# Einleitung

Der vorliegende Teil II des Deutschen Meteorologischen Jahrbuches für 1939 umfaßt die Monats- und Jahresergebnisse an den Stationen höherer Ordnung einschließlich der Sonnenschein- und Erdbodentemperaturbeobachtungen. Die Ergebnisse werden in der durch die Internationale Meteorologische Organisation vorgeschriebenen Form veröffentlicht. Die Veröffentlichung umfaßt eine Auswahl der meteorologischen Stationen.

Gegenüber dem Jahrbuch 1937 mußte der Umfang des Jahrbuches 1939 aus finanziellen Gründen gekürzt werden. Es entfallen fortan die Stationsbeschreibungen, die Veränderungen an den Stationen, das Verzeichnis der Stationen nach politischen Bezirken, die Aufstellung der Eis-, Frost- und Sommertage, die Minimumtemperaturen und die Summen aus dreimal täglichen Niederschlagsbeobachtungen.

Wichtige Veränderungen an den Stationen werden, soweit sie bekannt sind, weiterhin als Fußnoten zu den Monats- und Jahresergebnissen veröffentlicht.

**Bad Kissingen,** September 1950.

**Deutscher Wetterdienst in der US-Zone**
**Zentralamt, Abt. III**

# Erläuterungen zu den Tabellen

**I. Einleitende Zusammenstellungen.**

V e r z e i c h n i s d e r m e t e o r o l o g i s c h e n S t a t i o n e n. In dem Verzeichnis erscheinen sämtliche vorhandenen Stationen mit Angabe der Seitenzahl der Veröffentlichung, der Ordnung, der Ausrüstung mit Sonderinstrumenten, der Koordinaten, des Einrichtungsjahres und des Beobachters.

Es bedeuten:

II = Station II. Ordnung
II¹) = Station II. Ordnung ohne Barometer
III = Station III. Ordnung
E = Messung der Erdbodentemperatur
A = Registrierung der Strahlung Sonne + Himmel
⊙ = Registrierung der Sonnenscheindauer
B = Registrierung des Luftdrucks
T = Registrierung der Lufttemperatur
F = Registrierung der Luftfeuchtigkeit
W = Registrierung des Windes (Richtung oder Stärke).

**II. Monats- und Jahresübersichten.**

Angaben im Tabellenkopf:

$\varphi$ = geographische Breite
$\lambda$ = geographische Länge von Greenwich
g = Schwerebeschleunigung
$\triangle G$ = Zeitunterschied gegen Greenwich
$H_s$ = Höhe des Stationsgeländes über Normal-Null. (Angaben in ganzen Metern)
$H_b$ = Höhe des Barometers über Normal-Null
$h_t$ = Höhe der Thermometer über dem Erdboden. In Klammern ist die Art der Thermometeraufstellung (Hütte oder Gehäuse) angegeben
$h_r$ = Höhe der Auffangfläche des Regenmessers über dem Erdboden

Zeitangaben nach mittlerer Ortszeit.

Luftdruck Pm = Luftdruck in mm, auf 0° Quecksilbertemperatur und Normalschwere von 45° umgerechnet.
Po, m = Luftdruckmittel im Meeresspiegel.

Lufttemperatur in C°. Die Tagesmittel sind berechnet nach den Formeln

$$\frac{7^h + 14^h + 2 \times 21^h}{4}$$

Die Temperaturextreme werden zum Abendtermin (III) für die vorhergehenden 24 Stunden bestimmt und dem Datum des Messungstages zugeschrieben.

Windverteilung und mittlere Windstärke:

Zahl der Beobachtungen in einer bestimmten Windrichtung. Beobachtungen mit Zwischenwindrichtungen sind je zur Hälfte bei den benachbarten Hauptwindrichtungen gezählt (z. B.: NNE je zur Hälfte bei N und bei NE).
Die mittlere Windstärke ist gleich die Summe der Stärkezahlen einer bestimmten Windrichtung dividiert durch die Summe der Häufigkeit derselben bestimmten Windrichtung. Bei Zwischenrichtungen muß die Stärke je zur Hälfte bei den benachbarten Hauptwindrichtungen gezählt werden. (z. B.: NNE 4 = N 2 u. NE 2).

Beispiel: Bei N als Summe der Stärke = 48
als Summe der Häufigkeit = 16
die mittlere Windgeschwindigkeit = 48 : 16 = 3.0

Dampfspannung (Mittel) in mm.
Relative Feuchtigkeit in Prozent.
Bewölkung nach elfstufiger Skala (0—10).
} Die Tagesmittel sind arithmetische Mittel aus den Terminwerten.

Niederschlag in mm: Der Niederschlag wird für den Morgentermin (I) für die vorhergehenden 24 Stunden aus den Terminmessungen errechnet und dem Datum des Messungstages zugeschrieben.

Zahl der Tage n:

mit Lufttemperatur Max. $< 0.0$, Min. $\leq -10.0$, Min $< 0.0$, Max. $\geq 25.0$, Max. $\geq 30.0$, Min. $\geq 20.0$
mit Windstärke F $\geq 6$, $\geq 8$
mit Bewölkung N $< 2.0$, $> 8.0$ (Tagesmittel)
mit Niederschlag R $\geq 0.1$ mm, $\geq 1.0$ mm, $\geq 10.0$ mm
mit Regen (●)
mit Schnee (✳ ❄) : die von Schnee oder Regen und Schnee herrührende Schmelzwassermenge hat mindestens 0.1 mm betragen
mit Schneedecke (▩) zum Morgentermin
mit Hagel (△ ▲), (einschließlich Eiskörner)
mit Graupeln (△ △ ✳) (einschließlich Grieseln und Reifgraupeln)
mit Nebel (≡⁰⁻²), Sicht unter 1 km
mit Gewitter (↯)

Durch kursiven Druck sind hervorgehoben: Unsichere oder ganz bzw. teilweise ergänzte Werte.

**III. Besondere Zusammenstellungen.**

1. Frost- und Schneedeckengrenzen.

Frostgrenzen: Datum des letzten (ersten) Temperaturminimums unter 0°.
Schneedeckengrenzen: Datum des letzten (ersten) Tages mit einer Schneedecke von 1 cm oder mehr zum Morgentermin.

2. Fünftägige Mittel.

Die Abweichungen beziehen sich meist auf die Normalmittel 1851—1930.

3. Witterungsverlauf.

Der Text ist dem Deutschen Witterungsbericht in „Wirtschaft und Statistik" entnommen. — Die Abweichungen beziehen sich meist auf die Normalmittel 1851—1930.

**IV. Sonnenscheinbeobachtungen.**

Angaben im Tabellenkopf:

$\varphi$, $\lambda$ und $H_s$ wie bei II.
$h_s$ = Höhe der Sonnenscheinkugel über dem Erdboden.
Die Werte sind aus Registrierungen mit dem Sonnenscheinautographen Campbell-Stokes gewonnen.

**V. Erdbodentemperaturen.**

Angaben im Tabellenkopf wie bei II.

Die Gefäße der Thermometer für 0.1 und 0.2 m Tiefe sind unmittelbar in den Erdboden eingegraben. In den Tiefen von 0.5 und 1.0 m werden die Beobachtungen an Thermometern angestellt, die in das untere Ende von Holzstangen eingelassen sind und in Schutzröhren meist aus Neusilber in den Boden eingeführt werden.

# 1939

# Besondere Zusammenstellungen

1. Frost- und Schneedeckengrenzen

2. Fünftägige Mittel (Summen) für Luftdruck, Lufttemperatur, Sonnenscheindauer und Niederschlag
   Abweichungen der fünftägigen Mittel der Lufttemperatur vom langjährigen Mittel

3. Witterungsverlauf
   Temperatur in Abweichungen von den Normalwerten
   Niederschlagshöhe in Prozenten der Normalwerte

| Stationen | Das Thermometer sank zum letzten Male unter 0° | Das Thermometer sank zum ersten Male unter 0° | Zwischenzeit in Tagen | Eine Schneedecke lag ≧ 1 cm zum letzten Male | Eine Schneedecke lag ≧ 1 cm zum ersten Male | Zwischenzeit in Tagen |

# Witterungsverlauf im Jahre 1939

Der **Januar** war sehr mild, dabei zu trübe und überwiegend zu reich an Niederschlägen.

Der winterliche Witterungscharakter, der in der zweiten Hälfte des Vormonats stark zur Geltung gekommen war, fand zum Monatswechsel mit dem Vordringen einer westlichen Luftströmung unter Niederschlägen, die sich bis über die Oder hinaus fortpflanzten, bereits seinen Abschluß. Während das Alpengebiet nach den Niederschlägen am 2. und 3. sein Frostwetter einstweilen weiter behielt, kam im übrigen Reichsgebiet die Westwinddrift bei dem Vorstoß eines Tiefs von Irland nach der Ostsee unter Niederschlägen und steigenden Temperaturen zum weiteren Durchbruch, so daß schließlich auch Ostpreußen am 4. vom Tauwetter betroffen wurde. Mit einem flachen Tief, das an den deutschen Küsten entlang zog, folgte auf seiner Rückseite ein Einbruch kühlerer Luftmassen; sie überfluten am 6. und 7. unter mehrfachen Schneefällen das ganze Reich und brachten noch einmal mäßiges bis starkes Frostwetter, das an der Nordsee und im Berglande Nachtfröste bis zu 10° Kälte zeitigte. Doch ebenso schnell vollzog sich im Laufe des 8. mit einem energischen Vorstoß subtropischer Warmluft ein Wärmeausgleich, der unter Aufgleitregen am 9. nach Ostpreußen übergriff und mit seiner Erwärmung im größten Teile des Flachlandes die seit Dezember bestehende Schneedecke langsam verschwinden ließ. Im Süden des Reiches, wo die Tage vom 8. bis 11. unter dem Einfluß eines ausgedehnten Mittelmeerhochs niederschlagsfrei verlaufen waren, gelang es der Warmluft am 11., in den Alpen die dort noch lagernde Kaltluft wegzuräumen und damit auch dieses Gebiet der allgemeinen verbreiteten Erwärmung zu erschließen. Unter der Wirkung eines von der portugiesischen Küste nach der Nordsee ziehenden Tiefs, das Staffeln feuchter und kühlerer Meeresluft herbeiführte, griff vom 12. ab die in Norddeutschland rege Niederschlagstätigkeit auch nach Süddeutschland über. Einer kurzen Aufheiterung am 14. folgte am 15. bei Südwestwind ein neuer Vorstoß subtropischer Warmluft; unter Aufgleitregen stiegen die Temperaturen bereits derart hoch, daß sie von nun ab im Flachlande nachts nicht mehr den Gefrierpunkt unterschritten. Da auf der Vorderseite eines kräftigen über Irland verharrenden Tiefs die Zufuhr regenbringender Warmluft anhielt, äußerte sich schließlich die bis zur Weichsel fortgeschrittene Erwärmung in Mittagstemperaturen von mehr als 10°; gleichzeitig veranlaßte die im Bergland einsetzende Schneeschmelze ein erhebliches Steigen der Ströme und Flüsse. Die weitere Ausbreitung warmer Staffeln, die am 19. durch ein über Südskandinavien sich ausbildendes Hoch vorübergehend gehemmt wurde, erhielt neuen Antrieb gegen Osten durch neue von Südwesten her anrückende Warmluftfronten. Die Temperaturen, die wieder abgleitende Tendenz genommen hatten, beschleunigten mit den am 25. einsetzenden regnerischen Westwinden ihren Rückgang, so daß im Flachlande mehrfach wieder Nachtfröste beobachtet wurden. Ein Sturmwirbel, der am 26. vom Kanal nach dem Ostalpenrand und nach Verschmelzung mit oberitalienischen Druckstörungen über Ungarn ostwärts zog, veranlaßte bei nördlicher Luftzufuhr verbreitete Schneefälle und ein weiteres Sinken der Temperaturen. Die Niederschläge ließen teilweise schon am 28. nach, als mit der Annäherung eines über Island lagernden Hochs eine Umgestaltung der Großwetterlage sich vollzog; bei der dadurch bedingten nördlichen Luftströmung setzte neblig-trübes Frostwetter ein, dem erst am 30. und 31. teilweise Aufheiterung folgte.

Der überaus milde Witterungsverlauf ergab Temperaturmonatsmittel, die z. T. erheblich über dem langjährigen Durchschnitt lagen; die positive Anomalie betrug im Südwesten des Reiches bis nach Thüringen hinein, ebenso im Gebiet zwischen Oder und Weichsel rd. 4° und nahm nach der Nordsee auf $1^1/_2$° ab. Besondere Temperaturverhältnisse hatte anfangs das Alpengebiet, das bis zum 11. sein starkes Frostwetter behielt; im übrigen lagen die Einzeltagesmittel zu Anfang und Ende des Monats nur wenig unter dem Durchschnittswert, weit stärker dagegen in den Tagen des Kälterückfalles am 6. und 7., wo negative Abweichungen von 3 bis 5° festzustellen waren. Sonst lagen im ganzen Monat die Tagesmittel über dem langjährigen Normalwert und überschritten ihn vom 15. bis 18. meist um 10°, in der Thüringer Mulde und in der oberrheinischen Tiefebene um 13 bis 15°. Die Zahl der Frosttage blieb in Mitteldeutschland um rd. 10, im übrigen Gebiet um etwa 5 solcher Tage gegenüber der üblichen Häufigkeit zurück; in gleicher Weise war auch die Zahl der Eistage zu gering und beschränkte sich im Flachlande und in niederen Lagen des Berglandes auf 1 bis 3 Fälle.

Infolge der häufigen westlichen Warmluftzufuhr wies der Westen des Reiches einen erheblich größeren Anteil an Niederschlagsmengen auf; die Mittelgebirge zeigten hier Monatsbeträge von etwa 150 mm, der Schwarzwald, das Bergische Land, der Oberharz und Thüringerwald von mehr als 200 mm. Ostwärts fielen schon im mittleren Norddeutschland die Monatsbeträge von über 75 mm auf weniger als 50 mm ab und gingen im Lee der Sudeten noch unter 25 mm herunter. In gleicher Weise nahmen südwärts nach der Donau zu die Monatsmengen auf weniger als 50 mm ab und sanken an den Ostalpen teilweise noch unter 25 mm. Gegenüber den Mittelgebirgen des Westens erschienen die Alpen recht niederschlagsarm; nur stellenweise hatten die nördlichen Kalkalpen (an der Zugspitze und am Feuerkogl) wie auch die Karawanken 100 mm übersteigende Monatsmengen. In Prozenten des langjährigen Durchschnitts ausgedrückt waren weniger als 100 v. H. gefallen in einem Gebiete, das vom Leeschutz des Harzes und Thüringerwaldes ostwärts bis zur östlichen Reichsgrenze sich erstreckte, ferner im Alpengebiet mit seinem nördlichen Vorlande. Während in diesen Landesteilen stellenweise nur 50 v. H. der Normalmengen gemessen wurden, stiegen die Prozentbeträge an den deutschen Küsten, wie auch im Gebiet der Ems und des Rheines einschließlich des ganzen Main auf mehr als 175 v. H., in der Rheinpfalz und in Rheinhessen insbesondere auf mehr als 200 v. H. Die Niederschlagshäufigkeit, die nur in Ober- und Mittelschlesien etwas unternormal war, stieg besonders nach dem Westen zu auf 22 bis 26 Tage mit Niederschlag und übertraf damit die sonst übliche Zahl vielfach um 7 bis 10 solcher Tage; im östlichen Flachlande wie im Berglande rechneten 65 v. H. der Niederschlagstage als Schneetage, im Westen hingegen nur 15 v. H. Die vom Vormonat her bestehende

# Witterungsverlauf im Jahre 1939

Schneedecke schwand in den Rheinniederungen schon bei Monatsbeginn, hielt sich dagegen im norddeutschen Flachlande bis zum 9., in seinen östlichen Bezirken teilweise noch über den 14. hinaus.

