Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des R. f. W. in Potsdam werden die von 1893—1933 im Rahmen der Veröffentlichungen des früheren Preußischen Meteorologischen Instituts erschienenen „Ergebnisse der Meteorologischen Beobachtungen in Potsdam" fortgesetzt. Inhalt und Umfang der Publikation sind gegen die Vorjahre wenig verändert.

Die Terminwerte der Temperatur und Feuchtigkeit sind Ablesungen in der großen englischen Hütte auf der Beobachterwiese mit Aßmann'scher Aspirationsvorrichtung für das feuchte Thermometer; alle Feuchteangaben sind auf das aspirierte Psychrometer reduziert.

Die Beobachtungstermine sind 7^h, 14^h, 21^h Ortszeit. Die Gesamtsummen des Niederschlages und der Verdunstung werden um 8^h, die Temperaturextreme werden um 21^h für die vorgehenden 24 Stunden bestimmt und dem Datum des Messungstages zugeschrieben. Die Regen- und Schneemessungen werden auf der Beobachterwiese, letztere auf einem Zementfeld, gemacht; die Schneehöhen sind Mittelwerte aus mehreren Messungen.

Die Bewölkungsmengen werden 2 stündlich zur vollen Stunde geschätzt. Die Bodentemperaturen werden nach dem bisherigen Modus nur für den 14^h - Termin veröffentlicht; sie gelten für kiesigen humusfreien Sand, dessen Oberfläche im Winter schneefrei gehalten wird. Für die Tiefen von 0.5 bis 12 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in Schutzröhren aus Neusilber gesteckt werden.

Das Tagesmittel der Lufttemperatur ist aus den Terminwerten berechnet nach der Formel $(7^h + 14^h + 2 \times 21) : 4$, für Luftdruck und Dampfspannung ist das arithmetische Mittel aus den Terminbeobachtungen gebildet.

Von den hier veröffentlichten Registrierungen beziehen sich die für Luftdruck, Temperatur, Dampfdruck und Relative Feuchtigkeit auf die Angaben der vollen Stunden (Ortszeit); die Tagesmittel sind gebildet nach der Formel:

$$(\tfrac{1}{2}0^h + 1^h + 2^h \ldots\ldots\ldots\ldots + 23^h + \tfrac{1}{2}24^h) : 24$$

Die Werte für Windgeschwindigkeit, Windrichtung, luftelektrisches Potentialgefälle sind Stundenmittel, diejenigen für Niederschlag, Sonnenscheindauer und Wärmesummen der Sonnenstrahlung Stundensummen.

Für die Registrierungen werden nachstehend aufgeführte Geräte benutzt:

Luftdruck: Sprungscher Wagebarograph im Instrumentenzimmer, durch einmal tägliche Vergleichung bezogen auf Gefäßheberbarometer Wild-Fueß Nr. 248.

Lufttemperatur: Richardscher Thermograph mit 8 tägiger Umlaufzeit; engl. Hütte.

Rel. Feuchtigkeit: Richardscher Hygrograph mit 1 tägiger Umlaufzeit; engl. Hütte.

Wind: Mechanischer Schalenkreuz-Anemograph auf dem Turm.

Regenmenge und Dauer: Sprung-Fueßsche Registrierwaage für Niederschlag und Verdunstung; in Ergänzung mechanisch registrierender Regenmesser, System Hellmann-Fueß (Auffangfläche 200 cm^2).

Sonnenscheindauer: Autograph von Campbell-Stokes; in Ergänzung Jordan-Autograph (Zelloidinpapier).

Verdunstung: Wildsches Evaporimeter (Auffangfläche 200 cm^2) in Hütte, beschattet, regensicher und windgeschützt.

Sonnenstrahlungsintensität: Bimetall-Lamellen-Aktinometer nach Michelson-Marten unter Ueberwachung durch das Angström-Kompensationspyrheliometer und das Silverdisk-Aktinometer S I XII. Die Angaben sind reduziert auf die Smithsonian-Skala 1913; die „Luftmassen" auf den zur Zeit der Beobachtungen herrschenden Barometerstand umgerechnet. – Die mitgeteilten Wärmesummen sind nach den Aufzeichnungen eines thermoelektrischen Pyrheliographen, System Moll-Gorczynski berechnet; die Summenbildung ist durch planimetrische Auswertung nach den Registrierungen eines Schlagbügelgalvanometers von Hartmann und Braun vorgenommen worden.

