VORWORT ZUR ERSTEN AUFLAGE

Bei der weiten Verbreitung, die das *Assmann*sche Aspirations-Psychrometer und auch sein Aspirator für das feuchte Thermometer gefunden haben, ist der Mangel an dazu passenden Tafeln für die Berechnung der Feuchtigkeitswerte sehr fühlbar geworden.

Da diese Instrumente auch im Netze des Preußischen Meteorologischen Instituts bereits vielfach im Gebrauch stehen und künftig noch mehr in Benutzung genommen werden sollen, erschien es angezeigt, für die Herausgabe solcher Tafeln Sorge zu tragen.

Die hiermit zur Veröffentlichung gelangenden Aspirations-Psychrometer-Tafeln sind zwar vornehmlich für den Gebrauch an den meteorologischen Stationen bestimmt, doch ist durch verschiedenartige Hilfstafeln auch vielen anderen Zwecken in umfassender und wohl auch praktischer Weise Rechnung getragen.

Plan und Anordnung der Tafeln rührt von dem Abteilungsvorsteher Prof. Dr. *Kremser* her, dem auch die Redaktion sowie die Überwachung der Rechnungen oblag. In diesen wurde er außer von Beamten des Instituts, nämlich dem Observator Prof. Dr. *Lachmann,* dem Sekretär *Bauer* und dem Bürohilfsarbeiter *Nauck*, insbesondere von dem Beobachter an der meteorologischen Station in Hildesheim, Herrn Landmesser *Bötel,* unterstützt, dem der weitaus größte Teil der Berechnung der »Ausführlichen Tafeln« zu verdanken ist.

Berlin, im März 1908. *G. HELLMANN*

VORWORT ZUR DRITTEN AUFLAGE

Nachdem die 2. Auflage, die im Jahre 1914 erschien und im Jahre 1937 unverändert abgedruckt wurde, vergriffen ist und dadurch eine Neuauflage notwendig wurde, konnten viele aus der Praxis entstandenen Verbesserungswünsche berücksichtigt werden. Es wurden die internationalen Bestimmungen der Meteorologischen Organisation der Erde (WMO) (Sättigungsdampfdruck aus den Smithsonian Meteorological Tables, 1951) und die seit 1937 gewonnenen theoretischen Erkenntnisse (Psychrometerkonstante 0.43 über Eis) berücksichtigt.

Die ausführlichen Tafeln über Wasser konnten bis 45° feuchter und 55° trockener Temperatur erweitert und neu die Tafeln zur Bestimmung des Taupunktes sowie des Sättigungsdefizits eingefügt werden. Einem Bedürfnis der Praxis wurde Rechnung getragen, indem in den ausführlichen Tafeln eine Randleiste zur Bestimmung des Taupunktes aus dem herrschenden Dampfdruck aufgenommen wurde. Für die Luftdruckkorrektion wurden neue Tafeln beigefügt, welche auch die Konstante 0.43 über Eis berücksichtigen.

Als Herausgeber dieser neuen Auflage tritt der Deutsche Wetterdienst an die Stelle des früheren Reichsamtes für Wetterdienst.

Bad Kissingen, Juni 1954.

INHALT

Seite

Vorwort V

Einleitung . . . . . VII–XX

Erläuterungen zu den Tafeln VII

Gebrauchsanweisungen und Beispiele X

Tafeln des Sättigungsdampfdrucks des Wasserdampfes über Eis und Wasser 2–7

Ausführliche Tafeln für Dampfdruck und relative Feuchtigkeit, gültig für den Luftdruck von 755 mm . 8–15

Korrektionen für den Luftdruck 156–160

Abzugsglied der *Sprung*schen Formel 161, 162

Faktor $\frac{100}{E}$ zur Berechnung der relativen Feuchtigkeit 163

Mischungsverhältnis und spezifische Feuchtigkeit 164, 165

Unterschied zwischen Dampfdruck und absoluter Feuchtigkeit 166

Tafeln zur Berechnung des Dampfdrucks aus den Angaben des Haarhygrometers und der Lufttemperatur . . . . . 168—179

Tafeln zur Bestimmung des Taupunktes aus dem herrschenden Dampfdruck 180, 181

Tafeln zur Bestimmung des Sättigungsdefizits aus Temperatur und relativer Feuchtigkeit 182, 183

EINLEITUNG

Zur Ermittelung des Dampfdrucks aus Beobachtungen am *Assmann*schen Aspirationspsychrometer hat *Sprung*[1]) die Formel gefunden:

$$e = E' - C(t-t')\frac{b}{755},$$

wo e den gesuchten Dampfdruck in Millimetern, E' den Sättigungsdampfdruck bei der Temperatur des befeuchteten Thermometers t', C die Psychrometerkonstante, t und t' die Temperaturen des trockenen und feuchten Thermometers in °Celsius und b den Barometerstand in Millimetern bezeichnen. Spätere Untersuchungen[2]) haben ergeben, daß dies eine gute Näherungsformel ist. Die Psychrometerkonstante[3]) beträgt dabei für Wasser 0.5, für Eis 0.43.

Die zugehörigen Werte für die relative Feuchtigkeit sind alsdann durch die Formel

$$R = 100\,\frac{e}{E}$$

gegeben, wo E den Sättigungsdampfdruck bei der Temperatur des trockenen Thermometers bedeutet.

Erläuterungen zu den Tafeln

SÄTTIGUNGSDAMPFDRUCKTAFELN

In den obigen Formeln wird die Kenntnis des Sättigungsdampfdrucks des Wasserdampfes (E' und E) für die einzelnen Temperaturen vorausgesetzt. Da sie somit den Ausgangspunkt aller Feuchtigkeitsberechnungen bildet, erscheinen die *Tafeln des Sättigungsdampfdrucks des Wasserdampfes* auch in der vorliegenden Sammlung an erster Stelle (S. 2 bis 7). Sie wurden nach den Bestimmungen der meteorologischen Organisation der Erde (WMO) aus den Smithsonian Meteorological Tables (mb) übernommen und für mm umgerechnet.

AUSFÜHRLICHE TAFELN

Diese enthalten Dampfdruck (in mm) und relative Feuchtigkeit (in Prozenten) für gegebene Meßwerte des trockenen und feuchten Thermometers t und t', nach zehntel Grad fortschreitend, bei einem Luftdruck von 755 mm, wo die *Sprung*sche Formel die für die Berechnung sehr einfache Gestalt $e = E' - C(t - t')$ hat. Die Zahlen gelten also streng genommen nur für einen Barometerstand von 755 mm; sie können aber, da die Zunahme oder Abnahme des Luftdrucks nur ganz allmähliche Änderungen von e und R bedingt, ohne weiteres auch bei den anderen Barometerständen im Meeresniveau und in der Tiefebene verwendet werden — außer bei ganz ungewöhnlichen Luftdruckverhältnissen oder bei besonders strengen Genauigkeitsanforderungen. In letzterem Falle sowie

bei Beobachtungen an höher gelegenen Orten (etwa von 200 m an) und in der freien Atmosphäre sind freilich wegen des niederen Luftdrucks Korrektionen nötig, die weiter unten besprochen und mitgeteilt werden.

