up to more than 10 cm in the lowlands. On 24 November, nearly the whole of Germany was snow covered. It was the strongest winter outbreak in a November month since 1999. A period with rich snowfall began on 28 November in southern Austria where a snow cover of up to 2 m built within three days.

The snow also reached the alpine south side. The Ticino (southern Switzerland) was covered by enormous snow amounts, e.g. 12 cm in Locarno Monti (367 m above sea level) on 29 November. On this occasion, the second highest fresh snow amount in November in this place since 1931 was measured. The upper part of the Engadin received more than 1 m of fresh snow, which is very rare and even record-setting for some stations at this time of the season. Towards the end of the month, it also snowed over most of the continental parts of Slovenia, bringing a snow cover of 17 cm to Ljubljana on 29 November. Most of Serbia also received the first snow for this season in the third decade of the month. The number of snow days, however, was near normal in most places in Serbia. In mountainous regions of Bulgaria, the ground also remained covered with snow. It even snowed on mountain sites in Iberia.

In general, there was less snow than usual this month in European Russia due to anomalous warmth and little precipitation.

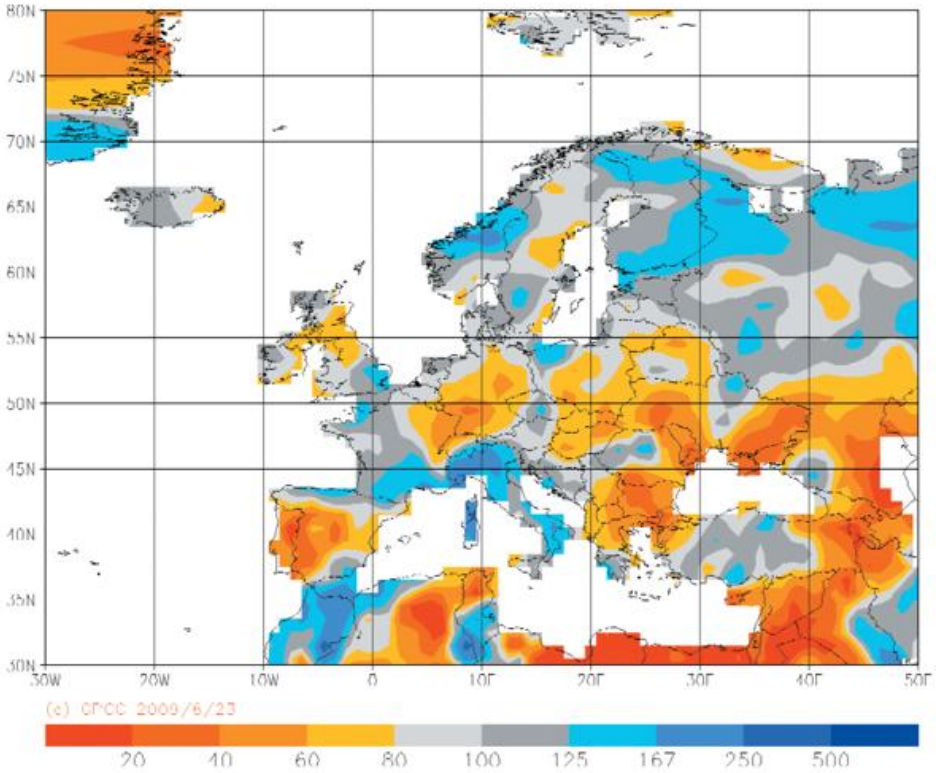

Fig. 11.2: *Monthly precipitation amounts for November 2008 in per cent of the normal 1951-2000 in Europe and adjacent areas.*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Significant weather events

November 02: Heavy precipitation in northeastern Spain (especially Costa Brava) and southern France with flooding. In Valencia, Spain, a total rainfall of 390 mm was recorded in 24 hours, 144 mm fell in less than 1 hour.

November 04: Supercell downburst over the area of Rome, Italy. Strong gusts causing numerous fallen trees and broken branches, flooding. Heavy precipitation particularly over eastern Corsica, southeast France and parts of the southern Alps.

November 10: Strong winds and heavy rains over parts of Malta. A waterspout was detected southwest of Malta (Fig. 11.3).

November 11: Heavy storm in Estonia with gusts up to 110 km/h, damage to houses and forests.

November 11-13: Heavy rain and thunderstorms caused flooding at southeastern coastal areas and later in Nicosia.

November 20: 59.7 mm of precipitation in 2 hours in Beirut, Lebanon.

November 21: Strong cold front passage with stormy winds (up to hurricane force over high mountains) and snow showers caused damage to houses and trees and traffic disruption in several regions of Germany.

November 22-23: Storm with gusts above 100 km/h over Italy, Ionian and Aegean Sea due to thunderstorms along a cold front. Turkey was also affected with damage to settlements. Seaway traffic stopped in Aydin, western Turkey.

November 23-24: Storm over the White Sea, wind speed up to 130 km/h due to a very intense low pressure system. A pressure level of 951.5 hPa was measured in Estonia on 23 November at 18 UTC.

Fig. 11.3: *Waterspout southwest of Malta observed from the airport in Luqa on 10 November 2008 at 11:38 local time.*
Source: Malta Meteorological Office

December

- **Warm in the north and in eastern Europe, cold in western Europe and the south-east**
- **Cold spell at the end of the year in many parts of Europe**
- **Dry in northwestern Europe and the southeast, wet over the central Mediterranean**

Atmospheric circulation characteristics

A cold trough extended over the western half of Europe and regenerated several times. In the middle of the month, a ridge formed over northwestern and western Europe and remained quite stable throughout the rest of the year, extending also to central Europe.

At the west flank of a high pressure system over Russia, mild air masses from Africa moved over southeastern Europe to the northeastern part of the continent until Christmas. The Arctic region remained under a mild and humid air flow from the Atlantic.

Strong cyclonic activity continued to persist over the western and central Mediterranean while dry air masses dominated in the eastern parts.

At the end of the year, very cold air flowed from the northern latitudes to southeastern Europe and the Middle East at the east flank of a central European high pressure system. Within an easterly air flow, cold continental air also reached central and western Europe.

Temperature

The year 2008 ended with very mild conditions in the Arctic region, northern, eastern and southeastern Europe, and over the eastern Mediterranean and most of the North Atlantic (Fig. 12.1). Anomalies exceeded +4°C in many places of the Arctic and northeastern Europe, coming close to +8°C in the far northeast of the Region.

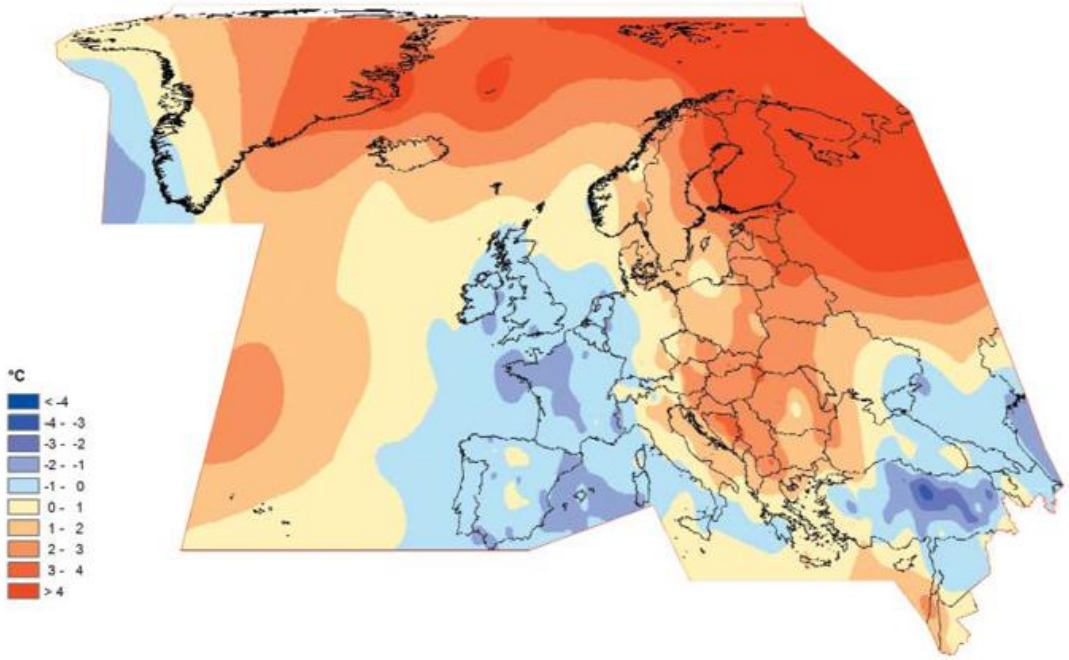

Fig. 12.1: *Monthly mean temperature anomalies in December 2008 (reference period 1961-1990) in WMO Region VI.*
Source: Deutscher Wetterdienst, Germany

With 10.1°C, a station in the county of Finnmark (northern Norway) measured a new daily maximum temperature record. Down in the south of the Region, various stations on the coast of the Black Sea saw maxima of more than 25°C, even on the Krim Peninsula. Some minimum temperatures were also unusually high, e.g. 9°C in Moscow.

Central Europe had monthly mean anomalies only slightly above normal (Germany +0.3°C, western Austria +0.5°C), in eastern central Europe the anomalies were around +2°C. Unusually high daily maxima up to 13°C were recorded in Poland at the beginning of the month.

The whole of western Europe including the western Mediterranean and some parts of the Middle East had a slightly colder-than-normal December. Some places within these areas had anomalies below -1°C; in parts of western France, in Turkey and west Kazakhstan they were below -2°C and locally even below -4°C. It was the coldest December since 1996 in Northern Ireland. The United Kingdom and Ireland had air frost throughout half the month, which is 2 to 5 days more than usual.

Very low temperature values were recorded in late December especially in Ireland, but also in other countries. The end of the year saw frozen ground in many places in Lithuania, locally reaching a depth of 15-20 cm. After a mild period around Christmas (the typical Christmas thaw singularity came almost in time), Germany experienced a temperature drop with daily minimum temperatures down to around 10°C in many places by the end of the year. Sea ice formed in the bays of the southwestern Baltic Sea. South of the Alps, Italy and southern Switzerland also experienced a sudden temperature decrease on 26 December. Malta had some warm days in the first half of the month with maxima around 20°C, whereas temperatures dropped to near-normal values in the second half. Serbia, too, was under the influence of colder air at the end of the year, reaching maximum daily temperatures below normal. Even Cyprus saw widespread frost on 31 December in the western coastal areas, causing damage to agricultural plantations.

Precipitation

Northwestern and northern central Europe experienced a drier-than-normal December (Fig. 12.2). Especially the areas along the western coasts of Norway and Sweden, Denmark, northwestern Germany and France, the Low Countries, the United Kingdom (except eastern Scotland) and Ireland were very dry. Southern Iberia was also very dry, resulting in a drought situation in this part of the Region. Parts of southern Norway received only 25-40% of the 1961-90 normal monthly precipitation. Parts of northwest Germany locally received even less than 15% (e.g. 9 mm in Bremen), making December 2008 at some locations the driest December since the beginning of measurements. Some areas in eastern Europe, especially southern European Russia, and the Middle East were also dry. Parts of the Turkish Mediterranean coast had less than 40% of the monthly normal (more than 100 mm less than normal), the southern parts of Israel less than 50% and the mid-Volga region in Russia only 5-30%.

On the contrary, it was wet south of the Alps over the whole of Italy and the western and central Mediterranean (except Malta), in Hungary, over most of the Balkan Peninsula and in the Arctic region. December precipitation was also well above average in southeastern France (locally up to 300% of the normal) and over southern Austria (up to 400% of normal; Fig. 12.3). This was largely due to persistent low pressure in the Gulf of Genoa. Monthly totals for the western Mediterranean area locally exceeded 200 mm which, in many cases, was more than twice the normal and caused local flooding. Various places in northern Slovenia received more than 300% of the normal precipitation. In Albania, December was by far the wettest month of the year (usually November) with the highest monthly total measured at Vlora in the western coastal zone (451.2 mm, i.e. around 350% of the normal). This was also the highest monthly total in the whole time series 1951-2008 of this station (Fig. 12.4).

Snow

Snow fell in most areas of the Region except the major part of the lower coastal areas and some of the southern parts. Mean snow depths above 20 cm were partly observed in Scandinavia and the Alpine region. Snow depths of more than 1 m occurred only on high mountains.

There was a persistent snow cover on Iceland during the first three weeks, which, however, has disappeared by Christmas.

Most parts of Lithuania saw dangerous black ice up to 3 mm thick due to freezing rain in the second half of December.

In central Europe, it snowed very frequently, but only above 1000 m Christmas was white. On 3 December, snowfall in the lowlands, especially in northern and western Germany, caused numerous road traffic problems. 15 cm of fresh snow was recorded in the hills (Eifel, Westerwald). A station in northern England recorded a snow cover of 21 cm on 4 December.

Another intense snowfall period occurred in the middle of the month, affecting particularly the Alpine region, various regions in France and northern Spain. On 18 December, a December record snow depth of 38 cm since at least 1931 was measured in Switzerland's capital Bern. In Austria, a new December record snow depth of 125 cm was reported from eastern Tyrol's capital Lienz on 12 December. Southern Alpine regions experienced heavy snowfalls until the middle of the month. The snow load heavily affected forests, power lines and rooftops. Thousands of households were repeatedly cut off from electrical power. Most of the snow in the alpine lowlands melted away before Christmas whereas the mountain regions of the Alps

remained covered by above-average snow depths over the Christmas holidays. Great amounts of snow were also observed in Slovenia where the mountain station Kredarica measured a snow depth of 3 m.

In the eastern parts of Europe, there was less snow than usual. Poland did not have any snow at all in the northwest whereas the southern parts of the country had 17 days with snow cover. In Serbia, the mountains were snow-covered throughout the month, the lower parts of the country, however, only during the last decade. Romania had snow cover in the mountain area and in Moldavia and occasionally also in the remainder of the country. Snow affected traffic in Turkey at the end of the year (24-29 December).

In Armenia, a snow cover formed with a delay of 15-20 days in mountain and submountain regions, threatening the winter wheat to freeze. Georgia received snow only in the third decade of the month, with a snow cover up to 50 cm in some places.

At the end of the year, it also snowed in northeastern Spain.

Significant weather events

December 01:	Heavy flooding in Venice; nearly the whole city was flooded to a depth of more than 150 cm, highest flooding level since 1986.
December 03-04:	Strong gusts in southern Greece (Corfu) and southeastern Italy up to around 110 km/h. Heavy rain in Venice (flooding), southern Italy (Brindisi) and Montenegro. Highest wind gust ever recorded in Montenegro on 04 December (236 km/h).
December 10-12:	A storm system brought heavy rainfall and strong winds to Italy causing flooding in several places. Rainfall around Rome was particularly high (more than 70 mm in 24 hours on 11 December), Tiber River and its tributaries almost rose to the critical levels (Fig. 12.5). Cumulative rainfall totals over three days partly exceeded the monthly average. 337 mm of precipitation in 24 hours were recorded in Palermo, Sicily. The same storm also affected Greece (Ionian and Aegean Sea) on 12 December.
December 14:	Foehn storm in Switzerland; gusts of more than 250 km/h on high mountains in 2300 m.
December 14:	Hail shower in northern Mallorca. Hail layer of several cm in mountainous areas and hailstones of 1 cm in diameter.
December 21:	Gusts up to hurricane force in the north-westernmost part of Jutland, Denmark.
December 22:	Heavy rain and thunderstorms affected the main cities in Cyprus, causing floods after the first three weeks of the month had been exceptionally dry.
December 24:	133 mm of precipitation in 20 hours in the mountain region of the Lebanon.
December 27:	2-hour hailstorm in Valletta, Malta, in the morning.
December 27:	Storm with heavy rain and snow on the eastern Spanish coast. Sea waves up to 8 m high at Costa Brava.

ECSN Activities Report 2008

Support and co-operation in best climate practices

Responsible Member: KNMI; Programme Manager: Aryan van Engelen

The objective of ECSN, the European Climate Support Network, is to support its 24 members in their climate practices in order to better serve the European user community with climate products and services for the benefit of environment, safety, economy and health.

This objective is reached by a portfolio of activities: carrying out projects such as ECA&D, S-EUROGRID, EuCLIS and HRT-GAR focusing on a better understanding of Europe's past, present and future climate and the provision of data and info products, participation in major EU projects like ENSEMBLES, MILLENNIUM and EURO4M, co-operation with other partners such as the EEA (European Environmental Agency) and the WMO (World Meteorological Organization) and organizing the biennial European Conferences on Applied Climatology and Data Management Workshops.

Fig. 13.1: *24 European NMHS's participate in the EUMETNET Programme ECSN Source: ECSN*

ECA&D, KNMI, http://eca.knmi.nl

The European Climate Assessment and Data set aims to create and maintain a European data set of daily high-quality observations and to produce assessments of Europe's climate on the basis of derived indices. ECA&D co-operates with 53 partners and offers a baseline data set of more than 10,000 time series of temperature, precipitation, air pressure, snow depth, relative humidity, cloud cover and sunshine duration observed at some 2800 European and North African stations. A set of 40 standardized indices is presented in graphs and maps. ECA&D will serve as the core platform for a WMO-RAVI (Europe) Regional Climate Centre on Climate Data, to be established in 2009.

S-EUROGRID, SMHI, http://www.e-grid.eu

Showcase EUROGRID demonstrates the potential of the EUROGRID concept as the future European central resource for gridded climate, meteorological, hydrological and environmental products. 11 national and two European transnational gridded data sets are incorporated: ERAMESAN (SMHI) and ECA&D/ENSEMBLES (KNMI). The project has been completed in 2008. The proposal for its successor, the full scale EUMETGRID which is to be submitted in 2009 sets a focus on gridded data sets derived from the high-quality observational network of the European NMHSs. Apart from providing operational long-term climate monitoring, it will generate detailed near-real time monitoring and warning products on extreme events, food and safety, and energy production and consumption.

EuCLIS / ECSM / GCMP, DWD, http://www.dwd.de/ecsm

The European Climate Information System will be the successor platform of GCMP (Generate Climate Monitoring Products) and as such give access to European national and regional climate monitoring products like maps, graphs, assessments as well as monthly and annual reports. Presently, an interim platform called ECSM (European Climate System Monitoring) has been established before the operational start of EuCLIS. Climate products provided by activities like ECA&D and the upcoming EUMETGRID will be incorporated. EuCLIS will serve as the core platform for a WMO-RAVI (Europe) Regional Climate Centre on Climate Monitoring to be established in 2009.

HRT-GAR, ZAMG,
http://www.zamg.ac.at/forschung/klimatologie/klimamodellierung/ecsn_hrt-gar/

Based on the Alpine high density network, a High Resolution Temperature climatology for the Greater Alpine Region was developed for a 30-year period with a temporal resolution of 1 month and a spatial resolution of 1*1 km. With the collection of monthly temperature series from more than 1700 stations, the calculation of multiple linear regressions and regionalisation, further significant improvements could be reached by adjustments for meso-scale effects in cold air pools, coastal and lakeshore belts, urban areas and slopes. The project has been completed in 2008.

ECAC

The 7th European Conference on Applied Climatology, organised by ECSN together with the 8th Annual Meeting of the European Meteorological Society (EMS), took place in Amsterdam in fall 2008. The theme was “tools for understanding of and adaptation to current and future climate”.

The conference served as a platform for experts and scientists of the EMI (European Meteorological Infrastructure) and the research community to meet private and public stakeholders. The session programme was organised by some 90 convenors and attended by 625 registered visitors.

The Ozone Layer over Central Europe in 2008

Wolfgang Steinbrecht, Hans Claude, and Ulf Köhler - Deutscher Wetterdienst

After a decade of almost continuous total ozone increases, 2008 shows an ozone decrease compared to the previous years. Amounting to 316 DU (Dobson Units), the 2008 annual mean of total ozone was significantly below the mean values of previous years by about 2% (compare Fig. 14.1). Other European stations show similar results. Throughout the entire 41-year time series at Hohenpeissenberg, only 6 years show lower values, three of which followed major volcanic eruptions (El Chichón 1983, Pinatubo 1992/1993).

Nevertheless, the annual mean of total ozone in 2008 was within the usual range of fluctuations around the „normal" long-term behaviour (green line in Fig. 14.1). This slow long-term variation is determined mainly by anthropogenic chlorine (from chlorofluorocarbons or CFCs), by the already mentioned major volcanic eruptions and by the 11-year solar cycle. Recovery from the Pinatubo eruption, together with the 2002 solar maximum, has resulted in a distinct ozone increase from 1993 to 2003. Lower total ozone values were to be expected due to the solar minimum from about 2005. It was, however, not before 2008, that the westerly phase of the quasi-biennial oscillation (QBO) and the positive phase of the Arctic Oscillation / North-Atlantic Oscillation combined, thus causing the annual mean of total ozone to fall 6 DU below the level of previous years.

Years with enhanced total ozone alternate with years with reduced values throughout the entire time series. Low-ozone years, for example, were the years 1997 or 2000 when air-masses from very stable winter vortices had substantially influenced chemical ozone depletion in the Arctic spring and had finally reached lower latitudes in central Europe in early summer. This resulted in very low total ozone values in the early summer, like the record-low total ozone mean in June 2000 at Hohenpeissenberg. The low total ozone value of 2008 (or 2000) shows that low values are possible anytime, even nowadays, given the right meteorological conditions. At this point, ozone recovery due to the beginning decline of chlorine is small and amounts to only 2 or 3 DU (red line in Fig. 14.1).

Fig. 14.2 takes a look at the expected future evolution of total ozone at northern mid-latitudes. It is based on state-of-the-art 3-dimensional chemistry climate model simulations, carried out for the 2006 WMO ozone assessment. In comparison with the Hohenpeissenberg measurements (red line), the combined models give a good representation of the long-term evolution and range of total ozone observations. The model average (blue line) follows the observed long-term evolution quite well. Random variations in the model runs and the spread between the models (light blue area) correspond well with the annual mean variations observed at Hohenpeissenberg. This lends great credibility to the model predictions. According to the models, low values as observed in 2008 are quite possible over the next decade. The model predictions do not include any major volcanic eruptions in the future. As chlorine concentration will remain high over the next decade(s), a major volcanic eruption would lead to substantial ozone depletion and very low total ozone values comparable to those recorded in 1983 or 1993.

A return to the high ozone values of before 1975, when CFC levels were low and ozone destruction by anthropogenic chlorine was negligible (grey bar in Fig. 14.2), is not predicted until after 2035. Even then, anthropogenic chlorine will not have disappeared completely. However, cooling of the stratosphere caused by future increases of CO2 is also expected to slow the normal chemical destruction cycles of odd oxygen (and ozone). Therefore, the models predict enhanced total ozone after 2050. This has been termed „super-recovery" of the ozone column causing even higher values than those observed in the 1960s and early 1970s. Still, the ozone profile in this changed climate after 2050 should be different from the undisturbed profile of the 1960s. The models predict higher ozone in the upper stratosphere, but less ozone in the lower stratosphere. Climate change is intrinsically linked with the future evolution of the ozone layer.

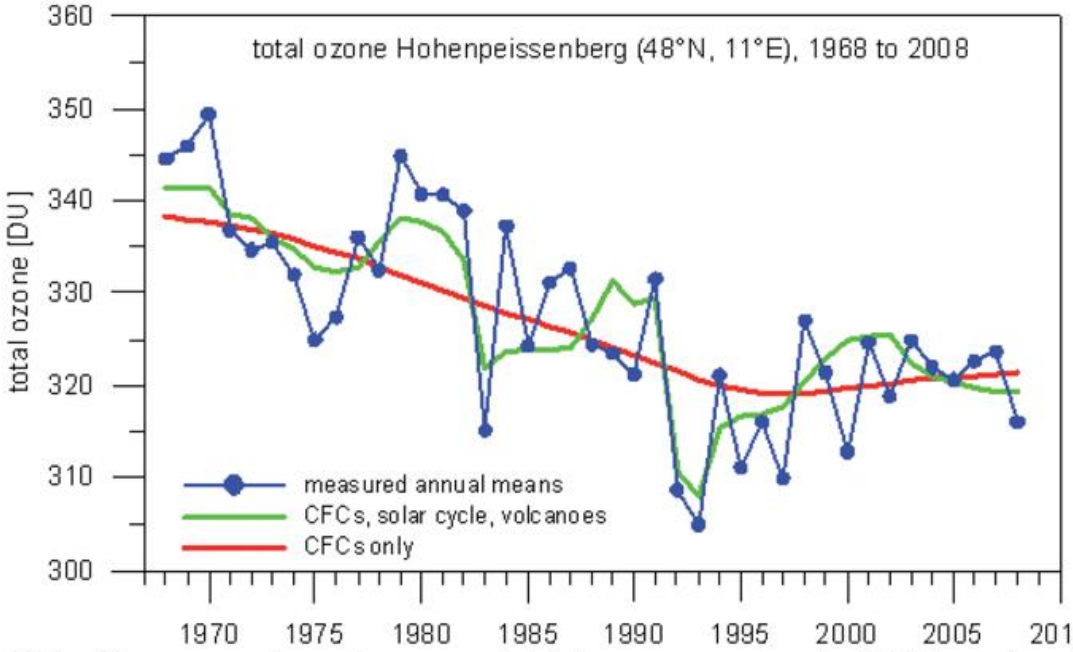

Fig. 14.1: *Blue curve: Annual means of total ozone measured at Hohenpeissenberg. Red curve: Long-term variation attributed to anthropogenic chlorine (from CFCs). Green line: Long-term evolution attributed to chlorine, volcanoes, and 11-year solar cycle. Red and green curves are estimated by multiple linear regression.*

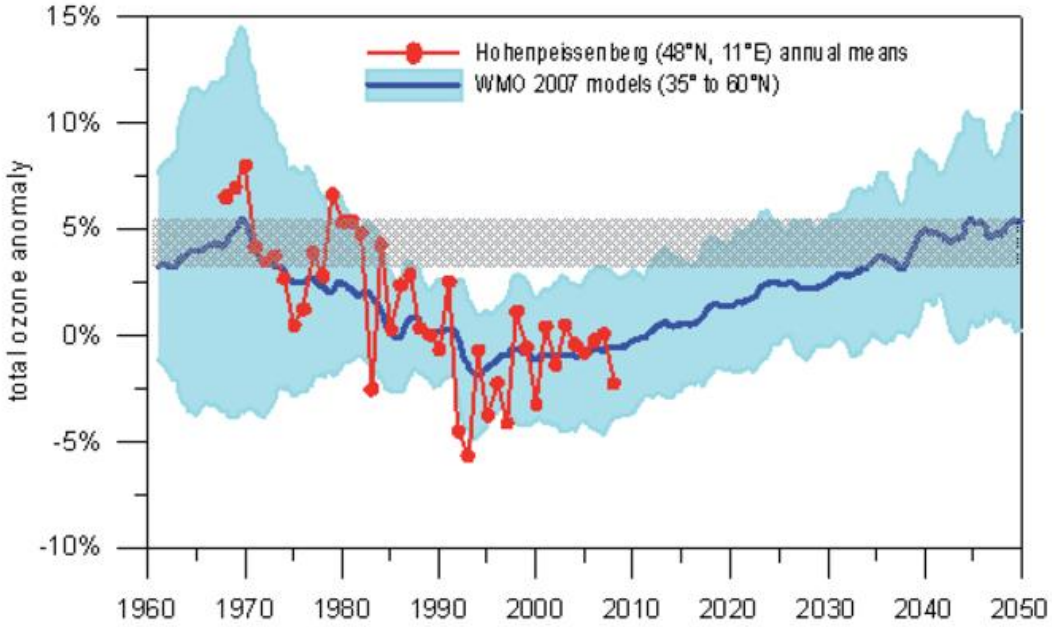

Fig. 14.2: *Blue: Evolution of Northern hemispheric total ozone from 1960 to 2050, according to calculations from chemistry climate models for the 2006 WMO Ozone Assessment. The blue line gives the model average, the shaded area the range of model predictions.*
Red line: Measured annual means at Hohenpeissenberg. All anomalies are relative to the 1980 to 2000 average. Grey bar: Range of undisturbed ozone values before 1975.

Foreword

The year 2009 completed the warmest decade on record since the beginning of widespread instrumental measurements around 1850 - in Europe and around the world. Against this backdrop and in the light of global warming, 2009 was just another warm year.

However, 2009 was characterised by some particularities which do not occur every year. It was no surprise that most of the warming took place in the Arctic during winter months – this is what had happened in previous years too. But what was outstanding in that year was the month of April: extremely warm and dry in large parts of Central Europe, in some places even topping April 2007, which had also been very warm over a large area. Interestingly, there were also some very cold months in 2009, especially October (in northern Europe) and even more December. The Arctic Oscillation, which is an important circulation pattern for the northern hemisphere in general and seems to be one of the key factors in the European climate, shows an extremely low value for December 2009, by far the lowest in any December since at least 1950 according to NOAA data.

In terms of precipitation, 2009 was a normal year only when looking at the annual average. April was not only warm but also extremely dry. On the other hand, some heavy precipitation events occurred, though confined to very limited areas and of high impact. Among these were the exceptionally heavy rainfall events in Istanbul in September, in the north-west of England in November and in southern Spain in December.

These few examples show that climate in Europe is far from being boring although it is generally less extreme than in other parts of the world. Climate monitoring, and especially climate monitoring in Europe, remains an important task to be accomplished to find out whether climate trends continue and which factors of climate variability and its extremes can modulate, mask or even change current trends. Climate monitoring is one link in a chain of climate activities from gathering of data, its evaluation and interpretation as well as the identification of interrelations through to climate modelling, long-range weather and climate predictions. It is for sure that climate predictions will be more convincing if today's climate variability already reveals indications for the future.

A very important action for climate assessment within our RA VI Region is the development of a Regional Climate Centre network. The approval of the RCC implementation plan in 2009 by RA VI was an important step in this direction. The RA VI Region consists of quite a large number of Member countries with a very diverse climate. In general, the RCC activities have a cross-border view (climate does not stop at national borders), but at the same time they also take account of the specific features characterising the climate in Europe and the Middle East.

The Annual Bulletin on the Climate in RA VI – now on its 16th issue presenting the overview assessment for 2009 – is one part of RCC climate monitoring activities in our Region. Its preparation would not have been so fruitful without the valuable contributions from nearly all Member countries and almost impossible without a reliable co-ordinator. The Deutscher Wetterdienst (DWD) has once again volunteered to take over this task. My sincere thanks go to the editorial team of DWD, especially to Peter Bissolli for compiling and writing the texts, Volker Zins for his technical support and, of course, to all the national contributors and internal reviewers. I wish everyone a pleasant reading.

Ivan Cacic
President of WMO Regional Association VI

Outstanding Events and Anomalies in 2009

Temperature

- Extremely warm April in central Europe
- Widespread cooling in December over northern Europe

Precipitation

- Unusual snowfall in February in the United Kingdom
- Extremely dry April in eastern and eastern central Europe
- Heavy rain with flooding in June in eastern central Europe
- Heaviest rain in Istanbul for 80 years on 9 September
- Exceptionally heavy rainfall and flooding in Cumbria, north-west England on 19-20 November
- Extremely heavy rainfall in southern Spain in late December

Storm

- Heavy storm (Klaus) in south-western France and northern Spain on 23-24 January

Annual Survey

1. Atmospheric circulation

The year 2009 was characterised by strong fluctuations in the atmospheric circulation patterns in the Region throughout the year, notably a transition from a La Niña to an El Niño phase, high fluctuations of the Arctic Oscillation (AO) and the North Atlantic Oscillation (NAO) with extremely low values for both indices at the end of the year, but also by several high pressure phases over Europe.

1.1. El Niño / La Niña

Moderate La Niña conditions in winter 2008/09 came to an end in March, as documented by the Southern Oscillation Index (Fig. 0.1). A typical feature of La Niña conditions is a dislocation of the frontal zone to northern latitudes and a stronger Azores high. This was to be seen on the seasonal scale for winter 2008/09. The consequence was a flow of mild and humid air to the Arctic whereas much of western and central Europe was cold and dry.