Luftelektrisches Potentialgefälle: Benndorf-Elektrometer mit Poloniumkollektor in 2 verschiedenen Empfindlichkeitsbereichen auf der Wiese, in Ergänzung auf dem Turm mit einem Radiothor-Kollektor. Die veröffentlichten Werte sind auf die freie Ebene reduziert.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Anm.: Die 2 cm- und 5 cm-Bodentemperaturen werden hier nicht veröffentlicht, da die Tiefen der Thermometer zeitweise fraglich waren. Eine genauere Untersuchung ergab, dass die Unrichtigkeit bis zum Jahre 1929 zurückgeht.

Die Terminbeobachtungen des Observatoriums Wahnsdorf sind im Deutschen Meteorologischen Jahrbuch, Teil I abgedruckt.

Einleitung

Mit der vorliegenden Veröffentlichung werden die bisherigen Publikationen des Observatoriums Wahnsdorf in dem vom Freistaat Sachsen herausgegebenen Teil des Deutschen Meteorologischen Jahrbuches fortgesetzt. Außer dieser Reihe sind die Beobachtungen der Jahre 1917/18 in einer Sonderausgabe 1919 von der Sächsischen Landeswetterwarte herausgegeben worden.

Diese Veröffentlichungen enthielten:

1. die täglichen Beobachtungen in Form von Monatstabellen,
2. die täglichen Niederschlagsmessungen,
3. die Monatsmittel von Luftdruck, Lufttemperatur, relativer Feuchtigkeit, Windgeschwindigkeit, Sonnenscheindauer und der Dauer von Temperaturintervallen,
4. eine Auszählung besonderer Tage.

Im vorliegenden Band erscheinen zum ersten Male die stündlichen Auswertungen der Beobachtungsergebnisse.

Das Observatorium Wahnsdorf liegt in 246 m Seehöhe, etwa 10 km nordwestlich von Dresden. Seine geographische Breite beträgt 51° 7′, seine Länge 13° 41′ östl. v. Gr. In früheren Jahren ist fälschlich 13° 40′ angegeben worden.

Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden. Entsprechendes gilt für die Terminbeobachtungen. Die Tagesmittel des Luftdruckes, der Temperatur und Feuchtigkeit sind nach der Formel $(1^h + \ldots\ldots\ldots + 23^h + 24^h) : 24$ gebildet worden.

Für die Einzelelemente sind nachfolgende Instrumente bzw. Beobachtungen zugrunde gelegt worden.

1. Luftdruck: Die Stundenwerte des Luftdruckes sind dem Schreiberschen Waagebarographen entnommen und werden durch Vergleichsbeobachtungen (täglich 5 mal) auf das Fueßsche Stationsbarometer Nr. 2294 reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Die Meßgeräte sind auf der Beobachtungswiese in einer Schreiberschen Hütte in 2,5 m über dem Erdboden aufgestellt. Im Jahre 1934 war das Psychrometer noch ohne künstliche Ventilation. Die Werte für Dampfdruck und relative Feuchtigkeit sind der Jelinekschen Psychrometertafel unter der Annahme einer mittleren Windgeschwindigkeit entnommen. Bei Temperaturen unter 0° wurden der Feuchtigkeitsbestimmung die Angaben des Hygrometers und des Hygrographen, zwei sehr verläßlichen Instrumenten, zugrunde gelegt. Als Registriergerät dienten ein Fueßscher Thermograph und ein Lambrechtscher Hygrograph.