Die ausführlichen Tafeln haben mit besonderer Rücksicht auf Beobachtungen in den Tropen eine erhebliche Erweiterung erfahren. Sollten sie trotzdem im Stich lassen, so kann man sich, wenn nicht große Genauigkeit erwünscht ist, meist durch einfache Extrapolation helfen, sonst aber wird die direkte Berechnung nach den obigen Formeln nicht zu umgehen sein.

Die ausführlichen Tafeln geben zunächst auf S. 8 bis 31 Dampfdruck und relative Feuchtigkeit für den Fall, daß das Thermometergefäß mit Eis bedeckt ist. Um dies deutlich hervortreten zu lassen und Verwechslungen zu vermeiden, ist jede der betreffenden Seite der Tafeln mit „Eis!" überschrieben. Man beachte, daß hier bei gleichem Stande des trockenen und feuchten Thermometers kein Sättigungszustand besteht und demnach die relative Feuchtigkeit nicht 100 Proz. beträgt; denn es wird ja nach dem Obigen der jeweilige Dampfdruck nicht zum Sättigungsdampfdruck über Eis, sondern zu dem etwas größeren über Wasser in Beziehung gesetzt. Soweit angängig, wurden die Tafeln bis zur relativen Feuchtigkeit von 100 Proz. fortgeführt, indem für das trockene Thermometer auch noch etwas tiefere Temperaturen als für das befeuchtete Thermometer angenommen und zur Berechnung verwendet wurden — wie es ja den tatsächlich vorkommenden Beobachtungsverhältnissen entspricht. Da aber bei tiefen Temperaturen eine Änderung von 0.1° sogleich eine Änderung der Feuchtigkeit von mehreren Prozenten bedingt, so bleiben naturgemäß die Höchstwerte in den Tafeln häufig gegen die Zahl 100, dem Kennzeichen des Sättigungszustandes, zurück; wenn man diesen äußeren Mangel vermeiden wollte, müßte man Beobachtung und Berechnung auf hundertstel Grad einrichten.

S. 32 bis 39 enthalten die Werte von Dampfdruck und Feuchtigkeit zu den Temperaturen unter Null bis — 10° für den Fall, daß das Wasser am befeuchteten Thermometer *nicht* gefroren, also unterkühlt ist. Am Kopfe dieser Seiten wird durch die Überschrift „Wasser!" hierauf aufmerksam gemacht.

S. 40 bis 154 endlich enthalten die Feuchtigkeitswerte für die Temperaturen über Null; beim feuchten Thermometer gehen die Tafeln bis 45.9°, beim trockenen bis 55.0°, was wohl für ganz Europa und auch für die Tropen ausreichend sein dürfte.

Zum leichteren Gebrauch dieser ausführlichen Tafeln im synoptischen Wetterdienst wurden Randleisten aufgenommen, welche die Bestimmung des Taupunktes τ aus dem herrschenden Dampfdruck e ermöglichen, siehe auch S. VIII.

BESONDERE TAFELN

Den *Ausführlichen Tafeln* schließen sich einige wichtige *Hilfstafeln* an. Die ersten von ihnen geben die *Korrektionen* des Dampfdrucks und der relativen Feuchtigkeit wegen des von 755 mm abweichenden *Luftdrucks*. Zu ihrer Ermittelung wurde die *Sprung*sche Formel in folgender Weise zergliedert:

$$e = E' - C(t - t')\frac{b}{755} = \left[E' - C(t - t')\right] + \left[C(t - t')\frac{755 - b}{755}\right].$$

Das erste Glied in eckigen Klammern rechts stellt die für $b = 755$ mm gültigen Dampfdruckwerte dar, wie sie in den ausführlichen Tafeln gegeben sind, das zweite ihre Luftdruckkorrektionen, die mit $\triangle e$ bezeichnet werden mögen. Diese $\triangle e$ sind auf S. 156, 158 und 160 nach b, von 10 zu 10 mm fortschreitend, und nach der psychrometrischen Differenz $t - t'$, von Grad zu Grad fortschreitend, gegeben, und zwar auf hundertstel Millimeter genau.

Für die relative Feuchtigkeit ergibt sich infolge dieser Korrektion des Dampfdrucks ebenfalls eine Änderung. Es wird nämlich

$$R = 100\frac{e + \triangle e}{E} = 100\frac{e}{E} + 100\frac{\triangle e}{E},$$

wo das erste Glied ganz rechts wieder den Wert der ausführlichen Tafeln, das zweite dessen Korrektion darstellt, die mit $\triangle R$ bezeichnet sei. Diese $\triangle R$ sind in der Tafel auf S. 157 und 159 nach $\triangle e$,

von zehntel zu zehntel Millimeter fortschreitend, und ferner der Vereinfachung halber nicht nach E, sondern nach der Temperatur des trockenen Thermometers, und zwar für jeden Grad zwischen -30^0 bzw. -20^0 und $+40^0$, zusammengestellt. Man geht also mit dem vorher gefundenen $\triangle e$ und der Lufttemperatur t in die Tafel ein, um $\triangle R$ zu erhalten.

Die nächsten Hilfstafeln dienen zur *Erleichterung der Berechnung des Dampfdrucks und der relativen Feuchtigkeit* für die Fälle, daß die ausführlichen Tafeln nicht ausreichen, also insbesondere bei sehr tiefen Temperaturen und großer Trockenheit.

Für den Luftdruck von ungefähr 755 mm erhält man den Dampfdruck sehr leicht durch $e = E' - C(t - t')$; bei abweichendem Luftdruck aber ist man genötigt, auf die ursprüngliche Formel $e = E' - C(t - t')\frac{b}{755}$ zurückzugehen. Für das *ganze Abzugsglied* $A = 0.5\ (t - t')\frac{b}{755}$ bzw. $A = 0.43\ (t - t')\frac{b}{755}$ ist nun auf S. 161 und 162 eine Tafel berechnet mit dem von Grad zu Grad fortschreitenden Argument $(t - t')$ und dem von 10 zu 10 mm fortschreitenden Argument b; durch Interpolation der Tafelwerte, die auf hundertstel Millimeter genau gegeben sind, kann man zu jedem b, t und t' den zugehörigen Wert von A und damit e finden.

Hat man den Dampfdruck ermittelt, dann ergibt sich die relative Feuchtigkeit $\left(R = e \times \frac{100}{E}\right)$ durch Multiplikation mit $\frac{100}{E}$, wo E den zum trockenen Thermometer gehörigen Sättigungsdampfdruck bedeutet. Dieser *Faktor* $\frac{100}{E}$ ist nun in der Tafel auf S. 163 für jedes zehntel Grad der Temperatur von -30^0 bis $+40^0$ angegeben.

Zur Charakterisierung des Wasserdampfgehaltes sind, insbesondere für theoretische Fragen, noch andere Ausdrücke als Dampfdruck und relative Feuchtigkeit in Verwendung, insbesondere das Mischungsverhältnis, die spezifische Feuchtigkeit und die absolute Feuchtigkeit. Mit Hilfe der Tafeln auf S. 164—166 lassen sich diese Größen leicht ermitteln.