An El Niño event started in June 2009 with first signatures in the tropical Pacific. In October 2009, the Southern Oscillation switched to a moderate El Niño phase. Here, the typical pattern is a southerly frontal zone due to a stronger subtropical jet and a weaker Azores high. This pattern occurred especially in October and December 2009 with northern Europe being cold and mainly dry whereas the Mediterranean was mainly wet.

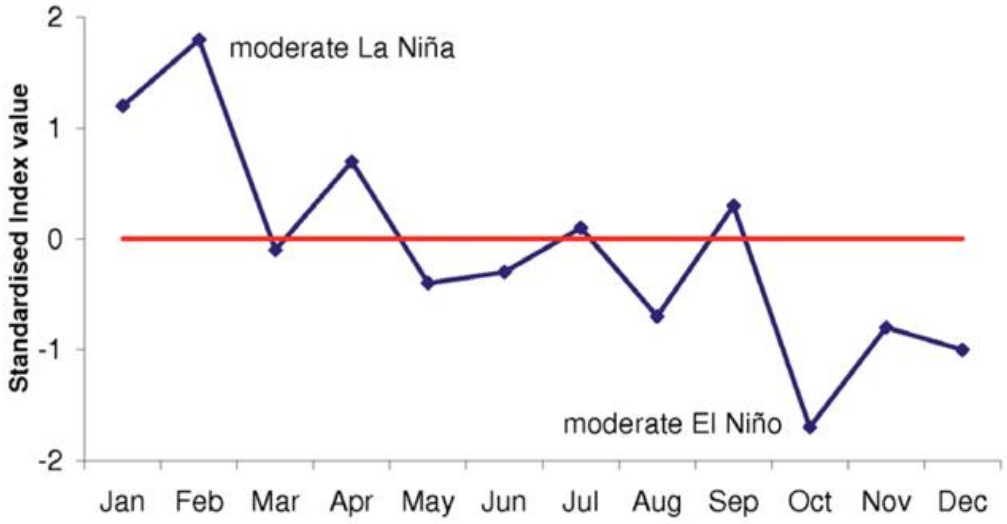

Fig. 0.1: *Standardised Southern Oscillation Index for 2009, as expressed by the difference of standardised sea level pressure anomalies in Tahiti and Darwin (Australia)*
Source: NOAA, www.cpc.ncep.noaa.gov/data/indices/soi

1.2. Arctic Oscillation (AO) and North Atlantic Oscillation (NAO)

On the monthly scale, AO and NAO were characterized by strong fluctuations during the year (Fig. 0.2). Positive AO and NAO phases, implying a stronger zonal flow component over the northern hemisphere (AO) and particularly over the North Atlantic (NAO), occurred in January, late spring (April/May), late summer / early autumn (August/September) and in November. In all these months, northern Europe was mainly warmer than normal because cold Arctic air was confined to the northern polar region.

In contrast, negative AO and NAO phases (weaker-than-normal zonal or a meridional flow) took place in February, early summer (June/July), October and December. The end of the year was characterized by an extremely negative phase of the Arctic Oscillation (AO) with high pressure dominating the higher latitudes of the Northern Hemisphere and affecting the weather in Europe. The AO Index in December 2009 was -3.4, the lowest value observed for any December in 60 years.

The NAO, too, was extraordinary in December and in June. During all these negative AO/NAO phases, parts or even the whole of northern Europe and some parts of the middle and southern latitudes were colder than normal.

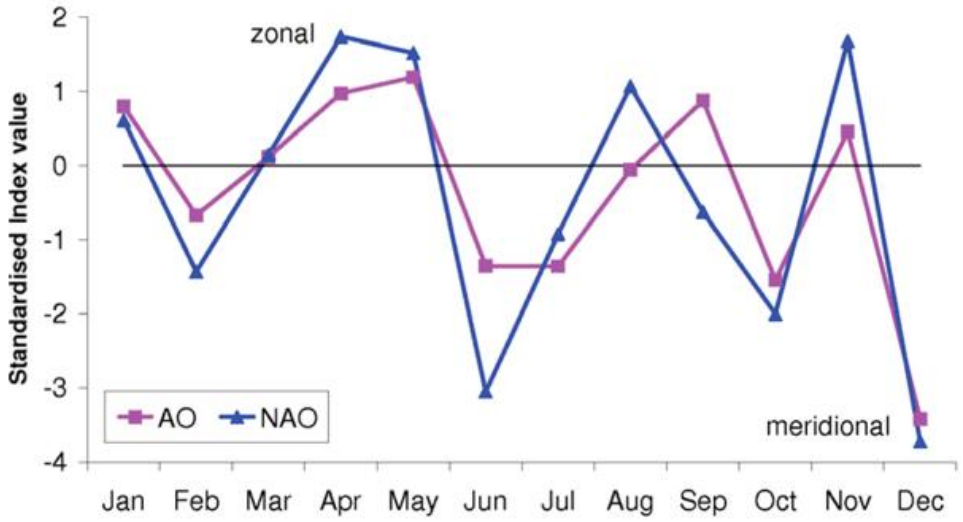

Fig. 0.2: *Standardised Arctic Oscillation (AO) Index and North Atlantic Oscillation (NAO) Index for 2009, as expressed by the difference of standardised sea level pressure anomalies between southern and northern latitudes over the whole northern hemisphere (AO) and the North Atlantic (NAO)*
Source: NOAA (AO), www.cpc.ncep.noaa.gov/products/precip/CWlink/daily_ao_index/ao.shtml and Climate Research Unit, University of East Anglia, United Kingdom (NAO), www.cru.uea.ac.uk/cru/data/nao/

1.3. Zonality over the North Atlantic and Europe

The zonal index over the North Atlantic and Europe for 2009 also reflects the monthly AO and NAO variations (Fig. 0.3). Whereas during positive AO/NAO phases the slightly enhanced zonality follows more or less the mean annual cycle, it shows large deviations during negative AO/NAO phases with a much higher meridional component than usual. In February 2009, the circulation was already as meridional as in April and May. June was by far the month with the highest meridionality instead of May as usual. October and December, normally months with high zonality, were more meridional than the spring months. The consequence was that the air mass exchange between north and south was enhanced during these months, and some exceptionally colder-than-normal periods occurred in larger parts of Europe, although the year on the whole was warm.

Especially January had a strong zonal circulation over the Atlantic, which was blocked, however, by high pressure over Europe. The situation was similar in April, although the Atlantic zonal circulation was weaker and the high pressure influence was very strong.

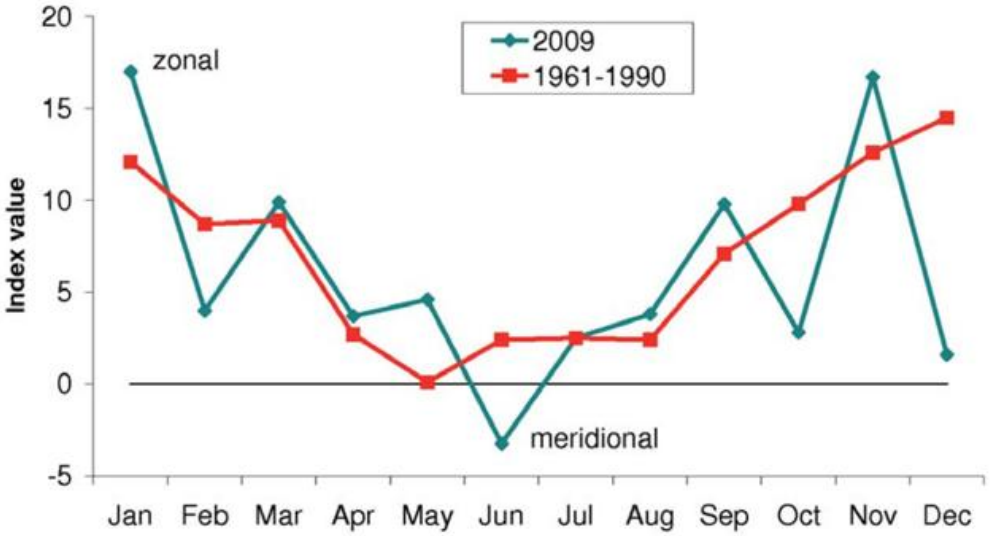

Fig. 0.3: *Zonal Index over the North Atlantic and Europe (20°W-40°E) for 2009, as expressed by the difference of zonally averaged sea level pressure between southern and northern latitudes Source: Deutscher Wetterdienst, www.dwd.de/GWL*

1.4. Sub-regional Overview

1.4.1. Central and eastern North Atlantic

Due to the high variability of the NAO, the circulation over the North Atlantic showed some quite unusual patterns in 2009 causing higher-than-normal air and sea temperature fluctuations. The very strong and early development of a meridional structure in February made especially the central Atlantic very mild. In summer, in contrast, the highly meridional situation caused a particularly strong meridional exchange of air masses resulting in a colder-than-normal central North Atlantic whereas the northern parts of the ocean were warm. In October, the whole central and eastern North Atlantic area experienced a warming due to the extreme meridional situation although in December, an easterly flow dominated, leading very cold air masses from the European continent as far as Atlantic regions.

1.4.2. Arctic regions in Europe

During most of the year, like in preceding years, the European Arctic experienced a mild southerly airflow, which was particularly effective in the winter months. Occasionally, very cold air masses affected eastern Greenland. April was an exceptional month with a strong Arctic oscillation that kept the cold air within the Arctic region while warm air remained in lower latitudes.

1.4.3. Northern Europe (Baltic countries, northern European Russia, Scandinavia)

Northern Europe experienced some outbreaks of cold Arctic air during the months of negative AO phases, notably in February, June, July, October and December. Partly only some limited areas were affected, but in October and December, the whole of northern Europe was concerned. During the other months, mild airflows or high pressure situations dominated.

1.4.4. Western and central Europe (Austria, Belgium, Czech Republic, France, Germany, Hungary, Ireland, Luxembourg, the Netherlands, Poland, Slovakia, Switzerland, United Kingdom)

These parts of Europe, too, experienced large temperature and precipitation fluctuations due to the large circulation variability. The strong zonal flow in January was blocked by high pressure, resulting in a cold and mainly dry month, except for the westernmost areas. In February and March, it was mainly the Azores high that caused the weather to be mostly dry in western Europe, sparing central Europe, however. Extended high pressure influence dominated in April, making it an extremely warm and dry month. In May, only the southern parts profited from the persisting high pressure influence. Very high pressure with warm and dry weather continued to dominate the weather in August and September.

The negative AO phases in June, October and December affected large parts of central Europe, bringing cold Arctic air particularly into the northern regions. In December, an easterly continental flow affected the whole northern parts of western and central Europe.

In June/July and October/November, many low pressure systems passed western and central Europe, causing some heavy precipitation events.

1.4.5. Iberia

After a more or less normal winter 2008/09 with several low pressure situations, high pressure influence dominated in spring, summer and autumn, with only occasional rainy spells and thus resulting in mostly warm and dry months. In December, however, a southerly frontal zone built up due to El Niño conditions, causing a very rainy end of the year.

1.4.6. Mediterranean (including Italy, Monaco and Malta)

A lot of low pressure activity occurred in various parts of the Mediterranean, especially over the central parts. However, several months of the summer half year (May, July and August) were characterised by dominating high pressure influence, causing summer heat waves and shortage of rain. On the other hand, particularly in February and October, both of which were colder and with negative AO, cold air from the north moved towards the Mediterranean.

1.4.7. Balkan Peninsula (Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Greece, the Former Yugoslav Republic of Macedonia, Montenegro, Serbia, Slovenia)

The Balkan Peninsula generally was not much affected by AO/NAO fluctuations, but by several Mediterranean low pressure systems throughout the year. An extensive high pressure phase took place in April/May and another one in September.

1.4.8. Eastern Europe (Belarus, western Kazakhstan, Moldova, Romania, European Russia, Ukraine) and South Caucasus region (Armenia, Azerbaijan, Georgia)

The Russian high was stronger than normal in winter 2008/09, and eastern Europe remained in a warm airflow at its flank most of the time from January to March. In April, however, when the large high was establishing over most of Europe, the eastern areas came under a northerly flow east of that high. During the summer, high pressure influence dominated again, although another cold airflow prevailed in August. Seasonal cooling in autumn was lower than normal due to frequent westerly airflows.

The negative AO phases did not have much impact on eastern Europe, except for the extreme situation in December when cold air from Siberia came into most parts of that area.

1.4.9. Middle East (Cyprus, Israel, Jordan, Lebanon, Syria, Turkey)

High pressure influence dominated most of the year until summer. It ended in September when strong low pressure activity set an end to the dry period and marked the start of the rainy period. The AO/NAO fluctuations had no noticeable effect on that area.

1.5. Stratospheric warming

The monthly mean temperature of February 2009 at 30 hPa over the North Pole has been the highest February mean since 1942. The polar vortex broke down as early as in January, and in the first days of February a warm high pressure area formed instead. This stratospheric warming was related to an increase of ozone.

2. Temperature

2.1. Overview

Widespread anomalous warmth averagely affected continental Europe in 2009. The annual average land surface air temperature anomaly from the CRUTEM3 dataset (http://www.cru.uea.ac.uk/cru/data/temperature/) referring to 1961-1990[1] was +1.05±0.07°C for the European region (35-75°N, 10°W-30°E). This ranks 2009 between the third and tenth warmest year since 1850, with the nominal ranking placing it seventh. Noteworthy is that 2000-2009 was the warmest decade on record for Europe, with an anomaly of 1.00±0.12°C and significantly warmer than previous decades (1990s: +0.58±0.11; 1980s: +0.06±0.10). In many countries, all years of the decade 2000-2009 were, on average, warmer than normal, although 2009 was not the warmest year in that period. Some months in 2009 were even much colder than normal over large areas.

Annual mean anomalies > +2°C in 2009 were mainly confined to the Arctic regions, notably Svalbard and some other islands, and some parts of the northern coasts of Greenland (Fig. 0.4). Over large parts of Europe, the Middle East and the northern North Atlantic, however, anomalies exceeded +1°C. Some other parts of the continent, the central North Atlantic and most of the Mediterranean recorded anomalies below +1°C, though above zero. Negative annual mean anomalies were found only locally in very few places, e.g. over the central North Atlantic and eastern Turkey.

During the year, however, there were some periods that were colder than normal on the monthly and seasonal scales, notably in the western parts of Europe in January/February, in northern Europe in June, October and December, in the Arctic and eastern Europe in April and over the North Atlantic in summer. In contrast, some very warm periods occurred in the Arctic and eastern Europe from January to March, over central Europe in April, in parts of southern Europe in May and late summer, in nearly the whole of Europe in November, and in the Middle East in October and December.

---

[1] The standard reference period used in this publication for European averages is 1961-1990 for temperature, and 1951-2000 for precipitation, unless otherwise expressly specified.

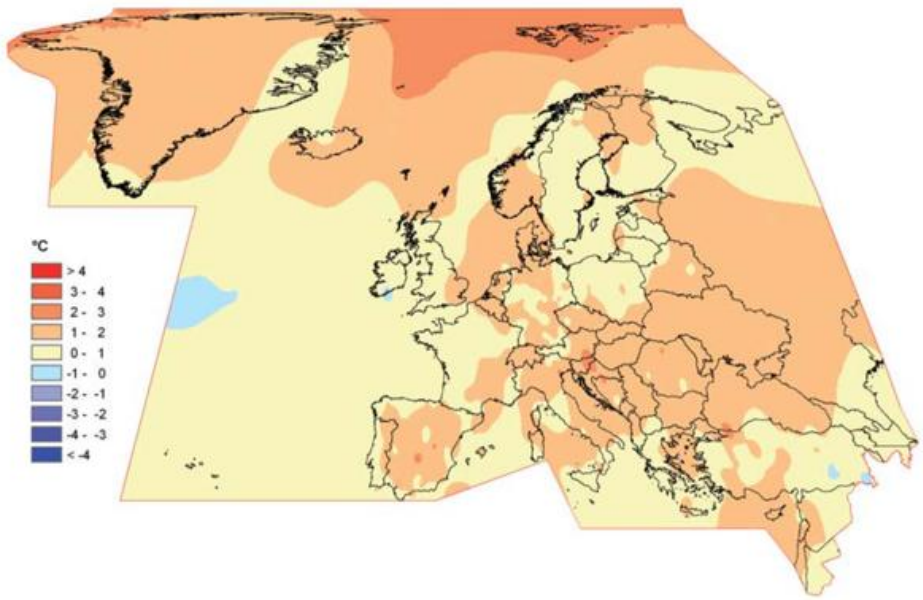

Fig. 0.4: *Mean annual temperature anomalies in 2009 (reference period 1961-1990) in WMO Region VI (interpolation of CLIMAT data)*
Source: Deutscher Wetterdienst, Germany

2.2. Northern Europe and Arctic region

Mean annual temperatures in the Nordic Countries were above normal, with annual temperature anomalies mostly ranging from +0.5 to +1.5°C, except in the Arctic where they were even higher. The highest positive anomalies were recorded in Svalbard (arctic Norway), where mean temperatures of 2-3°C above the 1961-90 average were recorded.

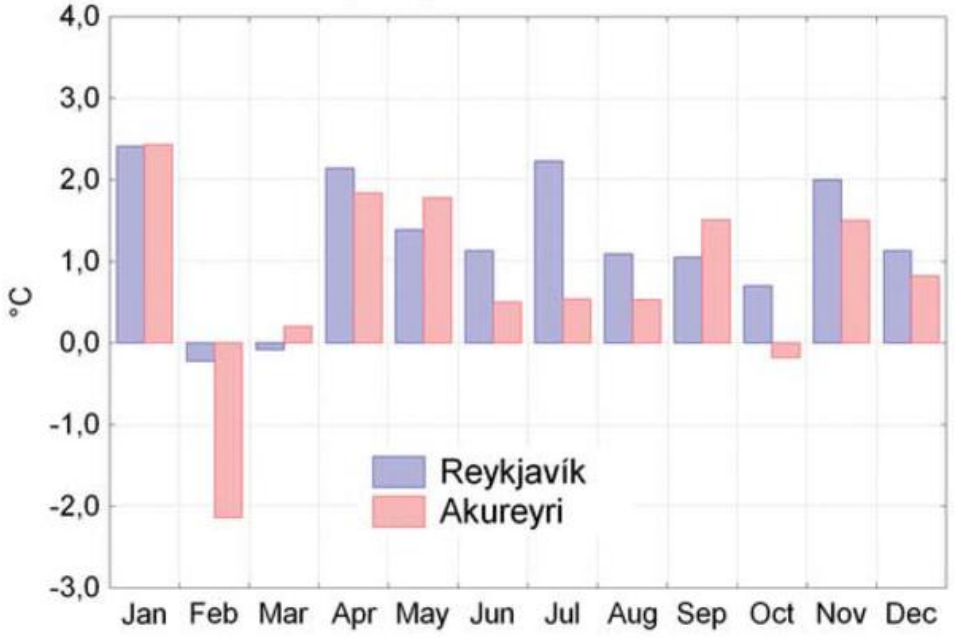

Fig. 0.5: *Mean monthly temperature anomalies in Reykjavik (south-west Iceland) and Akureyri (north Iceland) in 2009, reference period 1961-1990*
Source: Icelandic Meteorological Office, http://en.vedur.is/weather/articles/nr/1802

In the Arctic, monthly anomalies were particularly high in the cold months January, November and December 2009, but also in May (> +4°C). Monthly anomalies at Svalbard airport rose to +8.4°C in November and +10.9°C in December. Most of the other months were also warmer than normal there. A clear exception was April, which was colder in the whole European Arctic except western Greenland. Whereas many locations in Greenland were warmer than normal in most of the months, the temperatures in the summit area in the middle of the ice sheet were mostly below normal. In Iceland, only February was considerably colder than normal in the northern parts (Fig. 0.5). In the Faroe Islands' capital city Tórshavn, all months in 2009 were warmer than normal and 2009 as a whole was the second warmest year on record with an annual mean of 7.6°C (+1.1°C anomaly), together with 1933 and behind 2003 (Fig. 0.6).

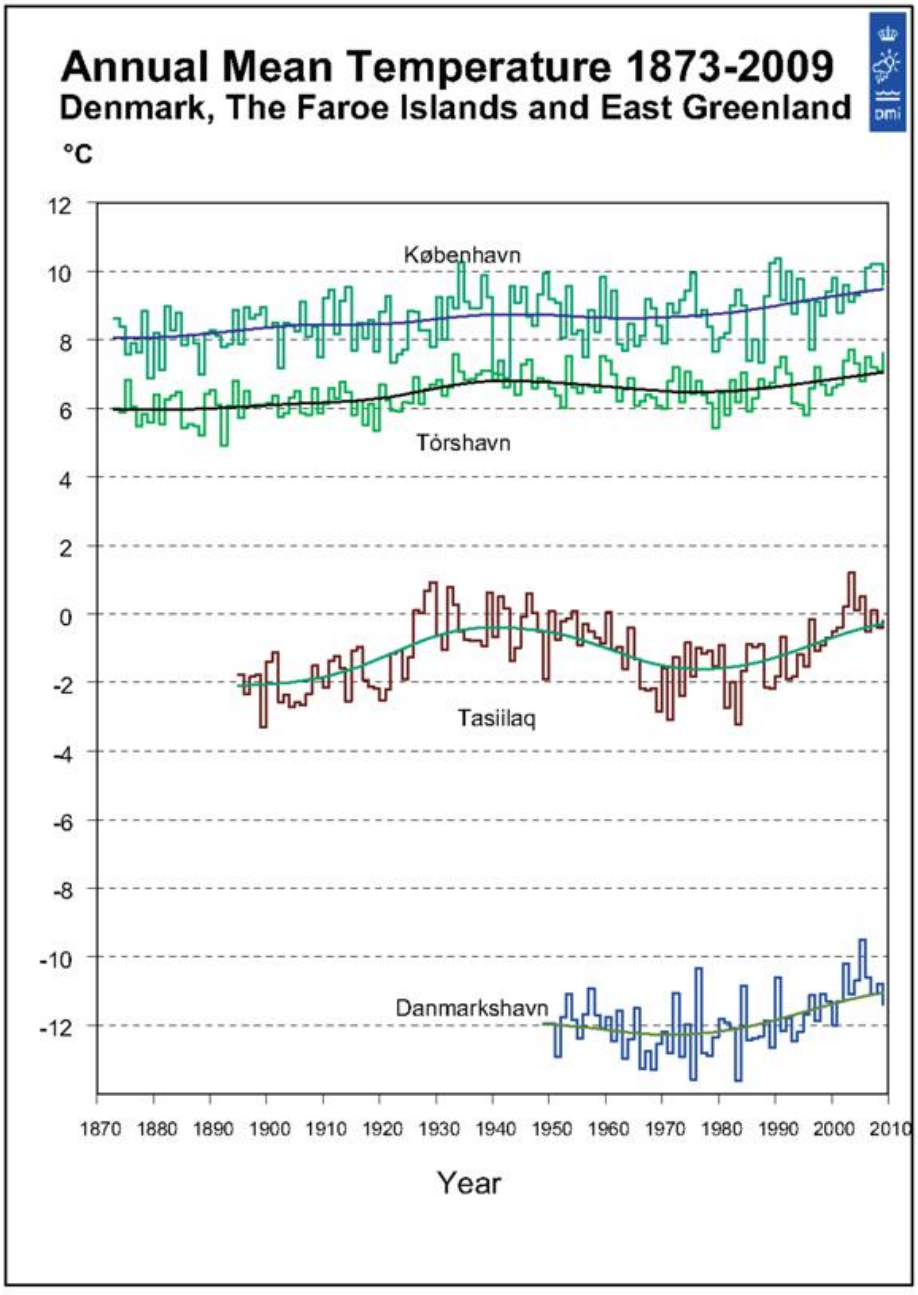

Fig. 0.6: *Mean annual temperature and smoothed values 1873-2009 for some locations in Denmark, the Faroe Islands and east Greenland*
Source: Danish Meteorological Institute

Northern continental Europe experienced a high variability of warmer- and colder-than-normal months. February was locally very cold, especially in Sweden. June, October and December were colder than normal in nearly the whole of Scandinavia and the Baltic countries. All the other months were, on average, warmer than normal across much of the Nordic and Baltic region; it was particularly warm in Scandinavia in August and in the southern parts of northern Europe, e.g. in Lithuania (Fig. 0.7), in April.

Annual means in Norway in 2009 were lower than in most of the previous years in the past decade; although the year was generally warmer than on average. Local means of up to 8.8°C were measured in the south of the country (Fig. 0.8) in 2009.

Throughout the Baltic countries, annual temperature anomalies were also around +1°C except Latvia and Lithuania where 2009 was colder than the previous three years 2006-2008 and 2008, respectively.

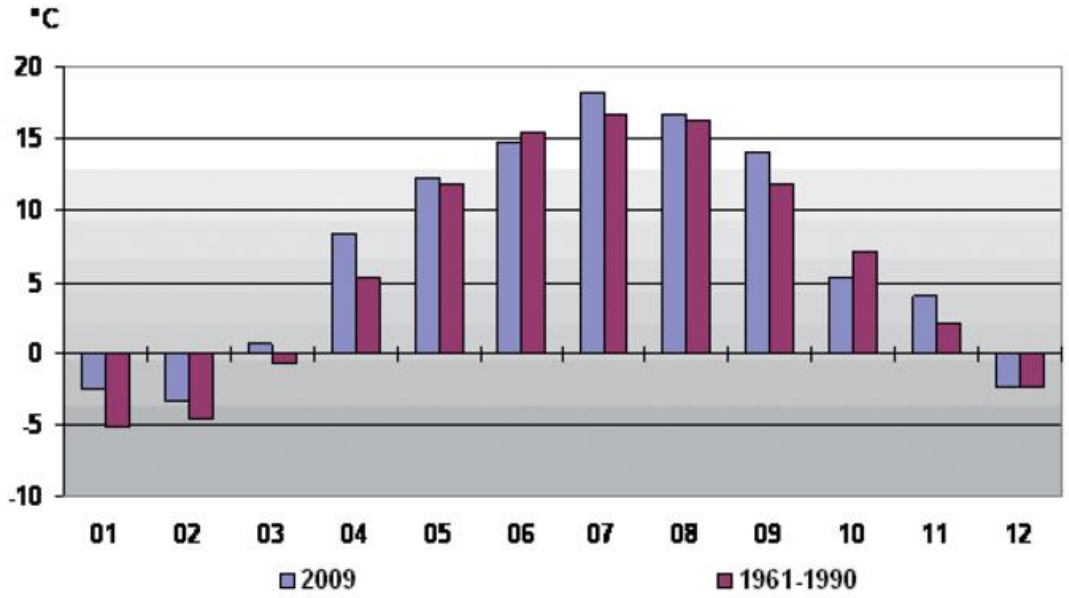

Fig. 0.7: *Mean monthly temperature in Lithuania in 2009, compared to the 1961-1990 normal*
Source: Lithuanian Hydrometeorological Service

2.3. North Atlantic

The central North Atlantic had near normal temperatures on annual average whereas over the northern North Atlantic, it was more than +1°C warmer than normal. It also was slightly warmer than normal on the Azores Islands.

The central North Atlantic was warm at the beginning of the year and in spring, but seasonal warming in summer was lower than usual. It was also colder than normal in November and December. Northern parts of the North Atlantic were mostly warmer than or near normal throughout the year.

2.4. Central and Western Europe and the Alpine region

Annual means in central Europe (including the Low Countries) and in the Alpine region were mostly around +1°C higher than normal. Anomalies in western Europe and in Poland were mostly below +1°C, but still above normal. Only some places (e.g. in south Ireland) were locally near to normal, mainly due to very cold weather at the end of the year. The Irish station at Cork Airport has seen its coldest year since 1996.

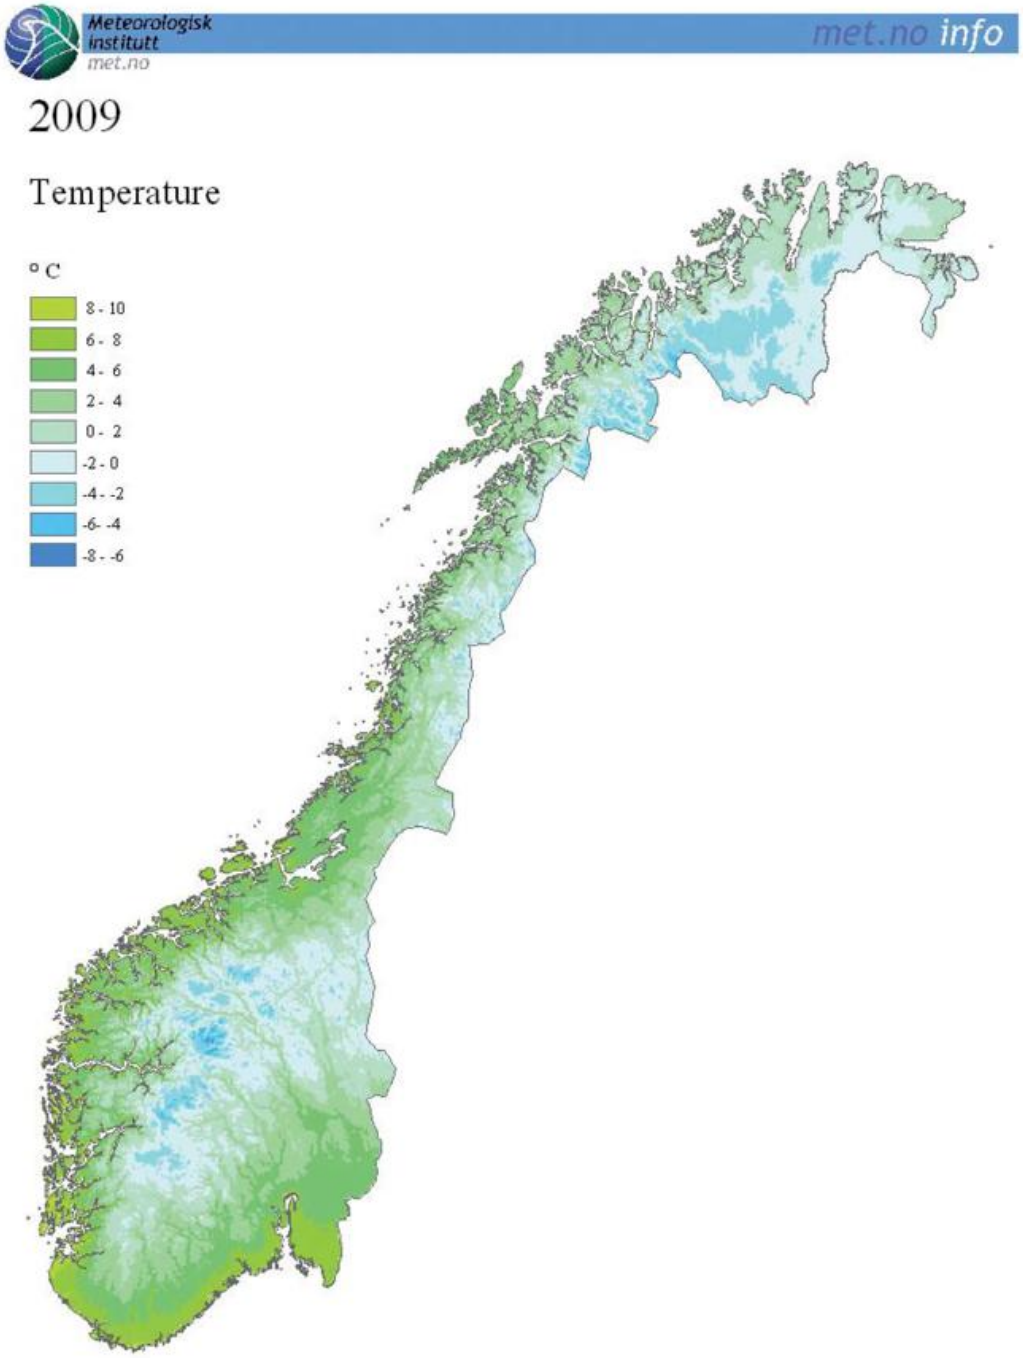

Fig. 0.8: *Mean annual temperature 2009 in Norway*
Source: Meteorologisk Institutt met.no, Norway

In Luxembourg, where the annual mean anomaly was slightly higher than in other adjacent countries (+1.6°C), the 2009 temperature corresponded roughly to the average of the last decade 2000-2009 (Fig. 0.9). Belgium, Luxemburg and Germany all recorded an abnormally high number of 36-37 summer days (maximum temperature >= 25°C) in places or on areal mean which was around one third more than normal. On the other hand, the number of hot days (maximum >= 30°C) was not considerably above normal because the summer had many cloudy days, and longer heat waves were missing. Days with air frost were less than normal e.g. in Luxembourg and Germany due to the mild months of April and November.