Bei dem vorherrschend neblig-trüben Charakter ergab sich im Monatsmittel ein reichlich hoher Bewölkungsgrad. Die Himmelsbedeckung betrug im westlichen Berglande und im Nordosten des Reiches mehr als 90 v. H., in den Alpen etwas unter 70 v. H. Damit war durchweg die Bewölkung normalen Verhältnissen gegenüber zu reichlich, in Schlesien um etwa 5 v. H., in den westlichen Reichsgebieten wie auch in Pommern und Ostpreußen um rd. 15 v. H. Während die Zahl der heiteren Tage meist um 2 bis 3 zu gering ausfiel, wies die der trüben Tage gegenüber dem langjährigen Durchschnitt einen zu hohen Betrag auf, der im Berglande des Westens wie auch im Nordosten des Reiches sich auf 22 bis 29 Tage steigerte; nur einzelne leegeschützte Lagen waren durch eine relativ geringere Zahl trüber Tage begünstigt. Durch zu reichliche Nebelhäufigkeit zeichneten sich neben den Gebirgen das westliche Bergland und das Küstenland aus. Einen klaren Gesamtüberblick über die Bewölkungsverhältnisse des Monats vermittelten die Werte der Sonnenscheindauer; diese blieben in Ostpreußen noch unter 10 Stunden, stiegen im mittleren Norddeutschland auf rd. 40, um im Bergland des Westens auf weniger als 25 Stunden wieder abzunehmen. Längere Sonnenscheindauer war dem gesamten Süden des Reiches beschieden, wo den Alpen eine Gesamtdauer von rd. 65 Stunden zuteil wurde. Mit Ausnahme des mittleren Neckartales und der Zugspitze blieb die Sonnenscheindauer sonst um 5 v. H., in einzelnen Gebieten auch um 15 v. H. hinter dem langjährigen Durchschnitt zurück.

Der **Februar** war fast durchweg zu warm und zu trocken. Das trockene Frostwetter, das unter der Wirkung eines Nordseehochs in den letzten Januartagen in Mitteleuropa eingesetzt hatte, dauerte über Monatsbeginn fort und verstärkte sich unter dem Zustrom polarer Luftmassen auf der Rückseite eines osteuropäischen Tiefs noch bis zum 4. Im Süden des Reiches war unter dem Einfluß des sich hier festsetzenden Hochs die Wolkenauflösung besonders stark, so daß bei warmen Oberwinden die Strahlungsverhältnisse kräftig zur Wirkung kamen, insbesondere die nächtliche Ausstrahlung in den Alpentälern Kältegrade bis gegen — 20° erzeugte. Während die kalte Witterung hier noch bis zum 8. anhielt, führten in Norddeutschland bereits am 5. die aufkommenden Westwinde mit stärkerer Bewölkung ein Ansteigen zu übernormalen Temperaturen herbei. Nachdem schon am 8. im Küstengebiet leichte Regen eingesetzt hatten, griff mit einer am 9. von den Britischen Inseln ostwärts wandernden Störungsfront einer nordatlantischen Depression die regnerische Witterung auch nach Süden über und brachte vom 10. an dem Reichsgebiet bis zum Zentralalpenkamm leichte bis mäßige Niederschläge, die in den höchsten Lagen der deutschen Mittelgebirge verschiedentlich als Schnee niedergingen. Die veränderliche, regnerische Witterung, die trotz eines vorübergehenden Vorstoßes des Azorenhochs am 11. in Norddeutschland vorherrschend blieb, äußerte sich im Süden des Reiches in zeitweiligen und vereinzelten Regenfällen; der anhaltende Zustrom subtropischer Meeresluft verursachte dabei eine Erwärmung, die am 11. und 12. mehrfach die Mittagstemperaturen über 10° hinaus ansteigen ließ. Ein Vorstoß arktischer Kaltluftmassen an der Rückseite eines über Mittelschweden ostwärts ziehenden Tiefs bewirkte am 13. weitere Niederschläge, die diesmal bei der merklichen Abkühlung schon in tieferen Lagen als Schnee fielen. Bereits am 15. und 16. machte sich in Norddeutschland wieder Zufuhr milder Meeresluft mit stärkerer Bewölkung, leichten Niederschlägen und schwacher Erwärmung geltend. Die Aufgleitniederschläge pflanzten sich mit dem 17. südostwärts bis zu den Alpen fort. Die Witterung gewann einen recht unruhigen Charakter mit dem 19., als zahlreiche Regen-, Schnee- und Graupelschauer zum Teil unter Gewittererscheinungen über Deutschland hinweggingen und ein vom Nordatlantik aufziehendes Tief vom 19. bis 22. sich über Polen festsetzte. In diesen Tagen kam es namentlich in den nordöstlichen Reichsgebieten zu weitverbreiteten Schneefällen. Mit der Annäherung eines osteuropäischen Hochs vollzog sich mit dem 23. eine Umgestaltung der Wetterlage. Unter schwachen südöstlichen Winden setzte in Deutschland heiteres, trockenes und wärmeres Wetter ein; die Temperatur erreichte in den Mittagsstunden des 25. zumeist den Höchstwert des Monats. Vom Atlantik heranziehende Störungsfronten feuchter Meeresluft brachten am 26. in Norddeutschland, am 27. dem Osten und dem Süden des Reiches regnerisches Wetter, das am Monatsschluß unter Bildung eines Zwischenhochs über Mitteleuropa wieder von heiterer Witterung abgelöst wurde.

Die zeitweise zur Wirkung kommende subtropische Luftzufuhr sowie die im letzten Monatsmittel vorherrschenden Südwinde brachten dem normalerweise kälteren Nordosten des Reiches eine Erwärmung, die sich in einem Temperaturmonatsmittel äußerte, wie es in der seit 1851 laufenden Beobachtungsreihe nur durch den Februar 1925 übertroffen wurde. So ergaben sich hier gegenüber den langjährigen Durchschnittswerten Temperaturanomalien + 4° bis + 5°. Die Abweichungen nahmen nach dem Südwesten des Reiches langsam ab, wo sie stellenweise im bayrischen Donaubecken schon zu negativen Werten übergingen. Die Einzeltagesmittel der Temperatur lagen nur zeitweise unter dem Normalwert; besonders zu Monatsanfang ergaben sich bei dem in Bayern bis zum 4. und in der oberrheinischen Tiefebene bis zum 8. anhaltende Frostwetter vereinzelt, wie in München am 3., um 9° zu niedrige Tageswerte. Gelegentlich der Kälterückfälle am 14. und 15. sowie am 22. zeigte nur der Süden des Reiches schwach unternormale Temperaturen. Im übrigen lagen die Einzeltagesmittel über dem Durchschnitt; die größte positive Abweichung von etwa 10 bis 11° hatte in den Tagen vom 10. bis 12. Norddeutschland, wo auch die am 16. erneut einsetzende Warmluftzufuhr nochmals um 6° zu hohe Tagestemperaturen zustande brachte. Im Süden des Reiches kam der Temperaturanstieg zum 25. und 26. zu stärkerer Ausprägung und erreichte um 6 bis 8° zu hohe Tageswerte. Entsprechend dem zu milden Witterungscharakter blieb die Zahl der Frost-

# Witterungsverlauf im Jahre 1939

tage meist zu gering, in Ostpreußen und in Ostpommern um rd. 10, in einer von der Unterelbe nach Oberschlesien verlaufenden Linie noch um 5 solcher Tage; nur am Rhein und im Maingebiet wurde die normale Zahl der Frosttage erreicht.

Die Tage mit Niederschlag, die vornehmlich in der regnerischen Periode vom 9. bis 20. sich stark häuften, traten nur im Nordosten des Reiches verhältnismäßig zu reichlich in Erscheinung. Im übrigen Gebiet war die Häufigkeit um rd. 2, am Schwarzwald um 5 Regentage zu gering. Schnee fiel an der Ost- und Westgrenze nur an 1 bis 2 Tagen, in Mitteldeutschland bis nach Niederschlesien und Bayern hinein an mehr als 5, in den Gebirgen an mehr als 10 Tagen. Das norddeutsche Flachland hatte nur für einen Tag, und auch nur strichweise, eine Schneedecke. So blieben die Monatsbeträge des Niederschlages meist zu gering. Sie gingen im Bereich der ostpommerschen und ostpreußischen Küste, sonst nur an den Mittelgebirgen und den nördlichen Kalkalpen, über 50 mm hinaus; sie übersteigen z. T. im Bergischen Land, Thüringer Wald und im Riesengebirge noch 75 mm, im Oberharz sogar 100 mm. Im Lee der Gebirge nahmen die Monatsmengen auf weniger als 20 mm ab. Dem leegeschützten Gebiet des Thüringer Waldes und des Harzes schlossen sich mit Beträgen unter 20 mm auch die Altmark, die Prignitz und das gesamte Havelgebiet an. Damit waren im Vergleich zu den langjährigen Durchschnittswerten die Monatsmengen teilweise bis zum $1^1/_2$fachen Betrag zu groß in der Westhälte Ostpreußens, am ostpommerschen Höhenrücken, in der Neumarkt und in Niederschlesien, ebenso in einem Gebiet, das von der Frankenhöhe zum Fichtelgebirge sich erstreckte und die Donauniederungen Bayerns umfaßte.

Wie die Niederschlagshäufigkeit war auch die Bewölkung im Monatsmittel gegenüber normalen Verhältnissen überwiegend zu gering, besonders im Süden des Reiches fast um 10 bis 18 v. H. der Himmelsbedeckung. In überreichlichem Maße trat sie im Osten des norddeutschen Flachlandes in Erscheinung, wo sich vereinzelt um 8 bis 13 v. H. zu hohe Bewölkungsgrade ergaben. Demgemäß war auch im Nordosten die Häufigkeit der trüben Tage um 1 bis 2 Fälle zu hoch, am Schwarzwald dagegen um 4 bis 6 zu niedrig. Die Zahl der heiteren Tage, die im östlichen Norddeutschland um 2 bis 3 zu gering ausfiel, blieb auch im Gebiet zwischen Oder und Weser infolge größerer Nebelhäufigkeit gegenüber den Erwartungen etwas zurück. Die Gesamtsonnenscheindauer war in Ostpreußen mit weniger als 40 Stunden besonders gering und stieg an der Oder auf 75, im Land Sachsen und Thüringen auf 90 bis 100 Stunden; südlich des 49. Breitengrades nahm sie auf mehr als 100, an den Gipfelstationen der Alpen auf mehr als 150 Sonnenscheinstunden zu. Im Verhältnis zum langjährigen Durchschnitt kam die Sonneneinstrahlung im Nordosten des Reiches um 10 bis 15 v. H. zu kurz, dagegen im mittleren Norddeutschland um 6 bis 8 v. H., im Süden um 8 bis 14. v. H. stärker zur Auswirkung.

Der **März** war mit Ausnahme der Küsten etwas zu kalt und meist zu reich an Niederschlägen.

Die Witterung hatte anfangs entsprechend den Verhältnissen des Vormonats noch einen heiteren, milden Frühlingscharakter. Zwar fielen am 1. mit dem Durchgang einer ozeanischen Warmluftfront schwache Regen, doch die Ausbreitung eines osteuropäischen Hochs über Mitteleuropa sicherte den Fortbestand der heiteren Witterung, bei der die Temperaturen mittags vielerorts auf 10—17° stiegen und das Tauwetter sich in Gebirgslagen bis zu 1000 m bemerkbar machte. Ein Übergang zu niederschlagsreichem Wetter vollzog sich vom 5. zum 6., als milde ozeanische, z. T. auch subtropische Luft Trübung und weitverbreitete Regenfälle brachte, die mitunter von Gewittererscheinungen begleitet, namentlich im Berglande des Westens erhebliche Tagesmengen absetzten. Noch in den folgenden Tagen gingen bei auffrischenden Westwinden kräftige Schauer nieder. Da hierbei das nordatlantische Depressionsgebiet sich über Mittelskandinavien nach den Ostseeprovinzen verlagerte, nahm die trübe, regnerische Witterung vom 10. ab einen rauheren Charakter an. Die Winde drehten mit Niederschlägen, die zu Schneefällen übergingen, langsam auf Nord; schon am 11. war ganz Mitteleuropa von arktischen Luftmassen überflutet, die damit einen recht kräftigen und an Schneefällen reichen Nachwinter einleiteten. Mit einer ausgeprägten Störungsfront, die vorübergehend noch einmal Regen brachte und die sich über Norddeutschland zu einem Teiltief entwickelte, setzten am 14. und 15. bei auffrischenden Nordwestwinden die Schneefälle verstärkt ein und arteten besonders an den böhmischen Randgebirgen, an den Alpen und in ihrem Vorlande zu heftigen Schneestürmen aus, die zu verkehrshindernden Verwehungen Anlaß gaben. Bei anhaltender Luftzufuhr aus nördlichen Breiten hielten die ergiebigen Schneefälle besonders im Stau der Gebirge an; bei zeitweiser Aufheiterung die eine stärkere nächtliche Ausstrahlung ermöglichte, glitten die Temperaturen mehrfach auf 6—12° Kälte ab; nur im Gebiet des Rheins griff am 17. ein von der Nordsee zum Mittelmeer abziehendes Teiltief mit vorübergehender Erwärmung und leichten Regenfällen ein. Eine ähnliche, wenn auch schwächere Wetterentwicklung wie am 14. und 15. vollzog sich zum 19. und 20. mit der Ausbildung eines Tiefs über Nordostdeutschland. Bei der rückläufigen Bewegung der Druckstörung nach dem Elbgebiet verschärfen sich am 21. Gradient und Luftzufuhr, so daß namentlich an den Gebirgen die Schneefälle recht ergiebig waren und die Schneelagen sich erhöhten. In diesen Tagen wurden bereits in Westdeutschland schwache Meeresluftstaffeln wirksam, die unter leichten Aufgleitniederschlägen Tauwetter herbeiführten. Nach langsamer Wetterberuhigung geriet Mitteleuropa gegenüber einem im Mittelmeer lagernden Tief immer mehr in den Bereich einer milden Südostströmung, die anfangs noch leichte Schneefälle auslöste, vom 26. ab schon dem Osten des Reiches Aufgleitregen und Tauwetter zuführte. Mit dem Vorstoß eines italienischen Teiltiefs traten am 28. und 29. ergiebige Dauerregen ein; erst vom 30. ab gelang es einem über Nordeuropa lagernden Hoch, mit seiner Südwärtsverlagerung die Regenzone nach Südosten abzudrängen. Bei rascher Aufheiterung und bei kalten Nordost- und Ostwinden kam am Monatsschluß die Sonnenstrahlung noch einmal in verstärktem Maße zur Geltung.