Das *Mischungsverhältnis*, d. i. die der Masseneinheit (kg) trockener Luft beigemischte Dampfmenge, ausgedrückt in Bruchteilen dieser Einheit, berechnet sich nach der Formel $0.622\ \frac{e}{b - e}$. Zweckmäßigerweise gibt man aber diese Werte nicht in Kilogrammen, sondern in Grammen, und multipliziert daher die Formel noch mit 1000. Diese Zahlen sind auf S. 164 und 165 für jedes Millimeter Dampfdruck und für den Luftdruck von 10 zu 10 mm so weit gegeben, als sie in der Natur vorkommen dürften oder zur Interpolation nötig erscheinen.

Die *spezifische Feuchtigkeit*, d. i. die Menge des Wasserdampfes in der Masseneinheit (kg) feuchter Luft, ausgedrückt in Bruchteilen dieser Einheit $= 0.622\ \frac{e}{b - 0.378\,e}$, oder in Grammen auf das Kilogramm $= 622\ \frac{e}{b - 0.378\,e}$, unterscheidet sich von dem Mischungsverhältnis so wenig, daß man häufig, besonders bei angenäherten Rechnungen, eines für das andere setzen kann. Nur bei höherer Feuchtigkeit wird man auf den Unterschied stets Bedacht haben müssen. Eine genaue Überführung der einen Größe in die andere ermöglicht die kleine Tafel am Schluß der S. 165, welche deren Differenzen in Grammen auf 1 kg, für e von 5 zu 5 mm und für b von 50 zu 50 mm fortschreitend, erkennen läßt.

Die *absolute Feuchtigkeit*, das Gewicht des Wasserdampfes in der Volumeneinheit, findet man in Grammen pro Kubikmeter zu $f = \frac{1.060}{1 + \alpha t}e$, wo α der Ausdehnungskoeffizient der Luft ist. Der Wert zeigt sich nur wenig verschieden von dem Dampfdruck e, so daß man für diesen Ausdruck vielfach absolute Feuchtigkeit gesetzt hat. Der Unterschied wird jedoch mit steigender Temperatur recht bemerkenswert. Er beträgt nämlich:

$$f - e = \frac{1.060}{1 + \alpha t}e - e = e\left(\frac{0.06 - \alpha t}{1 + \alpha t}\right) = e\left(\frac{16.4 - t}{273 + t}\right).$$

Auf Grund dieser Formel sind in der Tafel auf S. 166 die Differenzen $f - e$ für die verschiedenen Werte der Temperatur zwischen -40^0 und $+40^0$ und des Dampfdrucks bis zu 40 mm in drei Abstufungen so zusammengestellt, daß man den gesuchten Betrag auf Hundertstel unmittelbar entnehmen oder leicht interpolieren kann. In einer besonderen Spalte sind die Werte von $f - e$ für die den verschiedenen Temperaturen entsprechenden Dampfdruckmaxima gegeben. Man sieht aus ihr am besten, daß bei niederen Temperaturen die absolute Feuchtigkeit etwas größer als der Dampfdruck ist, daß dieser Überschuß von den tiefsten Temperaturen bis zu 0^0 allmählich ansteigt, dann aber schnell abnimmt, bis bei 16.4^0 beide gleich sind; von da an ist der Dampfdruck größer als die absolute Feuchtigkeit, und die Differenzen wachsen ziemlich rasch mit steigender Temperatur.

Tafeln zur Bestimmung des Dampfdrucks aus den Angaben des Haarhygrometers und der Lufttemperatur sind auf S. 168—179 vorhanden.

Auf S. 180 und 181 befindet sich eine Tafel, aus der man für den herrschenden Dampfdruck den Taupunkt ablesen kann. Er bezeichnet diejenige Temperatur, bei der der Wasserdampfgehalt der Luft am Beobachtungsort gleich dem maximal möglichen (Sättigungs-) Wasserdampfgehalt ist. In der Randleiste der ausführlichen Tafeln wird der herrschende Dampfdruck mit e, der Taupunkt mit τ bezeichnet. Zu beachten ist, daß im synoptischen Dienst bei Verwenden von ganzen Graden Celsius die Zehntel bei $\bar{5}$ nach der kleineren absoluten Zahl abzurunden, bei $\dot{5}$ nach der größeren absoluten Zahl aufzurunden sind.

Zur raschen Ermittlung des Sättigungsdefizits dienen die Tafeln S. 182 (in mm Quecksilber) und S. 183 (in $g \cdot m^{-3}$). Das Sättigungsdefizit bezeichnet die Differenz zwischen dem Sättigungsdampfdruck E bei der Beobachtungstemperatur t und dem tatsächlichen Dampfdruck e. Die Umrechnung in $g \cdot m^{-3}$ wurde dabei nach der Formel vorgenommen:

$$a = \frac{288.89}{T} E \frac{R}{100}$$

Hierbei ist E in mm Quecksilber, T in abs. Temperaturen und R in % zu rechnen.

Gebrauchsanweisungen und Beispiele

ERMITTELUNG VON DAMPFDRUCK UND RELATIVER FEUCHTIGKEIT AN TIEFLANDSTATIONEN

Man suche in den *Ausführlichen Tafeln* die zu der Angabe des feuchten Thermometers gehörige Seite und auf ihr die zugehörige senkrechte Spalte und gehe in dieser bis zu der Linie abwärts, auf der sich links oder rechts am Rande die Temperatur des trockenen Thermometers findet; die dort stehenden Zahlen sind die gesuchten Werte des Dampfdrucks und der relativen Feuchtigkeit. Weist das feuchte Thermometer Kältegrade auf, dann ist streng zu unterscheiden, ob sein Gefäß von einer Eisschicht umgeben oder von unterkühltem Wasser benetzt ist; im ersten Falle sind die mit „Eis!" überschriebenen Seiten der Tafeln, im letzteren Falle die mit „Wasser!" überschriebenen Seiten zu benutzen.

Beispiele

t Trockenes Thermometer	t' Feuchtes Thermometer	e Dampfdruck	R Relative Feuchtigkeit
27.8	23.6	19.7	70
1.9	0.4	4.0	75
1.1	— 0.6 (Wasser)	3.5	71
— 4.9	— 7.6 „	1.3	39
— 4.9	— 7.6 (Eis)	1.2	39
— 29.6	— 30 0 „	0.1	28

Reichen die *Ausführlichen Tafeln* nicht aus, dann müssen die oben angegebenen Grundformeln direkt ausgewertet werden.