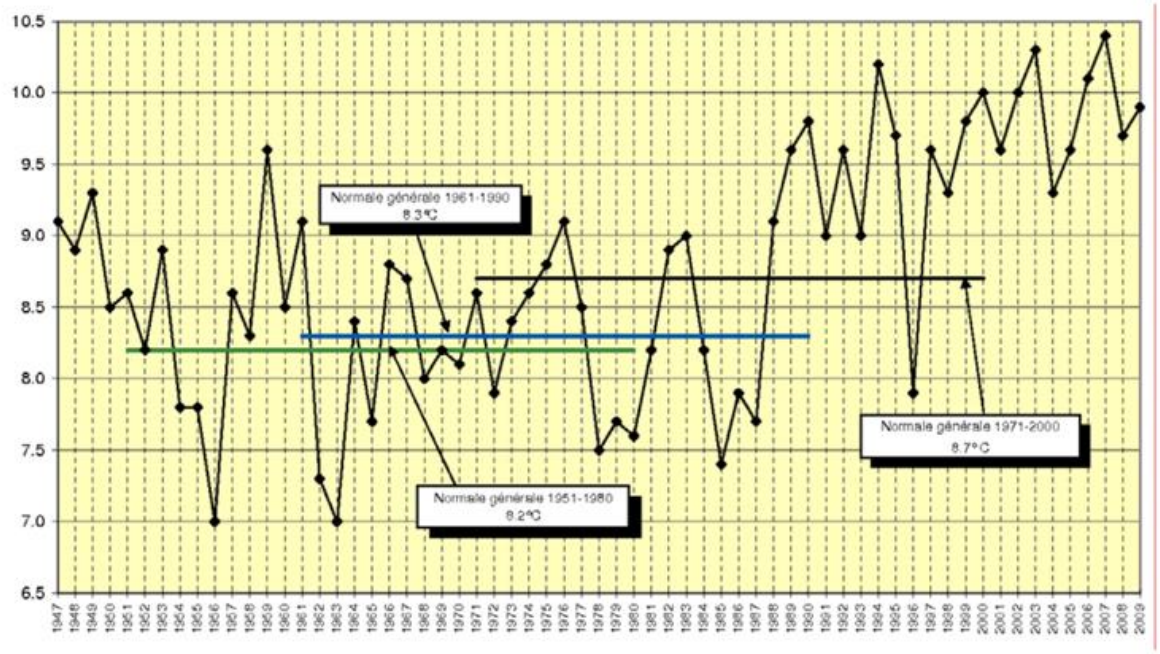

Fig. 0.9: *Mean annual temperature 1947-2009 in Luxembourg Airport, compared to various normal temperatures*
Source: Service Météorologique de Luxembourg, Administration de la navigation aérienne

Most of the months were warmer than normal in western and central Europe, especially April/May, July to September and November. On the other hand, January was generally a cold month; June and October were colder than usual particularly in north-eastern central Europe, e.g. in Poland (Fig. 0.10a), while December was colder than normal in the whole northern part of western and central Europe.

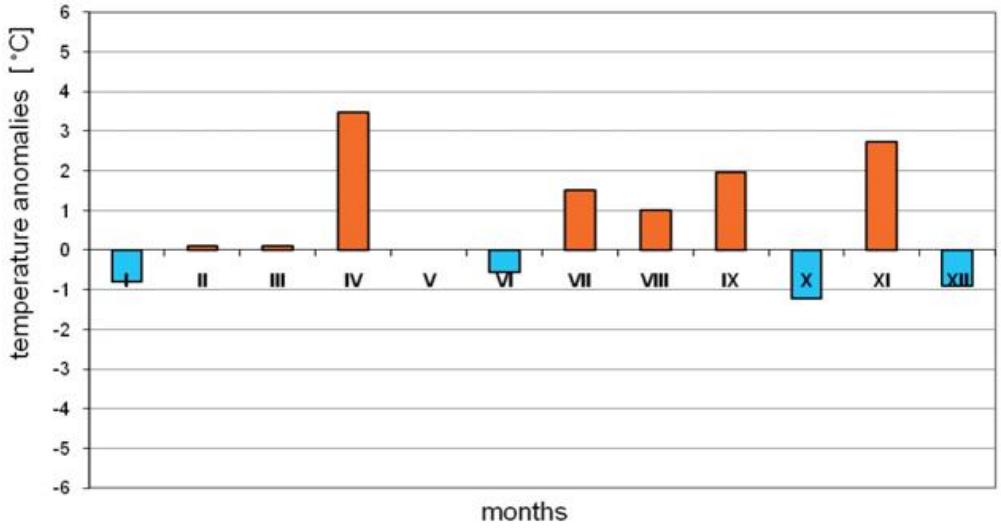

Fig. 0.10a: *Mean monthly temperature anomalies 2009 in Poland (reference period 1971-2000)*
Source: Institute of Meteorology and Water Management (IMGW), Poland

2.5. Iberia

Temperatures registered in 2009 over the Iberian Peninsula were significantly above the long-term average. The annual mean anomaly in most of Iberia ranged between +1 and +2°C and was higher in the east than in the west. In large parts of the western areas, especially near the coasts, anomalies were below +1°C, but still positive, particularly due to higher maximum temperatures. Portugal recorded seven heat waves[2] (periods of succeeding high temperatures) from spring to autumn.

It has been the 3rd warmest year in most areas of Spain since 1961 (behind 2006 and 1995, with an anomaly of +1.2°C referenced to 1971-2000, Fig. 0.10b), and also summer and autumn were the 3rd warmest on record. The largest annual anomalies were observed in the central and southern regions as well as on the north-western Iberian Peninsula. The lowest deviations were found in Asturias (northern Spain) and on the Balearic Islands (around +0.5°C). Temperature deviations in Portugal were highest in the north (+0.9°C, 1971-2000 base), but in general lower than in Spain (+0.5°C averaged over the whole mainland of Portugal, 1971-2000 base).

The year 2009 began with a negative temperature anomaly during winter (especially in January), continued with a warmer-than-average spring, a particularly warm summer and a moderately warm fall. In spite of some colder episodes in some areas of Iberia throughout the year, half of the months were much warmer than normal. The warmest months of 2009 in Spain (relative to normal) were May, June, October and November, when mean temperatures were around +2°C above average. Overall in Portugal, the warmest months (relative to normal) were March, May and October.

Fig. 0.10b: *Mean annual temperature anomalies 1961-2009 in Spain (°C, reference period 1971-2000) Source: AEMET, Spain*

2.6. Mediterranean, Italian and Balkan peninsulas

Much of Italy and south-eastern Europe were 1-2°C warmer than average during 2009, even exceeding +2°C in eastern Slovenia and +2.5°C in north-eastern Italy and western Slovenia. On the Slovenian coast, 2009 was the 2nd warmest year on record, together with 1994, 2000 and

[2] *There is no universal definition of a heat wave. The WMO recommended defining a heat wave as a period of at least 6 succeeding days with a daily maximum temperature exceeding the normal by at least +5°C*

2002. Throughout Croatia, very high annual temperatures prevailed, particularly in spring and summer, exceeding the 98th percentile of the 1961-90 distribution over most regions. In Zagreb, it has been the equal (together with 2008) 3rd warmest year since 1862, behind 2000 and 2007 (Fig. 0.11). Further to the west, it was the 3rd warmest year since 1969 in Monaco, behind 2006 and 2007 with an annual means of 17.2°C.

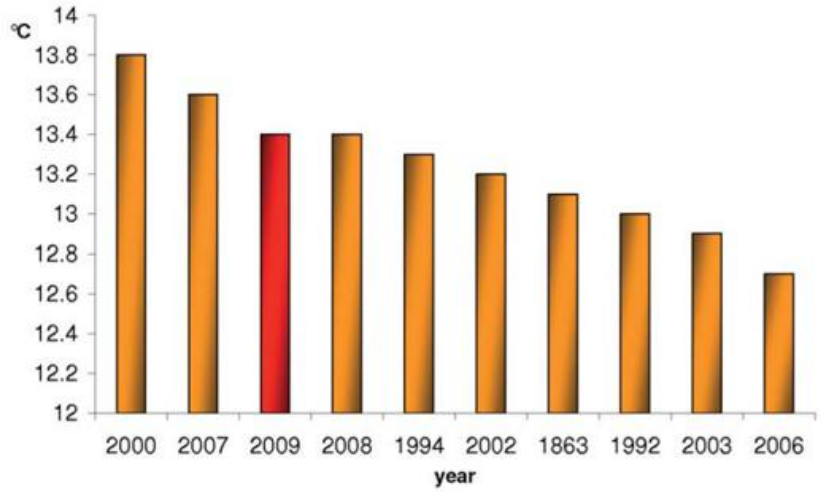

Fig. 0.11: *The ten warmest years (annual mean temperatures) in Zagreb Gric, Croatia, of the observation period 1862-2009*
Source: Meteorological and Hydrological Service of Croatia

Some periods of the year were considerably warmer than normal, notably April/May (except Bulgaria in April), August/September and November/December. In Ljubljana (Slovenia), all months in 2009 were warmer than normal, except January. In Malta, all warm months (May-September) as well as the winter months January and December 2009 had mean temperatures above normal. February, on the contrary, was a very cold month in the central Mediterranean.

2.7. Eastern Europe

Annual temperature anomalies over Eastern Europe ranged between +1°C and +2°C, with only northern parts of European Russia recording an anomaly below +1°C. Parts of Romania exceeded +2°C. Moldova experienced its second warmest year in history, beaten only by 2007 (Fig. 0.12a).

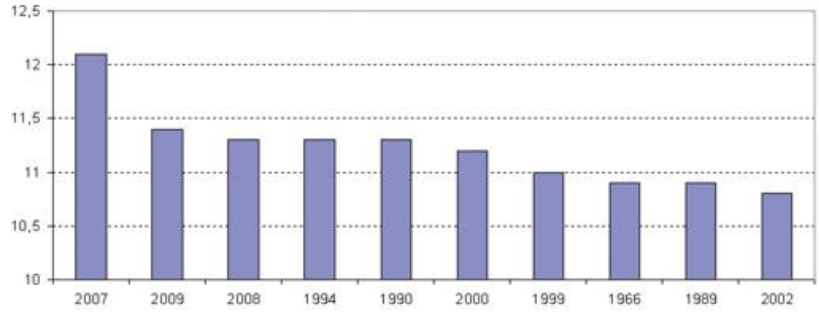

Fig. 0.12a: *The ten warmest years (annual mean temperatures in °C) in Chisinau, Moldova, of the observation period 1886-2009*
Source: State Hydrometeorological Service of the Republic of Moldova

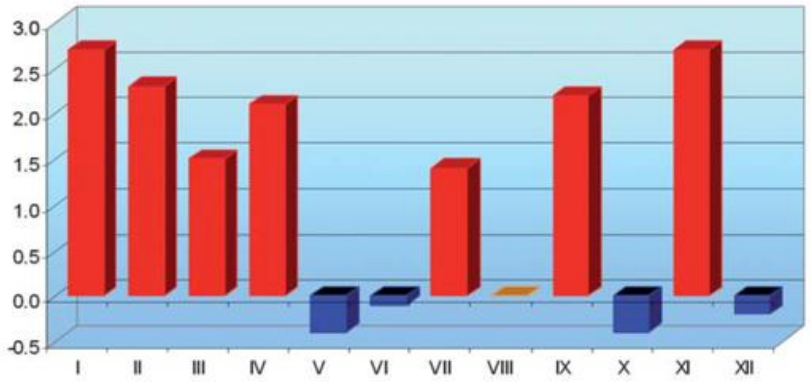

Fig. 0.12b: *Mean monthly temperature anomalies 2009 in Belarus (°C, reference period 1961-1990). Source: Republican Hydrometeorological Centre, Belarus*

Most of the months throughout the year were much warmer than normal, however, with some outstanding colder-than-normal periods in April or May, in July (only in northern European Russia), August (only in the east), October (only in the north-west) and December (Fig. 0.12b for Belarus). The westernmost parts of eastern Europe (e.g. Romania, Moldova) were also warmer than on average, except for March in Romania and December in Moldova.

2.8. Middle East and South Caucasus region

Warmer-than-average conditions prevailed in the entire region throughout the whole year. The largest anomalies were experienced in the eastern Mediterranean region in Cyprus, Israel, Lebanon and the western parts of Syria and Kazakhstan, with values generally ranging between +1° and +2°C. Other parts were less warmer (0-1°C) than normal on annual average (e.g. Turkey, Armenia, Azerbaijan), parts of eastern Turkey locally even slightly colder.

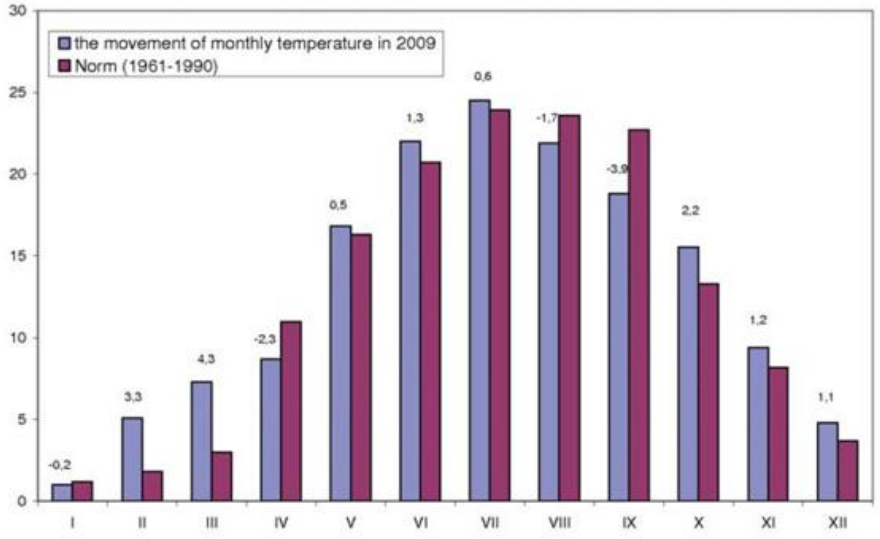

Fig. 0.13: *Monthly mean temperature (°C) in Azerbaijan in 2009 (blue bars) compared with the 1961-1990 normal (red bars). Numbers above the blue bars are monthly anomalies (°C) in 2009 from the normal*
Source: National Hydrometeorological Department Azerbaijan

Some of the months were much warmer than normal, particularly February, June, October and December. Western Turkey and Cyprus also saw a mild January, and March was very warm particularly in Azerbaijan (Fig. 0.13). November was generally warm in the South Caucasus region, Cyprus and most of Turkey whereas April and August/September were cold especially in the South Caucasus region. Jordan had significant heat waves even in May and October as opposed to frosts in mountainous regions in January-March and November-December; March and November were colder than normal in parts of the country. The station Ma'an in Jordan (around 1000 m above sea level) recorded 42 days of frosts in 2009.

3. Precipitation

3.1. Overview

Total precipitation for the year 2009 (Fig. 0.14) was above average over most of eastern and south-eastern Europe, Ireland, northern and southern parts of the UK, Iceland and in parts of Fennoscandia. Locally, it was particularly wet in several regions in Austria, where new annual precipitation records were set in several places in Belarus and adjacent parts of Russia and in the eastern half of the Mediterranean region including southern Italy.

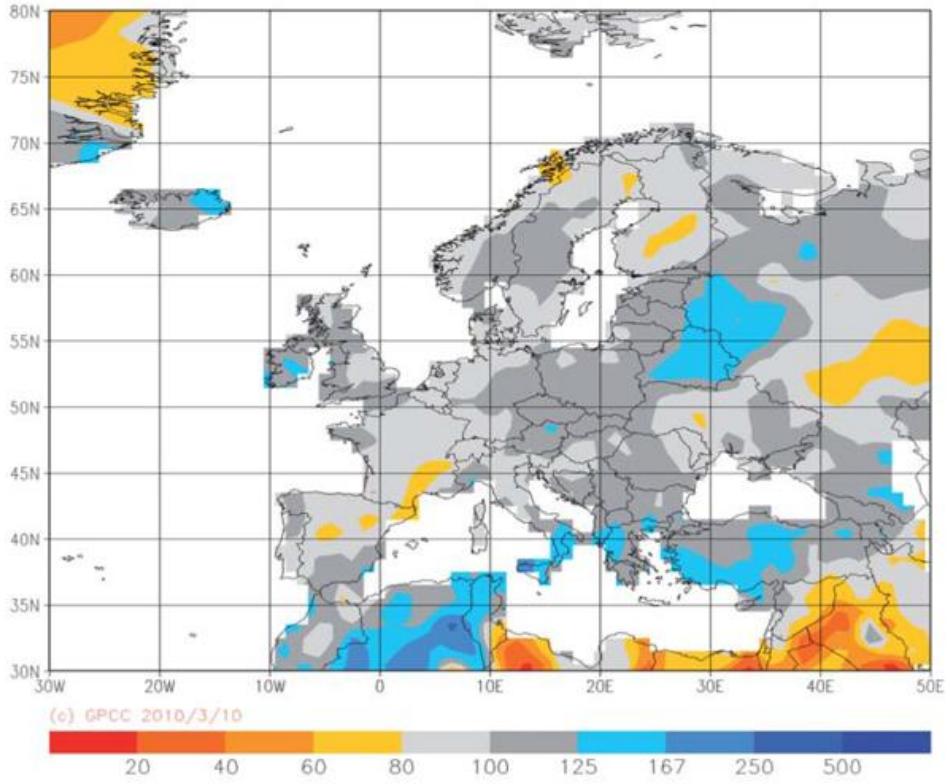

Fig. 0.14: *2009 annual precipitation amounts in WMO Region VI in per cent of the 1951-2000 normal*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Drier-than-average conditions occurred over large parts of Scandinavia, the Low Countries (Netherlands, Belgium and Luxembourg), the western parts of Germany, wide parts of France and Iberia, and the central parts of England, where totals were 80-100% of normal precipitation. Some smaller parts of Greenland, Scandinavia, Russia, southern Iberian region, southern France, and the Middle East received annual rainfall totals below 80% of the long-term average.

Throughout the year, there were some exceptional periods of high or low precipitation in the Region. High precipitation fell notably over the central Mediterranean in January, in central and south-eastern Europe in March, June and October, in the United Kingdom, Ireland and southern Scandinavia in July and November, and in southern and eastern Europe in December.

In contrast, April was outstandingly dry in large parts of northern, central and eastern Europe while August/September was a very dry period particularly in the middle latitudes and parts of the subtropics.

3.2. Northern Europe and the Arctic

The Arctic region was mainly dry in 2009, as were most of Iceland and the Faroe Islands. Especially some areas in Greenland received less than 80% of its annual normal. Reykjavik, which is located in south-western Iceland, had slightly below normal precipitation and below normal precipitation days (205 compared to 221 normally), recording its driest year since 1995. Only the south-eastern parts of Greenland and eastern Iceland were exceptionally wet, with more than 125% of the normal. Generally, the Arctic region was very dry in June-September, but wet in November/December.

The year was also dry in most parts of continental Scandinavia. Some parts of northern Scandinavia and Finland had less than 80% of its annual normal. Nevertheless, there were some wet areas particularly in south-eastern Norway, central Sweden and northern Denmark, which can be explained by heavy rain in July. In some places in central Sweden, 2009 has been among the 3 wettest years since 1901 while ranking among the driest years in both northern and southern Sweden (Fig. 0.15).

Most of Scandinavia saw some very dry months, notably January, March, April, June, October and December. July and November were wet in southern Scandinavia, September at the Norwegian coast. Helsinki in southern Finland was quite wet from May to July, but very dry in the months before and afterwards (Fig. 0.16).

The Baltic countries and most of northern European Russia had above normal precipitation, in some areas in Estonia and northern European Russia more than 125% of the normal. In Latvia, 2009 was the third consecutively wetter-than-normal year after a very dry year 2006.

April and May were also extremely dry in the Baltic countries while June, October and December, on the contrary, were wet. Precipitation was often very intense in summer and early autumn.

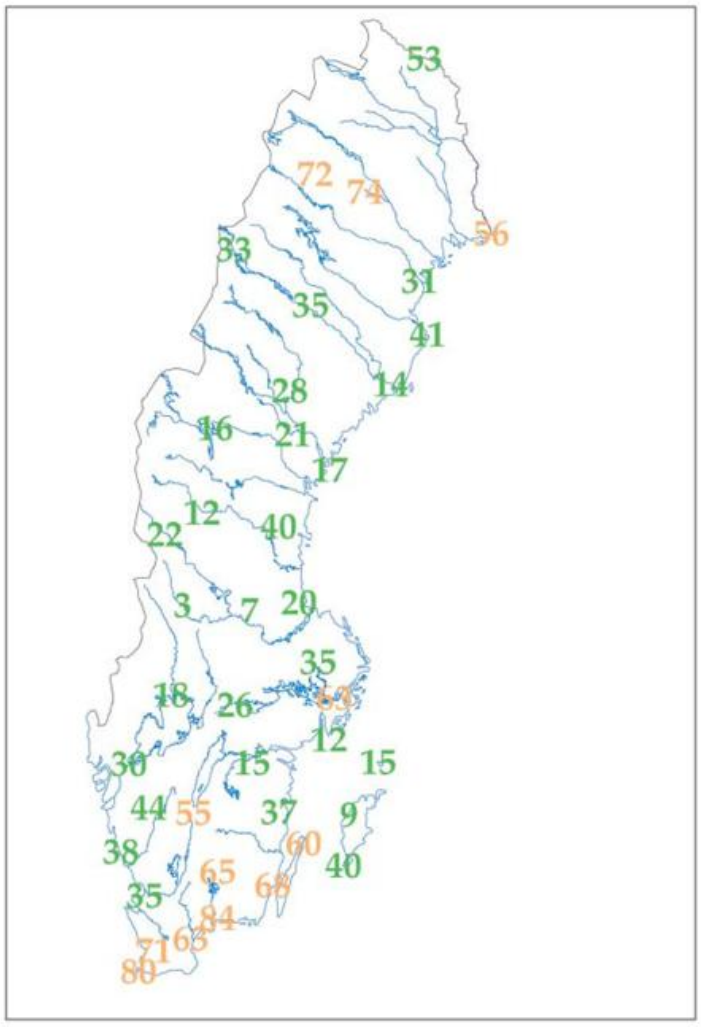

Fig. 0.15: *Ranking of precipitation 2009 in comparison with the years 1901-2008. 1= wettest, 109 = driest year*
Source: Swedish Meteorological and Hydrological Institute (SMHI)

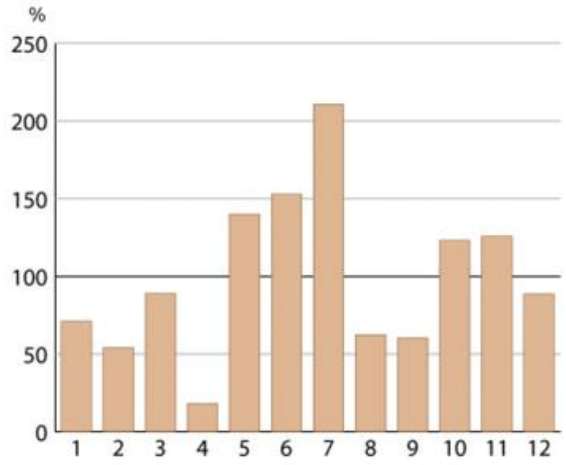

Fig. 0.16: *2009 monthly precipitation amounts in Helsinki Kaisaniemi (Finland) in per cent of the 1971-2000 normal*
Source: Finnish Meteorological Institute

3.3. Western and central Europe

Large parts of France, Belgium and the Netherlands, the western half of Germany, and Switzerland were slightly drier than normal on average. Some areas of southern France received less than 80% of their normal annual precipitation. Ireland, large parts of the United Kingdom, Luxembourg and nearly the whole of eastern central Europe had above normal precipitation.

In some areas in Ireland, the mean annual precipitation totals were exceeded by 25%. Valentia Observatory in Ireland has reported its highest annual rainfall total since records began in 1866. The high totals in Ireland were mostly due to heavy rainfall events in summer and November and to a 10-20% higher-than-normal number of rain days.

Eastern Austria, too, reported several very wet areas. Graz received in 2009 an annual precipitation total of 1205 mm, i.e. 143% of the 1971-2000 mean, making it the second highest annual total in the 173-year continuous station record.

Over the year, western Europe generally was especially dry in February/March and September/October whereas most parts of it were wet in July and November. Particularly Ireland and the United Kingdom received a lot of rain.

Central Europe saw a very dry January and an exceptionally dry April particularly in its eastern areas. August and September were also very dry, causing unusually low water levels in many rivers followed by restrictions to shipping transport. France and Switzerland had a prolonged dry period from August to October. Wet periods in central Europe occurred in February/March, during some periods in May-July and in October-December. Frequent heavy thunderstorms in late spring and summer caused much damage and local flooding in central Europe. In Austria, particularly April as well as October and November were dry, whereas most of the other months were wet, particularly February/March and June. In Hungary, the cold months (January-March, October-December) were wet while the summer half year (April-September) was much drier than normal, except June (Fig. 0.17).

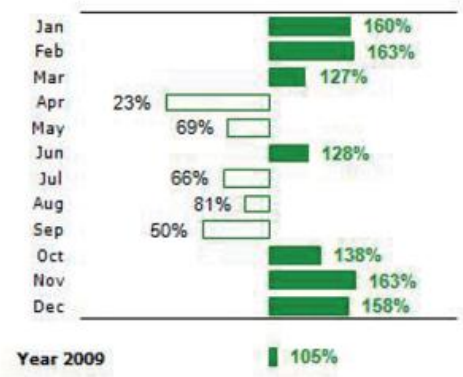

Fig. 0.17: *2009 monthly precipitation amounts in Hungary (country average) in per cent of the 1971-2000 mean*
Source: Hungarian Meteorological Service

3.4. Iberia

On average, Iberia experienced near-normal or slightly drier-than-normal conditions during 2009, with only few regions receiving less than 80% of the climatological average. The north-west of the Iberian Peninsula and southern Spain had above normal precipitation, the other parts below normal.

Dry episodes are relatively common in Iberia and, regarding the duration and intensity of dry periods, 2009 can in this context be classified as a moderately dry year, particularly when compared with exceptional dry years such as 2005. Nevertheless, all seasons recorded lower-

than-average precipitation for the aggregate area of Iberia in spring, summer and autumn (particularly from May to July) whereas December 2009 was an exceptionally wet month. Portugal reported drought conditions for almost the whole country between March and October (Fig. 0.18). Most of the Azores Islands were drier than the normal annual average, although October and December were wetter than normal.

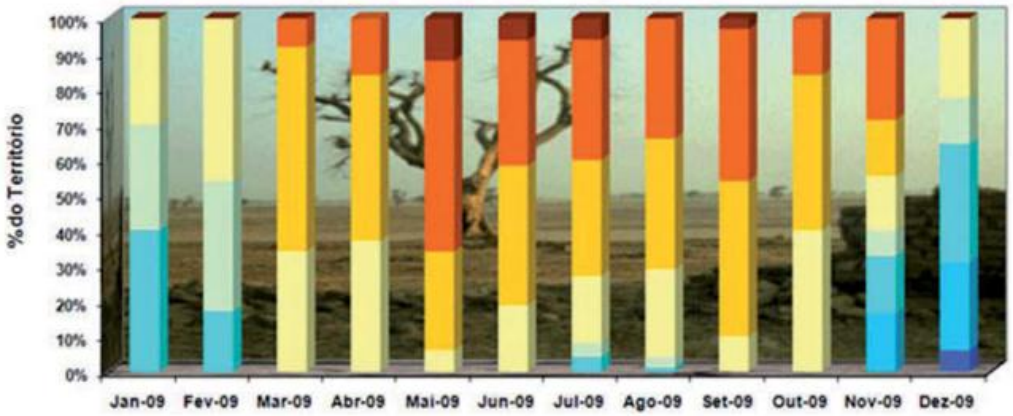

Fig. 0.18: *Monthly distribution of drought classes (Palmer Drought Severity Index) in % of the territory in Portugal for 2009. Classes range from very wet (dark blue in December 2009 on the bottom of the bar) – moderately wet – slightly wet – normal (light blue) – mild drought (light yellow) – moderate drought (white) – severe drought (orange) to extreme drought (dark red in the hot months on top of the bars)*
Source: Instituto de Meteorologia, Portugal

3.5. Italian and Balkan peninsulas, Mediterranean region

Most of the Balkan Peninsula and parts of Italy received above-normal precipitation in 2009. Southern Italy and parts of Greece recorded more than 125% of their normal annual total. In Bosnia and Herzegovina, some stations had an annual total of more than 1800 mm (Fig. 0.19a), on high mountains (station Bjelašnica) as well as near the Mediterranean (station Mostar), which was more than 20% of the normal. Some northern parts of Italy and of the Balkan Peninsula (e.g. in parts of Slovenia) had less precipitation than normal, whereas Monaco had quite a rainy year (880.5 mm, 114% of the 1969-1998 average).

Northern Italy and Slovenia were much wetter from January to March/April, relative to the normal reference period. The following months were mainly dry, although there were several severe thunderstorm episodes with hail particularly in summer. December again was characterised by very much precipitation.

Near the central Mediterranean and on the Balkan Peninsula, some periods with high precipitation occurred particularly in January, March, June, October and December. In contrast, it was very dry in Italy in May, July/August, November, and over most of the Balkan Peninsula notably in April/May and September. Monaco saw an extremely dry summer, but very wet months of April, November and December (Fig. 0.19b).

The south of the Balkan Peninsula, however, saw some special features, with a mainly wet spring in Macedonia and a particularly wet June in Skopje (Fig. 0.19c) and several heavy rain events with severe flooding in Greece from September to December.