# Witterungsverlauf im Jahre 1939

Die Temperaturmonatsmittel lagen größtenteils unter dem langjährigen Normalwert; in den maritim stärker beeinflußten Gebieten an der Nordsee wie auch in Ostpreußen waren zwar die Abweichungen noch schwach positiv, gingen aber binnenwärts zu negativen Werten über und nahmen im Vorland der Alpen bis auf etwa — $2^1/_2°$ zu. Im Westen des Reiches wie auch in Bayern, wo die warme Witterungsperiode zu Monatsanfang zu stärkerer Ausprägung gelangte, waren die Einzeltagesmittel vom 4. bis 6. mehrfach um 8° zu hoch. Dafür fielen sie hier teilweise auch in Schlesien, bereits am 8. zu unternormalen Werten ab, während im übrigen Reichsgebiet der empfindliche Temperaturrückgang erst vom 10. zum 11. sich vollzog. Der Nachwinter brachte in den Tagen vom 17. bis 19. Tagesmittel, die um 5—6°, in Bayern um 7°, in den Alpentälern um 9° zu tief lagen. Erst gegen Monatsende erreichten die Temperaturen wieder normale, im Westen des Reiches schon schwach übernormale Verhältnisse. Die höchsten Temperaturen des Monats entfielen meist auf die Zeit vom 3. bis 7., in den östlichen Landesteilen auf das Monatsende, als die warme südöstliche Luftzufuhr vom 26. ab zu wirken begann. Die tiefsten Kältegrade traten im äußersten Nordosten schon am 13. ein, sonst vom 17. bis 19. oder in den folgenden Nächten bei erhöhter nächtlicher Ausstrahlung; sie lagen im Osten und im Süden des Reiches mehrfach unter — 10°. Hier vor allem ergaben sich demgemäß im ganzen Monat vielfach 25 Frosttage, während im westlichen Norddeutschland ihre Zahl 10—13 betrug.

Die Niederschläge, die vom 8. bzw. vom 11. ab im allgemeinen bis zum 25. als Schnee niedergingen, zeigten in der Verteilung der Monatsmengen winterlichen Charakter. Die Beträge stiegen im Hunsrück, Taunus auf mehr als 100 mm, in der Eifel, im Sauerland, Oberharz, in den Sudeten und nördlichen Kalkalpen auf mehr als 150 mm, im Schwarzwald, Böhmerwald und Allgäu noch über 200 mm. In den übrigen Teilen des westlichen Norddeutschlands unter Einbeziehung des Maingebietes und des bayerischen Donaubeckens schwankten die Monatsmengen zwischen 50 und 75 mm und nehmen im Nordseegebiet, im westfälischen Bergland und in einem Landstrich vom Thüringer Becken bis zur Torgauer Elbniederung auf weniger als 50 mm ab. In Niederschlesien, in der Neumarkt, im nördlichen Teil der Mark Brandenburg, am westlichen pommerschen Höhenrücken sowie am oberschlesischen Höhenrücken betrugen die Niederschlagsmengen mehr als 75 mm. Dagegen hatte Ostpreußen weniger als 50 mm, das östliche Masuren und das Kurische Haff sogar weniger als 25 mm. Unter dem langjährigen Durchschnitt blieben damit die Monatsbeträge im Bereiche der Nordsee, im gesamten Einzugsgebiet des Pregels und an der Memel. Bereits von der Weichsel ab verzeichnete Teil des östlichen Binnenlandes mehr als das Doppelte; gleich hohe Prozentbeträge hatten das gesamte Schwabenland und die nördlichen Kalkalpen von Bayern. — Bei solch übernormalen Niederschlagsbeträgen war die Niederschlagshäufigkeit verhältnismäßig groß; während im Küstengebiet nur 15—17 Tage Niederschlag brachten, waren es im Binnenlande meist mehr als 20, im nördlichen Teile Brandenburgs fast 25 Tage. Zu 65—80 v. H. dieser Tage fiel Schnee, so daß das Flachland im Osten an etwa 10, im Westen weniger als 5 Tagen eine Schneedecke aufwies, das Bergland oberhalb 500 m dagegen schon an 20 Tagen.

Die Bewölkung ergab im Monatsmittel nur im Nordseeküstengebiet eine etwas unternormale Himmelsbedeckung von 55—65 v. H.; sonst ging sie über den langjährigen Durchschnitt hinaus besonders im Schwarzwald und nördlichen Alpenland, wo eine um 10 v. H. zu reichliche Bewölkung festgestellt wurde. Damit war an der Nordsee sowie an der mecklenburgisch-pommerschen Küste die Zahl der heiteren Tage mit 4—7 fast um das Doppelte zu hoch, die der trüben Tage um etwa 5 zu gering. Das übrige Reichsgebiet litt durchweg unter einem Mangel an heiteren Tagen, der im Bereich des Oberrheins und des Main sowie im Alpenland vielfach über 50 v. H. hinausging, und unter einer zu hohen Zahl trüber Tage; auffallend häufig waren die Bergstationen von Nebel beeinflußt. Die Sonnenscheindauer brachte es in Nordwestdeutschland auf mehr als 120 Sonnenscheinstunden oder mehr als 30 v. H. der möglichen Dauer, so daß gegenüber den Normalbeträgen ein Überschuß bis zu 15 v. H. sich ergab. Besonders wenig Sonnenschein hatten Schlesien, das Land Sachsen, der Sudetengau und das Maingebiet mit einem Ausfall bis zu 25 v. H.

Der **April** war zu warm, lediglich in der nordwestlichen Reichshälfte zu niederschlagsreich.

Der vielfach heitere und trockene Witterungscharakter, der zum Monatswechsel unter dem Einfluß eines skandinavischen Hochs sich eingestellt hatte, hielt bei Zufuhr kalter, trockener Festlandsluft nur wenige Tage an. Als vom 2. zum 3. das Hoch nach dem Schwarzen Meer zu sich verlagerte, griffen bereits mit einem über der Nordsee erscheinenden Teiltief milde ozeanische Luftmassen nach Nordwestdeutschland mit Trübung und schwachen Aufgleitniederschlägen ein; bei weiteren an Energie zunehmenden Meeresluftstaffeln breitete sich die etwas regnerische Witterung rasch ostwärts aus, weniger allerdings nach dem Süden des Reiches, wo am Nordrand der Alpen das föhnige, klare Wetter größtenteils vorherrschend blieb. Unter Zufuhr von Nordatlantikluft erfolgte vom 7. ab in Mitteleuropa stetiger kräftiger Druckanstieg; bei kühler, trüber Witterung kam es an den deutschen Mittelgebirgen noch zu leichten Niederschlägen, im böhmischen Raume auch zu einzelnen Gewittern, bis endlich zu den Osterfeiertagen überraschend allgemeine Aufheiterung eintrat. Bei kräftiger Sonnenstrahlung vollzog sich bis zum 14. eine Erwärmung, die namentlich im Nordwesten des Reiches Mittagstemperaturen von etwas über 25° zeitigte. Ein Einbruch kühler Meeresluft in der Höhe gab am 13. Anlaß zu verbreiteten Gewittern, die rasch von West nach Ost vorüberzogen; eine stärkere Belebung der Westwinddrift machte sich erst im Laufe des 14. unter der Auswirkung nordatlantischer Depressionen geltend. Die aufkommende meist trübe und zunächst noch schwach regnerische Witterung steigerte sich mit nachfolgenden Meeresluftstaffeln und nahm vor allem im Küstengebiet bei böigen, kühlen Winden und kräftigen Schauern einen rauhen Charakter an. Als am 18. die Winde

nach Nord drehten, fiel namentlich im Nordosten des Reiches mehrfach Schnee. Auch das gesamte Alpenland, das bis zum 15. trockenes Wetter gehabt hatte, geriet in den Bereich kühler, regnerischer Witterung und wies am 18. in den höheren Gebirgslagen ebenso wie an den Gipfelstationen der deutschen Mittelgebirge Neuschnee auf. Mit der Ausbreitung eines Atlantikhochs über Mitteleuropa vollzog sich am 19. eine Wetterberuhigung, so daß bei Aufheiterung der 20. und 21. verhältnismäßig sonnig und trocken, vereinzelt aber unter Nachtfrösten verliefen. Der Abbruch dieser kurzen Schönwetterperiode erfolgte am 22. mit einem Sturmwirbel, der von der Nordsee nach Finnland vorüberzog und bei stark auffrischenden, im norddeutschen Flachlande stürmischen Winden mit gewittrigen Schauern und mit Abkühlung sich selbst noch bis zu den Zentralalpen auswirkte. Die regnerische und zeitweilig von Nordwinden beherrschte Witterung hielt unter der Wirkung schwächerer nachfolgender Druckstörungen an; so daß verschiedentlich die Temperaturen nachts unter den Gefrierpunkt heruntergingen. Langandauernde Regen setzten am 27. ein mit einer von den Westalpen nach Schlesien wandernden Depression und verstärkten sich unter dem Einfluß eines am 28. nach Böhmen vorstoßenden Adriatiefs. Der dabei von Südost her andringenden subtropischen Warmluft gelang es, die umfangreiche Niederschlagszone, in der es mehrfach zu starken Gewitterentwicklungen (mit Überflutungen im östlichen Thüringen) kam, langsam nach Westen abzudrängen, so daß sie sich am Morgen des 30. auf das Rheingebiet beschränken mußte. Während im Bereiche der östlichen Strömung Aufheiterung und Erwärmung Platz griff, verbreiteten sich die Regenfälle zum Monatsschluß wieder über das ganze Küstengebiet, als das bisher über Böhmen und Franken befindliche Tief langsam nach Nordost abzuziehen begann.

Trotz des vielfach kühlen Witterungsverlaufes ergab der April im Monatsmittel durchweg zu hohe Temperaturwerte, die in den südlichen Landesteilen um $3\,^1/_2{}^\circ$ im Nordwesten des Reiches noch um rund $1^\circ$ über dem langjährigen Normalwert lagen. Die zu Monatsbeginn infolge des vorangegangenen Nachwinters noch unternormalen Temperaturen des mittleren und östlichen Norddeutschland erholten sich recht rasch, so daß die am 5. eintretende Erwärmung im äußersten Nordosten bereits um $9^\circ$ zu hohe Tagesmittel brachte. Die Abkühlung am 8. vollzog sich nur im mittleren Norddeutschland bis zu schwach unternormalen Werten, die des 11. dagegen in gleichem Ausmaße nur für den Nordosten. Die bis zum 14. steigernde Erwärmung führte die Tagesmittel zu einer Höhe, die vielfach den Normalwert um $10^\circ$ überstieg. Nach dem Temperaturrückgang am 15. gestalteten sich die Temperaturverhältnisse in den einzelnen Landesteilen recht schwankend und weniger einheitlich, geringe Erwärmungen über den Normalwert kamen am 20. bis 22. im Nordseegebiet kaum zur Geltung, solche am 25. und 26. blieben in Westdeutschland gänzlich aus. Während so im Westen unternormale Verhältnisse dauernd vorherrschend blieben, verhalf die gegen Monatsende von Südosten her vorstoßende Warmluft den östlichen Reichsgebieten wieder zu einem Anstieg bis zu übernormalen Tageswerten. Die Höchstwerte des Monats entfielen mit Ausnahme des Nordostens, der am Monatsschluß noch stärkere Erwärmung erfuhr, auf die Zeit vom 12. bis14., die dem Westen des Reiches auch einzelne Sommertage bescherte. Die tiefsten Temperaturen meist mit Werten unter dem Gefrierpunkt gehörten den ersten Tagen des Monats an, vereinzelt den vielfach zu kühlen Witterungsabschnitten in der zweiten Monatshälfte. Die Zahl der Frosttage blieb allgemein und z. T. beträchtlich hinter der sonst üblichen Häufigkeit zurück; in den Tälern des Rheingebietes wurden nur vereinzelt Frosttemperaturen beobachtet.

In der Verteilung des Niederschlags äußerten sich stark maritime Einflüsse. Begrenzt durch eine Linie vom pommerschen Höhenrücken über die Thüringer Mulde bis westlich des Bodensees hatte die nordwestliche Reichshälfte mit wenigen Ausnahmen Monatsbeträge von mehr als 50 mm; an der Unterelbe und Unterweser wie in den Mittelgebirgen gingen sie über 100 mm, im mittleren Schwarzwald über 150 mm hinaus. Im gesamten südöstlichen Teile, wo nur in der Oberlausitz und im Allgäu mehr als 50 mm gefallen waren, nahmen die Mengen stetig ab, und zwar bis auf weniger als 25 mm im südlichen Ostpreußen, in der Osthälfte Schlesiens, ferner in Mittelfranken und Oberbayern. Weniger als 10 mm hatten das östliche Oberschlesien und das von Passau ab sich längs der Donau erstreckende Hügelland. Gemessen an den langjährigen Durchschnittswerten stiegen die Monatsbeträge in dem zu niederschlagsreichen Nordwesten auf mehr als 200 v. H. im pommerschen Küstengebiet, im südlichen Schleswig-Holstein, an der Unterweser wie in der Letzlinger Heide und im Münsterland. Die Prozentbeträge fielen südostwärts merklich ab und sanken unter 25 v. H. im östlichen Oberschlesien sowie in Oberbayern. Die Niederschlagshäufigkeit hatte im westlichen Berglande mit 18 bis 20 Niederschlagstagen ihren größten Wert; ihre Abnahme vollzog sich besonders stark nach den südöstlichen Reichsgebieten zu, wo weniger als 10 Tage mit Niederschlag gezählt wurden. Einzelne Landstriche Norddeutschlands hatten an 4 bis 5 Tagen Gewitter. Schneefall zeigte sich im Flachlande nur im dänischen Grenzgebiet und im Nordosten des Reiches; die Schneelage hatte selbst in Ostpreußen höchstens für einen Tag Bestand.

Reichliche und etwas übernormale Bewölkung herrschte im westlichen Bergland vor mit 70 bis 75 v. H. mittlerer Himmelsbedeckung; sie nahm bis auf 53 v. H. in Oberschlesien ab. Den zu hohen Bewölkungsgraden des Wetters entsprachen nicht immer unternormale Häufigkeitswerte der heiteren Tage, wohl aber stets eine zu große Zahl an trüben Tagen; demgegenüber waren größere Landesteile Schlesiens stark bevorzugt, insofern sie mit 5 bis 7 heiteren Tagen fast das Doppelte des normalen Ausmaßes und bei weniger als 5 trüben Tagen noch nicht die Hälfte der üblichen Häufigkeit verzeichneten. Besonders kraß hoben sich die Unterschiede an den Zahlen der Sonnenscheinstunden heraus, die bei etwas zu geringen Beträgen von rd. 140 im Westen auf 200 bis 225 Stunden im südlichen Oberschlesien und im südlichen Ostpreußen anwuchsen.

# Witterungsverlauf im Jahre 1939

Der **Mai** war mit Ausnahme der nordwestlichen Landesteile im gesamten Reichsgebiet zu kalt und brachte vor allem in Ost- und Süddeutschland übernormale Niederschläge.