ERMITTELUNG VON DAMPFDRUCK UND RELATIVER FEUCHTIGKEIT BEI EINEM VON 755 mm WESENTLICH ABWEICHENDEN LUFTDRUCK

Im Tieflande, bis etwa 200 m Seehöhe, hat die Berücksichtigung der gewöhnlichen Luftdruckschwankungen bei der Berechnung der Feuchtigkeit keinen beachtenswerten Einfluß auf das Ergebnis; nur in ganz außerordentlichen Fällen kann die hierdurch hervorgerufene Änderung 0.1 mm oder 1 Prozent und mehr betragen. Im Hinblick auf die erreichbare Genauigkeit wird man also bei allen Stationen des Tieflandes die unmittelbaren Angaben der ausführlichen Tafeln zum praktischen Gebrauche allgemein als ausreichend ansehen können.

Überschreitet jedoch die Seehöhe 200 m wesentlich, dann muß man auf die Korrektion der Angaben der ausführlichen Tafeln wegen des verminderten Luftdrucks Bedacht haben. Zu ihrer Bestimmung dienen die Hilfstafeln auf S. 156–160. Die Tafel auf S. 156, 158 und 160 gibt, indem man von oben mit den ganzen Graden der psychrometrischen Differenz $(t - t')$ und von der Seite mit den Zehnern des Barometerstandes b eingeht, die „angenäherte" Barometerkorrektion des Dampfdrucks $= \Delta e$, die auf Zehntel abzurunden ist. Ist die psychrometrische Differenz größer als der in der Tafel vorgesehene Höchstbetrag von 20°, z. B. 23°, dann sind die Werte der Spalte unter 20 mit denjenigen der Spalte für die überschüssigen Einer, also hier unter 3°, zusammenzuzählen. So findet man

zu $b = 733$ unter 730
und zu $t = 14.9$, $t' = 10.1$; also zu $t - t' = 4.8$ unter 5 } $\Delta e = 0.08 = 0.1$ mm,

zu $b = 684$ unter 680
und zu $t = 0.3$, $t' = -4.0$; also zu $t - t' = 4.3$ unter 4 } $\Delta e = 0.20 = 0.2$ mm,

zu $b = 739$ unter 740
und zu $t = 36.6$, $t' = 14.0$; also zu $t - t' = 22.6$ unter 23 $(= 20 + 3)$ } $\Delta e = 0.23 = 0.2$ mm.

Mit dieser Korrektion Δe geht man alsdann in die Tafel auf S. 157 oder 159 oben ein und verfolgt die betreffende Vertikalspalte bis zu der Linie, auf welcher links am Rande die beobachtete Temperatur t des trockenen Thermometers zu lesen ist; die dort befindliche Zahl ist die angenäherte Korrektion der relativen Feuchtigkeit ΔR.

Die obigen drei Beispiele ergeben somit der Reihe nach für

$\Delta e = 0.1$	und	$t = 14.9$	unter	15°	$\Delta R = 1$ Proz.
$\Delta e = 0.2$	„	$t = 0.3$	„	0°	$\Delta R = 4$ „
$\Delta e = 0.2$	„	$t = 36.6$	„	37°	$\Delta R = 0$ „

Diese „angenäherten" Korrektionen können für die deutschen Bergstationen — mit Ausschluß der höchsten Gipfel — der Regel nach als definitive gelten, da die infolge Abrundung etwa entstehenden Abweichungen innerhalb der durch die unvermeidlichen Beobachtungsfehler gesteckten Grenzen liegen.

Bei großen Höhen und bei strengen Genauigkeitsanforderungen endlich, die bei sehr tiefen Temperaturen stets zu stellen sind, werden in beiden Hilfstafeln Interpolationen erforderlich. Diese Interpolationen sind aber in jedem Falle linear und gemäß der Art des Fortschreitens der Argumente in den Tafeln — nach Zehnern, Einern und Zehnteln — sowie bei der geringeren Größe der Differenzen für den geübten Rechner bequem im Kopfe zu bewerkstelligen.

In der Tafel für Δe auf S. 156, 158 und 160 müssen nun die zehntel Grade der psychrometrischen Differenz berücksichtigt werden. Zur Erleichterung für manche ist in der letzten Vertikalspalte der Betrag der Änderung des Dampfdrucks für je ein zehntel Grad von $(t - t')$ besonders aufgeführt; das Produkt dieses Betrages und der betreffenden Anzahl der Zehntel kommt zu der für die ganzen Grade gefundenen Korrektion hinzu, wobei nunmehr die Rechnung auf Hundertstel genau zu erfolgen hat. Ist z. B. $b = 630$ und $(t - t') = 5.7°$, so findet man zunächst unter $(t - t') = 5°$ den Wert 0.42 und sodann für 0.7° den Wert $7 \times 0.008 = 0.056 = 0.06$, also zusammen für Δe $0.42 + 0.06 = 0.48$. Andere werden es jedoch statt dessen vorziehen, die zehntel Grade der

psychrometrischen Differenz dadurch in Rechnung zu ziehen, daß sie den zehnten Teil der für die ganzen Grade von $(t-t')$ gegebenen Werte bilden und den Werten für die ganzen Grade zulegen — was naturgemäß zu demselben Resultate führen muß. So gibt das vorstehende Beispiel für 0.7^0 als den zehnten Teil von 7 in der zugehörigen Spalte $\frac{0.58}{10} = 0.06$, das zu dem für die ganzen Grade der psychrometrischen Differenz $(= 5^0)$ gehörigen Werte 0.42 zu addieren ist. Nur um diese Art der Berechnung zu ermöglichen, sind bei den ganz niedrigen Barometerständen noch für so große Werte von $(t-t')$ Zahlen für Δe in der Tafel gegeben, wie sie in der Natur niemals vorkommen werden.

Auch der Einfluß des Barometerstandes muß nun genauer als nach Zehnern von Millimetern — wie es in der Tafel unmittelbar geschieht — ermittelt oder wenigstens beachtet werden. Allerdings wird man, wenn es nicht auf absolute Genauigkeit, d. h. auf die letzte Stelle der Hundertstel bei Δe ankommt, nur bei größeren psychrometrischen Differenzen auch die Einer des Barometerstandes in Rechnung zu ziehen haben. Geübte Rechner werden diese geringfügige Änderung unmittelbar an den betreffenden Stellen der Tafel absehen können. Doch ist auch in der letzten Zeile der Tafel auf S. 156 u. 158 angegeben, in welchem Betrage 1 mm Luftdruckänderung bei den verschieden großen psychrometrischen Differenzen das Δe beeinflußt. Diese Zahlen, mit den Einern des Barometerstandes multipliziert, liefern, auf Hundertstel abgerundet, die etwa nötige Zusatzkorrektion.