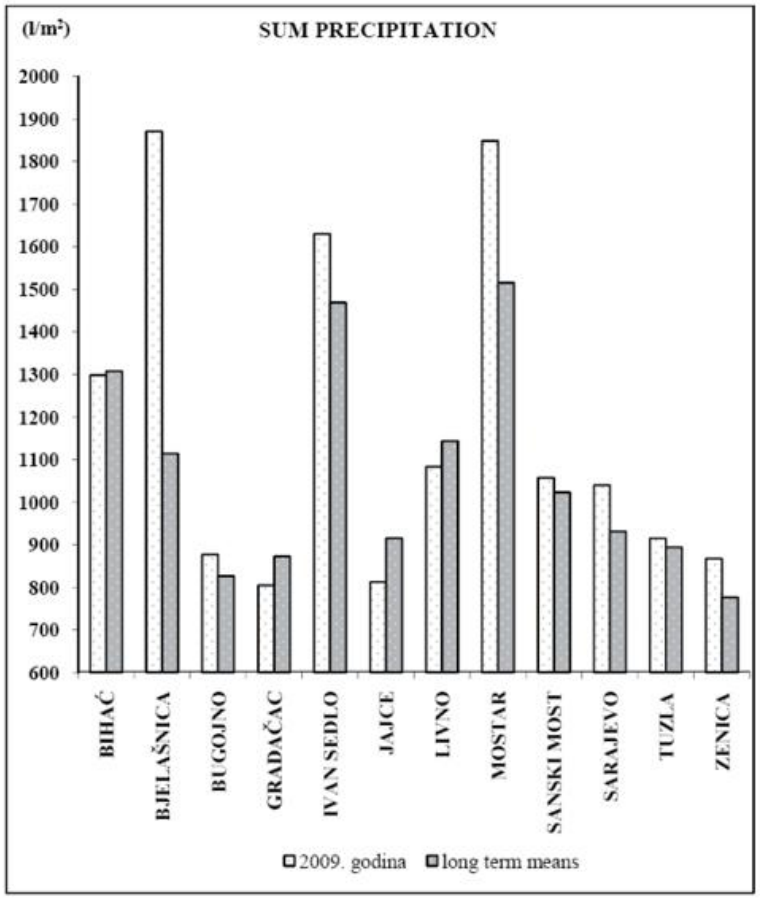

Fig. 0.19a: *2009 annual precipitation totals compared to the normal (long-term means) for stations in Bosnia and Herzegovina*

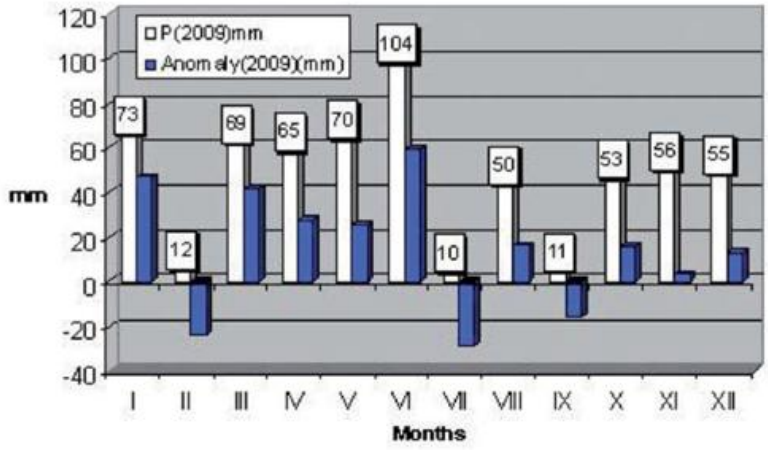

Fig. 0.19c: *2009 monthly precipitation totals and anomalies in Skopje Zajcev Rid (Macedonia), reference period 1983-1990*
Source: Hydrometeorological Service, Former Yugoslav Republic of Macedonia

Malta had extremely high precipitation in January and February. Then, after a usually dry summer, the year continued with a wet September and lower-than-normal precipitation for the rest of the year.

3.6. Eastern Europe

Precipitation totals in 2009 were generally close to average for most of eastern Europe with only a few areas well above or below. It was particularly wet over Belarus and western Russia (>125% of the annual normal). Only a few places in Moldova, the Ukraine and central European Russia reported a significant rainfall deficit between 60 and 80% of average, in a few cases even below. This set a new local record of lowest annual precipitation in Moldova with unfavourable effects on agriculture.

The whole of eastern Europe saw an extremely dry April, with eastern European Russia being also very dry in January/February, June/July and during the whole autumn. Belarus, the Ukraine, Moldova and parts of Romania had three very dry months (April, August and September; Fig. 0.20), causing drought conditions; the eastern Ukraine was also very dry in June. Eastern Europe was mainly very wet in March, October and December, triggering several flooding episodes e.g. in Romania.

In western Kazakhstan, the first half of the year featured a contrasting temporal pattern of rainfall. Winter was particularly dry, with areas receiving less than 40% of average precipitation, while spring rainfall was significantly above average, locally exceeding 160% of the normal.

3.7. Middle East and South Caucasus region

The western parts of the South Caucasus countries, Turkey (except south-eastern Anatolia), Cyprus and northern Jordan had above-normal precipitation in 2009. This brought an end to the 3-year drought period in Cyprus. Some places in Turkey recorded more than 150% of their annual average. Thus, 2009 has been the wettest year in Turkey since at least 1941, with 170 mm (27%) above the 1971-2000 average (Fig. 0.21).

Annual precipitation in western Syria and the Lebanon ranged between normal and slightly below normal.

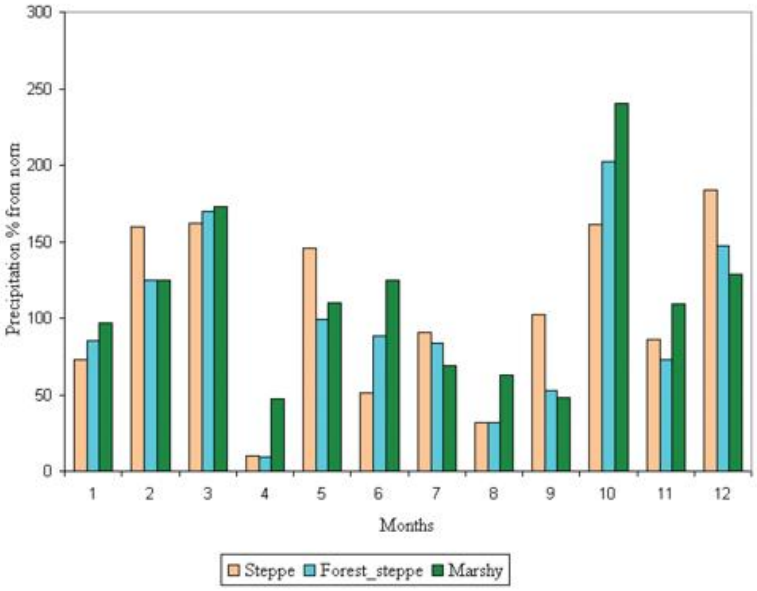

Fig. 0.20: *2009 monthly precipitation totals in per cent of the 1961-1990 normal for three vegetation zones in the Ukraine (steppe, forest-steppe, marshy)*
Source: Ukrainian Hydrometeorological Centre

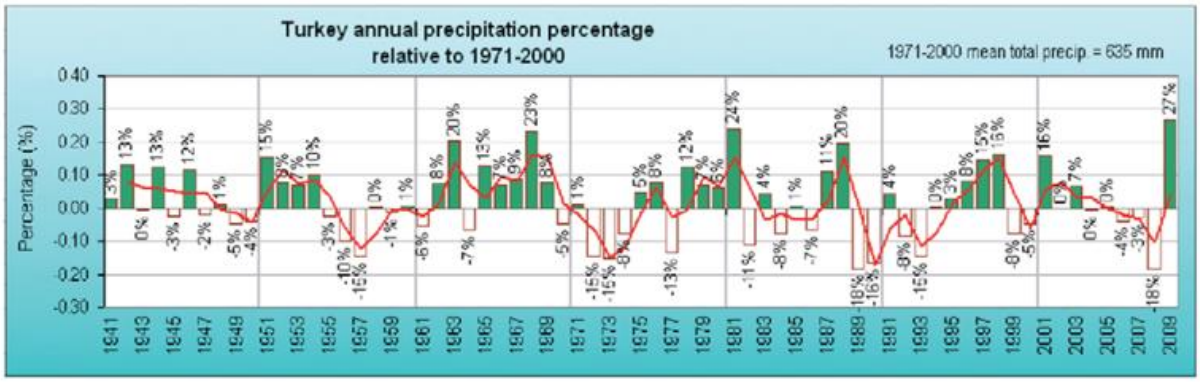

Fig. 0.21: *2009 annual mean precipitation in Turkey 1941-2009 in per cent of the 1971-2000 mean*
Source: Turkish State Meteorological Service

The southern Middle East was mainly dry, partly with less than 80% of the normal and, in the eastern parts of Jordan, even less than 40%. The spatial variability of precipitation anomalies, however, was quite high in Jordan, varying between up to more than 150 mm above or below the normal (Fig. 0.22). For the sixth year in succession, Israel's 2008/09 rainfall season delivered below-average rainfalls which resulted in water shortages and deteriorating quality of ground water reservoirs.

Armenia, which normally has a dry summer, experienced frequent showers in summer 2009; rainfalls were reported almost every day from July to September while October to December were drier than normal. Azerbaijan had very intense precipitation in August and September, spring and October, however, were dry. Turkey was very wet in February and partly in March, July, September, November and December, but dry in August. Cyprus was drier than normal in April, June, July and November and wetter than normal in the other 8 months, due to several heavy rains and hail storms except in summer. Most of the south-eastern Middle East (large

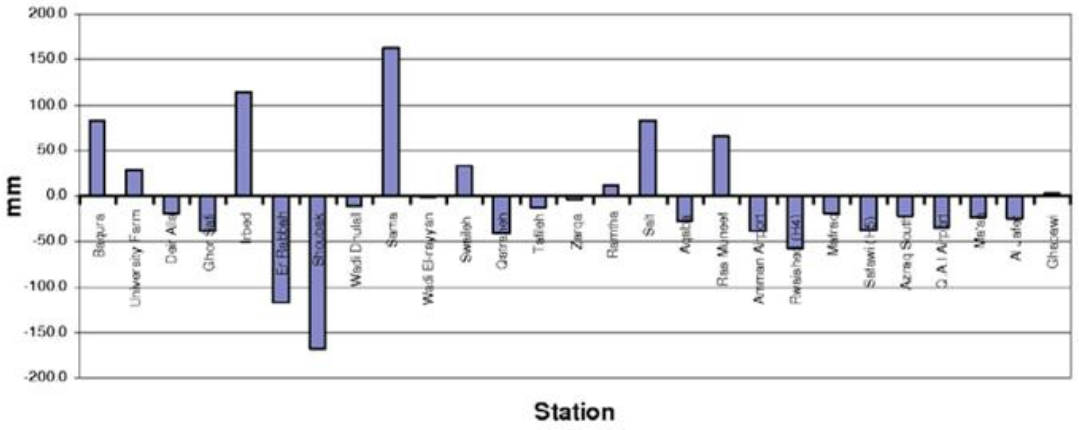

Fig. 0.22: *2009 annual precipitation anomalies at various stations in Jordan*
Source: Meteorological Department of the Hashemite Kingdom of Jordan

parts of Syria, Lebanon, Israel, Jordan) was particularly dry in January and April as opposed to more precipitation than normal including some severe rainfall in September and October, which meant an early start of the 2009/10 rainfall season.

4. Snow

In Iceland, the number of days throughout the year on which the ground was covered by snow was much lower than the 1961-90 normal (e.g. 40 days in Reykjavik compared to a normal of 65 days). The largest measured snow depth was 166 cm at the station Mýri in the northern inland on 18 January.

In Sweden, exceptionally high snow depths were recorded in February. Östersund recorded an average snow depth of 81 cm during February, which has been the highest monthly mean depth at this station since March 1988.

In the north-eastern areas of European Russia, the snow cover of the 2008/09 season persisted 20-38 days less than the long-term average in European Russia. Over most of the country, the maximum snow depth recorded in the season was below the 1961-90 normal; in some places, however, it was more than 40 cm above normal (Fig. 0.23).

5. Sunshine duration

The year 2009 was a sunny year for most of northern, western, central and southern Europe (Fig. 0.24). Most places within this area received 105-125% of normal annual sunshine, some stations 100-105% and only a few locations, mostly in higher elevations had below normal sunshine. Tórshavn on the Faroe Islands saw a new record of annual sunshine duration at 1139 hours (135% of the 1961-90 normal). The Malin Head station in Ireland has had its sunniest year since 1960. In the Netherlands, some places had more than 2000 sunshine hours that year, thus placing 2009 among the three sunniest years at these locations at least since 1908.

In contrast, nearly the whole of eastern Europe and the Middle East were dull compared to the normal, mostly with only 75-95% of the annual normal, in the easternmost parts of the Region even below 75%.

Northern, western and central Europe received more sunshine than normal already in January. It was the second sunniest January on record in Germany (behind 2006) and the Netherlands (behind 1940), respectively. In contrast, February was very dull in most of the Region except

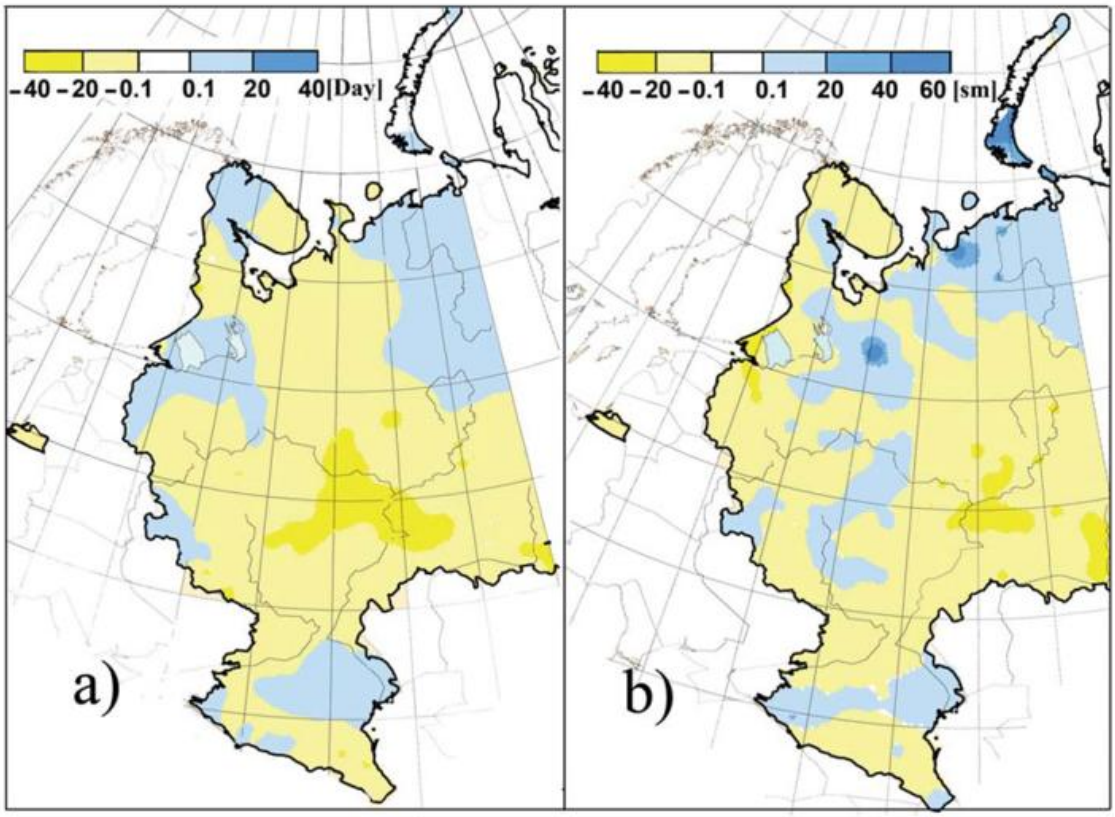

Fig. 0.23: *Snow cover anomalies in European Russia for the season 2008/09 (reference period 1961-1990) of a) the number of days with snow cover, b) the maximum snow depth in cm*
Source: Roshydromet, Russian Federation

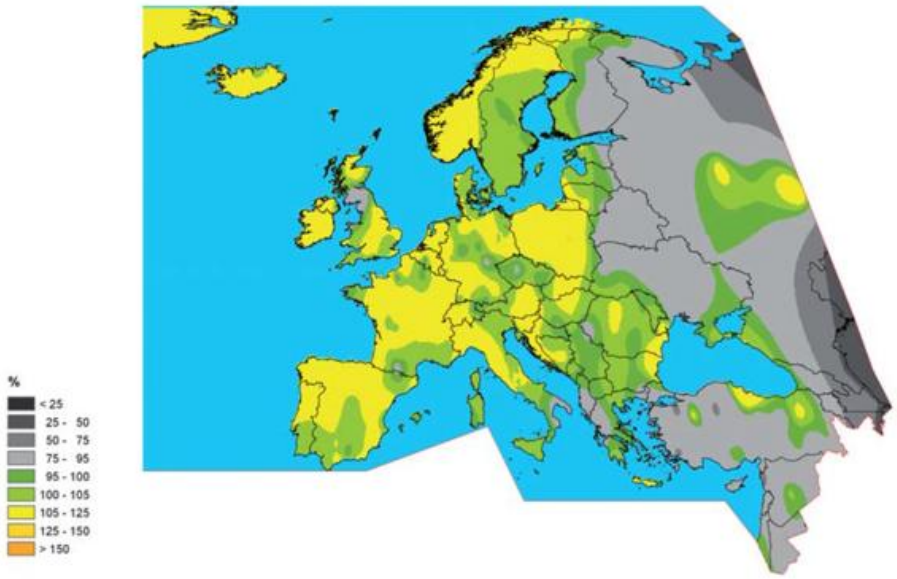

Fig. 0.24: *Annual sunshine duration in 2009 in per cent of the 1961-1990 normal in WMO Region VI (interpolation of CLIMAT data)*
Source: Deutscher Wetterdienst, Germany

south-western and northern Europe. In Germany, it has been the dullest February since 1970, in England and Wales the dullest since 1993, in Belgium (Brussels-Uccle) the second dullest since 1887 (behind 2006, Fig. 0.25). In March, especially the whole of western Europe was sunny and places in northern England received more than 170% of the monthly normal.

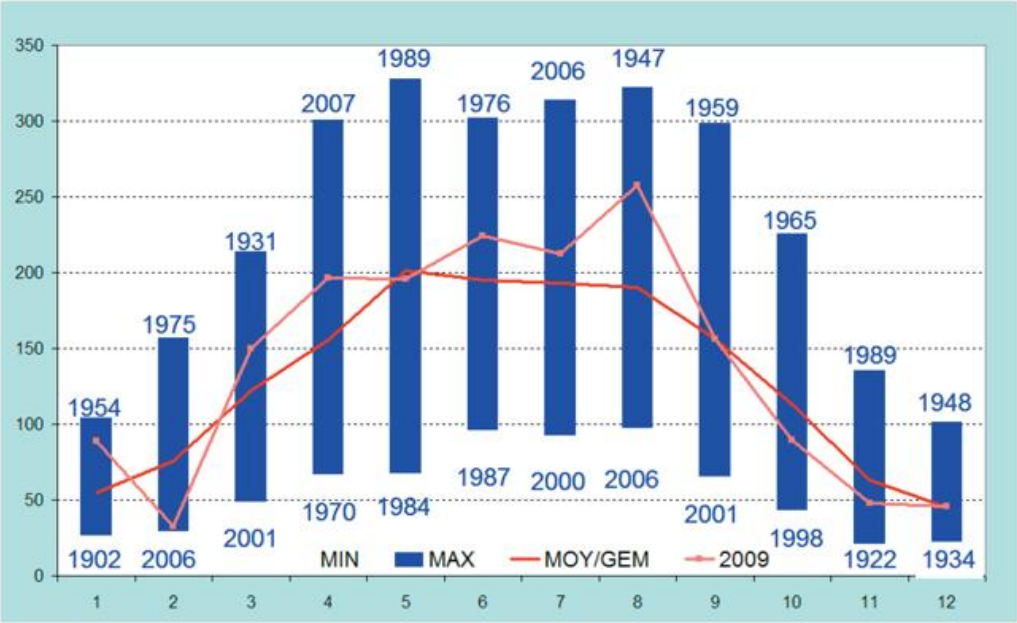

Fig. 0.25: *Monthly sunshine duration in 2009 in hours (pink line) in Brussels-Uccle, Belgium, compared to the 1901-2000 average (red line) and absolute monthly maxima and minima (bars, with years of maximum/minimum indicated)*
Source: Royal Meteorological Institute of Belgium

April, with its very extensive high pressure situation, was sunny over large areas, particularly in eastern central Europe with more than 150% of the normal, partly even 200%, e.g. in places in north-eastern Germany. It was the sunniest April on record in Denmark (272 hours of sunshine as compared with a normal of 162 hours) and locally in Sweden, and the second sunniest April in Germany, Austria and in some places of Slovenia since at least 1951.

During the summer half year, notably the months May, August and September were mostly sunnier than normal, June and July only partly. June sunshine in the United Kingdom was 120% of the normal, in the north partly 150%. In some places in Ireland, it has been the sunniest June for over 50 years. New records of August sunshine duration were measured e.g. in Berlin, Germany (295 hours, normal 197), and it was the second sunniest August in Germany as a whole since 1951 (behind August 2003) and the third sunniest August in Ljubljana/Slovenia. Malta in the Mediterranean was sunnier than normal during the whole warm season (May-August).

October was sunny in northern and south-western Europe and south of the Alps, but mainly dull in most of the other parts of the Region. November was extremely dull (partly <25% of the monthly normal sunshine duration) in most of northern and eastern Europe and dull in western Europe, but sunny in most of the Mediterranean region. December was dull nearly everywhere in the Region except the north-west and a few other places in the Region. Remarkably, it has been the second sunniest December on record in the United Kingdom since 1929.

6. Wind

The Nordic Region was hit by some significant storms that locally caused damage and even casualties. Three of them (occurring in June, July and November) were particularly severe. The highest mean wind speed measured in 2009 on some maritime stations in Norway was 96 km/h on 4 November.

Although a few storms had a high intensity, however, the number of heavy storms in northern Europe was quite low that year. In Iceland, easterly winds have been more prevalent than in any year since 1985, and the north to south pressure gradient was stronger than average, sign of a higher mean wind speed than usual, but the number of damaging windstorms remained considerably below average. A record-breaking 13-month storm-free period over Swedish coastal waters ended on 25 December when local stormy winds up to 90 km/h (mean wind speed) swept the Swedish east coast. Denmark did not report any severe storms. Finland likewise had less storm activity than usual; the number of stormy days (wind speed >75 km/h) was only 11, compared to the long-term average of 23. Latvia recorded both below normal mean and maximum annual wind speeds.

Mean wind speeds were higher than normal in north-western Europe, but lower on the continent. Annual mean wind speeds in Ireland were between 13 and 22 km/h, locally exceeding the normal and maximum annual values for up to 15 years. Not far away, in Belgium, the mean annual wind speed was lower than normal with 12.2 km/h (normal: 13.3 km/h); such an anomaly is expected only once in 10 years. The same was observed in Luxembourg (annual mean: 12.4 km/h, normal 14.0 km/h).

In January and February, a few severe winter storms mostly affected the western parts of Europe. The heaviest one was storm Klaus which hit south-western France and northern Spain in late January with gusts up to 193 km/h in the Pyrenees. Another storm in January with gusts up to 174 km/h affected Ireland.

Between May and July, some heavy thunderstorms swept across western and central Europe, locally with tornadoes. Unusually frequent thunderstorms were also recorded in Armenia in June and July with gusts up to 110 km/h. In Georgia, 12 strong wind gust events were recorded during the whole year, which has been the by far highest number since 1995 (Fig. 0.26). Azerbaijan also experienced strong gusts up to 108 km/h especially in April.

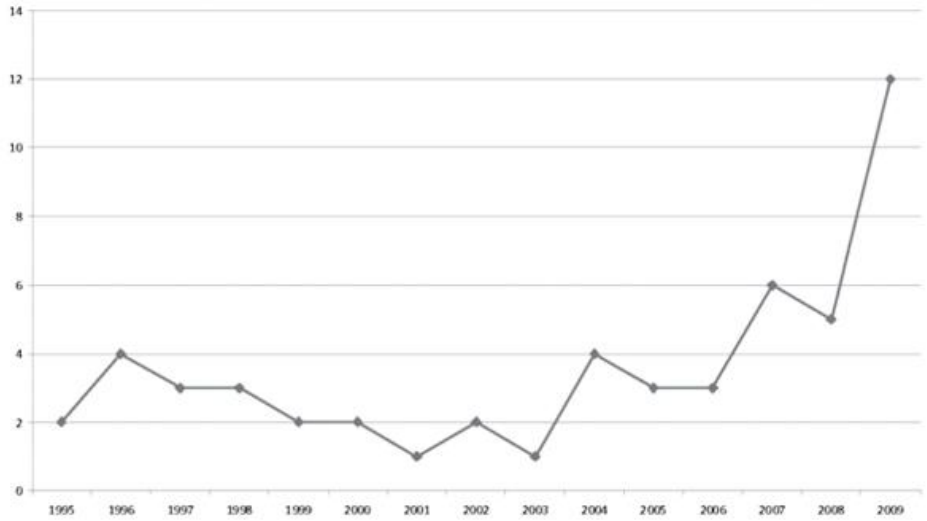

Fig. 0.26: *Number of strong wind gust events (causing significant damage) per year in Georgia 1995-2009*
Source: The State Department of Hydrometeorology of Georgia

In September and October, several severe thunderstorms hit mainly southern Europe.

Ex-tropical storm Danny crossed the North Sea in early October causing gusts near hurricane force. Another tropical storm (Grace) formed near the Azores islands in October, approaching England in a north-easterly direction; but it did not cause any serious damage.

An unusually high number of storm events occurred in Turkey in 2009. Cyprus likewise reported several severe storms and tornadoes throughout the year.

7. Sea ice

As documented by satellite data, the extent of the whole Arctic area covered by sea-ice in September 2009 has been the third lowest since 1979 (behind 2007 and 2008) with 5.1 million km² or 76% of the long-term mean of 1979-2000. This once more small sea ice extent was also due to the ongoing anomalous warmth of the European Arctic region in 2009. The cold April in the European Arctic, however, delayed the spring melting compared to the previous years 2007 and 2008. The annual maximum extent in March 2009 was about the same as in 2008; in April 2009, it was slightly higher than in April 2008.

Seasonal Survey

Temperature

All seasons were warmer than normal in most of the Region, though more or less with some colder-than-normal areas.

Winter 2008/09 showed mild temperatures over the Arctic and eastern Europe, with peak anomalies > +4°C in Svalbard, north-west Russia and Finland (see section "Seasonal Maps" Fig. S39) . It was also warmer than normal over most of the North Atlantic, central Scandinavia, eastern central and south-eastern Europe and the Middle East, but with smaller anomalies (< +2°C, only locally higher). In northern and central Europe, however, that winter was not as mild as previous winters. Anomalies in Denmark, for example, were +1°C, which is much less than in 2006/07 and 2007/08, when anomalies exceeded +4°C. Nevertheless, the warming of the central North Atlantic exceeded the 98% percentile. In Bulgaria and Montenegro, some locations recorded their warmest winter ever. Serbia reported a smaller number of freezing days than normal, especially in mountainous areas.

Western Europe, parts of central and south-western Europe including the western Mediterranean and parts of Italy were colder than normal. Anomalies were lowest in France and in high alpine regions (< -1°C) and only slightly below zero in other areas, but mostly not below the 10% percentile. The winter of 2008/2009[1] has been the coldest in the UK since 1996/1997, with a seasonal mean of 3.2°C. France had its 3rd coldest winter in 20 years and it was also one of the coldest winters within that period in Switzerland. It has actually been the coldest winter for 22 years on the Jungfraujoch in Switzerland. Severe cold waves during January and February brought temperatures of -25°C (and below) to Germany and Poland, and below -10°C to Belgium. Several cold spells in January and February also affected Iberia.

The warming of the central North Atlantic and the northern latitudes was mainly due to a stronger-than-normal south-westerly flow of mild air over the central North Atlantic which continued to move to the north. The NAO index was slightly negative due to negative values in December 2008 and, in particular, in February 2009, as the sign of a more meridional circulation during most of the winter with less mild westerlies flowing to western Europe followed by lower-than-normal temperatures there. A stronger-than-normal Siberian high led to a more intense blocking and a stronger-than-normal southerly flow of subtropical air to the Middle East and into eastern Europe.

Spring 2009 was very warm in most of Europe, although somewhat less in the east. Anomalies exceeded +2°C or the 90% percentile particularly in the central parts of central Europe, the Alps, northern Italy, the north-western Balkan Peninsula and in some places in northern and southern Europe and over the North Atlantic (Fig. S40).

In western Norway, it was the warmest spring ever registered. There were only 8 frost days in Denmark that spring, as compared with usually 22 days. The Netherlands, Belgium (Brussels-Uccle) and Switzerland reported their 2nd warmest spring in more than a hundred years (behind 2007, Fig. 0.27), Germany its 3rd warmest since 1901 behind 2007 and 2000. Some places in Slovenia had their 2nd or 3rd warmest springs ever recorded.

Especially April was outstandingly warm in central and northern Europe whereas May was warm in southern Europe and in the Alpine region. Two heat waves occurred in Portugal (March and May).

Source: MeteoSwiss, Switzerland

It was slightly or insignificantly colder than normal in the Caucasus region, in Turkey and partly along the coasts of Greenland.

The warming over Europe was mainly due to a large ridge dominating over the area during most of the season, whereas the Caucasus region lay mostly on the east flank of that high and in the flow of colder air from the north.

Summer 2009 was also warmer than normal over almost the whole of Europe and the Middle East, with partly smaller anomalies, however, than during the spring (Fig. S41).

In most of the northern half of Europe, anomalies were only slightly above zero (< +1°C), in some places they were even below zero. Large parts of the northern North Atlantic and western Greenland as well as land areas near the North Sea, especially western Norway and Denmark, were significantly warmer than normal, with a deviation of more than +1°C and even more than +2°C on the western coasts of Greenland. Northern Europe had some outstandingly warm spells; with some stations in Norway reporting new daily maximum temperature records.

Most of northern and central Europe started with a cold June, but became much warmer in the following summer months. Finland was mainly cold in June and July, but warm in August. The Baltic countries also started with a cold June, and warmed up only gradually and later than usual. Latvia had near-normal summer temperatures, although the highest maxima were well below the long-term average. In central Europe, the summer was characterised by a large variability of warm and cool periods, but here, too, a cool June was followed by a warmer July and a particularly warm August.

In the easternmost parts of the Region (eastern European Russia, eastern Ukraine, west Kazakhstan, Caucasus region), it was quite the contrary: after a very warm June, it became cool during the remaining summer from the north to the south. Monthly mean temperature anomalies reached +3°C in the Ukraine during June and July, with a highest daily maximum temperature of 40°C. Mean summer temperature anomalies exceeded +1°C in Romania and Moldova, while anomalies in European Russia (+0.5°C) and Belarus were closer to normal; only July was considerably warmer than normal in Belarus. Eastern Turkey and Armenia saw a rather cool summer (anomalies < -1°C). In Armenia, it was the first cool summer since 1995.

The southern half of Europe and the Middle East mainly had higher positive anomalies than the north. The anomalies were greater than +1°C, in some places even +2°C, exceeding the 98% percentile. The number of tropical nights was above normal in the Mediterranean region. On the other hand, the central North Atlantic was more than -1°C colder.

A significant heat wave affected the whole of western Europe during July; another one in France from 15–20 August resulted in temperatures above 36°C in the north and 40°C in the south of the country. Italy also saw a heat wave in July, with temperatures locally reaching 45°C. Iberia, too, experienced several heat waves during the summer. The summer of 2009 has brought record mean temperatures relative to the last 50 years to many stations in Catalonia as well as to other parts of northern and central Iberia. Spain as a whole has had the third warmest summer since 1970 (behind 2003 and 2005). Portugal saw three heat waves during that summer.

In south-eastern Europe, Slovenia had a higher-than-normal number of hot days, but no extremely high temperature maxima. Serbia, too, had a very hot summer; daily maxima above 30°C were measured much more often than normal, except in the mountains. In Mostar (Bosnia and Herzegovina), it was the warmest summer on record. In Cyprus, several heat waves were recorded in all summer months, most of them in July.

The warm summer in most of the Region was due to the high pressure influence which prevailed particularly over the southern half of the continent, while the north profited from a still warm North Atlantic and a quite weak Icelandic low during the season. The Azores high was weaker than normal and shifted to the south, with the result that the central North Atlantic was more affected by cold air masses from the north than usual. In the east of the Region, cold arctic air penetrated from the north into the south.

Autumn 2009 was another very warm season throughout nearly the whole Region, particularly in central and eastern Europe (Fig. S42). Seasonal anomalies were highest in the Arctic, with up to +4°C above the normal. In many other parts of the Region, anomalies were still greater than +1°C, partly exceeding the 90% percentile, in places particularly in eastern Europe more than +2°C.

Several countries reported their 2nd (France, Belgium) or 3rd warmest autumn (Netherlands, Switzerland, Spain) in at least 40 years, partly even in more than 100 years. However, autumn 2006 was even warmer in all these countries.