3. Windmessung. Windrichtung und Windgeschwindigkeit werden mit einem Schreiberschen Windmeßgerät registriert. Das Schalenkreuz (großes Schreibersches Modell) befindet sich auf dem Turm in 274 m Seehöhe, 28 m über dem Erdboden. Als Kontrollinstrument dient ein Fueßsches Schalenkreuz in annähernd gleicher Höhe mit Chronographenregistrierung. Ein 2. Fueßsches Schalenkreuz, ebenfalls mit Chronographenregistrierung ausgerüstet, ist auf der Instrumentenwiese in 2,5 m über dem Erdboden aufgestellt.

4. Niederschlagsmessungen. Als Meßgeräte wurden 2 Schreibersche Regenmesser mit 500 qcm Auffangfläche und ein registrierender Regenmesser nach Hellmann benutzt. Es ist versucht worden, den Betrieb des registrierenden Regenmessers auch im Winter durch Einfüllen eines Spiritus-Wasser-Gemisches in das Schwimmergefäß aufrechtzuerhalten.

5. Erdbodentemperaturen. Der Meß-Stand befindet sich auf der Instrumentenwiese auf lehmigem Kies und wird stets von Pflanzenwuchs freigehalten. Im Winter wird eine etwa vorhandene Schneedecke nicht entfernt. Die ersten 4 Thermometer (2, 5, 10 und 15 cm Tiefe) sind unmittelbar in den Boden eingegraben. Für die Beobachtungen in einer Tiefe von 0,5, 1,0, 1,5, 2,0 und 2,5 m Tiefe sind eiserne Röhren in den Boden eingelassen, in denen sich die an einem Holzstab befestigten Thermometer befinden.

6. Abkühlungsgröße. Zur Bestimmung der Abkühlungsgröße wird ein Davoser Frigorimeter benutzt, dessen Kupferkugel auf der Instrumentenwiese in 2,5 m über dem Erdboden (in der Nähe der Thermometerhütte und des Schalenkreuzes) aufgestellt ist. Die Aufzeichnung der Stundenmittel der Abkühlungsgröße erfolgt mit einem Registriergerät eigener Bauweise. Zur Kontrolle der Registrierungen werden an der Frigorimeteruhr täglich 5 Augenablesungen vorgenommen. Gemessen wird die Abkühlungsgröße in millical $cm^{-2}\,sec^{-1}$.

7. Sonnenscheindauer. Zur Messung wird ein Sonnenscheinautograph nach Campbell/Stokes der Firma Lambrecht verwandt. Zur Kontrolle dient ein 2. Instrument der gleichen Firma, das aber trotz wesentlich klarerer Glaskugel etwas geringere Werte liefert.

8. Sonnenintensität. Die Messung der Sonnenintensität wird vorwiegend mit einem Michelson-Marten-Aktinometer durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensations-Pyrheliometer Nr. 143 benutzt. Gemessen werden die Gesamtstrahlung und die Strahlung hinter dem Rotfilter RG 2 und dem Gelbfilter OG 1, beides Potsdamer Standard. An den mit den Filtern ausgeführten Messungen sind keine Korrektionen angebracht. Die Angabe der Intensitäten erfolgt in cal cm^{-2} sec^{-1}. Soweit es irgend möglich war, ist stets zur vollen Stunde wahrer Ortszeit gemessen worden. Mußte ausnahmsweise zu anderer Zeit gemessen werden, so erfolgte, wenn es sich nur um geringe zeitliche Abweichungen handelte und keine andere Bedenken dagegen sprachen, eine Reduktion der Intensitätswerte auf die volle Stunde wahrer Ortszeit.

9. Luftelektrisches Potentialgefälle. Als Meßgeräte dienten eine Radiothor-Sonde, an einem im Freien aufgestellten Mast befestigt, und 2 registrierende Quadrantenelektrometer nach Benndorf. Das eine Instrument besitzt einen Meßbereich bis $\pm$ 600 Volt, das andere bis $\pm$ 3000 Volt. Die in den Tabellen enthaltenen Zahlen sind Mittelwerte der einzelnen Stundenintervalle und in Volt pro Meter angegeben. Der Reduktionsfaktor, dessen Einzelwerte zwischen 0,8 und 1,2 schwanken, ist zu 1,0 angenommen worden.