Hat man Δe auf hundertstel Millimeter genau berechnet, so sind nun diese Hundertstel bei Berechnung von ΔR nach der Tafel auf S. 157 u. 159 ebenfalls durch Interpolation zu berücksichtigen. Man findet wiederum in der letzten Spalte den Betrag der Änderung der relativen Feuchtigkeit für je ein hundertstel Millimeter von Δe bei den verschiedenen Temperaturen; das Produkt dieses Betrages und der betreffenden Anzahl der Hundertstel kommt zu der wegen der zehntel Millimeter von Δe gefundenen Korrektion hinzu. Ist z. B. $\Delta e = 0.49$ bei $t = 3^0$, so gibt die Spalte $\Delta e = 0.4$ zunächst die Zahl 7, und zu dieser kommt nun noch $9 \times 0.2 = 1.8 = 2$ hinzu, so daß $\Delta R = 7 + 2 = 9$ Proz. wird. Man kann jedoch auch hier einfach den zehnten Teil der Tafelwerte bilden, um die zu den hundertstel Millimetern von Δe gehörigen Beträge zu erhalten, und den zu den zehntel Millimetern von Δe gehörigen Werten hinzufügen. Das vorstehende Beispiel kann hiernach auch so gerechnet werden, daß man zu dem aus der Spalte für 0.4 sich ergebenden Werte von 7% den zehnten Teil des Wertes aus der Spalte für 0.9, d. i. $\frac{16}{10} = 1.6 = 2\%$, addiert. Nur zu dem Zwecke dieser bequemen Interpolationsart sind in der Tafel noch so hohe Prozente als Korrektionswerte aufgenommen worden.

Die Interpolation bei Ermittelung von ΔR wegen der zehntel Grade am trockenen Thermometer ergibt lediglich bei ganz tiefen Temperaturen beachtenswerte Änderungen; man braucht sie übrigens nur zwecks äußerster Genauigkeit zu berücksichtigen, denn die Berechnung der relativen Feuchtigkeit zeigt bei diesen Temperaturen überhaupt große Unsicherheiten und Schwankungen. Einer Standänderung des trockenen oder feuchten Thermometers (Wasser und Eis) von nur 0.1^0 entspricht bei -20^0 eine Feuchtigkeitsänderung von 4—7%, bei -25^0 eine solche von 6—10%, bei -30^0 eine solche von 10—13%.

Im folgenden ist eine Reihe von Beispielen für die Ermittelung von „angenäherten" und gleichzeitig von genauen Luftdruckkorrektionen des Dampfdrucks und der relativen Feuchtigkeit und somit auch von diesen Elementen selbst aufgeführt. Die in Klammern gesetzten Abkürzungen W. bzw. E. bedeuten, daß das feuchte Thermometer mit Wasser bzw. Eis bedeckt ist.

Beobachtet seien:

b	728	719	709	674	653	628	583	492	456
t	21.6	29.2	5.8	— 13.4	— 4.5	3.8	— 0.4	— 28.5	— 22.2
t'	11.2	20.5	4.4	— 14.6 (E.)	— 6.1 (W.)	— 2.0 (W.)	— 5.1 (W.)	— 29 1 (E.)	— 23.1 (E.)
$t-t'$	10.4	8.7	1.4	1.2	1.6	5.8	4.7	0.6	0.9

Dann ist nach den ausführlichen Tafeln:

e	4.8	13.7	5.6	0.8	2.1	1.1	0.8	0.1	0.2
R	25	45	81	47	64	18	16	12	24

Die Tafeln auf S. 156—160 geben dazu unmittelbar die *„angenäherten"* Korrektionen:

Δe	0.2	0.2	0.0	0.1	0.1	0.5	0.6	0.1	0.2
ΔR	1	1	0	6	3	8	13	21	25

Hieraus folgen die *„angenäherten"* Werte:

e	5.0	13.9	5.6	0.9	2.2	1.6	1.4	0.2	0.4
R	26	46	81	53	67	26	29	33	49

Durch scharfe Interpolation in den Tafeln S. 156—160 erhält man die *genauen* Korrektionen:

Δe	0.19	0.20	0.04	0.06	0.11	0.49	0.53	0.09	0.16
ΔR	1	1	1	4	3	9	12	20	20

und damit die *genaueren* Werte:

e	5.0	13.9	5.6	0.9	2.2	1.6	1.3	0.2	0.4
R	26	46	82	51	67	27	28	32	44

Man beachte, daß nur bei sehr tiefen Temperaturen und Barometerständen und nur für die relative Feuchtigkeit Unterschiede zwischen angenäherten und genauen Werten bestehen, die nicht ganz zu vernachlässigen sind.

Gehen endlich die ausführlichen Tafeln nicht so weit, daß aus ihnen die für $b = 755$ geltenden Werte zu entnehmen sind, um daran die Korrektionen wegen des Luftdrucks anzubringen, so kann man

1. entweder zunächst die Werte für $b = 755$ vermöge

$$e = E' - C(t - t') \text{ und } R = 100\frac{e}{E}$$

direkt berechnen und dann hierzu die Luftdruckkorrektionen nach den Hilfstafeln S. 156—160 hinzufügen, wie bereits oben S. XI angegeben.

2. oder man kann sogleich — was vielen geläufiger sein wird — das ganze Abzugsglied der *Sprung*schen Formel,

$$A = C(t - t')\frac{b}{755},$$

berechnen und durch Subtraktion von E' das gesuchte e, und schließlich hieraus in üblicher Weise unter Benutzung der Faktorentafel auf S. 163 das gesuchte R erhalten. Die Auswertung dieses Abzugsgliedes ist erleichtert durch die Tafel auf S. 161 u. 162. Letztere enthält die Werte von A für ganze Grade der psychrometrischen Differenz und für die Zehner des Barometerstandes, gleicht also in ihrem Aufbau der Korrektionstafel auf S. 156, 158 u. 160. Um vor Verwechselungen mit der letzteren zu warnen, ist sie noch durch die Aufschrift „Ganzes Abzugsglied!" gekennzeichnet. Während man aber bei jener meist mit den unmittelbaren Tafelwerten ohne jede Interpolation auskommt, muß hier in jedem einzelnen Falle — insbesondere wegen der zehntel Grade der psychrometrischen Differenz — interpoliert werden. Durch das dezimale Fortschreiten der Argumente ist indessen diese Interpolation ziemlich einfach, sie gestaltet sich genau so wie bei der Tafel für Δe (s. vorher S. XI): Man multipliziert die in der letzten Spalte angegebenen Werte der Änderung von A für $(t - t') = 0.1$ mit der Zahl der Zehntel, oder man setzt in den Tafelwerten in der entsprechenden Spalte das Komma eine Stelle nach links; dieser Betrag wird dann den zu den ganzen Graden von $(t - t')$ gehörenden Werten hinzugefügt. Zur Interpolation wegen der Einer des Barometerstandes, die nur geringfügige Abweichungen hervorrufen wird, kann man sich der in der letzten Zeile dieser Tafel gegebenen Änderungen von A für je 1 mm Luftdruckänderung bedienen. Bei hohen und mittleren Temperaturen wird es genügen, A nur auf Zehntel genau zu berechnen, bei tiefen Temperaturen jedoch — und um diese wird es sich bei Benutzung dieser Tafel wohl meist handeln — muß die Rechnung auf Hundertstel erfolgen. Hat man so $e = E' - A$ berechnet, so wird man zur Ermittelung von $R = e\frac{100}{E}$ wieder die Tafel des Faktors $\frac{100}{E}$ auf S. 163 benutzen.

Beispiele zur Benutzung der Tafel für A auf S. 161, 162.

(1) Beobachtet seien:

$b = 612$, $t = -2.5$, $t' = -7.0$ (Eis), also $t - t' = 4.5$.

