1) Seit 01.04.1965 werden die Werte vom windgeschützten Standort des Niederschlagsmessers auf dem Wendelsteingipfel im Gelände des Sonnenobservatoriums (H = 1836 m) veröffentlicht. Die Messungen der Schneehöhe werden auf dem Ostgipfel des Wendelsteins (H = 1790 m) an einem 3 Meter hohen Schneepegel durch Fernablesung vorgenommen.

1) Seit vor 1983 werden die Messungen im Herbst und Winter durch hohe Gebäude und Bäume verfälscht. 2) Meßlücken wurden durch interpolierte Werte geschlossen. 3) Korrektur $h_s$ = 9,7 m seit April 1992. 4) Sommeraufstellung (IV–IX): $h_s$ = 1,2 m. 5) Ab 1. 1. elektr. Meßgerät.

1) Am 6. 4. Neuaufstellung eines elektr. Meßgeräts; zuvor $h_s$ = 1,5 m. 2) Seit 30. 9. 1992 elektr. Meßgerät; zuvor $h_s$ = 16,4 m. 3) Sommeraufstellung (15. 4. bis 31. 8.): $h_s$ = 1,7 m. 4) Ab 1. 6. wird mit einem elektr. Meßgerät am Flugplatz gemessen; zuvor $\lambda$ = 6° 58′ E, $H_s$ = 152 m, $h_s$ = 13,7 m. 5) Am 7. 2. Verlegung und Neuaufstellung eines elektr. Meßgeräts; zuvor $\lambda$ = 7° 10′ E, $H_s$ = 92 m, $h_s$ = 8,5 m.

1) Ab 1. 4. anstelle der aufgelösten Station Karlshuld, s. Seite 178; bis März Meßergebnisse von Karlshuld. Die Meßfühler standen im Grundwasser: in 0,5 m Tiefe zeitweise im Januar und April, in 1 m Tiefe von Januar bis April.
2) Die Meßfühler in 0,5 und 1 m Tiefe standen meistens im Grundwasser.
3) Die Meßlücke in 0,5 m Tiefe vom 20. bis 25. 2. wurde durch Interpolation geschlossen.

# III PHÄNOLOGISCHE BEOBACHTUNGEN

## Erläuterungen

Dieser Abschnitt des Jahrbuchs enthält eine Auswahl phänologischer Beobachtungen aus dem Jahr 1994. Auf den Seiten 218 bis 247 sind Meldungen der phänologischen Beobachter des Deutschen Wetterdienstes und auf Seite 217 Angaben von 22 in der Bundesrepublik Deutschland gelegenen *Internationalen Phänologischen Gärten*, die mit erbgleichen Bäumen und Sträuchern ausgestattet sind, zusammengestellt.

Der Anhang enthält vier phänologische Jahreskarten, die ab 1994 mit Hilfe der Rechenanlage automatisch erzeugt werden. Kurze Angaben zu den darin erkennbaren Entwicklungsabläufen und zu den auslösenden Witterungserscheinungen bieten die unten stehenden Hinweise.

Am Ende des Jahres 1994 waren in der Bundesrepublik Deutschland rund 2400 freiwillige Beobachter im phänologischen Beobachtungsnetz tätig.

### Die phänologischen Tabellen

Die Tabellen gliedern sich in drei Gruppen, A = wildwachsende Pflanzen (Seite 218 bis 227), B = landwirtschaftliche Kulturpflanzen (Seite 228 bis 237) und C = Obst (Seite 238 bis 247). Jede der drei Gruppen enthält die Beobachtungsergebnisse von 375 ausgewählten Beobachtungsstationen, die einigermaßen gleichmäßig über das Gebiet der Bundesrepublik verteilt sind.