10. Luftelektrische Leitfähigkeit. Die Messungen erfolgten nach der Scheringschen Methode. In einem Drahtkäfig von 17 m Länge und 1 qm Querschnitt ist ein Draht ausgespannt, der durch Uhrwerk und Relais in einem Wechsel von 10 Minuten entweder auf + 300 Volt oder auf — 300 Volt aufgeladen wird. Aus den Kurven der Entladungsgeschwindigkeit, die von einem Benndorfelektrometer aufgezeichnet werden, wird unter Berücksichtigung des Isolationsfehlers für jede volle Stunde die positive und negative elektrische Leitfähigkeit der Luft berechnet. Die Angabe der Werte erfolgt in elektrostatischem Maßsysteme in 10^{-4} sec^{-1}.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Einleitung

Mit der vorliegenden Veröffentlichung der Registrierungen des Meteorologischen Observatoriums Aachen des Reichsamtes für Wetterdienst werden die bisherigen Publikationen fortgesetzt, die die diesbezüglichen Werte gemeinsam mit den Ergebnissen des Klimanetzes des Wetterdienstbezirkes Aachen in nachfolgenden Veröffentlichungen niederlegten:

1895. Deutsches Meteorologisches Jahrbuch für 1895. Meteorologische Station I. Ordnung in Aachen. Ergebnisse der meteorologischen Beobachtungen. Jahrgang I. Aachen 1896.

1896—1899. Deutsches Meteorologisches Jahrbuch für 1896—1899. Beobachtungssystem der meteorologischen Station I. Ordnung Aachen. Ergebnisse der meteorologischen Beobachtungen an der Station I. Ordnung Aachen und deren Nebenstationen im Jahre 1896—1899. Jahrgang II—V. Karlsruhe 1897—1900.

1900—1915. Deutsches Meteorologisches Jahrbuch für 1900—1915. Aachen, Jahrgang VI—XXI. Karlsruhe 1901—1918.

1916—1929. Deutsches Meteorologisches Jahrbuch für 1916—1929. Aachen, Jahrgang XXII – XXXV. Aachen 1930.

1930—1932. Veröffentlichungen des Meteorologischen Observatoriums Aachen. Deutsches Meteorologisches Jahrbuch für die Jahre 1930—1932. Aachen, Jahrgang XXXVI–XXXVIII. Aachen 1933.

1933. Veröffentlichungen des Reichsamtes für Wetterdienst. Deutsches Meteorologisches Jahrbuch für das Jahr 1933. Aachen, Jahrgang XXXIX. Aachen 1935.

Die Terminbeobachtungen von Aachen für 1934 sind im Teil I des Deutschen Meteorologischen Jahrbuchs für 1934 abgedruckt.

Die hier ergänzend zusammengestellten Registrierungen beziehen sich für Luftdruck und Temperatur auf die Angaben der vollen Stunden (mittlere Ortszeit); die Tagesmittel sind gebildet nach der Formel

$$(\tfrac{1}{2}\,0^h + 1^h + \ldots\ldots + 23^h + \tfrac{1}{2}\,24^h) : 24$$

Die Werte der Windgeschwindigkeit sind Stundenmittel, die der Niederschlagsmengen Stundensummen. Niederschlagsdauer und Sonnenscheindauer sind in Stunden angegeben. Die Intensität der Sonnenstrahlung in drei Spektralbereichen ist in gcal/cm² min auf wahre Ortzeit bezogen.

Für die Registrierungen wurden folgende Instrumente benutzt:

Luftdruck: Frèresscher Wochenbarograph im Instrumentenraum kontrolliert durch ein Fueßsches Gefäßbarometer.

Lufttemperatur: Fueßscher Tagesthermograph in einer englischen Hütte in 2,1 m Höhe über einer Wiese. Die Werte sind durch dreistündigen Vergleich mit einem Normalthermometer kontrolliert.

Wind: Fueßscher Schalenkreuzanemograph auf dem Turm des Observatoriums in 27,0 m Höhe über dem Erdboden.