Man entnimmt der Tafel unmittelbar den Wert für $b = 610$ und $t - t' = 4$, nämlich 1.39

Auf der gleichen Linie erhält man den Wert für die Zehntel von $(t - t')$ gleich $\frac{5}{10}$, nämlich $\frac{1.74}{10} = 0.174$

Hierzu kommt die Korrektion wegen der Einer (= 2) beim Luftdruck, nämlich . $2 \times 0.002 = 0.004$

Zusammen $A = 1.57$

Da E' für $t' = -7.0$ (Eis) gemäß den Tafeln S. 2–4 = 2.53 ist, so wird $e = 2.53 - 1.57 = 0.96$ mm; und da $t = -2.5$, so wird $R = e\frac{100}{E}$ gemäß Tafel S. 163 $= 0.96 \times 26.2 = 25\,\%$.

(2) $b = 497$, t = -29.1, $t' = -29.9$ (Eis), also t $- t' = 0.8$.

Aus der Spalte für $t - t' = 8$ und $b = 490$ entnimmt man den zehnten Teil, nämlich 0.22

Die Korrektion wegen der Einer des Luftdrucks ist für $t - t' < 1°$ immer verschwindend, also . 0.00

Zusammen $A = 0.22$

Hieraus folgt, da E' für $t' = -29.9$ (Eis) gemäß den Dampfdrucktafeln = 0.28 ist, $e = 0.28 - 0.22 = 0.06$ mm, und $R = e\frac{100}{E}$ gemäß Tafel S. 163 $= 0.06 \times 235 = 14\,\%$.

DIE TAFELN FÜR DAS MISCHUNGSVERHÄLTNIS, DIE SPEZIFISCHE FEUCHTIGKEIT UND DIE ABSOLUTE FEUCHTIGKEIT

sind nur für Fachleute bestimmt, die nach dem angestrebten Endzweck den Genauigkeitsgrad der Rechnung einrichten werden.

Bei der Tafel für den Unterschied zwischen absoluter Feuchtigkeit und Dampfdruck ist der Wechsel des Fortschreitens der Argumente, sowohl von e wie von t, sorgsam zu beachten.

TAFELN ZUR BERECHNUNG DES DAMPFDRUCKS AUS DEN ANGABEN DES HAARHYGROMETERS UND DER LUFTTEMPERATUR, BESTIMMUNG DES TAUPUNKTES AUS DEM HERRSCHENDEN DAMPFDRUCK, BESTIMMUNG DES SÄTTIGUNGSDEFIZITS

Da das Haarhygrometer neben dem Psychrometer, besonders aber bei niedrigen Temperaturen, bei denen das letztere unsicher wird, sowie in den Registrierapparaten eine wichtige Rolle spielt, so erschien es angebracht, zur bequemeren Berechnung des Dampfdrucks aus den Angaben des Haarhygrometers und der jeweiligen Lufttemperatur eigene Tafeln herauszugeben. Ihre Einrichtung ist sehr einfach. Man erhält den Dampfdruck nach der Formel

$$e = E\frac{R}{100},$$

in der e wieder den Dampfdruck, E den der Temperatur des trockenen Thermometers entprechenden Sättigungsdampfdruck des Wasserdampfes und R die relative Feuchtigkeit bedeuten.

Die Werte für E entnimmt man den Tafeln für den Sättigungsdampfdruck (S. 2—4); eine Multiplikation mit der durch 100 dividierten Feuchtigkeit ergibt unmittelbar den gesuchten Dampfdruck

Die Tafeln enthalten nun die Werte des Dampfdrucks (in mm) für gegebene R von 6 bis 100% (obere Horizontalreihe) und t von $-40°$ bis $+40°$ (vordere Vertikalreihe). Bei R wurde ein Fortschreiten von 2 zu 2 Proz., bei t für die Temperaturen unter $+10°$ von halben zu halben Graden, dagegen für die Temperaturen über $+10°$ von fünftel zu fünftel Graden als genügend angesehen.

Der Gebrauch der Tafeln ergibt sich ganz von selbst, so daß jede weitere Anweisung als überflüssig erscheint.

Ebenfalls von selbst ergibt sich die Handhabung der *Tafeln zur Bestimmung des Taupunktes aus dem herrschenden Dampfdruck* (S. 180 u. 181) sowie des *Sättigungsdefizits* (S. 182 u. 183).

INTRODUCTION

For determining the vapour pressure from observations made on Assmann's aspiration psychrometer, Sprung has established the formula:

$$e = E' - C(t-t')\frac{b}{755}$$

where e denotes the vapour pressure to be determined, expressed in mm, E' the saturated vapour pressure at the temperature indicated by the wet-bulb thermometer t', C the psychrometer constant, t and t' the temperatures indicated by the dry and wet thermometers in degrees centigrade, and b the barometric height in mm. The psychrometer constant appearing in this formula is 0.5 for water and 0.43 for ice.

The relative humidity may then be determined by the formula

$$R = 100\frac{e}{E}.$$

Comments on the Tables

TABLES FOR SATURATED VAPOUR PRESSURE

Following the regulations issued by the WMO (World Meteorological Organization) the tables relating to the rates of pressure of saturated water vapour (pages 2—7) were taken from the Smithsonian Meteorological Tables (mb), and converted into mm.

DETAILED TABLES

These tables give the vapour pressure in mm and the relative humidity in per-cent for any values indicated by the dry and wet thermometers. They are based on 755 mm atmospheric pressure, and conform to Sprung's simple formula $e = E' - C(t-t')$. Strictly speaking, the values given in the tables refer only to a barometric height of 755 mm, but may in practice be used for sea level and lowland conditions in general. However, observations made at higher altitudes (from abt. 200 m = 650 ft. upwards) or in the free air will require corrections because of the lower barometric pressure there existing (see Special Tables).

The *Detailed Tables* give on p. 8 — 31 the values of vapour pressure and relative humidity for those cases where the bulb of the thermometer is covered with ice (headline "Eis"), whilst the values given on p. 32 — 39 refer to temperatures below zero, i. e. down to - 10 °C. for cases in which the water of the wet thermometer is supercooled, not frozen (headline "Wasser"); finally, the values of vapour pressure and humidity for temperatures above zero will be found on p. 40 — 154. For the wet thermometer, the tables go as far as 45.9, for the dry thermometer up to 55.0 degrees centigrade.

The marginal column serves to determine the dew point τ from the existing vapour pressure e, it being necessary in synoptic service when using whole degrees centigrade to round off the absolute numbers by throwing down those of $\bar{5}$ and throwing up those of $\dot{5}$.

SPECIAL TABLES

The *Detailed Tables* are followed by several auxiliary tables of importance, those following immediately giving the corrections that must be applied to the values of vapour pressure and relative humidity when the atmospheric pressure differs from the basic value assumed (755 mm). See formulae in the German text on page VIII. The corrections of the vapour pressure in relation to the *Detailed Tables* are denoted by Δe, and will be found progressing by 10 mm on pages 156, 158 and 160 after the atmospheric pressure b.