September and November were extremely mild months in most of Europe, especially throughout eastern Europe, with temperatures generally above the 90th percentile of the 1961-1990 distribution. October was very cold notably in northern Europe, but this did not compensate the warm September and November months. In Iberia, October was very warm and contributed much to the warm autumn there. Portugal saw heat waves in September and October.

Conditions colder than the autumn average were restricted to some small places in southern Norway, over the central North Atlantic, in the Mediterranean and eastern Turkey.

This autumn warming mainly resulted from a strong south-westerly flow of warm air to most parts of Europe which predominated throughout the whole season.

Precipitation

Precipitation patterns show a high spatial variability changing from season to season. Dry conditions predominated in winter and spring, wet conditions in summer and autumn, but with many regional exceptions.

Winter 2008/09 was drier than normal over most of western, central and northern Europe due to the predominating high pressure influence (Fig. S43a). It was also drier than normal over large parts of eastern European Russia and the Middle East which were much influenced by the Siberian high. Seasonal totals were below 80% in many places. Winter in Denmark was particularly characterized by well-below-average precipitation, recording only 66% of its average 1961-1990 total for the season.

The southern slopes of the Alps, the central Mediterranean and south-eastern Europe received considerably-above-average precipitation and increased winter storm activity. It was particularly wet in the southern Alps, Italy and over parts of the Balkan Peninsula due to a persistent cyclone over the central Mediterranean, locally with seasonal totals of more than 125% of the normal (in the Alps more than 200%) especially in January due to high precipitation amounts.

The snow period in the winter of 2008/09 was longer in most of the Region and especially in many parts of the middle and southern latitudes (Fig. 0.28). In western Europe, snow was rare in the lowlands due to little precipitation. However, some heavy snowfall occurred in western and central Europe particularly in February. Parts of the northern Alpine region saw peak snow depths of over four meters. Altogether, the amount of fresh snow in Austria came back to normal conditions after the previous two winters with little snow. Snowfall also occurred frequently south of the Alps and even in low-altitude coastal regions of Portugal - which is highly unusual for these areas. In some of the lowlands of Slovenia and in Serbia, the number of days with snow cover was smaller than normal. Armenia received below-normal snow depths, i.e. 80% of the 1961-1990 average.

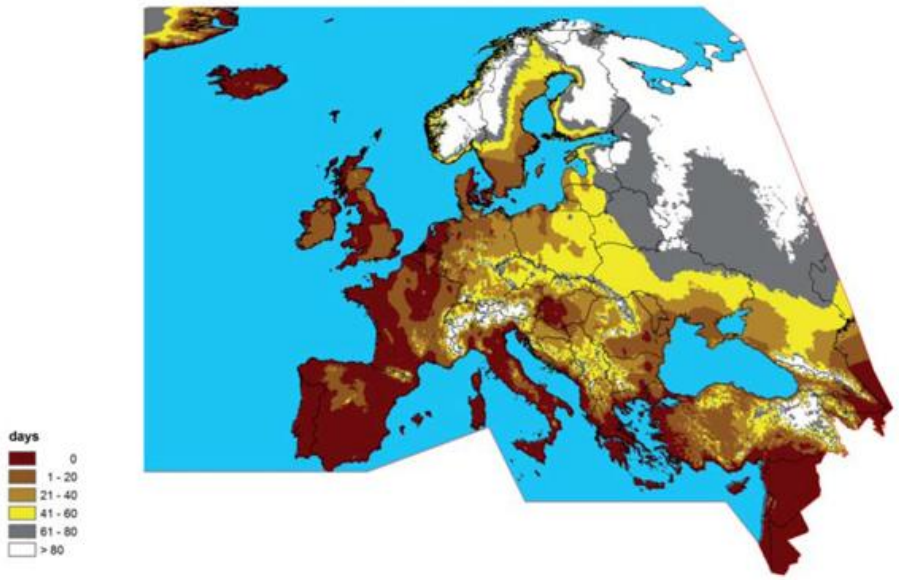

Fig. 0.28: *Number of snow days (number of days with at least 1 cm of snow cover on the ground) in Europe in winter 2008/9*
Source: Deutscher Wetterdienst, Germany

Spring 2009 was dry in most of the Region due to predominating high pressure influence (Fig. S43b). Various larger areas received less than 80% of the seasonal total. Places in eastern Scandinavia and in the Baltic countries, in particular, saw a precipitation total of less than

25 mm or less than 60% of the seasonal normal. It has been the driest spring since 1997 in England and Wales.

In most of central Europe, spring precipitation was near normal. The reason for this is that a dry April (particularly in eastern parts) was compensated by the mostly wet months of March and May. In the Alps, spring 2009 started wintry with much snowfall in March and record-breaking amounts of precipitation in eastern Austria. May brought intense convective precipitation to parts of central Europe and to Slovenia.

In eastern Europe, spring was particularly dry in Moldova, where some areas received only 50 to 75% of the average seasonal rainfall. Parts of Romania and the Ukraine were also very dry.

In the south, especially Iberia (except the south-east), the Balkan Peninsula and the Middle East all had a very dry spring with less than 50 mm or 80% of the seasonal total; some places even received much less. It was the driest spring since 1931 in Portugal, with well below normal precipitation in all three spring months.

Some smaller areas throughout the Region (in the north particularly the southern coasts of Greenland and Iceland and the north-western and northern coasts of Ireland, the United Kingdom and northern Norway) were wet, with more than 125% of the seasonal normal. These areas were affected by a stronger-than-normal Icelandic low. In the south, especially Italy, but also parts of Turkey and southern European Russia, was concerned with local excessive rain due to much convective activity particularly in March. Monaco had a very wet April, but a very dry May.

Summer 2009 was wetter than normal in large parts of the northern half of Europe except the Arctic, partly with more than 125% of the seasonal totals due to frequent low pressure influence (Fig. S44a). On the contrary, large areas in the south and east were very dry.

Summer was dry in the Arctic and in western Iceland. In western Greenland, especially July and August were very dry. In Iceland, it was especially the first part of the summer (June and July) which was very dry in the southern and western part of the island. The summer has been the driest for the capital, Reykjavik, since 1889. The northern Norwegian coasts were more or less dry in all summer months.

In southern Scandinavia, especially the southern parts of Norway and Sweden were very wet, mainly due to much rain in July.

North-eastern Europe received most of its rain in early summer already, often with sporadic heavy showers and sometimes with hail. Summer was unusually wet in Belarus (second wettest since 1936), mainly due to well-above-average precipitation during June and July.

The year 2009 brought the third consecutive wet summer to Ireland and the United Kingdom, behind 2007 and 2008, that had mostly been even wetter. Despite this, some total rainfall records were by far broken in Ireland, e.g. at Valentia Observatory with a seasonal total of 620 mm (Fig. 0.29). Ireland reported rainfall on almost every day during July and August. On 6 June and 16 -17 July, the United Kingdom experienced daily totals of more than 90 mm.

Western and central Europe, and even the northern parts of south-eastern Europe were affected by some severe thunderstorms, accompanied by heavy rain and hail and causing local flooding. Luxembourg Airport recorded 23 days with thunderstorms, which is well above the 1971-2000 mean of 14 days. Nevertheless, the seasonal precipitation total was low in most of these areas.

In Austria and northern Slovenia, summer was wet due to some heavy precipitation events; especially in the east; it has been the rainiest summer in Austria since 1966.

The eastern Ukraine and parts of southern European Russia were very dry; these areas had less than 50 mm or 40-80% of the normal.

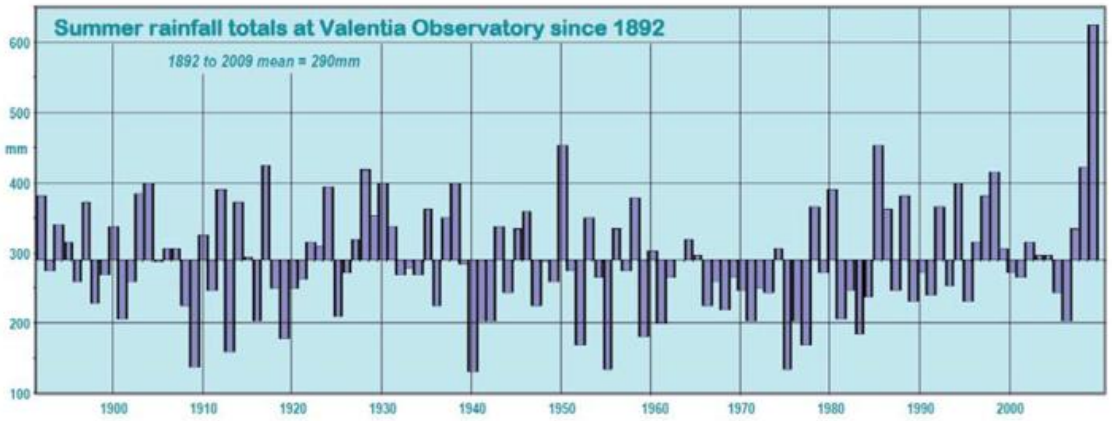

Fig. 0.29: *Summer rainfall totals at Valentia Observatory (Ireland) 1892-2009. The bars indicate anomalies compared to the long-term mean 1892-2009*
Source: Irish Meteorological Service

In the south, few regions were affected by higher-than-normal precipitation, particularly areas in southern Italy, the southern Balkan Peninsula, parts of eastern Turkey and in Armenia. The seasonal summer total in Armenia exceeded the 1961-1990 normal by 50%; the south-west of the country recorded even more than twice the normal precipitation (Fig. 0.30).

Most of the Mediterranean region and Iberia, however, were drier than normal due to frequent high pressure influence. Southern Iberia and eastern parts of the Mediterranean received less than 10 mm during the whole season which was partly less than 60% of the normal. Monaco had a summer total of 12 mm, only 14% of the 1969-1998 average.

The new DWD drought index for summer 2009 (Fig. 0.31) shows extremely dry conditions in the Middle East and locally severely dry conditions for southern Iberia, some places in the eastern Mediterranean and in the eastern Ukraine. Compared to the 1961-1990 reference, drought conditions were more severe than normal in the eastern Ukraine, whereas in the other affected areas this effect was not unusual.

Autumn 2009 showed very diverse precipitation anomalies throughout the Region (Fig. S44b).

Most of northern Europe had around-normal precipitation. However, northern middle latitudes were wet, with more than 125% of the seasonal total in many places due to frequent low pressure systems crossing these areas. In western and central Europe, there were also some heavy rain events with flooding.

In Germany, Switzerland, Austria and the Czech Republic, early snow fell in October, but melted again during the warm November even in higher elevations.

Eastern Europe was mainly wetter than normal, though with some very dry areas in the Ukraine and in central and eastern European Russia. Large parts of central European Russia had less than 25 mm or below 60% of the seasonal precipitation.

Abundant rainfall occurred in southern Italy and Sardinia in September and October, whereas drier-than-average conditions were to be found in Tuscany and north-eastern Italy, but also on the western Balkan Peninsula. Monaco had a near-normal seasonal total, but the seasonal maximum precipitation (normally in October) was shifted to the end of the year. Autumn was very wet in the southern and eastern parts of the Balkan Peninsula, near the eastern Mediterranean and in the northern Middle East. Israel, too, had very heavy rainfall during September and October, marking an early start of the 2009/10 rainy season.

South-western Europe (still affected by the Azores high), including the western Mediterranean, large parts of France and areas around the Alps was very dry. Especially Iberia experienced

another very dry season after having seen a dry spring and summer, partly with less than 60% of the seasonal total or less than 50 mm. Averaged across Iberia, autumn seasonal mean deficits were similar to spring and summer, although some regions, such as the southern Mediterranean coast, were much wetter than normal.

In general, autumn showed extreme temporal and spatial variation. While most of eastern and south-eastern Europe saw a very wet October, north-western Europe had exceptional precipitation in November.

Monthly Surveys

January

- **Milder than usual in northern and eastern Europe, cold in western and central Europe**
- **Extreme cold spell in the first ten days affecting large parts of Europe**
- **Dry in northern Scandinavia, central Europe and the Middle East, very wet over the central Mediterranean**

Atmospheric circulation characteristics

A strong westerly airflow prevailed over the North Atlantic whereas most of the European continent was frequently affected by high pressure. Both the Icelandic low and the Azores high were stronger than normal. For this reason, the Atlantic airflow was often blocked by the high pressure over Europe, and mild air flowed into the Arctic regions, northern and eastern Europe. Only in the first ten days, a large trough with polar air affected northern and north-eastern Europe. At its rear, very cold arctic air came into central Europe, and a cut-off low brought heavy snowfalls even to the Mediterranean.

In general, the central parts of Europe were mostly affected by cold and dry continental air, whereas some of the Atlantic low pressure systems (some of them were quite severe) at least touched the western parts of Europe. In some cases, these systems with snowfalls even crossed the whole of western and central Europe and extended far to the south, especially during the first and the last ten days of the month.

South-eastern Europe, in contrast, was often under a warm and moist airflow from subtropical latitudes south of the high pressure zone with much low pressure activity over the Mediterranean. At the same time, the Middle East was often under high pressure influence. At the beginning of the month, however, cold air reached even Turkey.

Temperature

The year 2009 began with a very mild January in the Arctic, Scandinavia and eastern Europe, with monthly mean anomalies partly exceeding +4°C (Fig. 1.1), e.g. +4.8°C in Egedesminde in Greenland, +4.4°C in St. Petersburg in Russia and up to +5.3°C in eastern Estonia (Fig. 1.2). Maximum temperatures in southern Greenland partly exceeded 10°C.

In north-western Europe, January temperatures were around normal over most of the United Kingdom as a whole, but it has been the coldest January for England and Wales since 1997.

Western, south-western and central Europe as well as northern parts of south-eastern Europe all saw a cold January. Anomalies below -2°C, locally even -3°C, were recorded notably in large parts of northern France, Belgium, Luxembourg, in the southern half of Germany and parts of Austria. It was the coldest month in France for 20 years and the coldest January in the Netherlands in more than 10 years. The number of ice days in central Europe was higher than normal. Especially in Germany, after two very mild winters, January 2009 has been the first winter month since February 2006 which was colder than normal. Water areas near the North German coasts had cooled to 1-3°C at the end of the month, and ice formed temporarily. In south-western Europe, Spain recorded minimum temperatures below zero in many places, e.g. in Madrid (600 m altitude).

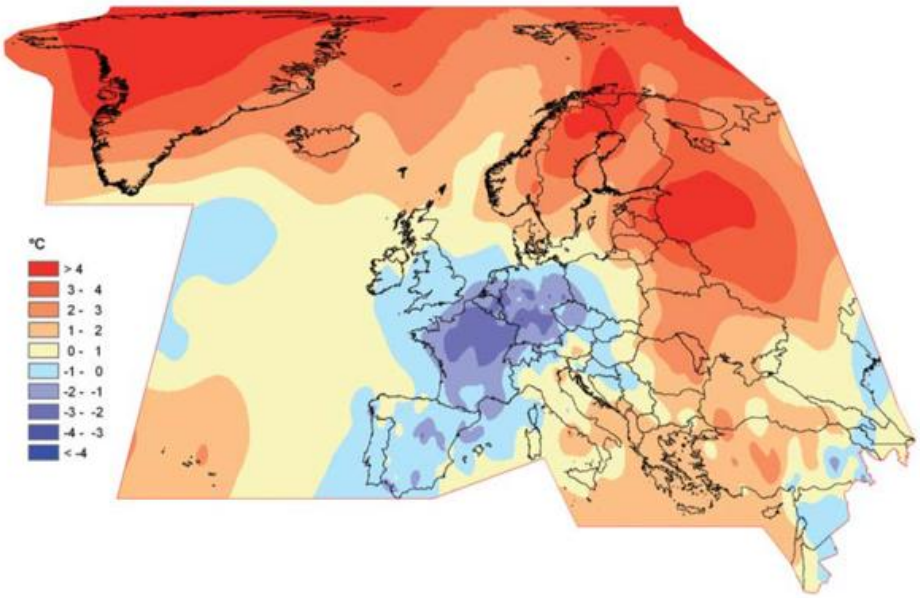

Fig. 1.1: *Monthly mean temperature anomalies in January 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

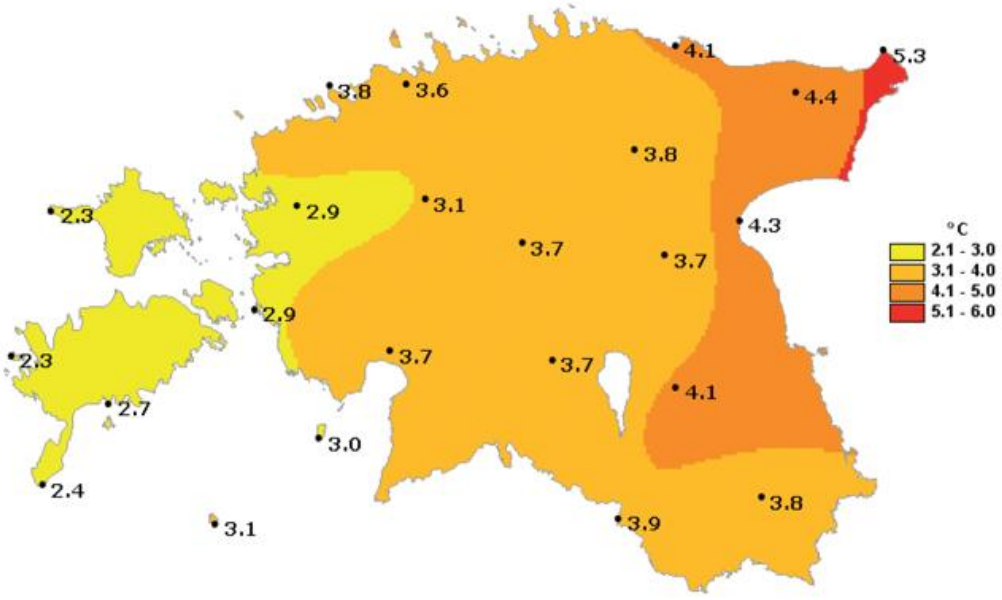

Fig. 1.2: *Monthly mean temperature anomalies in January 2009 (reference period 1961-1990) in Estonia*
Source: Estonian Meteorological and Hydrological Institute

A severe cold spell hit most of Europe in the first half of the month. The lowest monthly and annual minimum recorded at Norwegian arctic stations was -38.6°C. Northern and eastern Europe, too, saw quite low minima (e.g. central Sweden, Finland, European Russia and eastern Ukraine below -30°C, Lithuania below -25°C). Northern European Russia, however, became very mild later in the month and some new records of daily maxima were set in the north-western areas of the country.

Large parts of western and central Europe reported several-day-long periods with daily minima between -10 and -15°C. Absolute minima of the month dropped even to -20°C and below in many places from the Netherlands to Hungary. Extremely low, at several stations record-breaking temperatures below -28°C were measured in Germany and Poland on 7 January. Some rivers in northern Germany froze over including parts of the river Elbe.

In Austria, the cold spell started a few days later on 10 January. The Danube storage reservoirs and ports froze to a depth up to 30 cm, causing economical losses. The cold weather caused an inversion situation; smog alert was issued e.g. in Budapest on 10 January. In many places in southern and south-eastern Europe, daily minimum temperatures also dropped to low values, e.g. -17°C in Bulgaria, -10°C and below in mountainous regions in Spain (lowest value -13.4°C on 12 January) and -8.6°C in Portugal.

Some areas in the Middle East, including the western part of eastern Turkey, parts of the South Caucasus countries and western Kazakhstan were also colder than normal. In Turkey, minimum temperatures dropped to around -20°C at altitudes around 1000 m on 2 January after a far-reaching advance of cold air to the south locally causing new minimum January records below -25°. Azerbaijan also recorded minima around -20°C. In Jordan, the minimum temperature fell to -9.8°C on 4 January.

January 2009, however, also saw some warmer-than-normal areas in the southern parts of the Region (some of which were more than +1°C, in places even more than +2°C warmer than normal, namely the eastern Mediterranean region and the Azores Islands).

Precipitation

It was very dry in northern Scandinavia, central Europe, southern European Russia and the Middle East (Fig. 1.3). Over large areas, the monthly totals were below 60% of the normal, in Israel and Jordan even below 20%. It was one of the driest Januarys in the 70-year measurement history in Israel (Fig. 1.4).

Wetter-than-normal areas were found in southern Greenland and Iceland and in most of western, eastern, south-eastern and southern Europe. Ireland reported its highest January rainfall since 1974, with a total of 291 mm (including a 12-day period with more than 10 mm). South-eastern Austria received more than 300% of its monthly normal, the highest amount since 1979. In some places in Slovenia, it was the 2nd or 3rd wettest January on record. More than twice the normal precipitation also fell particularly in southern Italy and other parts of the central Mediterranean, on the Adriatic coast of the Balkan Peninsula, in parts of north-eastern Slovenia, on the southern Balkan Peninsula in Bulgaria, the Former Yugoslaw Republic of Macedonia, Greece, in Cyprus as well as in south-western Europe, e.g. Portugal. Italian stations reported several record-breaking precipitation totals of up to 362 mm or 4 times the normal. Luqa Airport on Malta has received its highest monthly January rainfall total in 85 years (247 mm).

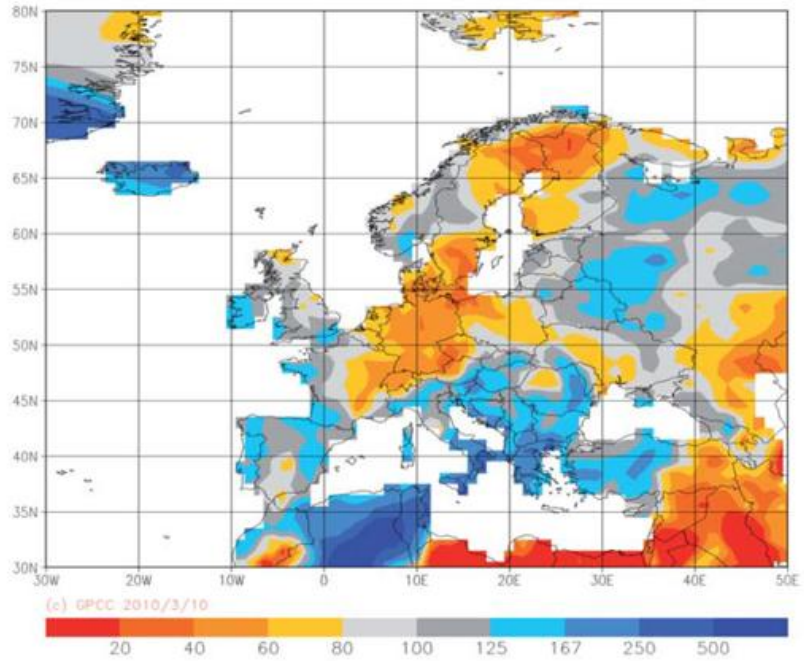

Fig. 1.3: *Monthly precipitation amounts for January 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*

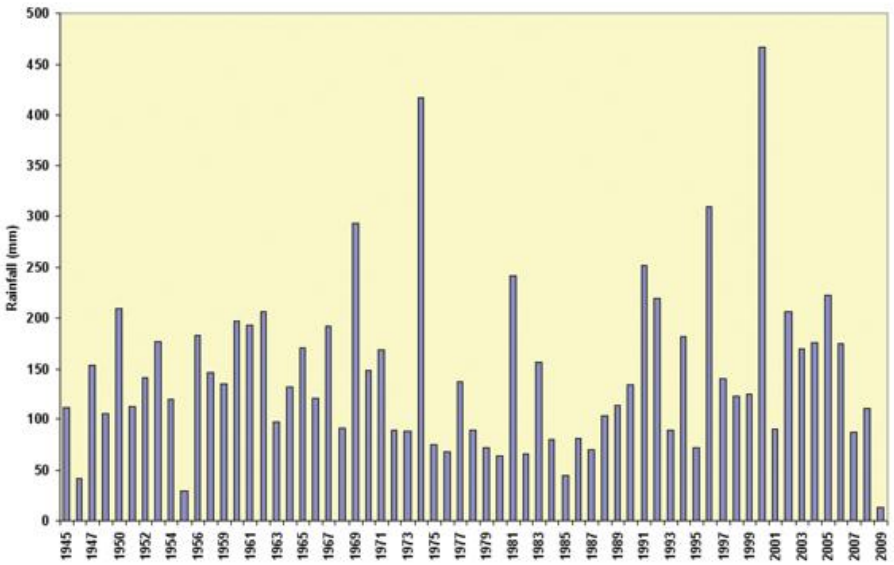

Fig. 1.4: *Monthly rainfall for January 1945-2009 in Tel Aviv, Israel*
Source: Israel Meteorological Service

Snow

In the north, much snow (up to 166 cm) was recorded in Iceland in the middle of the month after some heavy snow showers. In Kaunas (Lithuania), a heavy snow shower of 29.8 mm in 12 hours increased the snow cover by 44 cm.

At the beginning of the month, snow blankets formed after a winter storm over large parts of Europe, especially in the United Kingdom, France and Germany, in places reaching a snow depth of more than 30 cm. Due to the following cold spell, the snow cover persisted in central Europe at least until the middle of the month. Many flights had to be cancelled due to heavy snow. The Eiffel Tower in Paris had to be closed due to slippery icy conditions. Snowfall even reached southern parts of Europe; Marseilles in southern France has had its heaviest snowfall in 20 years; the Rhône river delta received 20-40 cm of snow on 6-7 January. Even Madrid in Spain was affected by up to 10 cm of snow, causing disruption of traffic on road and rail. New records in the number of snow days in Spain in January were reached, e.g. in León (14 days, highest since 1938, about 800 m elevation) and Ávila (11 days, highest for about 20 years, 1100 m). In Portugal, snowfall occurred on 29 January even in coastal and low latitude regions where this kind of weather phenomenon is very rare.

In the Alps, large amounts of snow were found especially in the south-eastern parts of Austria. Later in the month, on 27 January, a period with abundant snowfall started there. The snow load caused much damage on trees and power lines. Preitenegg in Austria at the south-eastern slope of the Alps reported 83 cm of fresh snow. A snow cover of 380 cm was measured on Kredarica Mountain in Slovenia; it was the third greatest snow depth in January on record there. In Hungary, snow in the second half of the month caused serious damage to power lines in parts of the country.

The outbreak of cold air from northern Europe also brought abundant snowfall over northern Italy from 3 - 10 January. On 7 January, Milan reported a snow depth of 26 cm (Fig. 1.5) which led to a temporary closing of airports. Other locations in the Po Valley recorded even more than 35 cm.

Fig. 1.5: *Milan under snow in January 2009*
Source: CNMCA (Centro Nazionale de Meteorologia e Climatologia Aeronautica, National Centre of Meteorology and Aeronautical Climatology), Italy

A snow cover persisted in mountainous areas of Serbia during the whole month, in lower parts of the country during the first half of the month. The maximum snow depth recorded in Serbia was 46 cm. A snow cover of up to 20 cm depth accumulated over most of Romania.

Later in the month, temperature increase caused rapid snow melting in southern parts of Europe, e.g. in northern Italy and Romania, snow melt followed by flooding.

Intensive avalanches were recorded in the first ten days of January in the northern Caucasian mountains. Among the South Caucasus countries, the area of Georgia was snowy during the first twenty days of the month. Azerbaijan reported snow depths of up to 35 cm. In the northern regions of Armenia and the very south of the country, no snow cover occurred that month.

Significant weather events

January 06-07: Extreme cold spell (minimum temperatures down to -28°C) and heavy snow over large parts of the Region. A Mediterranean storm dropped 20-40 cm of snow across south-eastern France for the first time since 1987. Three fatalities due to freezing. Ice on rivers.

January 12: 117.5 mm of precipitation in Norway (Rogaland) were measured within a large low pressure complex.

January 13-14: Severe icing in central and western Bulgaria due to rain falling on snow. Freezing rain also in Hungary; several cm thick glaze formed on the roads and disabled traffic.

January 17: A severe storm with strong gusts up to 174 km/h (local 50-year record in Ireland) and heavy rain crossed over much of the United Kingdom and Ireland. Electricity broke down in around 100,000 homes across Ireland. The Faroe and Hebrides Islands also recorded gusts of hurricane force. The central minimum mean sea level pressure of the depression located north of Ireland was 946 hPa. Iceland saw heavy snow showers.

January 19-25: Heavy precipitation in northern Italy. 3-day totals exceeded 200 mm over large areas. A series of cyclones generated in the Genoa Bay moved towards the Adriatic Sea and then continued to south-eastern Europe. Heavy precipitation in Montenegro up to 155 mm (new local record), locally higher-than-normal monthly totals and snow melt caused river flooding. Even Turkey was affected by these storms; water spouts were seen near Antalya. Floods were recorded in the Larnaca area in Cyprus on 23-24 January; suspended dust appeared at the same time.

January 23-24: Storm Klaus hit south-western France and northern Spain with torrential rains, very high waves in the eastern Atlantic and the Mediterranean, and gusts up to 193 km/h in the Pyrenees (Fig. 1.6). The storm's force was equivalent to a category 3 hurricane. At least 20 fatalities. About one million homes were left without power supply. Roads, airports and railways were forced to close. It has been the worst storm in that area since December 1999. In the aftermath of the storm, heavy avalanches were released in the French Alps. Storm Klaus had been preceded by storm “Joris”, which affected especially Switzerland with gusts of up to 155 km/h.

January 29-30: Southern Ireland saw heavy rain (around 100 mm within 2 days) with severe flooding due to an Atlantic storm coming from the south. The centre of the town Clonmel was flooded when the river Suir burst its banks.

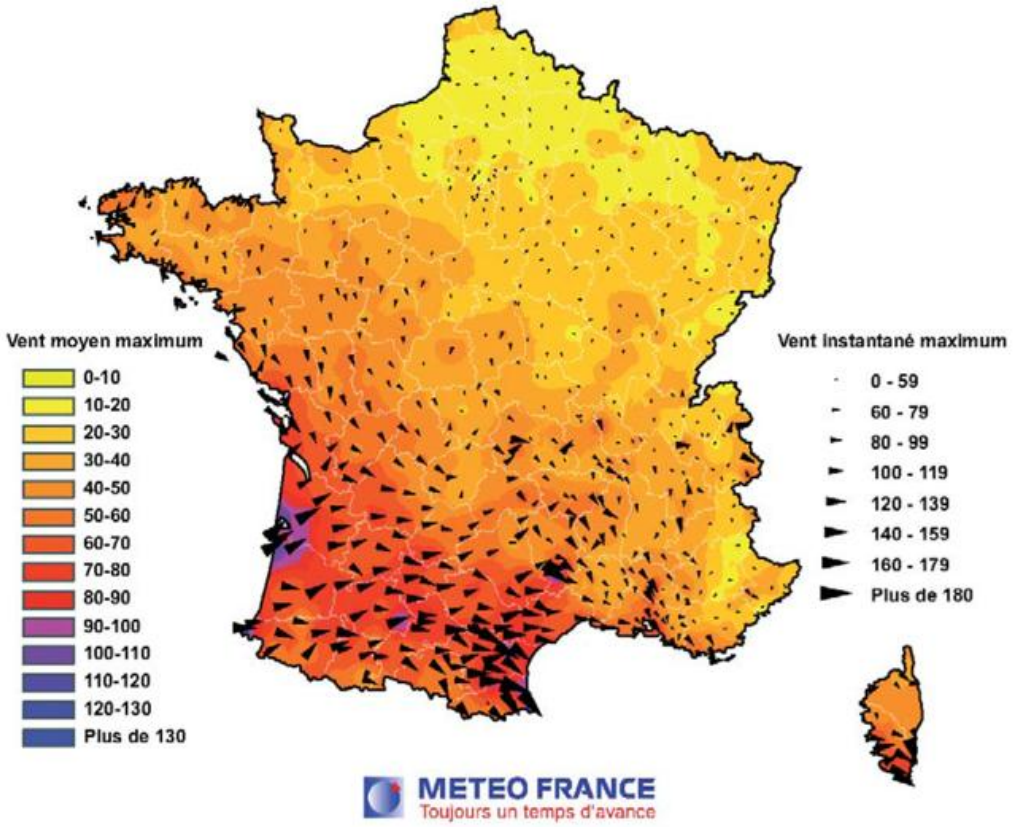

Fig. 1.6: *Maximum 10-minute-mean wind speeds (coloured shaded areas) and maximum wind gusts (arrows, both in km/h) in France on 24 January 2009 during passage of storm Klaus. Source: Météo France*

February

- **Milder in eastern Europe, Svalbard and over the central North Atlantic, cold over the Mediterranean and locally in northern Europe**
- **Western Europe dry, central and eastern Europe mainly wetter than normal**

Atmospheric circulation characteristics

At the beginning of the month, an intensive cut-off low crossed Europe from east to west and caused heavy snowfall over north-western Europe. Thereafter, a large trough extended over the eastern Atlantic and western Europe, and cold air masses moved southwards as far as Iberia, crossing from there the Mediterranean. In addition, a violent storm from the Atlantic (Quinten) affected western Europe early in the month and passed central Europe after weakening.