Niederschlag: Registrierender Regenmesser nach Hellmann mit 200 cm² Auffangfläche auf der Wiese in 1 m Höhe.

Sonnenscheindauer: Sonnenscheinautograph nach Campbell-Stokes auf dem Turm des Observatoriums in 22,5 m Höhe.

Intensität der Sonnenstrahlung: Bimetallaktinometer Michelson-Marten auf der Plattform des Observatoriums (214 m über N.N.). Die Angaben sind mittels Silverdiskaktinometers auf die Smithsonianskala von 1913 bezogen.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Wetterkundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee

Einleitung

Schon frühzeitig erkannte man, daß die vor der Küste verankerten Feuerschiffe sehr wichtige und sehr geeignete Punkte für regelmäßige meeres- und wetterkundliche Beobachtungen sind. Bereits 1872 richtete daher die Preußische Kommission zur Erforschung der deutschen Meere einen regelmäßigen Beobachtungsdienst ein, und zwar auf den Feuerschiffen „Borkum" und „Außenjade", 1875 auch auf dem Feuerschiff „Weser". Die Beobachtungen, die regelmäßig veröffentlicht wurden, hörten jedoch mit dem Jahrgang 1893 auf.

Nach dem Kriege richtete die Deutsche Seewarte nach und nach auf 10 Nordsee- und 2 Ostsee-Feuerschiffen einen regelmäßigen Beobachtungsdienst ein. Die Veröffentlichung der Beobachtungsergebnisse war allerdings wegen der Inflations- und Deflations-Jahre zunächst nicht möglich. Erst 1928 konnte ein Teil der meereskundlichen Beobachtungen gedruckt werden, nämlich die Jahrgänge 1924 und 1925, in der zu diesem Zweck von der Seewarte gegründeten Veröffentlichung „Meereskundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee". Als weitere Hefte sind inzwischen erschienen: 1929 die Beobachtungsjahrgänge 1926 und 1927, dann 1930 – 1935 in je einem Heft die Beobachtungsjahrgänge 1928—1934, außerdem 1932 in einem Ergänzungsheft die Beobachtungsjahrgänge 1924—1928 der Feuerschiffe „Weser", „Bremen" und „Elbe 4" sowie die Tiefenbeobachtungsjahrgänge 1924—1929 vom Feuerschiff „Fehmarnbelt".

Nachstehende Tabelle zählt die deutschen Feuerschiffe auf, die sich 1934 an den meeres- und wetterkundlichen Beobachtungen beteiligt haben und gibt gleichzeitig ihre wichtigsten Daten. Zwei Kartenskizzen zeigen die Lage der Feuerschiffe in der Nord- und Ostsee.

Die Bearbeitung der wetterkundlichen Beobachtungen konnte erst 1933 aufgenommen werden. Erschienen sind bisher die Jahrgänge 1932 und 1933 als Beihefte zum Deutschen Meteorologischen Jahrbuch (Beobachtungs-System der Deutschen Seewarte). Die vorliegende Arbeit enthält den Beobachtungsjahrgang 1934.

Die Zahl der täglichen Terminbeobachtungen hat auf einigen Feuerschiffen gegenüber dem Vorjahr abermals zugenommen. Neue Anforderungen kommen hier hauptsächlich vom Flugwetterdienst. Bei der Durchführung auch dieses vermehrten Beobachtungsdienstes fand die Deutsche Seewarte volles Verständnis und wirksame Unterstützung von seiten der Besatzungen der Feuerschiffe sowie ihrer vorgesetzten Dienststellen, nämlich der Wasserbauämter Emden, Tönning und Kiel, des Schiffahrtsamtes Cuxhaven, des Seezeichen- und Lotsenamts der Jade in Wilhelmshaven, der Wasserstraßendirektion Bremen und des Hafenbauamts Swinemünde. Allen diesen Stellen sei hier der wärmste Dank der Deutschen Seewarte ausgesprochen.

Vorbemerkungen

Zeitangaben stets nach mitteleuropäischer Zeit.