The table provided for the correction ΔR (formula p. VIII) of the relative humidity in terms of Δe and of the temperature t appears on pages 157 and 159.

The auxiliary tables which come next will be found very helpful for computing the vapour pressure and relative humidity under conditions of very low temperatures and great drought. If the atmospheric pressure differs from the basic value of 755 mm, the original formula (page VII) will have to be applied. The table contains on p. 161 and 162 the complete subtraction term A for calculating the vapour pressure (see formulae p. IX), and on p. 163 the factor $\frac{100}{E}$ for computing the relative humidity.

The tables on p. 168 — 179 are for calculating the vapour pressure from the values indicated by the hair hygrometer and from the air temperature.

Some further special tables have been provided which refer to such data as mixing ratio (p. 164 and 165), specific humidity (p. 165) and absolute humidity (p. 166), the formulae for these being given on p. IX. On pages 180 and 181 has been added still another table which enables the dew point to be read off for the existing vapour pressure. Finally, there are tables for quickly determining the rate of saturation deficit, i. e. on page 182 in mm mercury and on page 183 in $g \cdot m^{-3}$.

DIRECTIONS FOR USE

HOW TO FIND THE VAPOUR PRESSURE AND RELATIVE HUMIDITY

In the case of lowland conditions refer to the *Detailed Tables* and using the column corresponding to the temperature indicated by the wet thermometer go down to the line that corresponds to the temperature given on the dry thermometer. The figures printed there are the values required both of vapour pressure and relative humidity (see examples p. X).

When having to deal with conditions at 200 m (650 ft.) height above sea level and higher, there are two ways of finding the vapour pressure and relative humidity, proceeding either by the method mentioned above for lowland conditions applying the corrections Δe and ΔR by means of the tables on p. 156 – 160 (see examples on page XII below and page XIII above), or by referring to the table on p. 161 and 162 to apply directly the respective term of subtraction of Sprung's formula for calculating the vapour pressure. The relative humidity is then computed using the table on p. 163; see examples on page XIV, above.

The use of the other tables does not require explanation.

INTRODUCTION

Pour déterminer la pression de vapeur à partir des observations faites en utilisant le psychromètre d'aspiration système Assmann, Sprung a établi la formule:

$$e = E' - C(t - t')\frac{b}{755}$$

où e désigne la pression de vapeur recherchée en mm, E' la pression de la vapeur saturée à la température indiquée par le thermomètre humide t', C la constante psychrométrique, t et t' les températures indiquées par les thermomètres sec et humide en degrés Celsius, et b la hauteur barométrique en mm. La constante psychrométrique est de l'ordre de 0.5 pour l'eau, et de 0.43 pour la glace.

L'humidité relative se détermine alors par la formule

$$R = 100\frac{e}{E}.$$

Commentaires sur les Tableaux

TABLEAUX RELATIFS À LA PRESSION DE LA VAPEUR SATURÉE

Suivant les dispositions de l' OMM (Organisation Météorologique Mondiale), les tableaux concernant la pression de la vapeur saturée (pages 2—7) ont été empruntés aux "Smithsonian Meteorological Tables" (mb) et en donnent les équivalents en mm.

TABLEAUX DÉTAILLÉS

Ceux-ci contiennent la pression de vapeur en mm et l'humidité relative en pour-cent pour les températures indiquées par les thermomètres sec et humide, les valeurs y figurant ayant pour base une pression atmosphérique de 755 mm. Elles correspondent d'ailleurs à la simple formule de Sprung: $e = E' - C(t - t')$. A proprement parler, ces valeurs ne sont valables que pour une hauteur barométrique de 755 mm; toutefois, on pourra pratiquement les appliquer dans tous les cas où l'on se trouve au niveau de la mer ou sensiblement. Pour des observations faites en des endroits plus élevés, c.-à-d. à partir de 200 m d'altitude, il y a lieu d'appliquer certaines corrections, ceci en raison de la pression atmosphérique plus faible qui y règne (voirs les Tableaux Spéciaux).

Les *Tableaux Détaillés* donnent en pages 8—31 la pression de vapeur et l'humidité relative dans les cas où la cuvette du thermomètre serait recouverte de glace (rubrique "Eis"), alors que dans les pages 32—39 on trouve ces valeurs pour les températures au-dessous du zéro allant jusqu'à -10°, valeurs applicables au cas où l'eau entourant le thermomètre humide resterait en surfusion (rubrique "Wasser"). Les pages 40—154 donnent la pression de vapeur et l'humidité pour les températures au-dessus du zéro. Pour le thermomètre humide, les tableaux vont jusqu'à 45.9°, pour le thermomètre sec jusqu'à 55.0 °C.

La colonne marginale sert à déterminer le point de rosée τ à partir de la pression de vapeur existante e (ce qui est demandé pour les observations synoptiques), en employant des degrés Celsius entiers, obtenus en arrondissant les nombres absolus par la déduction du $\bar{5}$ et l'addition du $\dot{5}$ qui les suivent.

TABLEAUX SPÉCIAUX

Aux *Tableaux Détaillés* succèdent plusieurs tableaux auxiliaires importants. Ceux qui suivent immédiatement donnent les corrections à appliquer aux valeurs de la pression de vapeur et de l'humidité relative pour tenir compte des différences qui existeraient entre la pression atmosphérique effective et la valeur de base de 755 mm (voir les formules que présente le texte allemand en page VIII). La correction s'imposant par rapport aux *Tableaux Détaillés* est désignée par Δe et apparaît, en valeurs montant progressivement de 10 mm, en pages 156, 158 et 160 après la pression atmosphérique *b*. Le tableau pour la correction ΔR (formule p. VIII) de l'humidité relative, en fonction de Δe et de la température *t*, se trouve aux pages 157 et 159.

Les tableaux auxiliaires qui viennent après sont susceptibles de faciliter les calculs de la pression de vapeur et de l'humidité relative dans les cas de températures très basses et par une grande siccité. Lorsque la pression atmosphérique diffère de la valeur de base de 755 mm, on devra avoir recours à la formule primitive (page VII). Le tableau reproduit aux pages 161 et 162 contient le terme entier de soustraction A nécessaire pour calculer la pression de vapeur (formules p. IX), alors que la page 163 donne le facteur $\frac{100}{E}$ pour déterminer l'humidité relative.

Aux pages 168—179 on trouvera des tableaux permettant de calculer la pression de vapeur à partir des indications de l'hygromètre à cheveu et de la température de l'air.

D'autres tableaux spéciaux sont ceux de la proportionalité de mélange (p. 164 et 165), de l'humidité spécifique (p. 165) et de l'humidité absolue (p. 166), les formules respectives se trouvant à page IX. De plus, on trouvera, aux p. 180 et 181, un tableau permettant de lire le point de rosée pour la pression de vapeur existante. Finalement, pour trouver rapidement le déficit de saturation, il existe encore des tableaux dont celui de la p. 182 qui donne les valeurs respectives en mm mercure, et un autre à la p. 183 en $g \cdot m^{-3}$.