Während der Witterungscharakter Ende April und noch zu Beginn des Mai in den meisten Landesteilen durch die Herrschaft milder Kontinentalluft bestimmt wurde, machte sich an den Küstengebieten bereits subpolare Kaltluft bemerkbar, die an der Südostseite eines ausgedehnten nordeuropäischen Hochdruckgebietes südwestwärts vordrang. Die Begegnung dieser stark gegensätzlichen Luftmassen in einer Frontalzone, die am 1. und 2. entlang der deutschen Küste verlief, ließ an der Nordsee und in Ostpreußen die ersten Maigewitter aufkommen. Durch die Ausdehnung des Einflußbereiches eines Mittelmeertiefes nach Deutschland am 3. und 4. strömte die bis zur Küste gelangte Kaltluft in den größten Teil des Reichsgebietes ein, wobei die Verdrängung von in Süddeutschland und Schlesien liegenden Warmluftresten teilweise unter Gewittererscheinungen und starken Niederschlägen erfolgte. In den Küstengebieten der Nord- und Ostsee wurde der kühle Witterungscharakter durch Sonneneinstrahlung tagsüber etwas gemildert, wobei nächtliche Ausstrahlung dort die tiefsten Temperaturen des Monats und mehrfach Nachtfröste brachte. Im übrigen Reichsgebiet verursachte eine im Osten eingetretene Neubelebung der Zyklonentätigkeit starke Bewölkung und in den östlichen und südöstlichen Landesteilen verbreitet Landregen. Eine neue am 7. und 8. eindringende Kaltluftwelle verbunden mit Luftdruckanstieg brachte dem Küstengebiet und Norddeutschland vorübergehend wieder freundliches Wetter. Die im Mittelmeer weiterhin rege gebliebene Zyklonentätigkeit trug mit ihrer verstärkten Einflußnahme auf das Reichsgebiet dazu bei, daß vom 9. bis 14. mit Ausnahme der nordöstlichen Landesteile überall stark wolkiges Wetter in verbreiteten Niederschlägen herrschte; diese gingen in Süddeutschland infolge feuchtlabiler Luftmassenschichtung mehrfach in Form von gewittrigen Starkregen nieder. Durch Verlegung der Wirbeltätigkeit von Süd- nach Mitteleuropa gelangte wieder mildere Kontinentalluft nach Deutschland, so daß in den nördlichen Gebieten vom 15. bis 18. die Temperaturen zu normalen bis schwach übernormalen Werten ansteigen konnten, während sonst die Kaltluft noch die Vorherrschaft behielt. Vielfach bedingte die unregelmäßige Druckverteilung Gewittererscheinungen und trübes regnerisches Wetter mit Dunst- und Nebelbildung. Am 19. ließ vom Nordatlantik vorstoßende Meereskaltluft vor allem im Westen und Süden des Reiches die Temperaturen erneut zurückgehen. In den östlichen Landesteilen brachte dagegen vom Balkan herangeführte subtropische Warmluft übernormale Temperaturen; in Schlesien und Ostpreußen wurden dabei die höchsten Temperaturen des Monats beobachtet. Mit dem weiteren Vordringen der Kaltluft am 20. und 21. gelangten die westlichen und nördlichen Gebiete unter den Einfluß eines Azorenhoch-Ausläufers mit vielfach heiterem und freundlichem Wetter; in der östlichen Reichshälfte bedingte jedoch die osteuropäische Frontalzone mit ihren ausgeprägten Luftmassengegensätzen einen Fortbestand der regen Wirbeltätigkeit, die verbreitet gewittrige Niederschläge zur Folge hatte. Vom 22. bis 26. dehnte sich dieses Störungsgebiet vorübergehend nach Westen aus, so daß besonders am 24. und 25. im mittleren Norddeutschland und im Süden des Reiches Starkregen niedergingen. Die Temperaturverhältnisse bleiben dabei im ganzen Reich mit Ausnahme der nordwestlichen Bezirke, wo durch beständig heiterem Wetter die Erwärmung Fortschritte gemacht hatte, unter den Normalwerten. Der sich am 27. und 28. verstärkte Hochdruckeinfluß über dem Westatlantik setzte erneut subpolare und am 29. sowie 30. arktische Luftmassen in Bewegung, die allenthalben erneute Temperaturrückgänge mit sich brachten. Der damit verbundene Luftdruckanstieg ließ die Zyklonentätigkeit nahezu erlöschen, so daß im alten Reichsgebiet zum Monatsende starke Aufheiterung eintrat, die eine rasche Erwärmung der Kaltluft bis zu Höchsttemperaturen von 25° und teilweise darüber bewirkte. Nur an den Nordrändern der Gebirge und im Alpengebiet blieben die Temperaturen infolge einer durch Stauwirkung verstärkten Bewölkung noch unternormal; dort gab es aus diesem Grunde auch noch einige Niederschläge.

Die Vorherrschaft polarer Luftmassen ergab Temperaturmonatsmittel, die im größten Teil des Reiches unternormal waren; die stärksten Abweichungen von 2 bis 3 Grad wurden im Mittel- und Süddeutschland festgestellt, während sie in Ostpreußen und im größten Teil Norddeutschlands nur bis zu 1° betrugen; positive Abweichungen bis zu 1° fanden sich nur in Mecklenburg, Schleswig-Holstein und in den Küstengebieten der Nordsee. Die vom 2. bis 4. fast das gesamte Reichsgebiet überflutenden arktischen Kaltluftmassen brachten meistenorts die tiefsten Werte des Monats und verbreitet auch Bodenfröste. Mit einer in der Zeit vom 7. bis 9. eindringenden Welle subpolarer Kaltluft sanken die Temperaturen fast überall erneut ab; nur die Nordseeküste hielt infolge vorwiegend heiteren Wetters die Temperatur in der Nähe der Normalwerte und teilweise etwas darüber. Dieses bisher im größten Teil des Reiches vorhandene Wärmedefizit wurde vom 13. ab in Ostpreußen und Schlesien sowie im mittleren Norddeutschland durch den Zustrom milder Kontinentalluft teilweise wieder ausgeglichen, während sonst die Temperaturen sich wenig änderten. Im östlichen Reichsgebiet verursachte die Ausarbeitung subtropischer Warmluft am 18. und 19. Temperaturanstiege, die sogar beträchtliche Überschüsse gegenüber den Normalwerten und dort vielfach die ersten Sommertage mit Monatshöchstwerten brachten. Die Vorherrschaft inzwischen wieder von neuem eingedrungener Polarluft dauerte bis zum 26., wo ein Einbruch frischer arktischer Kaltluft nochmals stärkeren Temperaturrückgang im gesamten Reichsgebiet hervorrief; infolge starker Einstrahlung blieben im Nordwesten die Temperaturen meist über dem Regelwert, während sonst überall bis zum Monatsende der unternormale Temperaturcharakter erhalten blieb. Die Höchstwerte des Monats fielen im Nordwesten und im mittleren Norddeutschland auf den 31., in den übrigen Landesteilen meist auf den 18. und 19. Die Zahl der Sommertage war mit wenigen Ausnahmen im ganzen Reichsgebiet um 3 bis 6 zu gering. Die tiefsten Temperaturen mit Werten in Gefrierpunktnähe gehörten den ersten Tagen des Monats an. Die Zahl der Frosttage blieb als Folge der vorwiegend starken Bewölkung allgemein etwas unter dem Regelwert und betrug im Flachland höchstens 2.

# Witterungsverlauf im Jahre 1939

Die Verteilung der Niederschläge stellt ein getreues Abbild der vor sich gegangenen Wetterereignisse dar, dergestalt, daß nordwestlich der Linie Saarbrücken—Stettin die Niederschlagshöhen meist nur zwischen 20 und 40 mm lagen und an der Küste vereinzelt nicht einmal 10 mm erreichten. Hingegen stiegen die Regenmengen in Süddeutschland und in Schlesien an vielen Stellen auf 200 bis 300 mm an. Gemessen an den langjährigen Durchschnittswerten ergaben sich daselbst Monatsbeträge von über 200 v. H., während in den nordwestlichen Landesteilen um 25 bis 50 v. H. unternormale Verhältnisse angetroffen wurden. Längs der Linie Saarbrücken—Stettin zog sich ein schmaler Streifen mit im ganzen normalen Niederschlagshöhen hin, die außerdem auch an der pommerschen Küste und in Ostpreußen beobachtet wurden. Die Niederschlagshäufigkeit läßt die entsprechende Verteilung erkennen, indem in den westlichen und nordwestlichen Gebieten die Anzahl der Tage mit meßbarem Niederschlag mit 5 bis 10 unter dem Regelwert blieb; der entsprechende Überschuß kennzeichnete die Verhältnisse der übrigen Landesteile; dem Alpengebiet, dem Schwarzwald und den Sudeten mit teilweise über 25 Niederschlagstagen stehen so die Nordsee und westliche Ostseeküste mit nur 5 bis 10 Regentagen gegenüber. Die Zahl der Gewittertage blieb fast überall unter dem Regelwert und war in den südlichen Gebieten etwas größer als in Norddeutschland; dort gab es an der Nordseeküste kein einziges Gewitter. Tage mit Schneefall stellten sich nur in den höheren Lagen der Mittelgebirge vereinzelt und im Alpengebiet in den höchsten Lagen des öfteren ein.

Hohe und damit übernormale Bewölkungsgrade fanden sich im ganzen Reich mit Ausnahme des äußersten Nordwesten; und zwar lagen dieselben um 20 bis 30 v. H. über dem Regelwert, wohingegen die Küstengebiete der Nordsee und westlichen Ostsee mit um 10 bis 20 v. H. zu geringer Bewölkung ihr heiteres Maiwetter bezeugten. Entsprechend war die Zahl der heiteren Tage dort um 6 bis 8 zu hoch, in den übrigen Landesteilen mehrfach um denselben Betrag zu niedrig. Die hierzu spiegelbildliche Verteilung ergibt sich bei der Betrachtung der Anzahl der trüben Tage, die an der Nordseeküste rd. 4, im Süden und Südosten des Reiches 15 bis 20 betrug; hier hatte Schlesien, Sachsen und Süddeutschland einen Überschuß von teilweise bis zu 15 Tagen; der äußerste Nordwesten erfreute sich dagegen eines Ausfalls von 3—7 Tagen. Ebenso kraß hoben sich diese Unterschiede in der gemessenen monatlichen Sonnenscheindauer heraus, die in den südlichen und südöstlichen Landesteilen nicht einmal 150 Stunden, dagegen an der Nordseeküste 300 Stunden und darüber erreichte.

Der **Juni** war allgemein etwas zu warm und mit Ausnahme einiger von Gewittern häufig heimgesuchter Landesteile größtenteils zu trocken.

Das mit Vormonatsende eingetretene heitere und trockene Wetter hatte für das gesamte Reich, von geringen Störungen abgesehen, längeren Bestand. Eine am 4. von Island über Mittelschweden ostwärts wandernde flache Depresion rief im Küstengebiet für kurze Zeit stärkere Bewölkung und nur in Ostpreußen unwesentliche Niederschläge hervor. Die über Mitteleuropa vorherrschenden Kontinentalluftmassen erfuhren bei anhaltend heiterer trockener Witterung eine stetige Erwärmung, so daß mittags die Temperaturen über 25° und vom 7. ab über 30° hinausgingen. Das erste Eingreifen maritimer Luft arktischen Ursprungs erfolgte am 9. mit nordwestlichen Winden, die von der Ostseite eines britischen Hochdruckgebietes ausgehend über Westdeutschland bis zu den Alpen unter Gewittern vorstießen und bereits eine merkliche Abkühlung verbreiteten. Der Vorübergang von Depressionen in höheren Breiten bedingte mit der Zufuhr maritimer Subtropikluft in Mitteleuropa wieder eine leichte Erwärmung und vom 11. ab das Eindringen von Meeresluftstaffeln, die nunmehr auch in Norddeutschland die Schönwetterperiode mit Gewittern und Regenfällen endgültig abschlossen und die warme Kontinentalluft auf den Nordosten des Reiches zurückdrängten. Ein recht empfindlicher Temperaturrückgang, wie er im Jahresablauf im Volksmund unter der Bezeichnung „Schafskälte" bekannt ist, vollzog sich am 13. und 14. mit dem Einbruch arktischer Kaltluft. Nach verbreiteten Gewittern und Regenfällen sanken die Temperaturen nachts bis auf einige Grade über den Gefrierpunkt ab; mittlere Gebirgslagen, wie auch die Eifel, hatten vereinzelt Nachtfrost, die höheren Lagen der Alpen vielfach auch Neuschnee. Während im Westen die Bewölkung bald aufbrach, hielten die kräftigen Niederschläge in Schlesien z. T. auch in der Kurmark noch bis zum 15. an. Erst zum 16. führte anhaltender Druckanstieg zu allgemeiner Wetterverbesserung und durchgreifender Aufheiterung. Die allerdings immer wieder auflebende Westwindströmung schuf gegenüber der von Osten wirkenden Warmluft, die in der nordöstlichen Reichshälfte sich maßgebende Bedeutung zu sichern vermochte, die Grundbedingungen für eine sich täglich wiederholende Gewitterentwicklung; sie zeitigte wiederum in Süddeutschland und Schlesien mehrfach schwere Hagelschläge und griff schließlich am 19. mit Meeresluftstaffeln, die vom Südwesten des Reiches aus vorstießen, nach dem mittleren Norddeutschland über. Die Ausbreitung kontinentaler Warmluft gegen Westen bis zum Kanalgebiet veranlaßte am 20. merkliche Aufheiterung und Nachlassen des schwülen Witterungscharakters. Mit einer von einem Islandhoch gespeisten Nordströmung stellte sich zum 23. über Mitteleuropa ein flaches Teiltief ein, das mit weiterer Ausgestaltung dem ganzen Westen des Reiches Gewitter und Regenfälle bescherte. Diese traten in noch stärkerer z. T. verheerender Form und größerer Verbreitung auf, als am 25. gemäßigte Arktikluft über Deutschland hereinbrach. Druckanstieg brachte zum 27. Aufheiterung und damit nochmals vorübergehend heitere, trockene Witterung. Da auf der Südseite eines nordatlantischen Tiefs die Westwinddrift erneut einsetzte, zogen mit ihr schon vom 28. zum 29. leichte gewittrige Schauer über das Land, bis schließlich zum Monatsschluß auch eine ausgedehnte Regenfront heranrückte, die am Morgen des 1. Juli bereits am Inn, am Böhmerwald und Erzgebirge lag.

# Witterungsverlauf im Jahre 1939

Das Temperaturmittel des Monats lag allgemein über dem langjährigen Normalwert; die größten Abweichungen verzeichnete das nordwestliche, z. T. auch das nordöstliche Flachland mit rd. 2°. Wenn auch die Schwankungen der Einzeltagesmittel im ganzen Reich fast durchweg gleichartig verliefen, so zeigten sie in ihren Ausmaßen gewisse Unterschiede. So kam die Erwärmung am 7. und 8. im Westen des Reiches am stärksten zur Geltung, am schwächsten in den Alpen und im Nordosten des Reiches, wo die Luftzufuhr aus Nordosteuropa her nachhaltig blieb. Nach dem im Süden des Reiches wenig wirksamen Temperaturrückgang am 9. griff der Kälterückfall am 13. und 14. selbst südlich der Alpen so kräftig durch, daß die Tageswerte im Süden bis zu $7^1/_2$ unter dem Regelwert lagen. Die Erwärmung, die im Norden des Reiches schon zum 16. einsetzte, machte sich im Süden erst vom 20. ab bemerkbar. Ein schwacher nochmaliger Temperaturrückgang zu etwas unternormalen Werten erfolgte überall in den Tagen von 25. bis 27.; der Wiederanstieg zum Monatsende vollzog sich kräftig. Die Häufigkeit der Sommertage war allgemein recht hoch und überschritt im Rheingebiet, in Schleswig-Holstein, Oberschlesien und Ostpreußen den sonst üblichen Wert noch um fünf solcher Fälle.