Da die auf See vor Anker liegenden Feuerschiffe fast immer mehr oder weniger stark ausgeprägten Schwankungen im Seegang unterworfen sind, sind die Luftdruckbestimmungen hier infolge des „Pumpens" des Quecksilbers im Schiffsbarometer zumeist weniger genau als an Landstationen; von einer Veröffentlichung der Luftdruckangaben der Feuerschiffe wurde daher im Rahmen des meteorologischen Jahrbuchs abgesehen.

Lufttemperatur, Dampfdruck und relative Feuchtigkeit: Zur Aufstellung der Thermometer sind Thermometerhütten verwendet, deren lichte Höhe, Breite und Tiefe ungefähr betragen: bei Modell I 33, 15.5, 7.5 cm — bei Modell II 40, 18, 15 cm — bei Modell III 40, 49, 30 cm. (Modell III wurde auf Außenjade-Feuerschiff mit Bordmitteln hergestellt, nachdem die vorher dort vorhandene Thermometerhütte durch Wellenschlag zertrümmert worden war). Die feuchten Thermometer sind mit einem Aßmannschen Aspirator versehen.

Es wurde für ausreichend erachtet, von dem Dampfdruck und der relativen Feuchtigkeit nur die Monats- und Jahresmittel zu bringen. Diese Monatswerte sind für die zugehörigen Monatsmittel der am trockenen und feuchten Thermometer abgelesenen Temperaturen den Aspirations-Psychrometer-Tafeln (herausgegeben vom Preußischen Meteorologischen Institut) entnommen. Die durch dieses Verfahren bedingten Abweichungen sind nicht von praktischer Bedeutung. Die Jahresmittel wurden dann aus den zugehörigen 12 Monatsmitteln errechnet.

Wind: Die Windrichtung ist mißweisend angegeben. Die Deviation, die in den Original-Tagebüchern der Feuerschiffe stets vermerkt wird, hält sich innerhalb der Grenzen der Beobachtungsgenauigkeit und wurde deshalb nicht berücksichtigt. Die Windstärken sind nach der Beaufort-Skala geschätzt worden. Die Windrichtung ist in der im Wetterdienst üblichen Strich-Skala 00—32 gegeben.

00 Still	07 EzN	14 SSE	21 SWzW	28 NW
01 NzE	08 E	15 SzE	22 WSW	29 NWzN

05 NEzE	12 SE	19 SWzS	26 WNW	
06 ENE	13 SEzS	20 SW	27 NWzW	

Die Windrichtungen mit ungeraden Strichnummern sind nur sehr selten angegeben worden. Die Windstärken $\leqq 6$ sind im Druck hervorgehoben, und zwar Windstärke 6 und 7 durch kleine fette, Windstärke 8—12 durch große fette Typen.

Die Bewölkung ist in Zehnteln des Himmelsgewölbes geschätzt worden.

Hydrometeore: Da Zahl und Wert der in den Beobachtungsbüchern enthaltenen Bemerkungen von Feuerschiff zu Feuerschiff ziemlich stark wechselt, werden unter „Bemerkungen" allein die Symbole der im Laufe des betreffenden Tages notierten Hydrometeor-Erscheinungen angegeben.

Messungen des Niederschlags in kardanisch aufgehängten Regenmessern sind zwar auf den Feuerschiffen durchgeführt worden, jedoch wird von einer Veröffentlichung hier abgesehen, weil bei der bekannten Schwierigkeit der Aufstellung von Regenmessern an Bord die einzelnen Meßwerte nicht sicher genug erscheinen. Es wird aber in der Tabelle der Monats- und Jahresergebnisse wenigstens die Zahl der Tage mit Niederschlag ($\geqq 0.1$ mm) angegeben.

Für die ganze Bearbeitung des Materials war die „Anleitung zur Anstellung und Berechnung der Beobachtungen an den deutschen meteorologischen Stationen", herausgegeben vom Preußischen Meteorologischen Institut (4. Auflage) maßgebend. Tage mit Angaben von „leichter Nebel" bei gleichzeitiger Sicht $\geqq 1000$ m wurden daher nicht als Nebeltage gezählt. Die Auszählung der „Tage mit ..." wurde auf Regen, Schnee, Graupel, Hagel, Nebel, Gewitter (mit Donner), Wetterleuchten und Sturm beschränkt.