In the middle of the month, another broad trough centred over central Europe and the Mediterranean followed, remaining very stable for many days. Western and south-western Europe were under a high pressure area which frequently caused dry, but cold nights in these areas. Even the western parts of northern Europe occasionally came under high pressure influence and experienced much nocturnal cooling.

Due to dislocation and weakening of the Icelandic low, the mean airflow over the eastern North Atlantic took a more south-westerly direction. The flow of mild and moist air into the Arctic region continued and only east Greenland mainly remained under cold and dry polar air.

Central and parts of northern Europe were often affected by low pressure systems moving from north-west to south-east; occasionally, some cold air and snowfalls reached western and even south-eastern Europe.

The influence of the Siberian high retreated eastwards and the east of the Region came under an increasingly warm and moist airflow from the south. At the end of the month, however, a trough over eastern Europe extended far into the eastern Mediterranean, causing frequent precipitation in the Middle East.

Temperature

February was very mild in Svalbard and the whole of eastern Europe and the Middle East, with monthly mean anomalies exceeding +2°C over large areas (even +4°C in Svalbard and in some of the easternmost parts of the Region (Fig. 2.1). Yerevan in Armenia was even +5°C warmer than normal. The central North Atlantic was also warm.

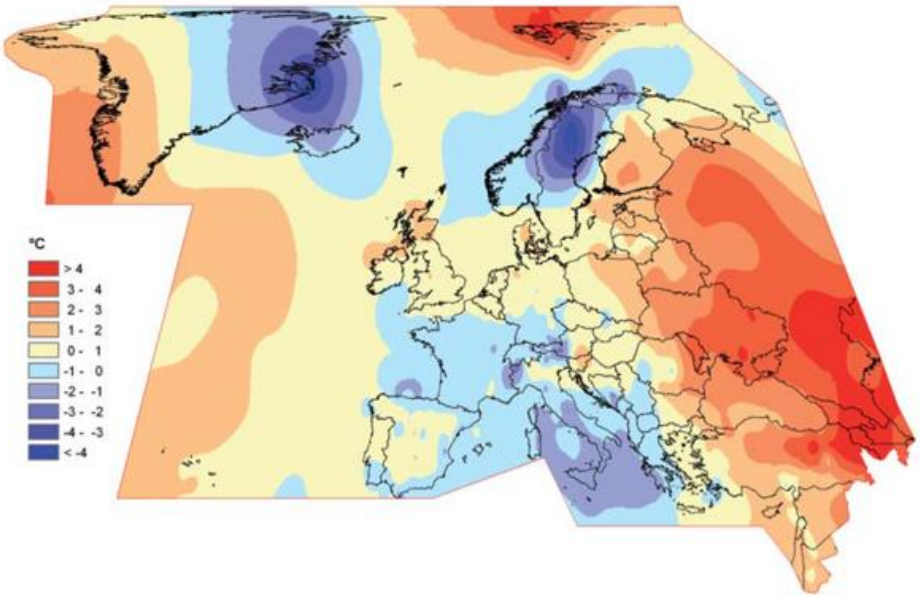

Fig. 2.1: *Monthly mean temperature anomalies in February 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

There were some very cold areas in eastern Greenland and Sweden, with local monthly averages of more than -4°C colder than normal. It was the coldest February in 15 years in northern Sweden. Norway was -2 to -4°C colder than normal. Lapland (northern Fennoscandia) saw minimum temperatures of around -35°C, locally below -38°C. Iceland was -2°C colder than

normal in the north, especially during the first part of the month, and a minimum of -29°C was recorded in the northern inland. The north-eastern coasts of European Russia were slightly colder than normal, also due to severe frosts especially in the first ten days.

The United Kingdom had a cold first half of the month, but this was compensated by milder conditions in the second half.

It was also colder than normal in France (although not as cold as in January), the Alpine region (except the east), south-western parts of the Balkan Peninsula and almost the whole Mediterranean (except the eastern parts but particularly the central Mediterranean, where the temperatures were -1°C below normal). Especially the second half of the month was colder in the central Mediterranean region.

Central Europe was slightly warmer than normal in the north and east, but colder or near normal in its southern parts. Temporary sea ice was still seen near the North German coasts. Southern Germany had a sharp cold spell on February 18-19, resulting in daily minimum temperatures around -20°C. Poland reported a minimum temperature of -20°C in the northeast of the country. A station in the Jura Mountains in Switzerland recorded -33.1°C. During the last days of the month, however, maximum temperatures in western Europe and the western parts of central Europe exceeded 15°C due to the mild airflow coming in from the west.

Some very warm days occurred in the Middle East and the Caucasus region. On 9 February, temperatures above 30°C were recorded in parts of Israel, while on 13-16 February maximum temperatures reached 18-20°C in southern Armenia. Similar temperatures were reached in Azerbaijan.

Precipitation

In northern Europe, it was wet in south-eastern Norway and large parts of Sweden (up to around 200% of the normal), but very dry in the other areas (Fig. 2.2). Iceland was very dry during the first part of the month whereas the country's south was hit by heavy precipitation by the middle of the month.

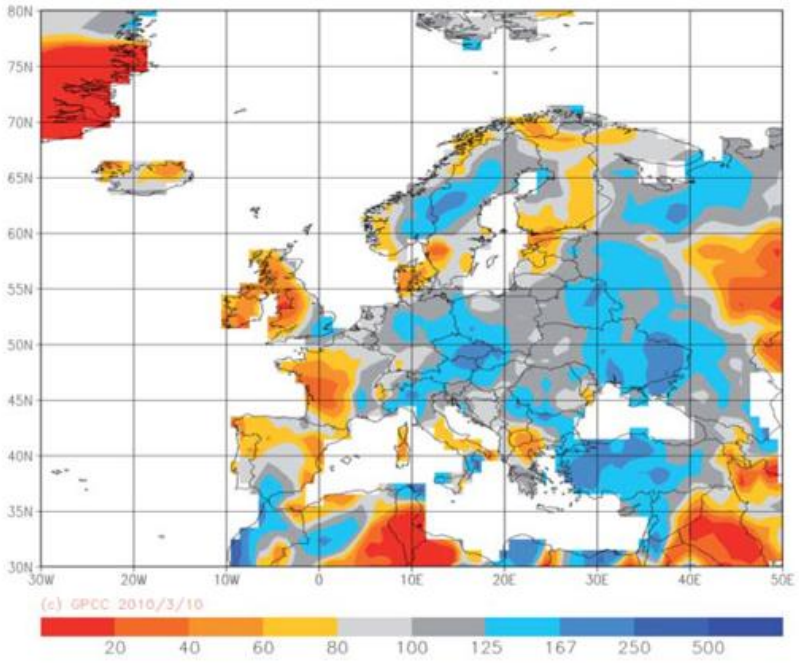

Fig. 2.2: *Monthly precipitation amounts for February 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Nearly the whole of western Europe was unusually dry, with less than 40% of the monthly normal precipitation in places. In the United Kingdom, only south-eastern England was very wet (70 mm or 200% of the 1961-90 normal in London), in contrast to the western parts of the country which reported their driest February since 1993.

The month was wet over most of central and eastern Europe, including most parts of the alpine region and locally with more than twice the normal monthly precipitation total. Precipitation was particularly high in south-eastern Austria (around 300% of the normal).

However, some of the easternmost parts of the Region (eastern European Russia, west Kazakhstan and Armenia) were very dry. Some valleys in southern Armenia received only 10-20 mm of precipitation, which is 20-25% of the 1961-1990 normal.

Most of the western and central Mediterranean region was drier than normal, except northern and southern Italy, Malta and southern Spain. 118 mm of rain fell at Malta International Airport - which is more than twice the normal; half of that amount resulted from one heavy rain event. Livorno in the Tuscany region of Italy had a daily total of 110 mm on 6 February.

Turkey and the Middle East were very wet, with locally twice the normal amount of precipitation. February 2009 was the 3rd rainiest February in 70 years in some areas in Israel. Salt in Jordan had a monthly total of 280 mm; this was also the highest local monthly total recorded in Jordan during the whole year.

Snow

Heavy snow at the beginning of the month disrupted air, road and rail travel in the United Kingdom, Belgium, north-western France, Spain and Italy. The United Kingdom has experienced its most widespread snowfalls since 1991, resulting in peak snow depths of up to more than 40 cm even in the lowlands. London received its heaviest snowfalls in 18 years, with up to 28 cm on 2 February.

During the course of the month, further snowfalls occurred in various parts of Europe, especially in Russia (35 cm in Moscow on 28 February), Poland and the Baltic countries, and in the south-east, e.g. Serbia, Montenegro, Romania and Bulgaria. It even snowed in the coastal area of Montenegro, which is the third time within the last 60 years.

Snowfall in the Alps was particularly frequent and high. Germany's highest mountain Zugspitze (approx. 3000 m a.s.l.) had reached a snow depth of 4 m towards the end of the month. The snow lasted until the end of February, even at low elevations in the Alpine region, which was unusual especially for the areas south of the Alps. Road and rail traffic was severely affected in various parts of Austria due to snow and avalanches. On Mount Kredarica in Slovenia, the maximum snow depth reached 487 cm, which has been Slovenia's 2nd highest record in February since observations started. In Ljubljana, the snow cover reached 23 cm on 4 February; there were 10 days with snow cover.

Mountains in Serbia were covered in snow during the whole month, while the lower parts of the country were covered only partly. The maximum snow depth in Serbia was 130 cm (on Kopaonik on 20 February).

Unusual snowfall occurred in Sicily (Italy) on 12-15 February even in lower elevations and particularly in the northern parts of the island, e.g. Palermo.

Intensive snowfall and avalanche conditions persisted in the northern Caucasian mountains. In the South Caucasus countries, a stable snow cover persisted in the high mountains of Georgia with a maximum depth of 135 cm. Azerbaijan had up to 33 cm of snow. There was no snow cover in central and southern Armenia due to the anomalous warmth during that month.

In Jordan, snowfalls occurred in mountainous regions in the southern, western and northern parts of the country, resulting in a temporary snow cover of up to 12 cm.

Significant weather events

February 08-10: Hail storms in s everal parts of Bulgaria and Turkey along with the passage of a cold front. This was an unusual event for that season. The same low pressure system also caused heavy rain and flooding in south-eastern Austria.

February 09-10: A depression named Quinten formed over the Atlantic Ocean and moved along the coasts of the English Channel, causing gusts of up to 148 km/h, which hit northern and western France, disrupting electricity and transport routes. The two main airports of Paris had to be closed for the first time in 34 years. The southern United Kingdom was also affected by heavy rain, sleet and snow, as were Switzerland and Germany where high wind gusts occurred. The large spatial extent and the long duration of the wind gusts especially affected air traffic. Even the Mediterranean area (e.g. Corsica) was affected by high wind gusts.

February 18-20: A violent storm disturbed road traffic due to heavy snowfall in Serbia and Montenegro. The Alps also received abundant snowfall due to that storm. Austria's Sonnblick Mountain received 66 cm of fresh snow. In Bulgaria, rain changed to abundant snow, disrupting electricity in many villages.

February 21-22: Snowstorm in north-western Armenia with gusts up to 80 km/h

February 24: Exceptionally heavy rainfall in Malta led to the cancellation of the National Carnival grand finale. 66 mm of precipitation were measured at Luqa Airport within 2 days (23-25 February).

February 26-28: Severe rainfall was recorded in northern Israel. Rainfalls of 100-180 mm in 48 hours caused flooding and extensive damage to agriculture. This event also affected Turkey (storm and hail) and Cyprus (flooding in a number of places). Salt in Jordan received 100 mm of precipitation in 24 hours.

March

- **Mostly warm, colder in Greenland and in some places in southern Europe and the Middle East**
- **Dry in northern and western Europe, wet in central, eastern and southern Europe**

Atmospheric circulation characteristics

The strong frontal zone over the North Atlantic persisted into March and moved northwards. Strong low pressure influence as well as mild and moist air affected particularly the northern parts of the North Atlantic, the North Sea and, on some occasions, central, eastern and south-eastern Europe. Mild air masses frequently penetrated Scandinavia. Particularly north-eastern Scandinavia also was under high pressure influence from the east. Greenland continued to be under cold and dry polar air.

Western and most of south-western Europe were mainly under strong high pressure influence, with warmer-than-normal and dry air masses.

The eastern parts of the Region were continuously affected by warm and moist subtropical air masses from the south while especially the eastern Mediterranean experienced much low pressure activity.

Temperature

In the north, only most of Greenland and western Iceland were colder than normal.

Most of the Region, however, was up to +2°C warmer than normal (Fig. 3.1). Svalbard in northern Norway even had monthly mean anomalies of +3°C. Southern Sweden was especially warm in early March, but wintry temperatures struck back later in the month.

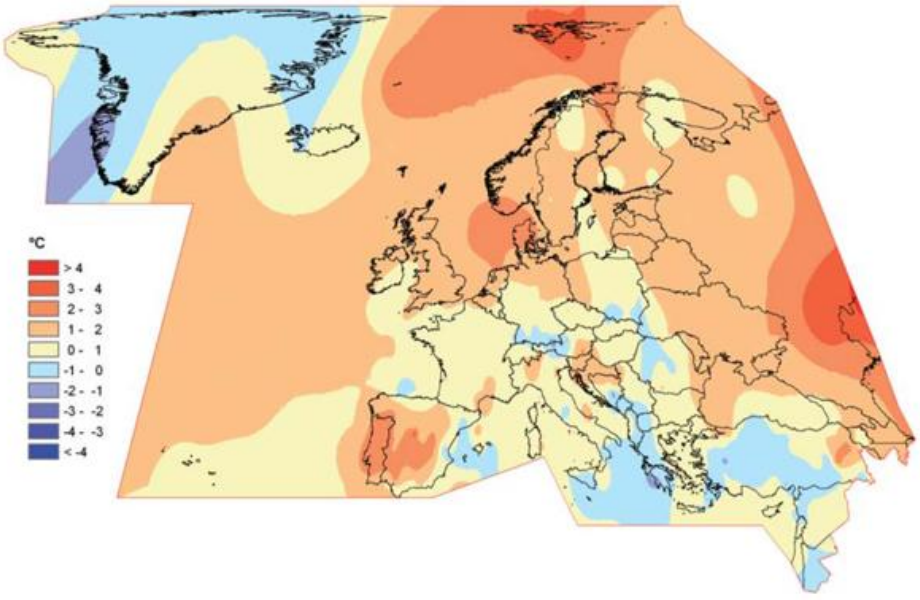

Fig. 3.1: *Monthly mean temperature anomalies in March 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

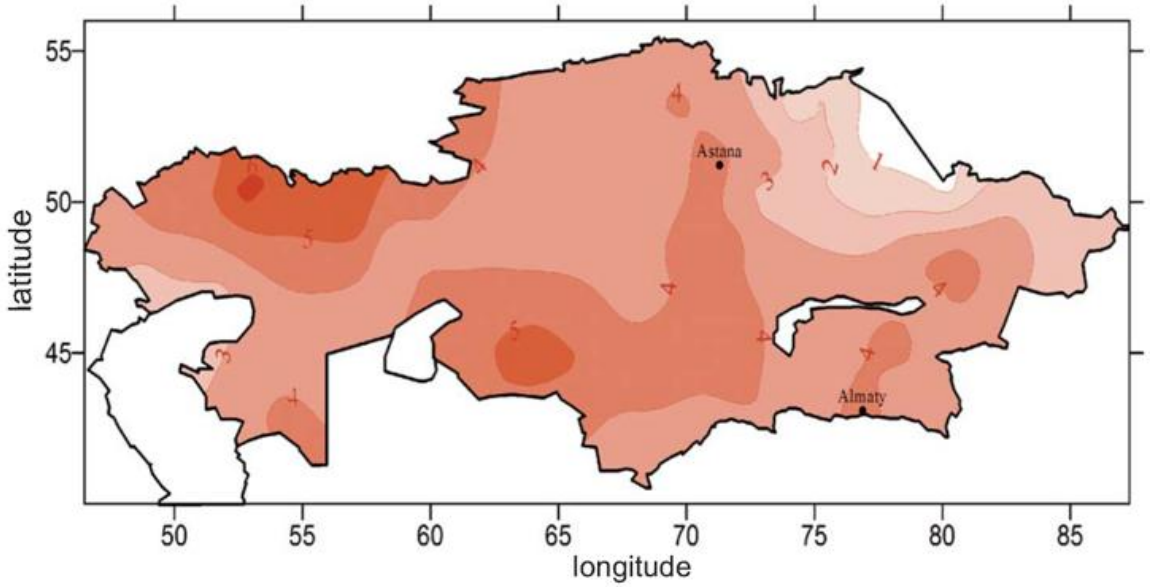

Fig. 3.2: *Monthly mean temperature anomalies (contours, °C) in March 2009 (reference period 1961-1990) in Kazakhstan*
Source: Kazhydromet, Kazakhstan

The eastern parts of the Region, too, were very warm in March. Monthly mean anomalies were highest over western Kazakhstan (+4°C, Fig. 3.2). Daily maxima were quite high during the month, 23-25°C in southern valleys of Armenia and locally more than 28°C in Turkey (new local record for March). In early March, new record-breaking maxima of daily air temperature were also recorded in southern European Russia (Krasnodar territory). In Belarus, daily temperatures above 0°C were measured already very early in the month, around 10-20 days earlier than usual.

Most of the North Atlantic was +1-2°C warmer than normal.

Some places in Iberia were over +2°C warmer than normal (e.g. Madrid and Lisbon). Maximum temperatures in southern Spain reached nearly 30°C.

Most of western, central and south-eastern Europe was only slightly warmer than normal (< +1°C). The warming took place especially in the lowlands, but not in the mountains. The number of freezing days in March in Serbia was lower than normal in the lowlands, but higher than normal in the mountains. Hoarfrost was reported in most parts of Romania during the last ten days of the month.

Several places in the southern half of Europe were slightly colder than normal, especially in the Alps, north-eastern France and southern Germany, parts of the Balkan Peninsula, the central Mediterranean as well as the Baleares, Malta, Turkey, Cyprus, and the Middle East.

Precipitation

March was very dry in most of northern and western Europe including Portugal and western Spain, but wet in many central, eastern and southern parts of the continent (Fig. 3.3).

A wet area in the region was to be found in the Baltic countries. Here, Estonia recorded 150% of the monthly normal precipitation, including some freezing rain.

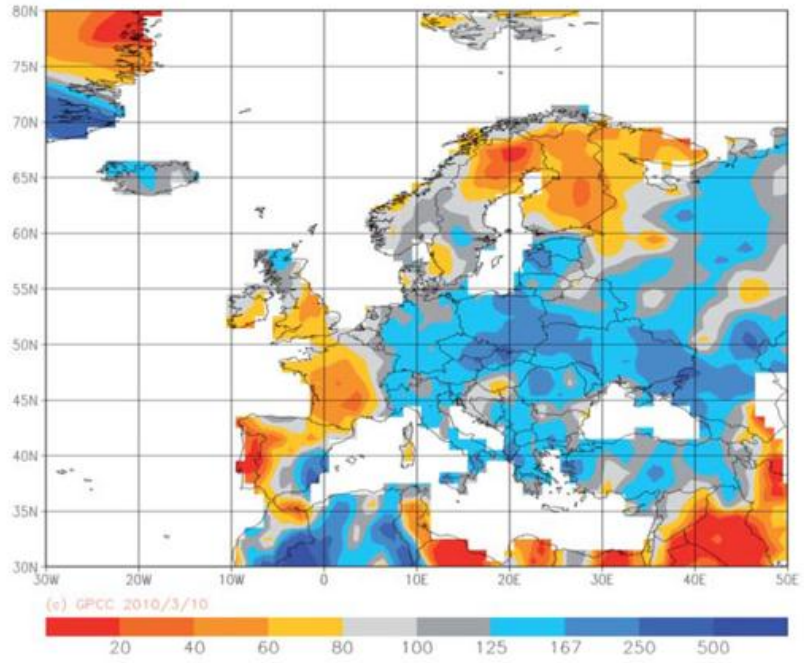

Fig. 3.3: *Monthly precipitation amounts for March 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

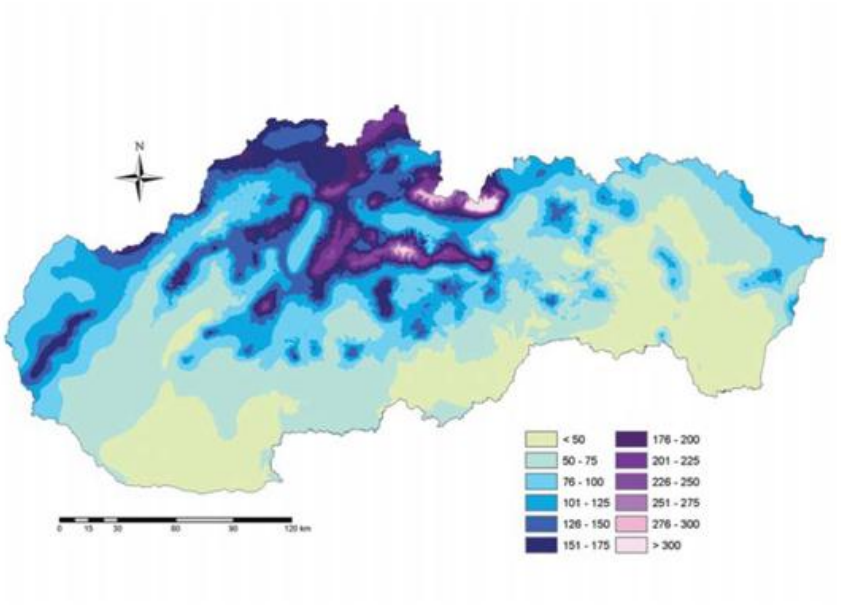

Fig. 3.4: *Monthly precipitation amounts for March 2009 in mm in Slovakia*
Source: Slovak Hydrometeorological Institute, Slovakia

March was exceptionally wet in eastern central and large parts of eastern, south-eastern and southern Europe (except parts of the north-western Balkan Peninsula), Cyprus and Turkey. Over large areas, the double amount of normal March rainfall was exceeded; locally it was more than 300%. In the more southern areas, precipitation was accompanied by thunder and local hail.

The eastern parts of Austria received even up to 400% of the normal, making March 2009 the second rainiest March on record since the start of measurements in 1820. Intense rainfalls caused regional flooding, e.g. in Slovakia and Slovenia; monthly totals exceeded 200 mm in several places, especially in the mountains (Fig. 3.4).

Portugal was extremely dry; most of the country received less than 20% of the normal monthly precipitation.

Snow

March 2009 was characterised by widespread snowfalls in many parts of Europe.

In the north, snow seriously affected traffic conditions in Iceland, especially in northern parts late in the month, and there was a persistent danger of avalanches.

A temporary snow cover of about 8 cm formed on the south coast of England, severely affecting roads and rails.

In the Baltic countries, up to 46 cm of snow were recorded in Latvia. Northern Lithuania saw heavy snowfall at the beginning of March, with the resulting snow cover persisting throughout the whole month. Eastern Germany and Poland had a snow cover of up to around 20 cm in the lowlands.

Abundant snow fell on mountains in Germany and in the Alps. On the Wendelstein mountain (over 1800 m a.s.l.) a snow depth maximum of 350 cm was reached, which has been the highest March snow depth since 1952. The snow cover on the Zugspitze in the Alps (approx. 3000 m a.s.l.) has exceeded 500 cm for the first time since 2002. Lower altitudes at the alpine north side also received several snowfalls. The southern slope of the Alps had unusually high snow depths, partly more than 3 m in high valleys.

Kredarica mountain in Slovenia reported a maximum snow depth of 560 cm, which has been the third deepest snow cover in March since observations began. Mountains in Serbia were snow covered during the whole month, with the maximum depth of 142 cm recorded on Kopaonik on 23 March. Other parts of Serbia temporarily saw some snow in the first and third ten days of the month. In Romania, it snowed in the mountain area during the first days of the month.

Northern Caucasian mountains continued to receive snowfall followed by avalanches throughout the month. In the South Caucasus region, a snow cover persisted in high mountains in Georgia during the whole month. In Azerbaijan, however, snow melting due to higher-than-normal temperatures caused several rivers to flood.

March even saw snowfalls in Jordan in the Middle East, with the snow cover reaching up to 6 cm on hills.

Heavy snow showers were also seen in Spain and Portugal.

Significant weather events

March 01: A series of avalanches affected some districts in southern Austria (Styria). Up to 900 people were cut off from the surroundings for 2 days.

March 04-06: A heavy thunderstorm developed over the western and central Mediterranean with gusts up to hurricane force, tornadoes, heavy rain, snowfall in the southern Alps and high seas due to a cut-off cyclone and caused damage to crops and roads in Sicily. Gusts up to 85 km/h at Luqa in Malta on 4 March; damaged a protective shelter being installed over the prehistoric Mnajdra Temples. Saharan

dust was observed over most parts of Greece and the western coast of Turkey, and there was a storm in Turkey.

March 25-28: A Tornado caused damage in Nea Manolada, Peloponnese, south-west Greece on 25 March (Fig. 3.5). Normally, tornadoes in Greece are rare. Strong winds were reported from Bulgaria: the port of Varna was temporarily closed. Storm with hail occurred in Turkey and Cyprus. Another tornado affected the area of Larnaca in Cyprus on 26 March.

Fig. 3.5: *Damage after tornado passage in Manolada, north-west Peloponnese, Greece on 25 March 2009*
Source: Hellenic National Meteorological Service, Greece

March 29-30: A very strong warm upper air south-west current caused wind gusts above 100 km/h in the higher mountainous region of northern Montenegro, resulting in damage to infrastructure.

April

- **Much warmer in Central Europe, colder in the Arctic and eastern Europe**
- **Extremely dry particularly in the eastern half of Europe**

Atmospheric circulation characteristics

The frontal zone over the North Atlantic persisted and was still stronger than normal; it moved further south and mainly affected the western parts of Europe, with some troughs extending far into the south.

The Arctic region was under dry and colder-than-normal polar air.

Most of the other parts of Europe (except the easternmost and westernmost parts) were dominated by a strong high pressure zone with a very dry air mass, stretching from the Middle East very far into the north and causing a strong and extended warming.

Low pressure activity was dominating over the western and central Mediterranean due to a dominating trough which extended from the eastern North Atlantic south-eastwards.

Eastern Europe and the Caucasian region came under the east flank of the high pressure area over central Europe and were influenced by cold and dry air masses from the north.

Temperature

April was warmer than normal in most of Europe including the Mediterranean and the North Atlantic (Fig. 4.1). But the Arctic, European Russia, west Kazakhstan and the eastern Ukraine, the Caucasian region, Turkey, Bulgaria, Malta and places in Iberia were colder than normal.

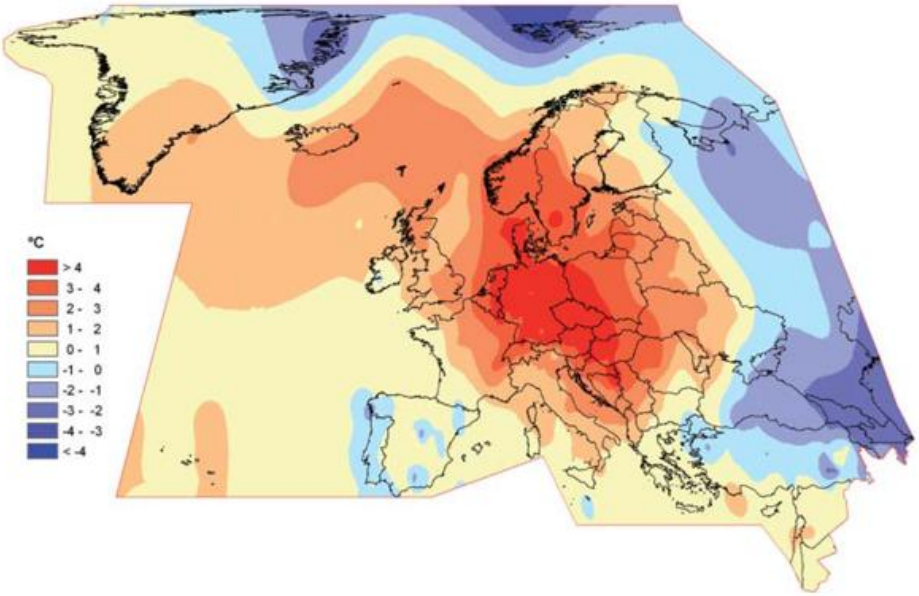

Fig. 4.1: *Monthly mean temperature anomalies in April 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Monthly mean anomalies were below -2°C in eastern Greenland, and below -4°C in places on Svalbard. April was the only month of the year with below-average temperatures on Svalbard. On 22 April, Longyearbyen recorded its coldest mean temperature in April (-19.5°C) since 1993. At Svalbard Airport, a daily minimum of -28.6°C was measured on 6 April.

It was much warmer than normal on the European continent. April was exceptionally warm in northern Europe. In Norway, it was the 3rd mildest April since 1900 (more than +5°C warmer than normal), with several stations in the south setting new monthly mean temperature records. At 9.4°C (which is +3.7°C above normal), Denmark noted a new mean temperature record for the country. In Sweden, April average temperatures were generally +1 to +4°C higher than normal. For the first time ever since records began in 1860, some areas had monthly mean temperatures above 10°C. The April mean temperature in Gothenburg was 10.4°C, thus beating

by far any former nationwide records. The Baltic countries were also considerably warmer than normal (around +2°C, in Lithuania even +3°C). Maximum temperatures in Lithuania reached 17-21°C already on 5 April, and new records were set in some places.

England and Scotland saw their third warmest April on record since 1914, with anomalies around +2°C.