Das Kartenbild der Niederschlagsverteilung war offenbar stark bestimmt von der Verbreitung der Gewitter; in Nordwestdeutschland und in den maritim beeinflußten Teilen Ostpreußens blieben die Gesamtbeträge unter 25 mm und stiegen erst in Süddeutschland sowie im Land Sachsen, in Brandenburg und Pommern, andererseits im ostpreußischen Binnenland auf mehr als 50 mm, weiterhin in den böhmischen Randgebirgen, in Oberdonau, im Schwarzwald und im Alpenland auf mehr als 100 mm. Im Verhältnis zum langjährigen Durchschnitt hatte dabei der größte Teil des Reiches, namentlich Nordwestdeutschland, noch zu wenig Niederschlag gehabt. Übernormale Beträge verzeichneten lediglich das ostpreußische Binnenland, das Gebiet der unteren Oder und mittleren Spree mit einem schmalen zur Saaleplatte reichenden Ausläufer. Enger begrenzte, namentlich von schweren Gewittern heimgesuchte Gegenden, hatten mehr als 150 v. H. Die Niederschlagshäufigkeit fiel zu klein aus; in Norddeutschland, wo vielfach nur 8 Tage mit Regen gezählt wurden, war sie um 5 Tage zu gering, ebenso in den Alpen, wo es immerhin an etwa 9 bis 13 Tagen geregnet hatte. Eine zu kleine Zahl von Gewittertagen hatte der Nordwesten des Reiches, wo meist nur ein einziger derartiger Tag verzeichnet wurde; reichlicher gestaltete sich die Gewittertätigkeit in Schlesien, ferner noch in Ostpreußen, wo an 9 bis 10 Tagen Gewitter auftraten.

Die Bewölkung entsprach größtenteils mit rd. 58 v. H. mittlerer Bedeckung den sonst üblichen Verhältnissen. Eine um 10 v. H. und mehr zu geringe Bewölkung hatten der Nordwesten des Reiches, Ostpreußen und Oberschlesien, so daß der Grad der Himmelsbedeckung vereinzelt noch unter 40 v. H. blieb. Diese bevorzugten Gebiete hatten mehrfach bis zu 10, vereinzelt auch bis zu 13 heitere Tage, im Gegensatz zum Oberrhein und der nördlichen Grenzmark, die nur 3 heitere Tage und damit zu wenig zählten. Entsprechend fiel die Zahl der trüben Tage mit 8 bis 12 in einem recht weiten Gebiete zu reichlich aus, das vom Südwesten des Reiches nach Böhmen und Mähren verlief und von dort aus nordwärts bis zum baltischen Höhenrücken sich erstreckt; auch die Westhälfte der Alpen hatte eine große Zahl von trüben Tagen. Nebel, im Berglande überall häufiger vertreten, stellte sich im Flachlande strichweise an 2 bis 3 Tagen ein. Der Sonnenschein brachte es allgemein auf übernormale Beträge; in Gebieten mit etwas reichlicher Bewölkung gewann die Sonnenscheindauer immer noch eine Stundenzahl, die um 5 bis 10 Stunden den zu erwartenden Betrag überstieg. Im Nordwesten des Reiches, wie auch am ostpreußischen Höhenrücken, wurde gegenüber dem langjährigen Durchschnitt sogar ein Überschuß von 80 bis 100 Sonnenscheinstunden erzielt; hier erreichte allerdings die Sonnenscheindauer den Betrag von rd. 60 v. H. der möglichen.

Der **Juli** war mit Ausnahme von Süddeutschland überall etwas zu warm und brachte vor allem in Norddeutschland, Schlesien und in den westlichen Gebieten Süddeutschlands zum Teil stark übernormale Niederschläge.

Die Ende Juni auf den Kontinent übergetretene Regenfront eines ausgedehnten nordatlantischen Tiefs hatte bereits am 2. ganz Deutschland überquert. Die ihr nachfolgenden kühlen Meeresluftmassen führten am 3. zum Aufbau eines Hochs über Mitteleuropa, das vorübergehend wieder Aufheiterung und Erwärmung brachte. Schon am 6. griff jedoch eine vor Irland liegende Zyklone erneut in das Wettergeschehen Mitteleuropas ein, innerhalb deren Vorderseitenströmung milde Meeresluftmassen eine wenn auch geringe Abkühlung in Deutschland bedingten. Am Ende eines am 7. und 8. bestandenen Hochdruckeinflusses, der mit einer Ausbreitung von Tropikluft bis zu den Küstengebieten einherging, setzte eine am 9. ganz Deutschland überquerende Gewitterfront der sechstägigen Warmwetterperiode endgültig ein Ende. Dieser einem skandinavischen Wirbel angehörende Luftmassenscheide folgten in rascher Strömung kühle Meeresluft und im späteren Verlauf am 10. und 11. noch niedriger temperierte maritime Polarluft. Diese ließ über Mitteleuropa die Ausbildung eines Zwischenhochs am 12. und 13. mit vorübergehender Aufheiterung zu. Die sich im östlichen Atlantik fortsetzende Zyklonenbildung beendigte jedoch diese kurzen Schönwettertage, indem am 14. und 15. in der Höhe vordringende Kaltluft allenthalben in Deutschland eine rege Gewittertätigkeit mit allerdings nur geringen Niederschlägen entfaltet hatte. Am 16. und 17. ließ die auf dem Atlantik weiter sich verstärkende Wirbelbildung auch am Boden kühle Meeresluft nach Mitteleuropa einströmen, die zu teilweise starken gewittrigen Niederschlägen in ganz Deutschland führte. Ein damit verknüpfter Druckanstieg bedingte fast überall wieder Wetterberuhigung, bis ein am 19. sich verbreitender Vorstoß von Meereskaltluft erneut die vor ihr liegenden Tropikluftmassen im Laufe des 20. nach Osten abdrängte; dabei gab es verbreitet Niederschläge zum Teil in Form von Gewittern. Diese Kaltfront kam jedoch in

# Witterungsverlauf im Jahre 1939

Deutschland zum Stehen, so daß am 21. die östlichen Gebietsteile noch innerhalb der Tropikluft verblieben. An der Frontalzone bildeten sich am 22. neue Störungen aus, die die gewitterreiche Wetterperiode der vergangenen Tage bei starker Bewölkung und verbreiteten Niederschlägen fortsetzten. Die inzwischen über dem Nordatlantik wieder besonders lebhaft gewordene Zyklonentätigkeit beendigte diese an Temperaturgegensätzen reiche Witterung, indem vom 23. bis 25. mehrere Staffeln kühler Meeresluftmassen Deutschland das Witterungsgepräge gaben; in ihrem Bereich fielen bei stark wechselnder Bewölkung vielfach ergiebige Schauerniederschläge. In dem Strömungsfeld zwischen dem von Südwesteuropa her sich ausbreitenden Hochdruck- und dem ostwärts abziehenden früheren mitteleuropäischen Tiefdrucksystem bewegten sich am 26. und 27. noch verschieden temperierte Luftmassen, so daß über Deutschland der unbeständige Witterungscharakter erhalten blieb. Erst die verstärkte Einflußnahme eines selbständig gewordenen Azorenhochausläufers begründete vom 28. bis 30. in Deutschland eine heitere und sehr warme Wetterperiode, die im Laufe des 31. infolge Zustroms von Meeresluft durch etwas kühleres, jedoch nicht ganz unfreundliches Wetter abgelöst wurde.

Die Temperaturmonatsmittel lagen in ganz Norddeutschland durchweg über dem Regelwert, wobei die Abweichungen in Schleswig-Holstein, Pommern und Ostpreußen vielfach 1 bis 2° betrugen; im größten Teil Süddeutschlands fanden sich dagegen unternormale Monatsmittel der Temperatur mit Abweichungen von über 1 Grad in einzelnen südwestlichen Bezirken. Mit Ausnahme von West- und Süddeutschland hatten sonst sämtliche Gebietsteile dieselben durch markante Luftmassenwechsel getrennten warmen und kühlen Witterungsperioden. Die Abkühlung am 2. und 3. wie auch die starke Erwärmung zwischen dem 4. und 9. traf man so in allen Landesteilen an, wobei die Temperaturtagesmittel überall in denselben Grenzen schwankten und die Tagestiefstwerte in der kühlen Periode mehrfach unter 5° absanken, in dem warmen Zeitabschnitt mehrfach die 30-Grad-Grenze überschritten. Nach einem durch den Zustrom kühler Meeresluft bedingten Temperaturrückgang hatten die Tage vom 10. bis 13. überall um 2 bis 4° unternormale Verhältnisse gebracht. Während vom 14. bis 16. die Höchsttemperaturen unter dem Einfluß der Mitteleuropa überflutenden Tropikluft besonders in den östlichen und südöstlichen Gebieten vielfach wieder 30° erreichten, führte ein erneuter Zustrom von Meeresluft am 17. zu vereinzelt unternormalen Temperaturwerten. Vom 18. bis 22. bestimmte vor allem in Ost- und Südostdeutschland die von Süden her sich wieder ausbreitende Tropikluft das Temperaturklima, dagegen lagen die Temperaturtagesmittel in West- und Süddeutschland in diesem Zeitraum nur wenig über den Normalwerten. Die längste kühle Witterungsperiode schloß sich vom 23. bis 28. an, wohingegen in Norddeutschland und Ostpreußen der Temperaturabfall unbedeutender war; dort war durch milde Kontinentalluft der maritimen Abkühlung Einhalt geboten worden. Zum Monatsende prägte wieder nordwärts vordringende Tropikluft in ganz Deutschland das Bild hochsommerlicher Witterung, die am 30. und 31. im alten Reichsgebiet vielfach Rekordtemperaturen bis zu 32° und darüber brachte. Die Zahl der Sommertage war in West- und Süddeutschland um 2 bis 3 Tage unternormal, in Mittel- und Norddeutschland vielfach um 3 bis 5 und in Ostpreußen um 5 bis 8 Tage übernormal.

Die Verteilung der Niederschläge läßt infolge relativ großer Häufigkeit der Luftmassenwechsel kein einheitliches Bild erkennen. Die größten Monatssummen mit über 150 mm meldeten Sachsen und Schlesien und mit teilweise über 200 mm Süddeutschland, während in der Rheinprovinz und in Ostpreußen die geringsten Regenhöhen von unter 50 mm verzeichnet wurden. In breiten Landstrichen Nord- und Mitteldeutschlands lagen die Niederschlagshöhen zwischen 70 und 90 Millimeter. Im Vergleich zum langjährigen Durchschnitt erscheinen nur Hessen, die Rheinprovinz und Ostpreußen als Niederschlagsdefizitgebiet, während sonst und vor allem in Nordwestdeutschland, Sachsen, Schlesien und Südwestdeutschland mehrfach Überschüsse von 50 bis 100 v. H. auftraten, und zwar meist als Folge ausgiebiger Gewitterniederschläge. Die Zahl der Tage mit Niederschlag war vor allem in den westlichen Reichsgebieten um rund 2 bis 3 Tage zu groß; nur die Grenzgebiete der Rheinprovinz und der Saarpfalz, sowie Teile von Westfalen und Niedersachsen hatten Ausfälle in derselben Größenordnung. In den östlichen Reichsteilen war mit Ausnahme der nördlichen Bezirke Pommerns und Ostpreußens die Zahl der Niederschlagstage um 2 bis 3 Tage zu gering. Wiederholte Schneefälle gab es nur in den höchsten Lagen der Alpen. Die Zahl der Gewittertage war mit Ausnahme von Süddeutschland um rund 2 bis 3 zu groß; die geringste Anzahl mit 2 bis 3 hatte die Rheinprovinz, die größte mit 10 bis 12 Tagen Süddeutschland, Sachsen und Schlesien.

Das Bild der Bewölkungsverteilung war im Reich entsprechend dem wechselvollen Wettergeschehen recht uneinheitlich, wobei im größten Teil des Reiches etwas übernormale Bewölkungsgrade auftraten. Nur aus Westfalen, Sachsen und Schlesien sowie teilweise aus Mecklenburg, Pommern und Ostpreußen wurden unter den Normalwerten liegende Bewölkungsmittel gemeldet. Die Überschüsse wie Defizite betrugen dabei 4 bis 8 v. H. bei einer mittleren Bedeckung von rund 61 v. H. Die Zahl der heiteren Tage unterschritt in weitaus dem größten Teil des Reiches den Normalwert um 2 bis 3 Tage, während die Verteilung der Zahl der trüben Tage einen Überschuß in den südwestdeutschen Gebieten sowie in Teilen der Mark Brandenburg und Ostpreußens erkennen läßt, der 3 bis 5 Tage beträgt. Am niedrigsten war die Zahl der heiteren Tage mit 1 bis 2 in Nordwest- und Mitteldeutschland, die der trüben Tage im größten Teil Norddeutschlands mit 4 bis 8. Das Auftreten von Nebeltagen hielt sich in normalen Grenzen, indem im Flachland strichweise 1 bis 2 Tage mit Nebel in den Kammlagen der Gebirge sehr viel häufiger derartige Sichtbehinderungen beobachtet wurden. Die Sonnenscheindauer ergab ein geringes Defizit von 2 bis 3 v. H. in der gesamten norddeutschen Tiefebene und im nördlichen Ostpreußen, einen größeren Ausfall von etwa 8 v. H. im Rhein-Main-Gebiet; im übrigen Reich war dagegen die Sonnen-

scheindauer um 5 bis 10 v. H. übernormal. Die geringsten Prozentbeträge der möglichen Sonnenscheindauer mit 35 bis 40 v. H. hatte das Küstengebiet der Nordsee und große Teile Westdeutschlands.

Der **August** war namentlich im Nordosten des Reiches zu warm und infolge reicher Gewittertätigkeit vorwiegend in der nördlichen Reichshälfte zu niederschlagsreich.