Die Beobachtungsergebnisse werden in Form von Jahrestagszahlen (Anzahl der Tage seit Jahresbeginn) und nicht als Kalenderdaten veröffentlicht; siehe dazu den "Schlüssel zu den Zeitangaben" auf der nächsten Seite. Die Daten wurden mit EDV bearbeitet und notwendige Korrekturen manuell vorgenommen. Korrigierte Daten sind in den Tabellen daran erkenntlich, daß ihnen die Zahl 500 hinzugezählt wurde; alle Werte über 500 sind somit korrigierte Werte. Eintrittsdaten, die bereits am Ende des Vorjahres beobachtet wurden, sind als negative Werte dargestellt.

### Die phänologischen Karten

Die vier im Anhang enthaltenen phänologischen Jahreskarten wurden mit folgenden Isophänenabständen erzeugt:

| | |
|---|---|
| Beginn der Schneeglöckchen-Blüte | von 15 zu 15 Tagen |
| Beginn der Apfel-Blüte | von 10 zu 10 Tagen |
| Beginn der Winterroggen-Vollblüte | von 10 zu 10 Tagen |
| Beginn der Winterroggen-Gelbreife | von 10 zu 10 Tagen |

*Beginn der Schneeglöckchen-Blüte*

Begünstigt durch die vorherrschend milde und feuchte Witterung im Januar begann mit der Schneeglöckchenblüte ab 2. Januarhälfte der Vorfrühling vor allem im Westen, gebietsweise im Südwesten, in der Nordhälfte und in Niederbayern.
Ab Februar konnte der Blühbeginn in den meisten Gebieten Deutschlands beobachtet werden, nur im Norden und Osten sowie im Gebirgs- und Hügelland verzögerte er sich häufig bis in die 3. Februardekade bzw. vereinzelt im Norden und in den höheren Gebirgslagen bis in die 1. Märzhälfte.

*Beginn der Apfel-Blüte*

Die Apfelblüte begann in der 1. Aprildekade im gesamten Oberrheingraben sowie vereinzelt an Neckar und Bodensee. Sie setzte sich in der 2. Aprildekade in größeren Gebieten der Westhälfte und in günstigen Lagen, z.B. im mittleren Saaletal, danach bei milder Witterung in der 2. Aprilhälfte auch in den übrigen Gebieten fort.
Nur im nördlichen Drittel Deutschlands sowie im Gebirgsvorland und in den Mittelgebirgen blühten die Apfelbäume erst in der 1. Maidekade, in den höheren Gebirgslagen meist ab Mitte Mai.

*Beginn der Winterroggen-Vollblüte*

Trotz wechselhafter Witterung begann die Winterroggen-Vollblüte verbreitet in der 3. Maidekade im Oberrheingraben, am Neckar, in Mainfranken sowie in größeren Gebieten Mittel- bzw. Ostdeutschlands und in Niederbayern.
Im Norden, in der Nordwesthälfte Deutschlands und in den Mittelgebirgen verzögerte sich der Beginn meist bis in die 2., gebietsweise auch bis in die 3. Junidekade.

*Beginn der Winterroggen-Gelbreife*

In günstigen Lagen - vor allem gebietsweise an Rhein, Main und Donau - wurde der Gelbreifebeginn ab Ende Juni beobachtet. Die trockene und heiße Witterung ab 2. Julidekade ließ das Getreide beschleunigt reifen, so daß die Gelbreife fast überall bis zum Ende der 2. Julidekade erreicht wurde.
Nur im Norden und in den Mittelgebirgen trat der Reifebeginn erst in der 3. Julidekade und vereinzelt sowie in höheren Lagen auch danach ein.

# V. ERGEBNISSE DER AEROLOGISCHEN AUFSTIEGE 1994

ERLÄUTERUNGEN

An den nachstehend aufgeführten Stationen wurden vom Deutschen Wetterdienst regelmäßig aerologische Messungen durchgeführt:

1) RW = Radiosondenmessung und gleichzeitige Radarmessung des Höhenwindes; W = Radarmessung des Höhenwindes.
2) Vom 15.10.1993 bis 1.7.1994 Startplatzhöhe = 98 m wegen Bauarbeiten an der Ballonhalle.