INSTRUCTIONS

POUR DÉTERMINER LA PRESSION DE VAPEUR ET L'HUMIDITÉ RELATIVE

Lorsqu'il s'agit d'une station établie dans une contrée de faible altitude, on cherchera, sur les *Tableaux Détaillés*, dans la colonne correspondant à la température indiquée par le thermomètre humide, la ligne qui correspond à la température indiquée par le thermomètre sec. Les nombres qui s'y donnent représentent les valeurs recherchées de la pression de vapeur et de l'humidité relative (voir les exemples à p. X).

A partir d'une altitude de 200 m au-dessus du niveau de la mer, on peut opérer de deux manières pour déterminer la pression de vapeur et l'humidité relative: soit en procédant de la manière indiquée ci-dessus pour les stations basses et appliquer ensuite les corrections Δe et ΔR à l'aide des tableaux aux p. 156—160 (voir les exemples à page XII en bas, et à page XIII en haut), soit en consultant les tableaux aux pages 161 et 162 pour calculer la pression de vapeur directement à partir du membre de soustraction de la formule de Sprung que l'on y trouvera. L'humidité relative sera déterminée ensuite à l'aide du tableau à p. 163 (voir les exemples p. XIV, en haut).

Les autres tableaux n'exigent aucun commentaire.

INTRODUCCIÓN

Para determinar la tensión del vapor a base de observaciones hechas con el psicrómetro de aspiración de Assmann, Sprung ha establecido la fórmula

$$e = E' - C(t - t')\frac{b}{755}$$

en la cual e designa la tensión del vapor buscada, expresada en mm, E' la tensión del vapor saturado a la temperatura t' señalada por el termómetro húmedo, C la constante psicrométrica, t y t' las temperaturas de los termómetros seco y húmedo en grados centígrados, y b la altura barométrica en mm. La citada constante psicrométrica vale 0,5 para el agua y 0,43 para el hielo.

La humedad relativa se determinará luego por la fórmula

$$R = 100\frac{e}{E}.$$

Explicación de las tablas

TABLAS RELATIVAS A LA TENSIÓN DEL VAPOR SATURADO

De acuerdo con las disposiciones de la OMM (Organización meteorológica mundial), las tablas relativas a la tensión del vapor de agua saturado (págs. 2 a 7) se han tomado de las Smithsonian Meteorological Tables (mb), dándose su valor equivalente en mm.

TABLAS DETALLADAS

Estas tablas dan la tensión del vapor (en mm) y la humedad relativa (en %) para las temperaturas de los termómetros seco y húmedo, suponiendo una presión atmosférica de 755 mm y según la fórmula de Sprung simplificada:

$$e = E' - C(t - t').$$

Aun cuando los valores de las tablas se refieren solamente a una presión atmosférica de 755 mm, son también válidos en la práctica para el nivel del mar, y en general para las estaciones bajas. Pero para las observaciones efectuadas en lugares altos (de unos 200 metros para arriba) o en la atmósfera libre, es preciso aplicar ciertas correcciones, valiéndose de las tablas auxiliares, por ser allí más baja la presión.

En las páginas 8 a 31 (encabezamiento *Eis*) las tablas detalladas dan la tensión del vapor y la humedad relativa para el caso en que el depósito del termómetro húmedo esté cubierto de hielo, mientras que en las páginas 32 a 39 se dan los valores correspondientes a temperaturas inferiores a cero, hasta -10^0, para cuando el agua que rodea el termómetro húmedo no está helada, sino sobrefundida (encabezamiento *Wasser*). Finalmente, las tablas de las páginas 40 a 154 dan la tensión del vapor y la humedad relativa para temperaturas superiores a cero. Estas tablas llegan hasta $45{,}9^0$ para el termómetro húmedo y $55{,}0^0$ para el seco.

La columna marginal sirve para determinar el punto de rocío τ a base de la tensión del vapor actual e. Para darlo en grados centígrados enteros con fines sinópticos, se redondeará el número absoluto por disminución en el caso de ser $\bar{5}$ la cifra final, y por aumento cuando ésta sea $\dot{5}$.

TABLAS ESPECIALES

A continuación de las tablas detalladas, siguen unas, tablas especiales importantes. De ellas, las primeras dan las correcciones que hay que aplicar a la tensión del vapor y a la humedad relativa a causa de la diferencia entre la presión atmosférica efectiva y la básica de 755 mm (véanse, en el texto alemán, las fórmulas de la página VIII). La corrección que hay que aplicar a la tensión del vapor dada por las tablas detalladas se designa por $\triangle e$, y su valor se da en las páginas 156, 158 y 160, en función de la presión atmosférica b, para valores de 10 en 10 mm. La corrección $\triangle R$ de la humedad relativa en función de $\triangle e$ y de la temperatura t (fórmula de la pág. VIII) se encuentra en las páginas 157 y 159.

Siguen luego tablas auxiliares para calcular la tensión del vapor y la humedad relativa para temperaturas muy bajas y para grandes sequedades. Para presiones diferentes de 755 mm hay que recurrir a la fórmula primitiva (pág. VII).

Para ello, la tabla de las páginas 161 y 162 da el término sustractivo A que se ha de aplicar para el cálculo de la tensión del vapor (véanse las fórmulas en la página IX), y la de la página 163 da el factor $\frac{100}{E}$ para determinar la humedad relativa.

Las tablas de la páginas 168 a 179 sirven para calcular la tensión del vapor a partir de los datos del higrómetro de cabello y de la temperatura del aire.

Otras tablas especiales dan la relación de mezcla (págs. 164 y 165), la humedad específica (pág. 165) y la humedad absoluta (pág. 166), encontrándose las respectivas fórmulas en la página IX. Además, en las páginas 180 y 181, otra tabla da el punto de rocío para la tensión del vapor actual. Para el cálculo rápido del déficit de saturación sirven las tablas de las páginas 182 (en mm de mercurio) y 183 (en $g \cdot m^{-3}$).

USO DE LAS TABLAS

PARA LA DETERMINACIÓN DE LA TENSIÓN DEL VAPOR Y DE LA HUMEDAD RELATIVA

Para las estaciones de baja altitud, búsquese en las tablas detalladas la columna correspondiente a la temperatura del termómetro húmedo, bajando hasta la línea correspondiente a la temperatura del termómetro seco. Los valores que asi se encuentran son el de la tensión del vapor y el de la humedad relativa (véanse los ejemplos de la página X).

Para altitudes desde 200 m en adelante, se pueden seguir dos procedimientos. El primero consiste en determinar la tensión del vapor y la humedad relativa como para las estaciones bajas, y luego aplicar las correcciones Δe y ΔR mediante las tablas de las páginas 156 a 160 (ejemplos en la parte inferior de la página XII y en la superior de la XIII). El segundo procedimiento consiste en buscar directamente el término sustractivo de la fórmula de Sprung en las tablas de las páginas 161 y 162 y calcular la tensión del vapor; la humedad relativa se calculará mediante la tabla de la página 163 (ejemplo en la parte superior de la página XIV).

Para el uso de las demás tablas, no es necesaria ninguna explicación.