Kühle, feuchte Meeresluft, die zu Monatsbeginn die bisher herrschende Warmluft weit ostwärts zurückdrängte, bedingte in Deutschland eine vielfach trübe, von heftigen Gewittern und Regenfällen durchsetzte Witterung. Diese Störungen traten mit verheerenden Hagelschlägen und Windbrüchen vornehmlich im Böhmerwald und in Ostpommern in Erscheinung. Ein von Frankreich herankommendes flaches Tief führte zum 4. vom Süden subtropische Warmluft zu und löste in West- und teilweise auch im mittleren Deutschland am Rande flacher Druckstörungen verbreitete Wärmegewitter aus. Mit der Verlagerung des französischen Tiefs nach dem Nordseegebiet gingen am 6. über Nordwestdeutschland bis nach Mittelpommern hinein, ebenso in Schlesien (im Riesengebirge starke Waldverwüstungen infolge Hagelschlags und Wolkenbruchs) vielfach folgenschwere Gewitter nieder. Unter Veränderung der Kontinentalluft gewann die kühle Meeresluft am 7. südostwärts stark an Raum, so daß die Gewittertätigkeit schließlich bis zur Ostgrenze wirksam wurde und auch unter Einwirkung flacher Tiefs von Frankreich her nach Süddeutschland übergriff. Eine Besserung der Witterungsverhältnisse mit teilweiser Aufheiterung und schwacher Erwärmung machte sich am 10. und 11. geltend, als ein von den Azoren her ostwärts vorstoßender Hochdruckkeil mit dem nordosteuropäischen Hoch in Verbindung trat. Gegenüber der warmen Festlands-Antizyklone und dem westlichen Azorenhochs bildete sich dabei zum 13. im Raume der Oder und der March eine flache Tiefdruckrinne, die bis zum 16. die Witterungsverhältnisse bestimmte. Während im äußersten Westen und Osten vorwiegend heiteres Wetter herrschte, bedingte der Gegensatz der verschieden temperierten Luftmassen stärkere, z. T. von Gewittern begleitete Niederschläge, und zwar vom 13. bis 16. in dem Gebiet zwischen Elbe und Weichsel. Die vom 15. ab über der Ostsee sich vollziehende Vereinigung des westlichen und östlichen Hochs brachte vom 17. ab immer weiter in Mitteleuropa um sich greifende Aufheiterung und steigende Erwärmung. Die Mittagstemperaturen erreichten vielerorts am 18. 25°, am 20. auch 30°; dabei gaben die an sich noch nicht einheitlichen Temperaturverhältnisse auch wiederholt Anlaß zu Wärmegewittern, so am 18. im mittleren Norddeutschland, am 20. und 21. in den westlichen Grenzbezirken. Die sonst trockene, durch Ausbreitung der kontinentalen Warmluft vorherrschende Schönwetterperiode wurde in stärkerem Maße im Westen des Reiches beeinträchtigt durch eine von Frankreich nach der Nordsee sich verlagernde flache Depression, die mit Trübung und stärkerem Regen noch am 23. im Nordseegebiet zur Geltung kam. Nach Auflösung dieser Störungsfront rückte die östliche Warmluft bereits im Laufe des 24. wieder stark gegen Westen vor, so daß im Rheinland vereinzelt Mittagstemperaturen von mehr als 30° verzeichnet wurden. Eine vorübergehende Störung im Südosten wurde durch den Einfluß eines italienischen Tiefs bedingt, das im Alpengebiet Trübung und Gewitterbildung zeitigte. Die sich auch hier wieder durchsetzende Hochdruckwetterlage zeigte vom 27. ab bei ihrem hohen Feuchtigkeitsgehalt, der sich im Auftreten von Frühdunst oder Frühnebel äußerte, mit ihrer mittags sich wiederholenden Gewitterentwicklung gewisse Auflösungserscheinungen. Mit dem langsam nach Nordeuropa sich verlagernden Hoch traten Anzeichen einer Umgestaltung der Wetterlage auch bei Monatsschluß kaum in Erscheinung.

Bei diesen für die Erntearbeiten günstigen Witterungsverhältnissen ergaben sich für den Monat Temperaturmittel, die z. T. erheblich über den langjährigen Normalwerten lagen. Die Abweichungen beliefen sich in Ostpreußen auf mehr als 4°, gingen auf der Linie der schlesischen Gebirge bis zur deutschen Bucht auf 2° und in den südlichen Reichsgebieten auf wenige Zehntelgrade herunter. Die Einzeltagesmittel waren im Nordosten des Reiches dauernd übernormal, in den übrigen Landesteilen erst vom 16. oder 17. ab, in Bayern nach vorangegangener stärkerer Abkühlung, die um 4 bis 5° zu tiefe Temperaturen gezeitigt hatte, erst vom 18. bis 20. ab. Die stärkste Erwärmung hatte der Osten östlich der Oder am 5. und 6. (z. T. um 6 bis 8° übernormal), die sonstigen Gebiete in den Tagen der Hochdruckwetterlage vom 19. bis 25. (mehrfach um 4 bis 6° übernormal), vereinzelte Lagen erst gegen Monatsende. Den niedrigsten Stand wiesen die Thermometer in den Tagen des 6. und 7., sowie des 15. und 16. auf; Frostgrade wurden erst in Höhen über 2300 m beobachtet. Bezeichnend für den Monat war die ungewöhnlich hohe Zahl an Sommertagen, die in Ostpreußen zwischen 21 bis 27 schwankte und an der Oder auf 17 bis 19, etwa längs des 12. Längengrades auf 14 (noch um 5 bis 6 übernormal) herunterging.

Infolge der überreichlichen Gewittertätigkeit ergaben sich im Bilde der Niederschlagsverteilung starke Ungleichheiten. Größere Gebiete hatten weniger als 50 mm Niederschlag, so die östliche Hälfte Ostpreußens, das ostpommersche Küstenland, das Gebiet von der mittleren Spree bis zur Obra und dem niederschlesischen Odergebiet, ferner der Niederrhein und das bayrische Donaubecken einschl. des Nabgebietes, insbesondere hatten der Landstrich von den Seesker Höhen bis zur Kurischen Nehrung wie auch Regensburg mit seiner Umgebung noch unter 25 mm Regen. Demgegenüber wuchsen die Monatsbeträge auf 100 mm und mehr in Mittelpommern und am Südrande des ostwärts verlaufenden baltischen Höhenrückens, an den schlesischen Gebirgen, im mittleren Erzgebirge, vor allem im gesamten Einzugsgebiet der Weser unter Einschluß der Elbmündung und mittlerer Teile Schleswig-Holsteins. Diesen Gebieten schlossen sich an im Süden des Reiches Teile des Schwarzwaldes und des schwäbischen Berglandes und der südöstliche Böhmerwald, wo vielfach mehr

als 150 mm gemessen wurden. Starke vereinzelte Gewitterniederschläge hatten auch in den Gegenden von Jever, Stettin und Grünberg i. Schles. Monatsbeträge von 150 mm und mehr zur Folge.

Im Vergleich zu den langjährigen Durchschnittswerten ergaben sich übernormale Beträge im größten Teile Norddeutschlands von Ems- und Wesergebiet ostwärts bis zur Mulde, Mittelmark und dem unteren Küddowgebiet in der Grenzmark, ferner im westlichen Ostpreußen und in Schlesien. Wie schon mit dem Taunus, Hunsrück und der Eifel traten im Süden des Reiches lediglich Gebirgszüge mit mehr als 100 v. H. in Erscheinung, und zwar die bayrischen Alpen mit ihrem Vorland. Während die höchsten Prozentbeträge in Mageburg mit 262 v. H., in Stettin mit 224 v. H. und in Grünberg i. Schles. mit 214 v. H. erreicht wurden, blieben sie in Teilen des östlichen Ostpreußens, in der Gegend von Regensburg noch unter 25 v. H.

Während die Niederschlagshäufigkeit nur an vereinzelten Stellen und meist an Mittelgebirgen den Regelwert überstieg, war die Zahl der Niederschlagstage zu gering, an der ostpommerschen und ostpreußischen Küste um 6 bis 8 Tage, an der Nordsee um 4, im Donaulande Bayerns um 4 bis 6 Regentage. Dabei war die Zahl der Gewittertage lediglich in Norddeutschland überreichlich groß; zwischen Rhein und Elbe, ebenso im Sudetenland, in Schlesien bis zur südlichen Neumark hinein wurden vielfach 10 bis 12 solcher Tage gezählt.

Bei weitgehenden Unterschieden in den Bewölkungsverhältnissen hatte das westliche Bergland Norddeutschlands wie auch die Alpen im Monatsdurchschnitt eine Himmelsbedeckung von mehr als 60 v. H. Mit weniger als 50 v. H. Bewölkung waren begünstigt das nördlich der Alpen verlaufende Donauland, das Nordseegebiet, das Elbegebiet mit Einschluß der Prignitz sowie Mecklenburg, Vor- und Mittelpommern, ferner noch Ober- und Mittelschlesien, vor allem das östliche Ostpreußen, wo der Bewölkungsgrad bis auf 35 v. H. zurückging. Alle diese Gebiete wiesen daher auch mehr als 5 heitere Tage auf und hatten dementsprechend zu wenig trübe Tage, besonders das Nordseegebiet. Morgennebel machten sich im Flachlande meist an 2 bis 4 Tagen geltend, im Küstenland der Nordsee wie in mittelhohen Gebirgslagen an 10 bis 14 Tagen. Im Gesamtergebnis blieb die Sonnenscheindauer nur im Rheingau und in den Alpen etwas hinter den langjährigen Erwartungen zurück. Dagegen konnte das Gebiet des Donaulaufes und das mittlere Norddeutschland einen Mehrbetrag von 20 bis 25 Stunden aufweisen, der sich im norddeutschen Flachlande vielfach auf 40 bis 50 Sonnenscheinstunden steigerte.

Der **September** war für das südliche Drittel des Reiches ewas zu kühl und vom oberen und mittleren Rheingebiet ab bis nach Schlesien hinein meist erheblich zu naß.

Der Zustrom merklich erwärmter Luft aus dem über Nordeuropa lagernden Hoch blieb auch die letzten Augusttage hinaus noch für die mitteleuropäischen Witterungsverhältnisse bestimmend. Bei übernormalen, mittags sommerlichen Temperaturen und bei wechselnder Bewölkung kam es mehrfach zu starken Gewitterentwicklungen. Gegenüber den kühlen Luftmassen, die im Laufe des 3. aus dem sich nähernden nordeuropäischen Hoch zuflossen und die im Berglande verbreitete Nebelfelder erzeugten, rückte am 4. vom Ozean eine feuchte Warmluftfront heran, die dem gesamten Westen des Reiches Trübung und Niederschläge bescherte, jedoch vor dem etwas nach Osteuropa zurückweichenden Hoch rasch erlosch. Damit setzte sich vom 6. ab bei schwach südöstlichen Winden das heitere, nur vom Morgennebel beeinträchtigte warme Spätsommerwetter wieder allgemein durch. Eine Änderung erfolgte erst nach dem 10., als die bisher auf das Nordmeer beschränkte Zyklonentätigkeit nach Mitteleuropa eingriff und das Hoch nach dem Schwarzen Meer, z. T. nach der Biskayasee zurückdrängte. Mit einem am 11. über der Nordsee erscheinenden Teiltief erhielt der Nordwesten des Reiches Trübung und Niederschläge, die sich am 12. über ganz Norddeutschland, langsam dann auch südwärts bis zu den Nordalpen — hier unter Entwicklung starker Stauregen — ausbreiteten. Ein vom Nordatlantik her nachstoßendes Hoch veranlaßte mit seinen Kaltluftmassen vielfach Gewitter und Regenschauer und dabei einen Temperaturrückgang, der im Süden des Reiches schon zu dauernd unternormalen Temperaturen führte. Als dem nach Osteuropa anziehenden Hoch ein ausgedehntes flaches Tief folgte, wurde der Norden des Reiches am 14. von einzelnen Staffeln milder Meeresluft und von leichten Aufgleitregen betroffen. Nach allgemeiner kurzer Wetterberuhigung am 15. erfolgte der Vorstoß eines ausgedehnten kühlen Hochdruckgebietes vom hohen Norden nach Mitteleuropa, das die Tiefdruckstörungen südwärts abdrängte und nach einleitenden Gewittererscheinungen zu wiederholten verbreiteten kräftigen Regenfällen Anlaß gab. Die in den Tagen vom 16. bis 19. gemessenen Mengen überstiegen in dem Gebiet vom Oberrhein bis zur oberen Oder vielfach 50 mm, vereinzelt auch 100 mm. Erst als die nach dem Karpatenland abgewanderten Tiefdruckstörungen vom 20. ab verflachten, ließen die Regenfälle bei Nordwinden am 20. im östlichen Norddeutschland, am 21. und 22. auch im schlesischen Odergebiet nach. Trotz des Ausgleiches der mitteleuropäischen Druckunterschiede behielt die Witterung ihren zu vereinzelten leichten Regen neigenden, trübnebligen Charakter bei. Der empfindliche Temperaturrückgang, der am 23. mit dem Einbruch nordischer Kaltluft sich verstärkte, ließ nun auch in Norddeutschland die Temperaturen zu unternormalen Werten abgleiten. Während der Süden des Reiches bei Ausbildung eines Zwischenhochs Aufheiterung verzeichnen konnte, geriet Norddeutschland mit dem 26. wiederum unter den Einfluß eines vorübereilenden Teiltiefs; nach strichweise stark auftretenden Regenfällen setzte bei der energischen Nordströmung auf der Rückseite kaltes Schauerwetter ein, das nur vorübergehend am 27. nach dem Süden übergriff und noch bis zum 29. wirksam blieb. Erst bei Annäherung

eines nordatlantischen Hochs riß zum 30. unter Wetterberuhigung die meist geschlossene Wolken- und Nebelbedeckung auf, so daß der Monat auch in Norddeutschland mit vorübergehend heiterem Himmel abschließen konnte.

In Auswirkung der Witterungsverhältnisse war der Monat im Süden, z. T. auch im äußersten Nordosten des Reiches etwas zu kalt. Die Temperaturabweichungen gegenüber den langjährigen Normalwerten beliefen sich an der Nordseeküste auf 1,4° und fielen in der Rheinpfalz, in Franken wie auch östlich des Pregel-Allee-Gebietes zu negativen Werten von rd. 0,5° ab. Die Einzeltagesmittel hielten sich in Norddeutschland etwa bis zum 22. auf übernormaler Höhe, während sie im Süden des Reiches schon am 12., spätestens am 15., zu unternormalen Werten absanken. Die kräftige Wärmeentwicklung, die (mit 6 bis 7° zu hohen Temperaturen) im Südwesten in den ersten Tagen des Monats, im Südosten am 11. und 12., sonst aber vom 7. bis 10. sich geltend machte, brachte die übliche Zahl von Sommertagen mit sich. Die recht kühle Periode, mit der der September ausklang und die vom 27. bis 29. um 6 bis 8° zu tiefe Tagesmittel zeigtigte, führte im binnenländischen Flachlande zu vereinzelten, im Berglande mehrfach zu Frosttagen.

In der Niederschlagsverteilung zeichneten sich starke, wenn auch nicht schroffe Gegensätze ab. Das nordwestliche Flachland, das teilweise weniger als 25 mm Niederschlagsmenge verzeichnete, hatte ostwärts noch, über Mittelpommern nach der nördlichen Grenzmark ausgreifend, weniger als 50 mm, ebenso auch kleinere Gebietsteile bei Aachen und Köln und das obere Einzugsgebiet des Main. Nach dem Berglande zu, im Osten bereits vom Spreegebiet und der südlichen Neumark ab, stiegen die Monatsbeträge wie schon am ostpommerschen Höhenzuge und im mittleren Ostpreußen auf mehr als 75 mm und mit größerer Annäherung an die Gebirge auf mehr als 100 mm. In Mittelschlesien, im Erzgebirge, Thüringerwald, an der Frankenhöhe und im Böhmerwald, ferner im Iller-, Lech- und Isargebiet wurden 150 mm, im nördlichen Schwarzwald und im Riesengebirge 200 mm noch überschritten.