Grundlage der Jahrbuchbearbeitung sind die auf Diskette von den aerologischen Stationen übermittelten und im Klima-Archiv gespeicherten aerologischen Daten an Hauptdruckstufen und markanten Punkten. Die Auswertung der Aufstiege nach markanten Punkten erfolgt nach einem objektiven Verfahren automatisch.

Tägliche Werte der Radiosondenaufstiege und Radarmessungen des Höhenwindes sind im "Europäischen Wetterbericht" des Deutschen Wetterdienstes, Beilage 2 veröffentlicht.

*) Die Höhenwindmessung erfolgt ab 1994 mit einem Radargerät des Typs WFX 300.

In den nachstehenden Tabellen sind für ausgewählte Druckstufen bis 30 hPa von geopotentieller Höhe, Temperatur, Relativer Feuchte und Wind Monats- und Jahresmittel, von der Temperatur auch absolute Maxima und Minima, sowie Mittel- und Extremwerte der Tropopause von 9 oben genannten Radiosondenstationen des Deutschen Wetterdienstes zusammengestellt. Ferner werden die skalaren Mittelwerte der Windgeschwindigkeit dieser Stationen für 06 und 18 Uhr UTC mitgeteilt.

Als Überblick über die erreichten Höhen der Radiosonden, zur Kennzeichnung der Repräsentanz dieser Werte für die höheren Schichten und zur Berechnung von gewichteten Mittelwerten mehrerer Jahre wurde auch die Anzahl der Messungen für einige Druckstufen hinzugefügt. Sofern weniger als 5 Meßwerte vorlagen, entfallen Monatsmittel und Jahresmittel; letzere auch dann, wenn nur 5 bis 9 Meßwerte vorhanden waren.

Auf den letzten Tabellenseiten erscheinen von den 9 Radiosondenstationen monatlich und jährlich Häufigkeiten und Mittelwerte des vertikalen Temperaturgradienten in den Schichten 0-299, 300-599 und 600-999 m über Grund. In diesem Zusammenhang werden noch die folgenden Hinweise zur Stationslage gegeben. Schleswig: 2 km nördlich der Schlei in flacher Kuppenlage; Hannover: am Flughafen Hannover-Langenhagen; Essen: in Essen-Bredeney, 100 m höher als die Sohle des benachbarten Ruhrtales gelegen; Stuttgart: auf dem Schnarrenberg, nahe des steilen Geländeabfalls zur 100 m tiefer liegenden Talsohle des Neckars; München: auf der Münchener Ebene in Oberschleißheim, nördlich des Stadtgebietes von München. Greifswald: östlich des Altstadtkernes, in der Talaue des Ryck; Lindenberg: etwa 30 km südöstlich vom Stadtrand Berlins, an der SW-Seite der bis 122 m über NN aufragenden, bewaldeten Kalkberge; Wahnsdorf: Hochfläche am Nordrand des Dresdner Elbtalkessels, nahe des steilen Geländeabfalls zur 100 m tiefer liegenden Stadt; Meiningen: Hochfläche, westlich der im Werratal liegenden Stadt Meiningen.

Um ein anschauliches Bild über die jahreszeitlichen Änderungen der Stabilitäts- und Windverhältnisse bis zur Höhe von 26 gpkm zu vermitteln, sind von 4 Stationen die vertikalen Gradienten der Lufttemperatur und die Zonal- und Meridionalkomponenten des Höhenwindes in Form von Isoplethen sowie die mittlere Luftversetzung als Vektorfeld dargestellt worden (siehe Abbildung 1 bis 4 im Anhang).

Die "mittlere Luftversetzung" wurde in den Abbildungen 3 und 4 der Jahrgänge 1991 bis 1993 aufgrund eines Programmierfehlers falsch dargestellt.