Central Europe was also extremely warm, with monthly anomalies of up to more than +5°C in places in Germany (Fig. 4.2), Austria and the Czech Republic. In most of central Europe, the mean temperatures for April ranged between 10 and 15°C, compared to normal values of 5 to 10°C. De Bilt in the Netherlands had its second warmest April on record (1706-2009), with a monthly average of 12.2°C and only April 2007 being warmer. In April, several new national records were set in Hungary (mean anomaly of +4.2°C, 1971-2000 reference) and Germany

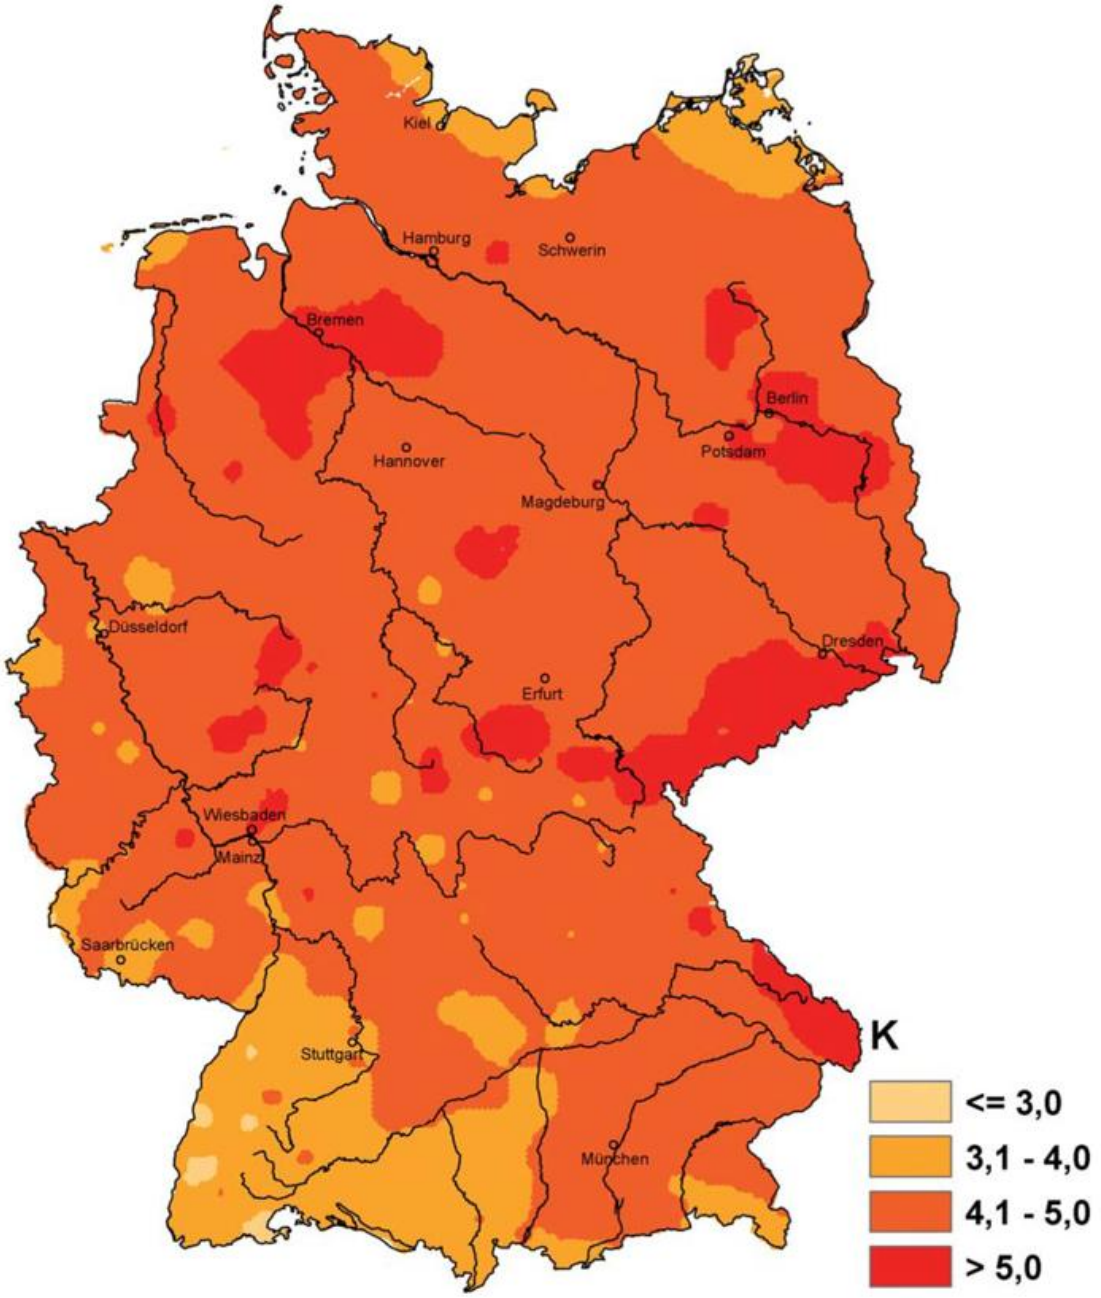

Fig. 4.2: *Monthly mean temperature anomalies in April 2009 (reference period 1961-1990) in Germany*
Source: Deutscher Wetterdienst, Germany

(+4.5°C, 1961-1990, see Fig. 4.2). Daily maxima in Germany went up to 27°C on several occasions. The monthly mean daily maximum in Berlin reached 20.1°C, which is +7°C more than normal. Temperatures in flat water areas near the German coasts rose to 10-14°C. In some parts of eastern Austria, it was the warmest April in more than 200 years.

It was also particularly warm in Slovenia, Serbia and Croatia (anomalies up to more than +4°C); even the number of freezing days in the mountains was much lower than normal. The highest temperature in Serbia in April was 26.2°C. During a warm spell on 17-19 April, maxima in Greece locally exceeded 25°C (in Athens, e.g., the normal is around 20°C).

In contrast to many other states in Europe, the eastern countries of the Region experienced a cold and frosty April. A 10- to 20-day frost period occurred in particular in eastern parts of the Ukraine, producing air temperature minima between -5 and -12°C which caused damage to crops and fruit buds. The Caucasus region was much colder than normal, with anomalies below -2°C. Armenia experienced a cold spell on 10-14 April with the result that blossoming fruit trees were damaged. Southern European Russia was also affected by extended damage to agriculture due to frost from -6 to -8°C.

Precipitation

April was very dry in most of the Region and extremely dry in most of the eastern half of Europe and in the Middle East (Fig. 4.3). Only a few parts of the Region received more than the monthly normal, locally twice as much, among which were southern Greenland, Iceland, northern Norway, Ireland, southern and western France, the southern slopes of the Alps in Switzerland, parts of Slovenia, most of Italy, Monaco and several locations in Turkey and southern Armenia.

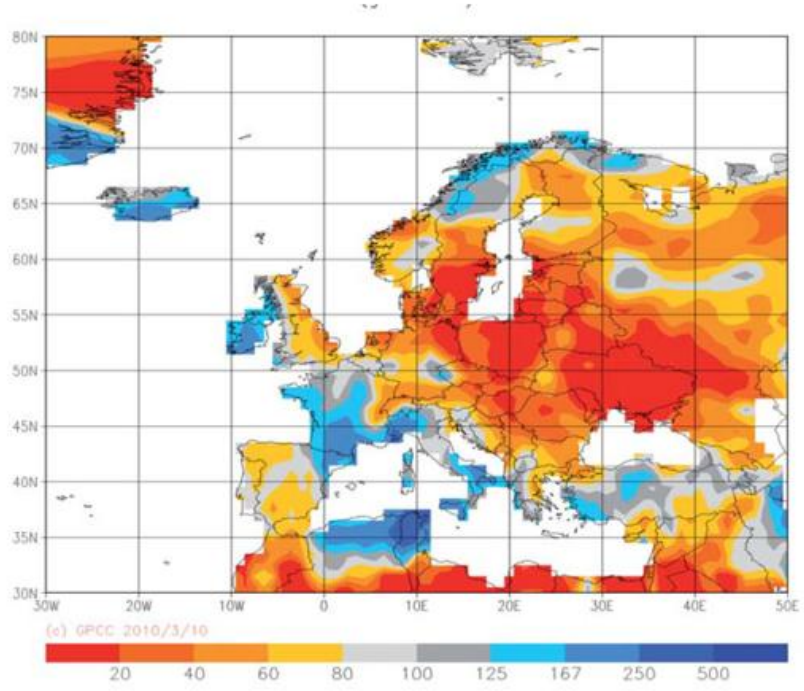

Fig. 4.3: *Monthly precipitation amounts for April 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

It was an especially wet month for Iceland. A station in south-east Iceland received 523.7 mm during the month, thus setting a new local April record.

Most of northern Europe, however, was very dry, in particular the southern areas of that region. Parts of southern Norway registered the driest April in more than 30 years. April was also particularly dry in south-eastern Sweden (in places the driest since 1974), where only less than 5% of the 1961-1990 average amount of rain was recorded. Locally, no measurable precipitation at all was reported; in some parts of Sweden the last month without any measurable precipitation had been August 2002. Denmark, too, was very dry, as was most of the United Kingdom, in particular its eastern parts.

The region around the southern Baltic Sea and large areas south-east of it received less than 20% of the normal monthly precipitation total, partly even less than 10%. In Latvia, it was the second driest April ever recorded, with only 7 mm on average. Similar values were recorded in Lithuania (8 mm and only 3 days of rainfall during the whole month).

Soils were very dry due to the missing rain. In eastern Germany, the uppermost 20 cm of the soil were very dry. However, there were still large soil water resources in lower layers of ground due to the wet March.

Some north-eastern parts of Austria recorded no more than 1 mm of precipitation during the whole month, some places in Slovakia even less. Hungary recorded 23% of its average April rainfall (1971-2000 reference), while Poland, north-eastern Croatia, Montenegro, the Ukraine and Russia experienced rainfall in the 10th percentile of their precipitation distribution (Fig. 4.4). The major part of the Ukraine, including Odessa was rainless during the whole month. Kiev received no more than 2 mm. In Moldova, 11.5 mm (26% of normal) of rainfall was recorded, making April the second driest in 60 years behind April 1974 (9 mm).

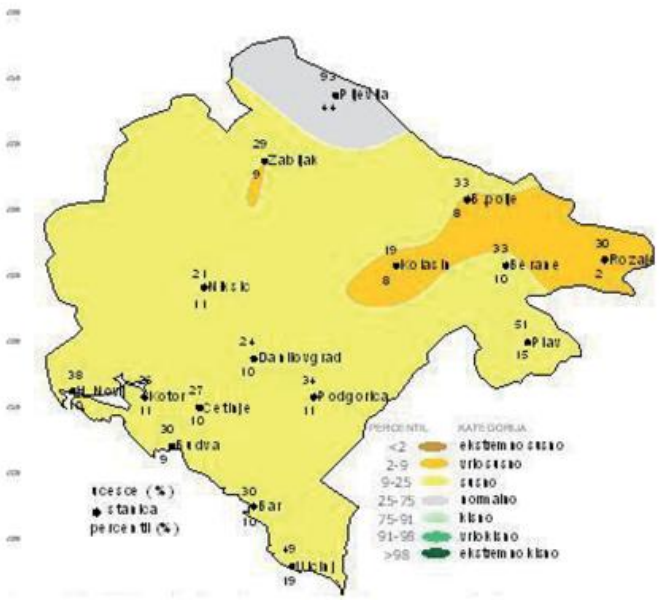

Fig. 4.4: *Monthly precipitation amounts for April 2009 in per cent (upper numbers) and in percentiles (lower numbers) of the normal 1961-1990 in Montenegro*
Source: Hydrological and Meteorological Service of Montenegro

In the south-west, Iberia was dry except the north-eastern areas. Large parts of the peninsula received less than 80% of the normal monthly precipitation.

Dryness in many parts of Europe was one reason for the increased number of forest fires.

The western Mediterranean, however, saw a wet month. Lots of rain fell in southern France, Monaco and over large areas of northern and southern Italy. Some regions in northern Italy registered the second wettest April of past 75 years or even more, resulting in flooding of the Po River banks. In Monaco, it was the second wettest April since at least 1969 with a monthly total of 193.7 mm, only slightly behind April 1989 (194.7 mm).

Snow

Due to the strong and extended warming, the area covered by snow decreased considerably compared to the preceding months, even in Scandinavia and the Alps, although much snow was still left.

A snow cover of more than 50 cm continued to persist in Lapland until the beginning of the month. Tromsø in northern Norway had even more than 100 cm.

The Alps still had snowfall down to elevations of about 1100 m. Southern Germany temporarily recorded more than 100 cm of snow at elevations around 1500 m. On 5 April, three skiers were buried beneath 4 m of snow in an avalanche in the high alpine region of eastern Tyrol in Austria. A snow cover also persisted in the mountains of Slovenia.

In Serbia, the Kopaonik Mountain reported 9 days with snow cover and a maximum depth of 66 cm on 1 April. Romania had snow on high mountains.

Large parts of European Russia were also still covered with snow (14 cm in Moscow on 3 April), although snow had already started to melt before.

In the South Caucasus region, a snow cover was still found in western Georgia on the mountains (snow depth of up to 160 cm) and in Azerbaijan (up to 16 cm). Heavy snowfall was reported in north-eastern Armenia on 23 April.

Significant weather events

April 02-03: Flooding on Kurmukchay River in Azerbaijan after heavy rainfall resulting from a cold front passage.

April 14-15: Sharav event (hot and dry spell due to hot winds from the Arabian Desert) in Israel with temperatures up to 35-37°C, gusts up to 93 km/h, sandstorms, severe haze. Suspended dust in Cyprus, causing reduced visibility.

April 17-18: Low Quirin crossed central Europe and caused heavy rain, in particular in central and southern Germany. Locally, there was more rain during these 2 days than is normally recorded for the whole month. At the same time, many other parts of central Europe were very dry. Heavy rain was also recorded in Switzerland, even south of the main chain in the Ticino. In central European Russia, wind gusts up to 70-90 km/h were measured.

April 21-23: Winds up to hurricane force and local heavy rain in Bulgaria, hail in Turkey.

April 30: Severe flooding of the Po River banks after days of intense precipitation.

May

- **Mostly warmer than normal, especially in the Arctic and in southern Europe**
- **Mostly wet in the north, dry in the south**

Atmospheric circulation characteristics

The Atlantic frontal zone moved northwards again. Atlantic low pressure systems mainly crossed the northern half of Europe and much warm air flowed to these parts and to the Arctic. A high pressure system formed over Scandinavia, but persisted only temporarily.

Most of the southern half of the Region was dominated by high pressure influence, causing again a strong warming in these areas. Within the warm air, however, thunderstorms occurred occasionally, sometimes growing to severe events.

The eastern parts of the Region were on the flank of the high pressure zone so that colder air masses occasionally advanced to these areas.

Temperature

May was another warmer-than-normal month in most of Europe and in the Arctic (Fig. 5.1), especially at the end of the month. Only some areas in eastern Poland, eastern Europe, the Middle East and over the North Atlantic were slightly colder than normal.

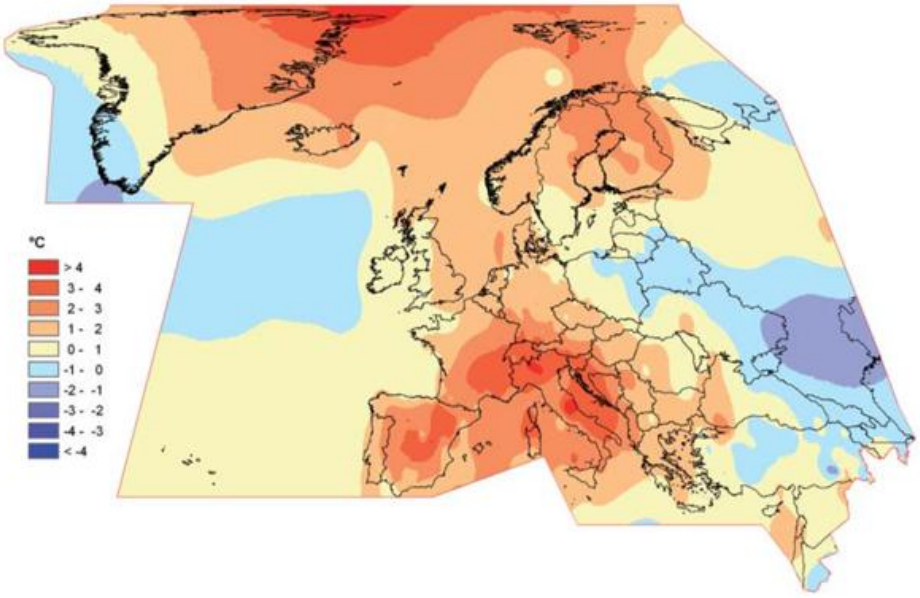

Fig. 5.1: *Monthly mean temperature anomalies in May 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

The Arctic region warmed considerably compared to the preceding cold April. Anomalies reached up to more than +4°C in north-east Greenland. On Jan Mayen, this May was the warmest ever registered.

Large areas of the Nordic countries were more than +1°C warmer than normal, northern parts even more than +2°C. In central Scandinavia, a maximum temperature of 25°C were exceeded at the end of the month.

Many parts of western and central Europe were also more than +1°C warmer than normal. It was particularly warm in southern and south-eastern Europe. Places in Iberia, southern France, the Alpine region, Slovenia, western Croatia and Italy were more than +3°C warmer (in some places in Italy even more than +4°C). In Monaco, it was the warmest May since 1992 with a monthly average of 19.5°C (+2.6°C compared to the 1969-1998 reference).

Several countries in central Europe, the alpine region and in southern and south-eastern Europe widely reported maximum temperatures above 30°C, especially at the end of the month. At several locations, records were broken, which also led to high monthly mean temperatures. The new absolute May record in Luxembourg was at 30.4°C. It was the 2nd warmest May since 1864 in Switzerland and the 3rd warmest May in the last two centuries in Italy, mainly due to a heat wave on 22-27 May. The peak temperatures in Switzerland and Italy were 35.1°C in Sion and 36.8°C at a station in Rome, respectively. Due to heat stress, this heat wave in Italy affected agriculture during wheat grain filling and led to a reduction of wheat yield by 20-30%. Malta was also affected by this heat wave.

Mountain stations, too, reported increased temperatures. The maximum air temperature recorded at the Slovenian mountain station of Kredarica reached 14.4°C, which is the highest temperature ever measured there. Some places in Slovenia saw their warmest or second warmest May ever recorded.

Minimum temperatures also were quite high, especially in the south. 10 stations in Portugal reported tropical nights, partly setting new local records.

Jordan had a maximum temperature of 45°C in the Jordan Valley already on 18 May, which is nearly +9°C more than the typical maximum value for this time of year.

In eastern Europe, May continued the cold spell from April. The northern parts of eastern Europe, however, had near normal monthly mean temperatures due to high maxima at the end of the month. This was also the case in other parts of Europe. Lithuania reached 25°C at the end of May, as did Scandinavia which, however, also saw morning frosts during the active vegetation period in more than one third of the country. It was colder than normal in southern parts of eastern Europe and in parts of the Middle East. Southern European Russia and western Kazakhstan saw monthly mean anomalies below -1°C. Many areas in European Russia still experienced frost even in the last ten days of the month.

Precipitation

Most of the northern half of Europe was wetter than normal, although a few very dry areas were also to be found, for example, in the Baltic countries and north of it (Fig. 5.2). May was the second wettest on record in northern Norway, resulting in a nation-wide mean rainfall value that was 165%, locally even more than 200%, of its 1961-90 average. Several places in Russia and western Kazakhstan also received more than twice the normal.

Frequent, locally heavy thunderstorms occurred especially in northern central Europe, occasionally also in southern Germany, Austria and Slovenia. Partly, they were accompanied by hail. Thunderstorm activity was very high even in the eastern Carpathians in Romania and in Bulgaria. Frequent hailstorms were also recorded during the second half of the month in north-western Armenia. Very high precipitation amounts (twice the normal) due to local thunderstorms were to be found locally along the southern Turkish coast. Cyprus received 29 mm of precipitation, which is about 150% of the normal.

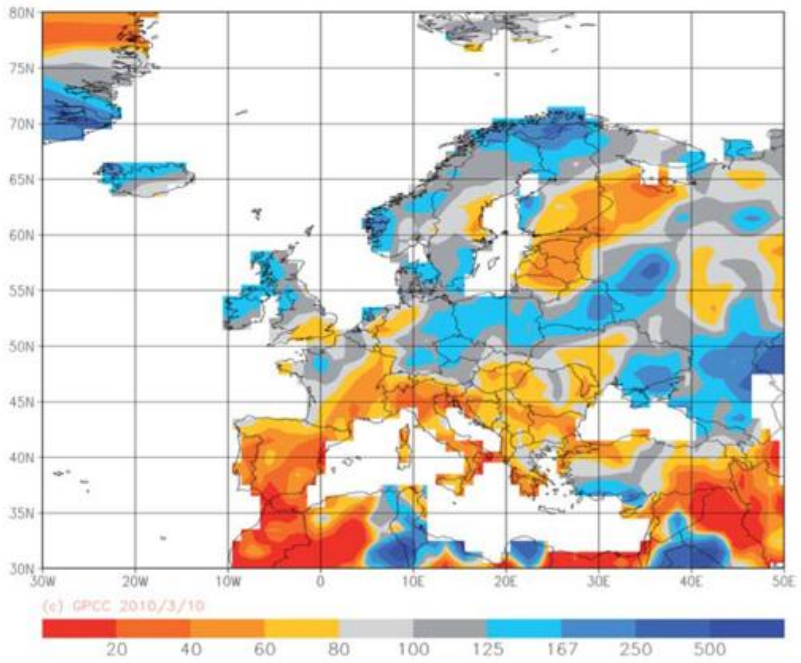

Fig. 5.2: *Monthly precipitation amounts for May 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

Apart from these thunderstorms, the southern half of the Region was mainly very dry in May. Many places received less than 60% of the normal monthly precipitation. It was especially dry (40% of normal, locally less than 25%) in large parts of Iberia, with some stations in north-eastern Spain recording new historical minima (as low as 1.1 mm) in up to 130 years. Many places in western Croatia had less than 10% of its normal precipitation. Athens in Greece reported no measurable precipitation at all. In Armenia, May normally is one of the wettest months of the year; in 2009, however, there was a shortage of precipitation during the wet season.

Snow

The high temperatures in the alpine regions, together with a high sunshine duration, caused rapid snowmelt. At altitudes between 1500 and 2500 m, the snow depth partly decreased down to 250 cm. Kredarica in Slovenia still had 520 cm of snow. In Montenegro, it still snowed at the end of the month, covering northern mountains with a few centimetres of snow. In Romania, snow cover continued to exist on mountains above 1400 m.

Significant weather events

May 04-05: Sharav event in Israel with temperatures up to 39-41°C in the Jordan Valley and gusts up to 100 km/h in mountain areas. Storm with hail in Turkey.

May 09: Hail in the mountains of Cyprus, causing damage to fruit trees.

May 11: Heavy rain in southern European Russia (Krasnodar region): 107 mm of precipitation in 6 hours.

May 12: Heavy thunderstorm in south-western Germany and near the northern slopes of the Alps, with a hail cover up to 15 cm in the Black Forest.

May 18-22: Flooding in Lower Austria due to heavy rain during cold front passage, road traffic disrupted, gas pipelines washed out. Hailstorms in various parts of Austria, with up to hen's egg-sized stones, crop losses, agricultural damage in the value of around 6 billion Euros; ice cover of 20 cm near Graz. Severe thunderstorms in Slovenia, with locally up to more than 50 mm of rain in 10 minutes and strong gusts up to 113 km/h at the airport of Pécs in Hungary.

May 20: Tornado in Nicosia (Cyprus) at noon, with uprooted trees and damaged house roofs.

May 25-26: After temperatures of 32-33°C in parts of France, Switzerland and western Germany, a cold front passage caused severe thunderstorms with hailstones of up to 7 cm and heavy rain about 50 mm in 24 hours, gusts > 100 km/h. 65 mm of daily precipitation were measured near Lake Constance. The city of Konstanz in south Germany was covered with at least 10 cm of hail. The Netherlands, Denmark, Austria, Slovenia and Italy were affected by heavy thunderstorms. Road and rail transport was disrupted by fallen trees and branches.

May 24-29: Frequent hailstorms in north-western Armenia with hailstones of 20-25 mm diameter.

May 28-30: High wind speeds on mountains in Sweden. Mean wind speed up to 122 km/h, gusts up to 176 km/h (both are new records for May).

May 29-30: Southern European Russia (Astrakhan region) was affected by a quite intense low pressure system and received 75-141 mm of precipitation in 4-5 hours. More than 3000 ha of green crops were flooded.

May 30: Heavy thunderstorm spoiled the yearly rose festival in Kazanluk, Bulgaria (Fig. 5.3), with 34 mm of rain, wind gusts of 90 km/h and hailstones as big as walnuts.

Fig. 5.3: *Emergency in Kazanluk (Bulgaria) on 30 May 2009 after heavy rain and a strong hailstorm Source: BGNES, provided by the National Institute of Meteorology and Hydrology, Bulgaria*

June

- **Warmer in southern Europe and the Middle East, cooler in northern and parts of central Europe**
- **Higher than normal precipitation mainly in Italy, the central Mediterranean, the Balkan Peninsula, eastern central Europe and northern central Russia, dry in the western and eastern Mediterranean and southern Russia**

Atmospheric circulation characteristics

During the first ten days of the month, a large low pressure complex affected most of Europe. Arctic air advanced southwards, causing a noticeable cold spell particularly in northern and central Europe.

In the second ten days, low pressure systems embedded in a mainly zonal flow crossed Europe, in particular central Europe.

During the last third of the month, a strong meridional circulation pattern formed. While western and south-western Europe, the western Mediterranean and the eastern North Atlantic were mostly in a warm and dry airflow from the south, cold polar air, rainfall and thunderstorms affected most of north-eastern and central Europe. A high pressure system over Scandinavia caused a warm and sunny spell there at the end of the month.

Due to frequent cut-off lows, high thunderstorm activity occurred over the central Mediterranean.

The Russian high was stronger than normal and a southerly airflow carried warm and dry air to the eastern Mediterranean and eastern Europe.

Temperature

Most of northern and central Europe, especially around the Baltic Sea, was colder than normal. The anomalies were locally below -1°C, as they were in eastern Greenland and parts of the central North Atlantic (Fig. 6.1). In Sweden, especially the first ten days of June were the coldest for this time of the year in locally more than 50 years. Right at the beginning of the month, Stockholm experienced a sharp temperature drop from 26°C on 31 May to 10°C on 2 June as a result of a Baltic sea storm. It was the first colder-than-normal month in Denmark since October 2007. Maximum temperatures on 6 June remained below 10°C in Germany even in the lowlands; in some parts this was the lowest temperature on record for this time of the year. Lithuania recorded an unusually cold night on 17-18 June, with morning frosts down to -2°C on the ground in the western and northern parts of the country. However, the end of June was warm in parts of northern and central Europe, with maxima of up to 26°C in Iceland, 29°C in Lapland and central Finland, over 30°C in some valleys of Norway, Sweden and the southern parts of Germany.

Based on monthly average, June was warmer than normal in western, southern and eastern Europe. The highest monthly mean anomalies were to be found in the southern parts, particularly in Spain, southern France, northern Italy, the eastern Ukraine, southern European Russia, western Kazakhstan, Cyprus and Israel (+2°C or more, in some places in Spain, the eastern Ukraine and west Kazakhstan even more than +3°C).

Portugal reported two heat waves, one at the beginning of the month, the other from 10-22 June, with daily maxima of up to more than 40°C.

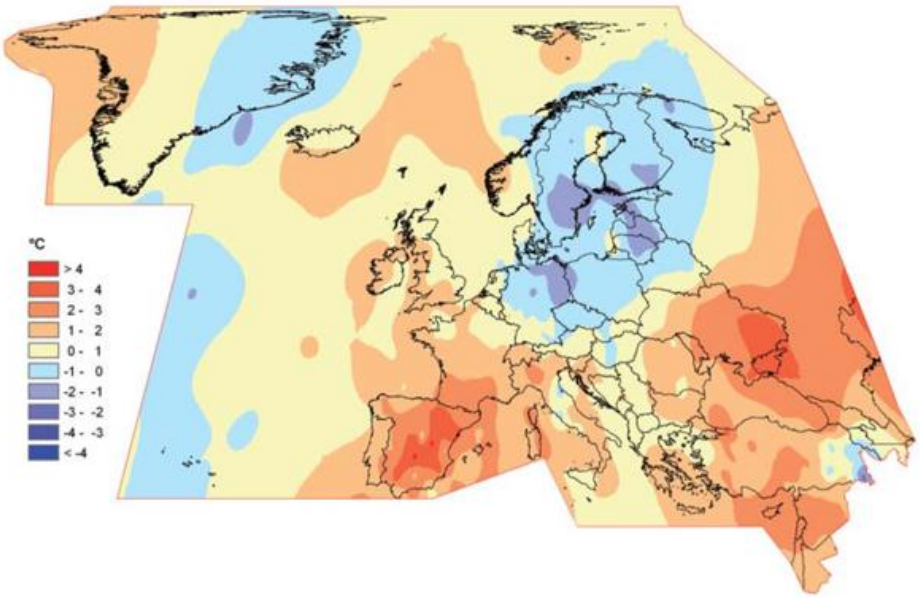

Fig. 6.1: *Monthly mean temperature anomalies in June 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

Serbia, southern Romania and Bulgaria, Greece, western Turkey, Georgia, Azerbaijan and European Russia saw daily maxima (partly record-breaking) of up to 35° to 40°C. Especially in southern European Russia, the hot weather was accompanied by soil drought and hot winds.

June 2008 and 2009 were the two warmest Junes in the last 40-50 years in Israel, due to several Sharav (hot winds from the Arabian Desert) events. One extreme Sharav event at the end of the month caused temperatures of up to 44-46°C in the Jordan Valley and 38-40°C in the coastal plain. Sharav events normally occur in the inner parts of the country, but are very unusual in summer in the coastal plain (during the last 40-50 years there have occurred only three such events, in 1979, 1995 and 2009).

Precipitation

Most of the Region saw a wetter than normal June (Fig. 6.2). Particularly high precipitation totals of more than twice the monthly normal were recorded over large areas in eastern central and eastern Europe, but also over the central Mediterranean and in Portugal. Monthly precipitation records were broken locally.

In the north, the most affected countries were eastern Denmark (Sjælland Island, due to a 2-day heavy rain event), Poland, Belarus, the Baltic countries and parts of northern Russia. In Belarus, Minsk reported a new record of monthly precipitation in June (187 mm). In the Alps, places in north-eastern Austria even received more than 300% of the normal; some were the wettest on record since the 19th century. Much precipitation also occurred further to the south, i.e. in some places in Slovenia, in southern Italy and the south-western Balkan Peninsula. Precipitation totals over the Adriatic Sea partly reached four times the normal or more. With a monthly total of 162 mm, which is more than 10 times the normal, it also was a very wet June in Messina on Sicily. Locally, heavy rainfall was also reported from Armenia, with daily totals of more than 60 mm (which was about double the monthly normal).

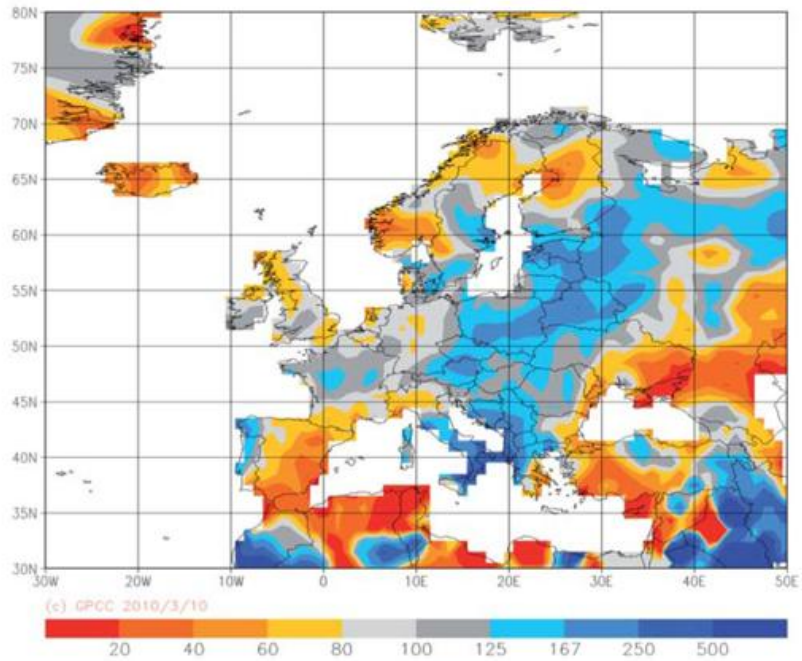

Fig. 6.2: *Monthly precipitation amounts for June 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

There were, however, also some large very dry areas, especially in northern Europe and in eastern Iberia, southern France, Monaco (8 mm), northern Italy, southern Greece, western Turkey, Cyprus, the Middle East, the eastern Ukraine, west Kazakhstan and southern European Russia. Many places there received less than 60% of the normal precipitation, some even much less. Locations in west Kazakhstan did not have any rain at all in that month. Both Greek stations Athens and Heraklion (Crete) were also without any rain at all. Luqa Airport in Malta recorded 1.4 mm (the normal is 3.2 mm).