Die in Prozenten des Normalwertes ausgedrückten Niederschlagsbeträge ergaben ein ähnliches Bild. Neben dem bereits bezeichneten nordwestlichen Flachlande mit teilweise weniger als 50 v. H. hatten unternormale Beträge einzelne kleinere, vor Nordwinden geschützte Tallagen, ebenso größere Teile der ostbayrischen Alpen. Demgegenüber zeichnete sich als niederschlagsreich das vom Ober- und Mittelrhein nach Schlesien sich erstreckende Gebiet ab, in das gesamte Schwabenland, das Erzgebirge und Mittelschlesien mit mehr als dem doppelten, das mittelschlesische Flachland sogar mit dem mehr als dreifachen Betrage des langjährigen Durchschnitts hervortrat. Die Niederschlagshäufigkeit war im Berglande wie im Nordosten des Reiches mit 16 bis 18 Regentagen um 3 bis 4 solcher Fälle zu groß, blieb hingegen im norddeutschen Flachlande mit 10 bis 11 Regentagen hinter dem Regelwert etwas zurück. Die Gewittertätigkeit ging nur in Mittelfranken und im Nordosten des Reiches mit 4 bis 5 Gewittertagen über das übliche Maß hinaus; Schneefall trat erst in Höhen über 1000 m in Erscheinung.

Die Bewölkung war im Monatsdurchschnitt im Küstengebiet um annähernd 10 v. H. zu gering, dagegen im übrigen Reichsgebiet bei etwa 65 v. H. Himmelsbedeckung meist um 10 bis 15 v. H. zu groß. Die Begünstigung, die dem Küstengebiet damit zuteil wurde, äußerte sich entsprechend in einer etwas übernormalen Zahl von heiteren Tagen (etwa 6 bis 8 gegenüber 2 bis 5 im übrigen Gebiet) und in einer mit 5 bis 7 zu geringen Zahl trüber Tage, die im Berglande meist zum doppelten Betrage anwuchs. Herbstnebel zeigten sich im Flachlande in schwankender Häufigkeit an 2 bis 6 Tagen, hingegen in der Nähe von Wasserflächen und im Berglande in stärkerem Maße an mehr als 10 Tagen. Im Gesamtergebnis erzielten die Nordsee rd. 200 Sonnenscheinstunden und damit 50 v. H. der möglichen Sonnenscheindauer; das übrige Gebiet selbst in begünstigten und vor Nordwinden geschützten Lagen und damit auch in vielen Weinbaugebieten hatten dagegen nur etwa 140 Sonnenscheinstunden, also nur rd. 35 v. H. der möglichen Sonnenscheindauer.

Der Monat **Oktober** war für das ganze Reich zu kalt und weit überwiegend zu naß.

Die Ende September eingetretene Wetterberuhigung hielt bei geringen Luftdruckunterschieden und meist zu tiefen Temperaturen bis etwa zum 12. Oktober an. Dabei erstreckte sich eine flache Tiefdruckrinne von Südengland und Nordfrankreich über Deutschland nach dem mittleren Polen. Sie verlagerte sich unter dem Einfluß eines über Skandinavien vorstoßenden Hochdruckgebiets namentlich in ihrem mittleren und östlichen Teil allmählich weiter nach Süden bis zum Mittelmeer. Bei meist leichten bis schwachen, gelegentlich mäßigen Winden aus vorwiegend östlichen Richtungen war das Wetter meist heiter bis bewölkt. Flache, die Tiefdruckrinne von W nach O durchziehende Druckstörungen brachten jedoch Süddeutschland öfter Regenschauer und stärkere Bewökung. Mit einem kleinen Randtief war am 13. Oktober der erste wirksame Schwall maritimer Luft nach Nordwestdeutschland gelangt, wo es beim Zusammenstoßen mit den kontinentalen Luftmassen zu kräftiger Nebelbildung kam; auch tagsüber blieb es vielfach diesig. Ab 15. machte sich in Norddeutschland, von Westen nach Osten fortschreitend, eine langsame Drehung der meist schwachen Winde bis zum 17. vorwiegend auf westliche Richtungen geltend. Anschließend bis zum 28. war aus verschiedenen Richtungen und bei absinkender Temperatur trübes, vielfach regnerisches Wetter im ganzen Reich vorherrschend. Ein Auffrischen von nordöstlichen Winden bis auf Sturmesstärke brachten südlich vorbeiziehende Tiefdruckgebiete am 19. und 28. der deutschen Nordseeküste, am 19. auch der westlichen deutschen Ostseeküste. Der Monat schloß unter Nachlassen der Windstärken, allgemeinem Aufreißen der Wolkendecke und Drehen der Winde auf östliche Richtungen und mit einer Wetterberuhigung bei erheblich unter dem Mittelwerte liegenden Temperaturen.

# Witterungsverlauf im Jahre 1939

In Auswirkung der Witterungsverhältnisse war der Monat in seinen Mittelwerten zu kalt, um 3° bis 1,5° in Nord- und Mitteldeutschland, um 2° bis 0,5° in Süddeutschland.

Der Anfang des Monats war zu kalt mit Mindesttemperaturen unter dem Nullpunkt vornehmlich am 8. und 9. Von Westen nach Osten fortschreitend setzte alsdann Erwärmung ein. Die normalen Temperaturen werden westlich des Rheins bereits am 11., in Ostdeutschland am 13. oder 14. überschritten. Der wärmste Tag war im allgemeinen der 14. oder 15. Ab 21. lagen die Tagesmittel der Temperaturen allgemein wieder unter den normalen Werten, so daß Monatsmindesttemperaturen wiederum vielfach am 26. oder 27. verzeichnet wurden. Über 20° lag im allgemeinen das absolute Monatsmaximum noch im südlichen Mitteldeutschland, Oberschiesien und Süddeutschland. Von Frosttagen völlig verschont blieben nur noch wenige durch ihre Lage besonders geschützte Gegenden, namentlich an der Küste. Bereits 23 Eistage hatte die Zugspitze, 12 die Schneekoppe.

Die Niederschlagsverteilung zeigte starke, allerdings nicht schroffe Gegensätze. Der Niederschlag nahm im allgemeinen von NO nach SW zu. Unter 50 mm blieben die Monatsmengen in Teilen des südlichen Ostpreußens und des südöstlichen Hinterpommern und stiegen nach S und W auf 100 mm in der norddeutschen Tiefebene, Nieder- und Mittelschlesien bis zu den mitteldeutschen Gebirgen und den Sudeten. Monatsbeträge über 200 mm hatten der südliche Schwarzwald (Feldberg 417 mm, Furtwangen 414 mm, Rippoldsau 405 mm), das Allgäu (Röthenbach 308 mm) und die Rheinpfalz (Kaiserslautern 212 mm). — In Prozenten des Normalwertes ausgedrückt ergab die Verteilung der Niederschläge ein ähnliches Bild. Unternormal waren die Niederschläge nur im mittleren Ostpreußen, sowie vereinzelt in Hinterpommern, Nordschleswig, der Neumark und Sachsen, doch betrugen sie meist über 80 % der normalen Höhe. Demgegenüber betrugen die Niederschläge mehr als das Doppelte des Normalwertes in einem Gebiet, das sich vom Ober- und Mittelrhein über das westliche Thüringen, den Süden der Provinz Sachsen und über Brandenburg nach dem nördlichen Niederschlesien erstreckte. Die Niederschlagsmengen erreichten mehr als das Dreifache der normalen in Mittelbayern und der Pfalz (Augsburg 366 %, Nördlingen 362 %, Kaiserslautern 336 %). — Dementsprechend war auch die Niederschlagshäufigkeit, die an der Nordsee und im südöstlichen Ostpreußen mit 14 Regentagen verhältnismäßig niedrig blieb, meist erheblich übernormal. Über 24 Regentage hatten die mittelrheinischen Gebirge, der Schwarzwald und die Schwäbische Alb, je 30 sogar Freiburg i. Br. und der Feldberg im Schwarzwald. Ein, höchstens 2 Gewitter wurden nur noch von sehr wenigen Stationen gemeldet. — Frei von Schneefällen war die norddeutsche Tiefebene mit Ausnahme des östlichen Hinterpommern und Ostpreußens. Im Alpengebiet und in den höheren Erhebungen der deutschen Mittelgebirge fiel bereits häufiger Schnee (Zugspitze 23, Feldberg i. Schwarzwald 12, Fichtelberg 10, Schneekoppe 9 Schneetage). Eine zusammenhängende Schneelage bedeckte täglich die höchsten Erhebungen der Alpen, gegen Ende des Monats häufiger auch die Mittelgebirge (Feldberg i. Schwarzwald an 13, Fichtelberg an 9, Kahler Asten, Wasserkuppe und Brocken an je 7 Tagen). Innerhalb der norddeutschen Tiefebene wurde eine zusammenhängende Schneedecke nur an 1 bis 3 Tagen aus dem östlichen Hinterpommern und dem ostpreußischen Binnenland gemeldet.

Die Bewölkung war mit 60 bis 70 % durchschnittlicher Himmelsbedeckung um wenige Prozente zu niedrig im Küstengebiet der Nordsee, mit 70 bis 75 % zu hoch in der nordwestdeutschen Tiefebene, Mecklenburg und Pommern und mit über 80 % erheblich zu hoch im Maingebiet. Dementsprechend war die Zahl der heiteren Tage mit 2 bis 4 normal nur in einigen Küstengegenden, sonst blieb sie mit 0 bis 2 unter dem Regelwert. Die Zahl der trüben Tage blieb mit 11 bis 12 nur wenig unter den normalen Werten allein im Küstengebiet der Nordsee; im übrigen Gebiet lag sie z. T. sehr erheblich über den Regelwerten bis zum doppelten Betrag, und zwar mit 20 solchen Tagen. Mehr als 25 trübe Tage wurden gezählt im Gebiet des Mittelrheins sowie im Norden von Ostpreußen. Nebel, der auf den Bergen fast täglich beobachtet wurde, war am 17. und 18. namentlich in Mittel- und Süddeutschland recht verbreitet. Bei weitem den meisten Sonnenschein hatte mit 125 Stunden oder rund 39 % der möglichen Dauer das Nordseegebiet. Im übrigen Gebiet blieb die Sonnenscheindauer hinter der normalen zurück; die Fehlbeträge nahmen von N nach S und in Norddeutschland auch von W nach O, in Süddeutschland von O nach W zu. Mit weniger als 50 Sonnenscheinstunden, stellenweise sogar weniger als 25 Stunden, war Südwestdeutschland am stärksten benachteiligt.

Der Monat **November** war allgemein im Reich zu warm und zu regnerisch.

Die Ende Oktober erfolgte Wetterberuhigung hielt noch in den ersten Novembertagen an. Unter dem Einfluß eines Hochdruckgebietes, das sich von Mittelskandinavien nach Finnland und dann weiter südostwärts verlagerte, hatte das Reich bei schwachen bis mäßigen östlichen Winden anfangs noch heiteres, kaltes Wetter. Am 2. bereits machte sich Eintrübung bemerkbar, der unter Temperaturzunahme schwache, später stärkere Niederschläge folgten. Ein kräftiger südlicher Ausläufer des umfangreichen nordatlantischen Tiefdruckgebietes, das südlich Island vorbeizog, schwenkte vom 4. bis 6. vom Kanal bis zur mittleren Nordsee. Dieser Ausläufer leitete eine Umgestaltung der Wetterlage ein und veranlaßte in ganz Deutschland ein Drehen der Winde auf südliche Richtungen, in Nordwestdeutschland bei westlicher Komponente auch ein Auffrischen zur Sturmesstärke. Bei Temperaturanstieg fielen stärkere Niederschläge vom 4.—6., namentlich in Süddeutschland. Der Vorstoß des Azorenhochs nach Nordost und die Verlagerung des russischen Hochdruckgebietes führten über Deutschland in den nächsten Tagen unter Nachlassen der Niederschläge bei schwachen bis mäßigen, an der Nordseeküste starken Südwinden zu einem Verlauf der Isobaren in Richtung von Südwest nach Nordost, ab 10. von West nach Ost. Die im hohen Norden vorbeiziehenden Tiefdruckgebiete konnten keinen stärkeren Einfluß

mehr auf das Wetter Deutschlands gewinnen. Eine Hochdruckbrücke erstreckte sich bis gegen Mitte des Monats vom Azorenhoch über Spanien, Frankreich und Deutschland nach dem südlichen Rußland. Bei vorwiegend südwestlichen, meist nur schwachen bis mäßigen Winden hatte das Reich keine oder nur geringe Niederschläge, dabei zu hohe Temperaturen, wechselnde Bewölkung, in West- und Süddeutschland vom 11. bis 14. auch verbreitete Morgennebel. Eine Umgestaltung der Wetterlage setzte mit dem 16. ein; die erwähnte Hochdruckbrücke wurde durchbrochen, und Kaltluft floß über West- und Süddeutschland weit südwärts bis Nordafrika. Deutschland hatte vom 15. bis 19. meist regnerische Witterung bei veränderlichen, am 19. in Nordwestdeutschland steifen Winden, bei wechselnder Bewölkung und bei immer noch übernormalen Temperaturen; stellenweise unter Gewittern fielen an diesen Tagen für die Jahreszeit beachtliche Niederschlagsmengen. Der 20. brachte einen erneuten Aufbau der Hochdruckbrücke von den Azoren bis nach Mittelrußland und damit dem Reich eine allgemeine Wetterberuhigung. Unter Aufreißen der Wolkendecke, Nachlassen der Niederschläge, bei vorwiegend schwachen Winden und häufigem Auftreten von Morgennebel erfolgte allgemein ein steter Temperaturrückgang; selbst die Tagesmitteltemperaturen sanken unter den Gefrierpunkt: im allgemeinen vom 21. bis 24., im äußersten Westen am 22. oder 23., in Masuren vom 19. bis 25. Während am 24. Ostdeutschland noch unter der Herrschaft des russischen Hochdruckgebiets blieb, beeinflußte ein vom Eingang des Kanals kommendes und nach NO ziehendes Teiltief einer Nordmeerdepression bereits das Wetter in Nordwestdeutschland und in geringerem Maße in Mittel- und Süddeutschland. Die Temperaturen stiegen wieder bei stark auffrischenden Winden zu übernormalen Werten im äußersten Westen am 24., in Ostelbien am 26.; sie blieben auch bei trübem und regnerischem Wetter im ganzen Reich bis zum Monatsschluß unternormal trotz eines Temperaturrückgangs am 28., der sich besonders in Süddeutschland auswirkte.

Im Ergebnis der jeweiligen Witterungsverhältnisse war der Monat nach seinen Temperaturmittelwerten zu warm: um 1° bis 2° in der Norddeutschen Tiefebene, in Sachsen und im westlichen Schlesien, um 2° bis etwa 3° im übrigen Deutschland. Der Gang der Mitteltemperaturen war im ganzen Reich sehr gleichmäßig. Sie lagen vom 1. bis 3. und 21. bis 23. unter den normalen Werten, vom 6. bis 19. und 26. bis 30. z. T. erheblich darüber. Meist war der 8. oder 9., in Bayern der 30. der wärmste Tag. Von Fosttagen völlig verschont blieben nur wenige durch ihre Lage besonders geschützte Gegenden, namentlich an der Küste. In Ostpreußen und im südöstlichen Schlesien wurden 10 bis 13, auf den höheren Bergen 20 und mehr Frosttage gezählt; ihre Anzahl blieb entsprechend den zu hohen Mitteltemperaturen merkbar unter dem Regelwert. Eistage wurden vereinzelt östlich der Elbe, in größerer Anzahl bis zu 11 in den Mittelgebirgen und weit über 20 auf den hohen Berggipfeln ermittelt.

In der Niederschlagsverteilung waren Teile des mittleren Ostpreußens mit weniger als 25 mm am niederschlagsärmsten. Unter 100 mm blieben sie weiter nordöstlich der Linie Borkum-Chemnitz, ferner in Mittel- und Nordbayern, in der oberrheinischen Tiefebene, der Pfalz und im südwestlichen Rheinland. Mehr als 200 mm fielen in einem größeren Gebiet des südlichen Schwarzwaldes. — In Prozenten des Durchschnittwertes ausgedrückt lagen die Niederschlagsbeträge unter 100 % in Ostpreußen, abgesehen vom äußersten Norden, in Pommern, an der holsteinischen Nordseeküste, in der oberrheinischen Tiefebene und im östlichen Oberschlesien, wo sie stellenweise noch unter 20 % blieben. Mehr als 200 % erreichten sie in Nordwestdeutschland ohne Küstengebiet, im nordöstlichen Bayern, auf der Schwäbischen Alb und in Oberbayern; sie stiegen auf fast 350 % auf der Zugspitze. — Dementsprechend war die Zahl der Tage mit Niederschlag in den zu regenreichen Gebieten zu hoch und in den regenarmen zu niedrig. Die meisten Niederschlagstage mit mehr als 20° wurden im Rheinland und in Westfalen beobachtet. Gewitter wurden vereinzelt an einem, höchstens an zwei Tagen gemeldet. Völlig ohne Schneefall blieben außer größeren Teilen der Nordseeküste nur noch wenige kleinere Gebiete in besonders geschützter Lage. Sonst fiel Schnee im Reich überwiegend an 1 bis 4, auf den Bergen meist an 5 bis 12, auf den Gipfelstationen an 14 bis 16 Tagen. Etwa ebenso hoch war im allgemeinen die Zahl der Tage mit einer zusammenhängenden Schneedecke; sie stieg nur auf den Bergen infolge längerer Beharrung zu übernormalen Häufigkeitszahlen, bei Wasserkuppe von 5 auf 14, bei Brocken von 12 auf 18, Schöckel von 5 auf 13, Feldberg im Schwarzwald von 12 auf 18, Zugspitze von 16 auf 23.

Die Bewölkung betrug im Monatsdurchschnitt allgemein 6 bis 8 Zehntel, mehr als 8 Zehntel nur im östlichen Ostpreußen und auf den Bergen der Mittelgebirge; sie blieb auf den Alpenbergen allgemein unter 7 Zehntel. Sie entsprach damit nahezu den Normalwerten und war nur in sonnigen kleineren Gebieten um 1 bis 1½ Zehntel zu gering. Die Zahl der heiteren Tage (meist 1 bis 2) wich ebenfalls nur wenig von den normalen Werten ab. Die Häufigkeit der trüben Tage lag im östlichen Ostpreußen, im nordwestlichen Schlesien, im südöstlichen Bayern sowie im nördlichen Rheinland über dem Regelwert, sonst etwas darunter. Östlich der Elbe wurden im allgemeinen weniger als 5, westlich der Elbe mehr als 5, auf den Bergen mehr als 10, z. T. sogar über 25 Nebeltage gezählt.

Die Zahl der Sonnenscheinstunden nahm von Nord nach Süd etwas zu. Sie belief sich in Norddeutschland meist auf 40 bis 60 Stunden (oder 15 bis 25 % der möglichen Dauer), in Süddeutschland auf 50 bis 75 Stunden (oder 20 bis 30 % der möglichen Dauer). Am meisten Sonnenschein meldete die Zugspitze mit 123 Stunden oder 42 % der möglichen Dauer.

Der **Dezember** war im ganzen Reich zu kalt und nur in Teilen Sachsens und Schlesiens zu niederschlagsreich.

Das Ende November einsetzende milde, trübe und regnerische Wetter hielt bei vorherrschenden Winden aus südwestlichen Richtungen auch noch Anfang Dezember an. Auf der Rückseite eines von der nördlichen Nordsee über Süd-

# Witterungsverlauf im Jahre 1939

schweden ostwärts gewanderten Teiltiefs herrschte am 2. in der südlichen Nordsee Südweststurm, am 3. in der südlichen Nordsee und der westlichen Ostsee stürmischer Westwind. Die Temperatur sank allgemein zum 3. und 4.; vorübergehend ließen auch die Niederschläge nach und riß die Bewölkung auf, namentlich in Ostdeutschland sowie im Süden des Reiches. Eine Umgestaltung der Großwetterlage über Europa wurde am 5. unter Auffüllung des Islandtiefs durch kräftigen Luftdruckanstieg von Nordwesten her unter Abschwächung der Luftdruckgegensätze über Mitteleuropa eingeleitet. Am 8. war eine Hochdruckbrücke vorhanden, die sich von Spanien über Südfrankreich, Süd- und Nordwestdeutschland nach Skandinavien erstreckte. Der Schwerpunkt der Tiefdrucktätigkeit verlagerte sich demgemäß ins nördliche Mittelmeer. Die Witterung war bis dahin bei weiter absinkenden Temperaturen meist veränderlich; stärkere Niederschläge, vielfach als Schnee, fielen verbreitet in Süddeutschland, Land Sachsen und Schlesien und hielten in Süddeutschland noch bis zum 10. an. Der südwestliche Teil der Hochdruckbrücke büßte bis zum 17. seine Wirksamkeit ein, ihr nördlicher skandinavischer Teil verschmolz nach Monatsmitte mit dem russischen Hoch, das mit seinem Kern am 19. nach Südwestrußland sich verlagerte. Bis dahin blieb das Deutsche Reich bei meist leichten bis mäßigen östlichen Winden und wechselnder Bewölkung unter dem Einfluß der diesem Hoch entströmenden kontinentalen Kaltluft. Ausläufer und Teiltiefs von Tiefdruckgebieten, die über das europäische Nordmeer nordostwärts zogen, brachten bei meist trüber Witterung am 19. und 20. den deutschen Küstengebieten mäßige bis starke Nordwestwinde, vom 22. ab starke bis stürmische Westwinde, die am 24. nochmals auffrischten, bis am 26. frische bis starke Winde aus dem Nordwestquadranten sich einstellten. Leichte bis mäßige, stellenweise stärkere Niederschläge teilweise als Schnee fielen vom 22. bis 26. in fast ganz Norddeutschland, abgesehen von Gebieten westlich der Weser. Die Temperaturen stiegen unter dem Einfluß der durch die westlichen Winde herangeführten Meeresluft bis zum 24. oder 25. an, um beim Vordringen eines Schwalls extrem kalter polarer Luftmassen von Norden nach Süden fortschreitend wieder kräftig zu fallen. In den folgenden Tagen, meist am 29. und 30., wurden die tiefsten Temperaturwerte erreicht mit Kältegraden, die vielfach unter —20° lagen. Gleichzeitig riß die Bewölkung auf und flauten die Winde ab. Ein Umschwung erfolgte, im Nordseegebiet einsetzend, durch ein über das Kattegat südostwärts ziehendes Teiltief. Die Nacht vom 29. zum 30. brachte der Deutschen Bucht, anschließend auch der westlichen Ostsee, orkanartigen Südweststurm, der 31. nach Osten und Süden sich ausbreitende Eintrübung, Temperaturzunahme und Schneefälle.

In Auswirkung der Witterungsverhältnisse war der Monat in seinen Mittelwerten um 1° bis 2° zu kalt, sogar um 3° bis 2° im östlichen Westfalen und Hannover, im südlichen Brandenburg und nordwestlichen Schlesien und im Land Sachsen. Der Anfang des Monats war allgemein zu warm und hatte fast ausnahmslos am 1. oder 2. den wärmsten Tag. Am 7. oder 8. fielen die Temperaturen auf normale Werte, überschritten aber in Nordwestdeutschland und dem westlichen Süddeutschland am 9. und 10. nochmals die Normalwerte; die folgenden Tage brachten erst ein allgemeines Absinken der Temperaturen unter den Gefrierpunkt. Nachdem zu den Weihnachtstagen die Temperaturen nochmals vorübergehend zu übernormalen Werten angestiegen waren, erfolgte ein kräftiger Temperatursturz bis zu den kältesten Tagen des Monats am 29. und 30. — Entsprechend den zu tiefen Mitteltemperaturen war allgemein die Zahl der Frosttage (Tagesminimum unter 0° C) und der Eistage (Tagesmaximum unter 0° C) zu hoch. Es wurden festgestellt 15 bis 20 Frosttage im Rheingebiet und im Küstengebiet, 26 bis 31 Frosttage im Berglande, 21 bis 25 Frosttage im übrigen Reich. Die Zahl der Eistage blieb im Rheingebiet und in der nordwestdeutschen Tiefebene meist unter 10 und nahm nach Osten und Süden in den tieferen Lagen bis auf etwa 15, in den Gebirgen bis auf etwa 25 zu.

Die winterlichen Verhältnissen brachten in den Gebirgen höhere Niederschlagsmengen als in den tiefer gelegenen Gegenden. Weniger als 25 mm waren niedergegangen in größeren Gebieten östlich und südlich des Harzes; über 100 mm dagegen verzeichneten der östliche Teil des Landes Sachsen, das nördliche Niederschlesien, der südliche Schwarzwald sowie die höheren Lagen der Gebirge. — Im Vergleich zum langjährigen Durchschnittswert waren die Beträge unternormal im östlichen Hinterpommern und nordwestlichen Ostpreußen sowie westlich der Linie Bodensee—Bayreuth—Vorpommern. Unter 50 Prozent sanken sie südlich des westlichen Harzes und erreichten mehr als 250 Prozent im östlichen Land Sachsen und im Nordwesten Niederschlesiens. Die Zahl der Tage mit Niederschlag war, von wenigen Ausnahmen abgesehen, zu niedrig. Die wenigsten Niederschlagstage (5 bis 10) wurden östlich und südlich des Harzes beobachtet, die meisten mit mehr als 20 im Thüringer Wald und in Oberschwaben. An Schneefalltagen wurden im Gebiet der Nordseeküste 3, in Ostpreußen 8 gezählt, in den Gebirgen hingegen zwischen 10 bis 18. Die Zahl der Tage mit einer zusammenhängenden Schneedecke nahm abgesehen von der Höhenlage zu von Westen nach Osten wie auch von Norden nach Süden; ihre Häufigkeit, die in der Norddeutschen Tiefebene bis zur Weichsel auf 10 stieg, belief sich in Ostpreußen zwischen 10 bis 22, in den Mittelgebirgen meist zwischen 20 bis 25. Im Bereich der Nordseeküste konnte noch ein Gewitter festgestellt werden.

Die Bewölkung war mit 65 bis 80 % Himmelsbedeckung in Norddeutschland etwas unternormal, mit mehr als 80 % vielfach in Süddeutschland schon zu hoch. Entsprechende Abweichungen zeigten die heiteren bzw. trüben Tage. Norddeutschland hatte etwa 2 bis 6 heitere und 11 bis 20 trübe Tage, Süddeutschland dagegen 0 bis 2 heitere und 11 bis 20 trübe Tage. Die Häufigkeit der Nebeltage betrug in Ostelbien 0 bis 5, im übrigen Gebiet meist 5 bis 10, um in den Bergen meist auf mehr als 20 anzusteigen.

Die Sonnenscheindauer in Stunden blieb gegenüber den langjährigen Erwartungen nur im Zuflußgebiet des Rheines zu gering und lag sonst zu hoch. Zu wenig Sonnenschein mit etwa 30 Stunden (oder 9 bis 12 Prozent der möglichen Dauer)

hatte der Süden Nordwestdeutschlands, während schon 50 bis 60 Stunden Sonnenschein (oder 20 bis 28 Prozent der möglichen Dauer) der ostelbischen Tiefebene und dem östlichen Bayern zuteil geworden war. Die Gipfelstationen der Alpen konnten sogar mehr als 120 Sonnenscheinstunden aufweisen und kamen damit auf mehr als 45 Prozent der überhaupt möglichen Dauer.

Das Jahr 1939 war nur in der bayrischen Donauniederung, sowie um Stuttgart und Grünberg i. Schles. um wenige Zehntel Grade zu kalt, sonst etwas zu warm, und zwar um etwa 1 Grad und mehr im nördlichen Schleswig-Holstein, in Mittel- und Hinterpommern, Ostpreußen (mit fast 1,5° als größtem Wärmeüberschuß) und im östlichen Oberschlesien. Erheblich zu warm war der Januar, zu warm der Februar, April, August und November; zu kalt blieben dagegen der Mai (besonders in Süddeutschland), Oktober und Dezember (letzterer namentlich im lezten Drittel). Die Jahresniederschläge lagen etwas unter den Normalwerten nur im mittleren und nördlichen Schleswig-Holstein (Westerland auf Sylt meldete den niedrigsten Wert mit 81 v. H.) Sie überstiegen 120 v. H. in fast ganz Süddeutschland, dem südlichen und östlichen Hessen-Nassau, in Thüringen und südlich des mecklenburgisch-baltischen Höhenrückens im Gebiet ostwärts der Elbe bis zum mittleren Hinterpommern. Die höchsten Werte erreichten Ulm und Stettin mit 165 und 160 v. H. Im allgemeinen waren zu niederschlagsarm der Februar und Juni, zu niederschlagsreich die übrigen 10 Monate, besonders der März, Mai, Oktober und November, teilweise mit Beträgen über 200 v. H. Im einzelnen erhielten noch reichliche Niederschläge im Februar Ostpreußen, Nordschlesien und Nordbayern, im Juni Oberschlesien und das südliche Süddeutschland. Zu niederschlagsarm blieben im April vorwiegend die südöstliche Hälfte des Reichsgebietes, im Mai der Nordwesten des Reiches, im Juli große Teile der südwestlichen Reichshälfte, im August vor allem Süddeutschland, im September der Nordwesten des Reiches, im November östliche Gebietsteile, im Dezember Teile im Westen des Reiches.

Die Bewölkung war in ihren Jahreswerten meist um etwa 5 v. H. zu niedrig im Küstengebiet der Nordsee sowie der westlichen und mittleren Ostsee. Sie war um 5 bis 10 v. H. zu hoch in Süddeutschland sowie in dem angrenzenden Teil Nordwestdeutschlands mit Einfluß von Teilen des Landes Sachsen und der Provinzen Brandenburg und Schlesien.

Entsprechend den Jahreswerten der Bewölkung war die Zahl der heiteren Tage zu hoch, die der trüben zu niedrig nur im Küstengebiet der Nordsee und der westlichen und mittleren Ostsee. Die Zahl der Stunden mit Sonnenschein war bis zu etwa 6 v. H. zu niedrig in Süddeutschland, den angrenzenden Teilen von Nordwestdeutschland sowie im östlichen Schlesien, sonst zu hoch, teilweise bis zu 6 v. H.