June showed a remarkable dipole pattern over Iberia. While the eastern half of the Peninsula, particularly the Mediterranean coast, was dry, it was extraordinarily wet in Galicia and much of Portugal. Monthly totals exceeded 150% of the normal along the Atlantic coast. In Lisbon, they even reached 59 mm or nearly 300%, because June in general is a relatively dry month and hence moderate precipitation can result in a large percentage anomaly.

Snow

Heavy snow showers were recorded from the Kola Peninsula in northern European Russia on 8 June.

A depth of 70 cm fresh snow was measured on Germany's highest mountain, the Zugspitze (approx. 3000 m a.s.l.), in the Alps on 23 June due to depression Qinton (see below).

Kredarica in Slovenia had a maximum snow depth of 210 cm at the beginning of the month.

Significant weather events

June 02: Heavy thunderstorm in Romania. Damage to roofs, trees and power lines, especially in Bucharest. Hailstorms (hailstones of fist size) and tornadoes in Bulgaria

June 04: Large hail (50-70 mm) in southern European Russia (Krasnodar region)

June 06-07: A hailstorm with a small tornado crossed the county of Suffolk in the United Kingdom. 93 mm of rain in Exeter within 13 hours on 06 July. Tornadoes were also seen in western and northern Germany. Many houses in a quarter of Cologne were damaged.

June 06: Severe thunderstorms with record-breaking precipitation, partly with hail in Switzerland. Locarno registered more than 100 mm within 3 hours. A tornado hit several towns in north-eastern Italy.

June 10: Heavy downpours in the Sheffield area of the United Kingdom blocked roads and a railway line; 48 mm of rain fell in 24 hours.

June 11-12: Sjælland in the eastern part of Denmark received more than twice its monthly normal rain within these two days. One station on Sjaelland recorded 160 mm during that event.

June 11: Heavy rain in Taktaharkány, Hungary with a daily total of 97 mm. Tornado near Adács, Hungary.

June 13: Hailstorm with walnut-sized hail affected villages in the mountains of Cyprus, causing damage to fruit trees, vineyards and other agricultural products.

June 14-15: Severe hailstorm in Armenia with hailstones up to 30 mm in diameter. Crop damaged, trees and roofs broken, people injured.

June 16: Severe thunderstorm with heavy rain in north-eastern Slovenia and Hungary, partly with hail, caused significant damage on fields.

June 18-19: Gusts up to 108 km/h in west Kazakhstan during cold front passage. Heavy rains in the eastern parts of the north Caucasian region in European Russia; flooding of Sunzha River. In Azerbaijan local heavy precipitation (85 mm within 6 hours in Guba), a few villages were flooded, damage to agriculture, bridges, animals. Heavy rain and flooding in Turkey.

June 19-25: A strong disturbance moving from the Atlantic into the Mediterranean (depression Qinton) affected most of Italy and the Adriatic coasts with heavy rainfall and strong winds including some tornadoes. Daily precipitation on 21 June set new records in the 58-year time series at four locations in Italy. Austria had extreme precipitation, too, and reported up to 207 mm within 3 hours on 23 June. An event such as this is estimated to occur once in 50 years. Southern Germany registered a local total of 155 mm of precipitation. Widespread flooding of rivers occurred in southern Germany and Austria. Around 1000 ha of fields and grassland were under water. Later, the cold front of Qinton also affected Turkey with storm and hail.

June 25-28: Heavy rain caused river levels to rise and flooding in the eastern Czech Republic on June 25. This flooding was the worst in central Europe since 2002. In Austria, the Danube river rose after some of the heaviest rainfalls in 50 years. Three days later, heavy rain flooded the southern parts of the Czech Republic, with mudslides damaging houses and roads. Heavy rain and flooding occurred also in south-east Poland.

June 28: A supercell thunderstorm hit the southern part of central Finland, an event, which is quite rare for that area. Storm downbursts (estimated > 118 km/h) caused extensive forest damage. Furthermore, extremely large hailstones with diameters up to 8 cm damaged buildings and cars.

July

- **Mostly warmer, cooler than normal only in north-east Europe and the central North Atlantic**
- **Wet in western, central and northern Europe, mostly dry in the south and in the Arctic**

Atmospheric circulation characteristics

Strong low pressure zones persisted for a longer time than normal most of the month particularly over north-western and northern Europe, causing frequent rainfall and thunderstorms over these areas. Western and central Europe and the areas around the Black Sea were under occasional low pressure influence.

Most of the other parts of the Region were mainly under high-pressure influence and a warmer air mass, but high pressure systems did not persist for very long and were frequently interrupted by cyclonic disturbances. Arctic cold air affected north-eastern Europe only here and there.

During the last ten days of the month, warm air advected from northern Africa towards the western and central Mediterranean, leading to high temperatures there.

Temperature

July continued the series of warm months in most of the Region. In most of Europe, the Arctic and over the Mediterranean, monthly mean anomalies were higher than +1°C, in large parts from eastern central Europe to the Ukraine over +2°C, locally even up to +3°C (Fig. 7.1). North-eastern Europe, parts of Turkey and Armenia and the central North Atlantic were colder than normal, with anomalies partly below -1°C. Some places in western Europe were also colder (though only slightly).

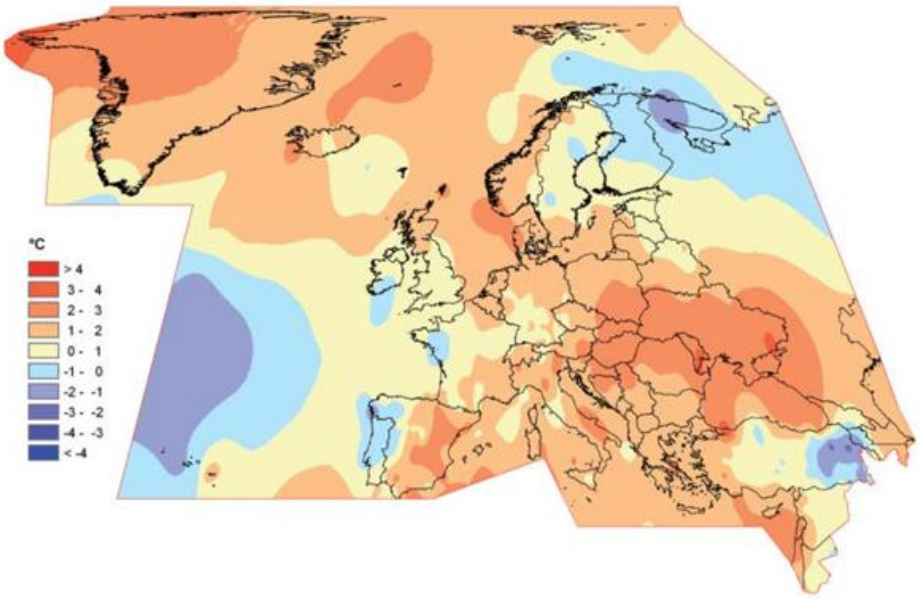

Fig. 7.1: *Monthly mean temperature anomalies in July 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

The Arctic and northern Europe saw quite high maximum temperatures. Svalbard Airport reached a maximum of 14.8°C on 28 July. Norway recorded local monthly mean anomalies of up to +3°C, while some stations in southern Norway set new maximum temperature records. Norway's highest maximum of that month and year was 34.2°C; the same value was reached in Belarus. Lithuania recorded 29-32°C in mid-July on the coast, which in some areas was also record-breaking for this time of the year.

Although Greenland and Iceland were much warmer based on the monthly average, a severe cold spell hit Iceland during the last days of July. Night frosts in the southern lowlands caused large damage to the potato crop, in some places reducing the harvest by up to 80%.

Very cold air masses also affected northern European Russia, Finland and Estonia. On 6 July, some locations in Estonia recorded their lowest minimum 2 m temperature (4-5°C) for that day of year and frost on the ground during the night.

The United Kingdom continued to experience its strongest heat wave in three years. The heat wave also affected Belgium, France and Germany, whereas the periods before and after were much cooler. In Germany, the highest maximum temperature for 2009 was recorded at 37.0°C on 23 July, which was slightly below the record of 37.4°C in 1984. Similar or slightly lower values (34-37°C) were also reached in Poland, the Czech Republic, Austria (where new records were set) and Hungary.

Temperatures of around 40°C favoured numerous forest fires, mainly in Spain and Greece, but also in other parts of the Mediterranean region (Corsica, Sardinia, Sicily). A heat wave in the second half of the month brought temperatures of 40-45°C to various places in Spain and Italy. The peak value registered at official Italian stations was 45.0°C in Decimomannu, Sardinia, setting a new local record for this location. Malta (Fig. 7.2) and large parts of south-eastern Europe, e.g. Montenegro, Romania and Bulgaria, as well as the south-eastern Ukraine, the north and south of the Caucasus in European Russia (Volgograd and Astrakhan regions) and Azerbaijan also reached 40°C or more. Serbia had daily maxima above 30°C during nearly the whole second half of the month (the highest value was 38.4°C). Jordan had its highest annual maximum on 1 July with 45.5°C in the Jordan Valley.

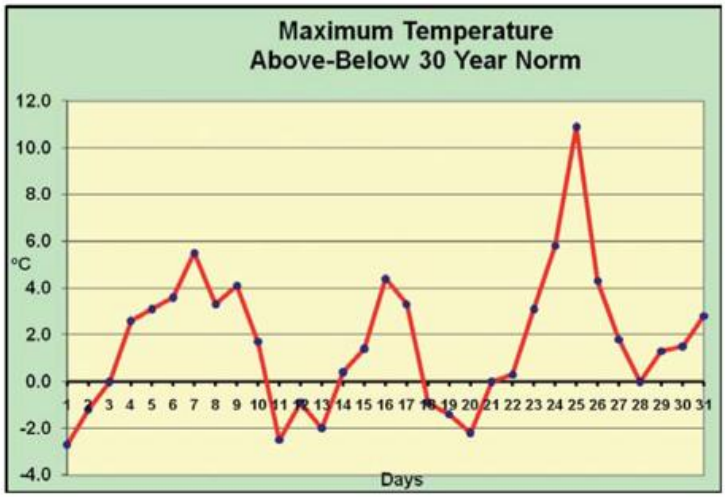

Fig. 7.2: *Daily maximum temperature anomalies in July 2009 (reference period 1961-1990) at Malta International Airport. The peak value (41.6°C) recorded on 25 July during a heat wave exceeded the monthly normal by more than +10°C and was the highest temperature since 1998*

Precipitation

July was wetter than normal in western, central and northern Europe (except for the Arctic) and around the Black Sea and Turkey (Fig. 7.3). Large parts of southern and eastern Europe and some of the Middle East were drier.

The Arctic was exceptionally dry. In western Greenland, the station of Nuuk recorded its second driest July since 1890, with a total of only 1.4 mm. In Iceland, it was the driest July in Reykjavik since 1889.

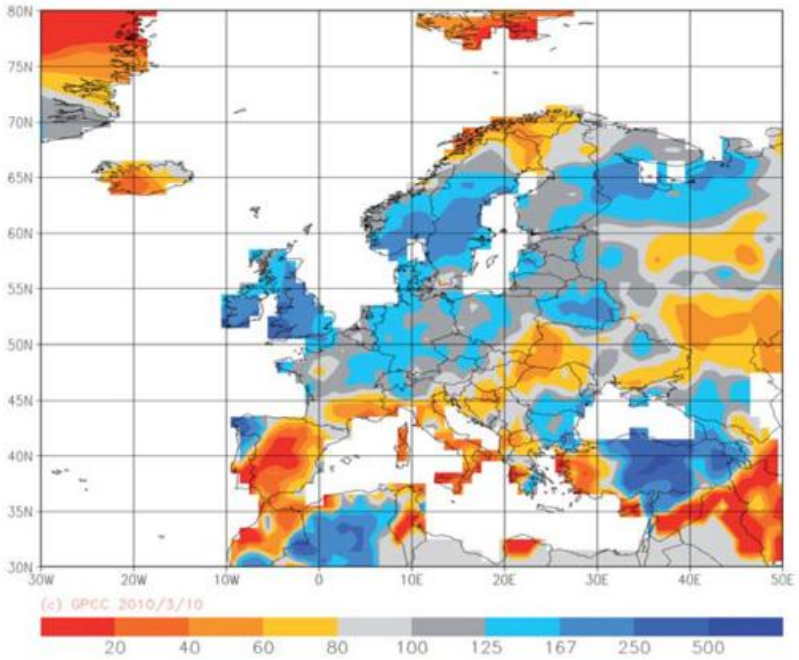

Fig. 7.3: *Monthly precipitation amounts for July 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

In many places in Norway and Sweden, July was among the wettest since records began in 1900. Some areas in Sweden recorded up to 350% of their average July totals, setting new monthly July records at several stations as the result of some days with very heavy rainfall. The Baltic countries also saw some heavy rain events.

England and Wales as well as some places in Ireland had their wettest July on record. Monthly totals exceeded 300% of the normal in parts of the United Kingdom and south-eastern Ireland.

Central Europe including the alpine region saw much rain due to frequent thunderstorms, partly with much hail and locally twice the normal precipitation. In southern Switzerland, the city of Lugano reported its highest July precipitation (397 mm) since records began in 1864, mainly due to two large thunderstorms during the middle of the month.

It was also very wet in north-western Iberia, several places in Serbia, southern Romania, Bulgaria, eastern Turkey, Georgia and Armenia due to frequent and intense thunderstorms. Some regions in western Georgia registered 400% of the normal. Some locations in the Ararat valley in Armenia received 500-600% of the monthly normal precipitation. Azerbaijan was not so wet, but unstable weather with rainfall and hail, partly with flooding, prevailed during the last ten days of the month.

Most of Iberia and the Mediterranean region saw a very dry July. Less than 20% of the monthly normal total fell in central Spain and southern Portugal and in several areas in southern France and other parts in the Mediterranean region. Some places, e.g. Lisbon in Portugal and Pisa in Italy, did not have any precipitation at all in that month. In Monaco, it was the 4th consecutive dry July.

Snow

In the northern highlands of Iceland, snow appeared in the last days of July during a severe cold spell.

In the middle of July, a cold spell with snowfall occurred in the Alps down to elevations below 2000 m a.s.l. The Zugspitze, Germany's highest mountain (approx. 3000 m a.s.l.), recorded 45 cm of fresh snow within 24 hours.

Significant weather events

July 02: Dublin was affected by flooding after torrential rainfall due to heavy thunderstorms. Parts of the city received 40-50 mm within 9 hours; 26.5 mm fell within one hour at Dublin airport in the early morning, the largest clock-hour rainfall ever recorded at the station. During the afternoon and evening of the same day, even heavier falls affected various parts of Ireland.

July 02-04: Hail as large as 43 mm in diameter was recorded in Petrozavodsk (Karelia, north-western European Russia) on 2 July, although hail rarely occurs in these latitudes (almost 62°N). On 4 July, heavy prolonged rain in the east of the Kaliningrad region; 144 mm of precipitation fell in 12 hours.

July 03-07: Hailstorm, a tornado and local flooding mainly in southern and western Germany, local flooding also in Austria. Several cm of hail in the streets of Essen in western Germany.

July 04-05: Severe storms, partly with hail over large areas of northern and central Armenia with hailstones of 20-25 mm.

Fig. 7.4: *Cumulonimbus above Belgrade (Serbia) on 8 July 2009*
Source: Republic Hydrometeorological Service of Serbia

July 08: Nearly 90 mm of precipitation in 24 hours fell at a station in Sweden (Munktorp) in a large low pressure complex over northern Europe.

July 08: Heavy storm in Serbia in the afternoon over a large area due to extended and high-reaching convective cells (Fig. 7.4).

July 11: Hailstorm with walnut-sized hailstones and heavy local rain up to 80 mm within 24 hours in Bulgaria.

July 15: Hailstorm in southern Austria (Styria); tennis ball-sized hailstones smashed several roofs.

July 16-17: An area of unusually low pressure brought prolonged and heavy rainfall across the United Kingdom. Torrential downpours of more than 94 mm in 24 hours in Cornwall. Flooding particularly in north-east England.

July 17-18: Intense convective events with strong gusts, heavy rain, hail, and snow on the mountains in northern regions of Italy. Roads were closed and railways interrupted. Heavy rain and flooding also in many places in Austria, heavy thunderstorms with hail in large parts of France. An intense cold front passed Hungary; several people were killed, trees fell on power lines, causing serious property damage.

July 21-24: Very intense thunderstorm in Armenia with precipitation up to 70 mm in 4 hours (local record). Heavy rain and flooding also in Turkey.

July 22-23: A thunderstorm with heavy rain, hail and gusts up to hurricane force due to extreme lability following high surface temperatures affected Poland, the Czech Republic, Austria, Switzerland and parts of eastern and south-eastern Germany, causing trees to fall and local flooding (Fig. 7.5). Much damage on houses, vineyards, crops. Electricity was disrupted in 50,000 households in Austria.

Fig. 7.5: *Flooding in the town Steyr in upper Austria on 23 July 2010 after heavy thunderstorms*
Source: Zentralanstalt für Meteorologie und Geodynamik (ZAMG), Austria

July 30-31: An intense low-pressure system over southern Norway produced very strong winds in Denmark, southern Sweden and southern Norway. Wind speeds of up to more than 100 km/h were locally measured along the Danish and the Swedish west coast; on the southern Norwegian coast it even reached hurricane force. A ship sank off the Swedish west coast, causing the death of six people; a bulker grounded in southern Norway, causing an oil spill across a wide area. Normally, storms are rather rare events in this region during summer.

August

- **Mostly warmer, but colder in eastern Europe and over the central North Atlantic**
- **Mostly very dry, some very wet places in north-western Europe and in the east**

Atmospheric circulation characteristics

The frontal zone over the North Atlantic became stronger than in the months before. Again, low pressure systems crossed north-western and northern Europe. In Scandinavia, temporary high pressure periods caused high summer temperatures only in the first half of the month.

Most of the western, central and southern parts of the Region were mainly under the influence of high pressure. There was only rare convective activity over the Mediterranean. The warm air mass frequently spread over the whole of Europe and the Arctic.

Eastern Europe often lay on the east flank of the high pressure zone, and cold air masses from the north moved across these areas as far as the Caucasus.

Temperature

The third summer month, too, was warmer than normal in most of Europe and the Arctic (Fig. 8.1) and much more settled than July. Monthly mean anomalies were highest in the Alpine region and south of it, locally even exceeding +4°C, which was particularly due to warm nights. Large parts of central, south-eastern and southern Europe were more than +2°C warmer than normal.

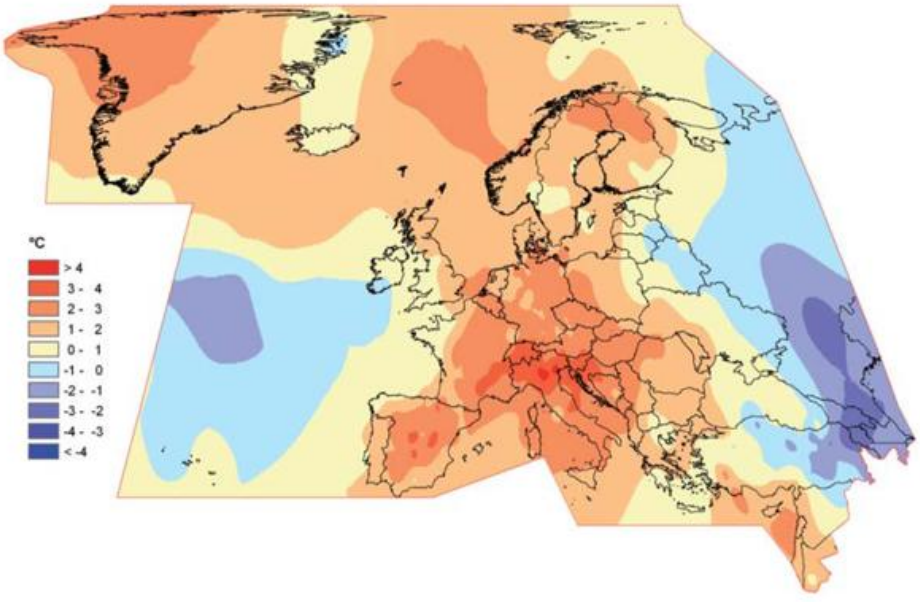

Fig. 8.1: *Monthly mean temperature anomalies in August 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

At the beginning of the month, temperature maxima above 25°C were reached in northern Scandinavia, however followed by frosts after a cooling in the middle of the month.

During a short heat wave in western and central Europe around 20 August, maximum temperatures rose to 37.8°C in north-western parts of Germany, but did not reach the German record values of summer 2003. A maximum temperature of 37°C was also reached or exceeded in the Netherlands, Luxembourg and in many places in south-eastern Europe. Locally, temperatures reached or exceeded 40°C in southern France, Italy, Spain and Romania, while Malta reported a maximum of 35°C and Monaco 34.5°C (the highest since at least 1990).

The long persistence of high temperatures was unusual even for Spain, where temperatures usually tend to decrease at this time of the year. It was the warmest August in Madrid since 1970. Maxima in Italy were not as high in August as in July, although the perceived temperature was very high due to high humidity and the resulting unfavourable thermal stress conditions causing physical discomfort. During the nights, temperatures remained above 20°C (tropical nights) even in southern Switzerland. It was the third warmest August in Switzerland since 1864. In Monaco, it was the warmest August since 1969 with a monthly mean of 26°C.

Eastern Europe, the Caucasus region and the central North Atlantic were colder than normal. In southern European Russia and in parts of the south Caucasus region, mean anomalies were below -2°C. Southern European Russia has not seen such a cold August for more than 30 years and new daily minimum records were measured in many places.

Precipitation

It was a very dry August in most of the Region (Fig. 8.2). Many places particularly in the south and around the Black Sea received less than 20% of their normal monthly precipitation. Some heavy thunderstorms, however, occurred in many parts of the Region.

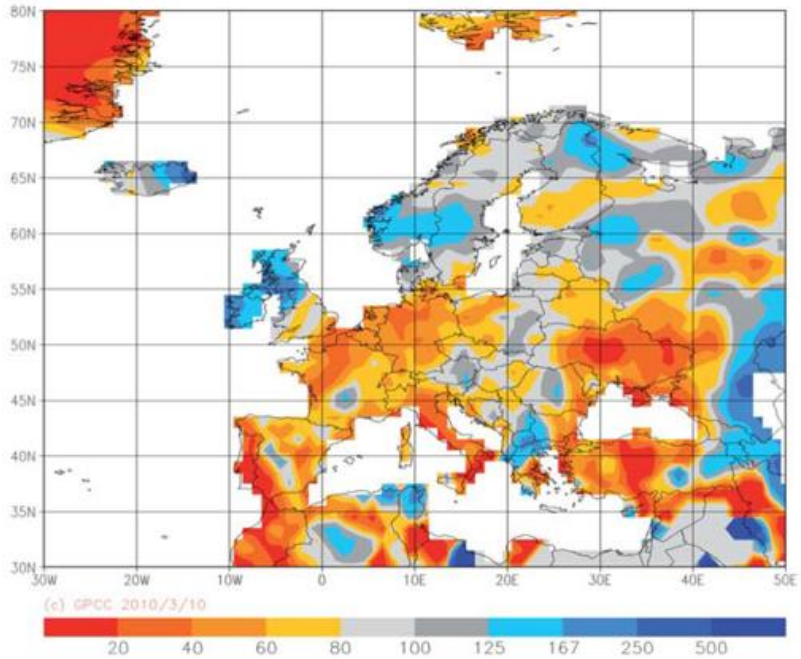

Fig. 8.2: *Monthly precipitation amounts for August 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
Source: Global Precipitation Climatology Centre (GPCC), Deutscher Wetterdienst, Germany

In Iberia, Madrid and Lisbon, as well as Pisa in Italy did not see more than 1 mm of precipitation throughout the whole month. Monaco registered only 0.1 mm the whole month (long-term average: 33 mm); it was the driest August since at least 1969. Severe drought conditions also

affected eastern Syria during August. Thousands of Syrian farming families were forced to migrate to cities after two years of drought and failed crops.

There were only a few areas which were wetter than normal, mainly in north-western Europe (eastern Iceland, Ireland, northern United Kingdom), in Fennoscandia, the eastern alpine region, on the southern Balkan Peninsula and in the east (particularly around the Caspian Sea, where more than 200% of the normal were reported).

Western Scotland had its wettest August since records began in 1910, with about twice the normal August rainfall. Northern parts of southern Norway received over 200% of the normal, partly with new local monthly and daily records. Armenia received nearly 200% of the long-term average precipitation due to frequent heavy precipitation with hail. Similar precipitation anomalies were recorded in Azerbaijan, while parts of eastern Georgia even received 500% of the normal.

Snow

Very intense snow melting was observed on the glaciers in the Alps and on the Sonnblick mountain in Austria.

Significant weather events

August 03-05: Heavy precipitation in Austria: locally 100 mm or more within 24 hours. Severe thunderstorms with hail in Slovenia.

August 05-07: Torrential rain caused floods and damage in Bulgaria (district of Sofia and in the east).

August 08: Heavy shower in the upper Volga region (Mordovia, European Russia); 80 mm of precipitation fell in 48 minutes.

August 22: Severe hailstorms and heavy precipitation in Austria and Slovenia. Floods and mudflows south of Innsbruck and in southern Austria.

August 22-23: Strong north-eastern winds up to 82 km/h over eastern Greece, contributing to the extension of forest fires in north-eastern Attica.

August 24-26: Thunderstorms with locally heavy rainfall in France: 136 mm (Puy-de-Dome), 152 mm (Loire).

August 29: Heavy rainfall in southern Lithuania with 57 mm of precipitation in 8 hours.

August 29: Intense convective storm with hourly precipitation totals over 60 mm at several stations around Bologna, Italy.

September

- **Warmer nearly in the whole of Europe, particularly in the eastern parts, colder in the Middle East**
- **Mostly dry, wet in northern Fennoscandia, the Mediterranean region and the Middle East**

Atmospheric circulation characteristics

A frontal zone extended from the North Atlantic to northern Europe. The Arctic was mainly influenced by low pressure, middle latitudes mostly by high pressure.

The Mediterranean region was located at the south flank of this large high pressure zone. Frequent and strong low pressure activity occurred there, causing heavy rain in various parts of that area.

Temperature

September was another warmer-than-normal month in nearly the whole of Europe and in the Arctic. Highest monthly mean anomalies were to be found in European Russia (more than +3°C over large areas) and places in the Ukraine (Fig. 9.1). In the whole of northern, central and eastern Europe and the central Mediterranean region it was more than +1°C warmer than normal (except for the southern parts, e.g. Malta: +0.5°C), while in eastern Europe and many places of eastern central and south-eastern Europe the temperatures were more than +2°C higher than normal. Based on the monthly average, western and south-western Europe were only slightly warmer (< +1°C).

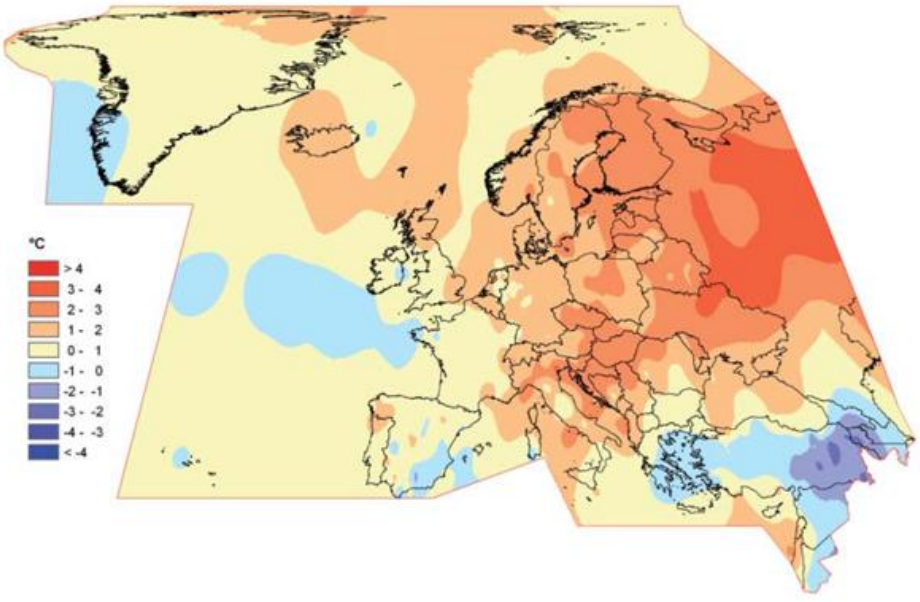

Fig. 9.1: *Monthly mean temperature anomalies in September 2009 (reference period 1961-1990) in WMO Region VI*
Source: Deutscher Wetterdienst, Germany

At the end of the month, cold arctic air reached the Nordic and Baltic countries, bringing the first morning frosts of the coming cold season to Lithuania.

The beginning of the month was particularly hot in Germany and Austria, with maximum temperatures above 30°C and marking 1 September as the hottest September day on record in central Germany. Serbia had a daily maximum of 36.8°C on 4 September. Northern and central Serbia had twice as many summer days (daily maxima >=25°C) as normal. The nights were also warm, and tropical nights were recorded in Romania.

Portugal experienced two heat waves of 6-7 days each and peak temperatures above 35°C, one early in the month, the other at the end, largely affecting the central region of Portugal. Near the western Mediterranean, Monaco saw its highest September maximum temperature (33°C) since 1990.

The Middle East including the Caucasus region and some places in southern Europe, over the Mediterranean and the North Atlantic were colder than normal. Anomalies below -2°C were recorded particularly in eastern Turkey and at some locations in Armenia. However, temperature maxima in Turkey locally exceeded up to 37°C.

Precipitation

September was very dry in most of Europe, especially in the middle latitudes and in the southern parts of northern Europe, but also in mainland Portugal, western Spain and south-eastern Europe, with less than 20% of the normal monthly precipitation in various places (Fig. 9.2). Drought conditions affected various parts of the continent, even central Europe (e.g. the Czech Republic) at the end of the month. However, some areas in the north and in the south were much wetter than normal.

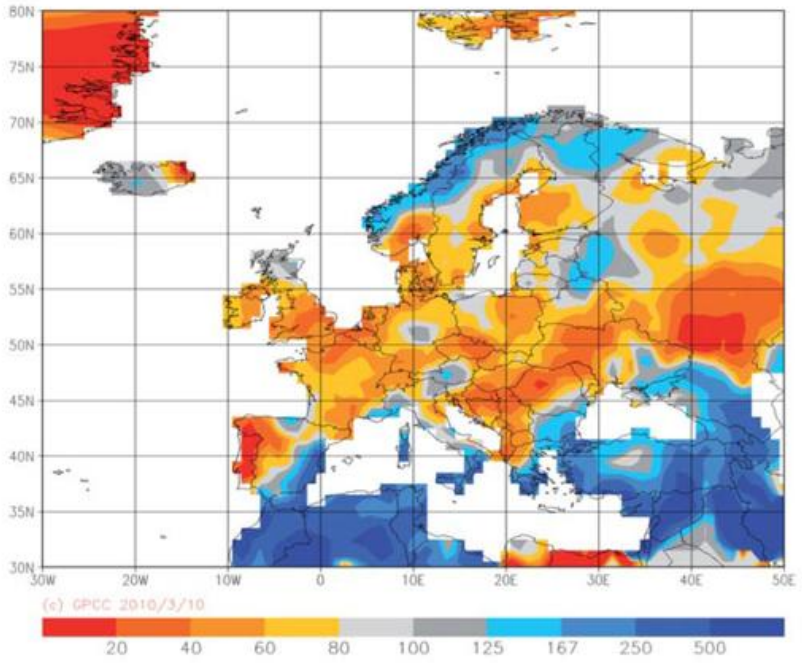

Fig. 9.2: *Monthly precipitation amounts for September 2009 in per cent of the normal 1951-2000 in Europe and adjacent areas*