Die Reihenfolge der Feuerschiffe ist stets wie folgt gegeben (im allgemeinen von West nach Ost fortschreitend): Zuerst die 4 Feuerschiffe in der Nordsee: Borkumriff, Außenjade, Elbe 1, Amrumbank; dann die 2 Feuerschiffe in der Ostsee: Fehmarnbelt und Adlergrund. Seite 1—36 enthält die Extenso-Beobachtungen von Lufttemperatur, Richtung und Stärke des Windes, Bewölkung und „Bemerkungen". Auf Seite 37—41 folgt die Zusammenstellung der Monats- und Jahresergebnisse für Lufttemperatur, Dampfdruck, Relative Feuchtigkeit, Windstärke, Bewölkung, dazu „Häufigkeit der Windrichtungen in Prozenten" und Anzahl der Tage mit den einzelnen, oben genannten Hydrometeoren; und zwar als Mittelwerte der durchgeführten einzelnen meteorologischen Termine, deren Zahl bei den verschiedenen Feuerschiffen verschieden ist. Diese Verschiedenheit der Beobachtungstermine macht eine gesonderte Zusammenstellung von Gesamtmittelwerten der Monate und des Jahres notwendig. (Seite 42 ff.)

Zum Schlusse folgt eine Tabelle, welche gleichzeitig gemessene Luft- und Wassertemperaturen bei den 6 Feuerschiffen in Beziehung setzt. (Seite 44).

Allen Feuerschiffen gemeinsam sind aber die 5 Beobachtungszeiten *8, 11, 14, 17, 19h*. Die Gesamt-Monats- und Jahresmittel sind daher, um die unmittelbare Vergleichbarkeit untereinander zu gewähren, auf Grund dieser gemeinsamen 5 Termine berechnet worden. Die Mittelbildung geschah arithmetisch, da eine besondere Formel zur Annäherung an das „wahre" (24stündige) Mittel für diese 5 Beobachtungszeiten noch nicht festgestellt ist.

Bei den 3 Feuerschiffen mit Terminen zur Nachtzeit wurden auch die Mittelwerte für *alle* Beobachtungszeiten berechnet (ebenso arithmetisch) und der nachstehenden Tabelle in *Schrägdruck* zum Vergleich hinzugefügt. Diese letzteren Mittelwerte werden bei der Gleichmäßigkeit der Verteilung über die 24 Stunden dem wahren Mittel sehr nahe kommen.

Bei einem Vergleich der Ergebnisse der Feuerschiffsbeobachtungen mit denen der Landstationen ist auf den Unterschied der Mittelbildungen zu achten.

Bei Elbe 1 sind im Januar die Beobachtungstage 12.—19. ausgefallen, bei Adlergrund fehlt der 5. April; die entsprechenden Monatsmittel (und auch Jahresmittel) sind daher in den folgenden Tabellen eingeklammert.

Mittelwerte von Luft- und Wassertemperaturen und deren Unterschiede nach ausgewählten Terminen.

Im folgenden werden die zu einigen meteorologischen Terminen auf den Feuerschiffen gemessenen Wassertemperaturen in Beziehung zu den gleichzeitigen Lufttemperaturen gesetzt.

Für folgende Beobachtungszeiten sind gleichzeitige regelmäßige Messungen beider Temperaturen vorhanden:

Feuerschiff:	*Beobachtungszeiten:*
Borkumriff	3 Termine: 8 14 19h
Außenjade	2 „ : 8 19h
Elbe 1	5 „ : 8 11 14 17 19h
Amrumbank	2 „ : 8 19h
Fehmarnbelt	5 „ : 8 11 14 17 19h
Adlergrund	1 Termin: 8h

Es wurde über diese Termine arithmetisch gemittelt. Wegen der verschiedenen Zahl der Beobachtungstermine ist das Material inhomogen, und die Mittelwerte erlauben daher keinen unmittelbaren Vergleich. Selbst bei übereinstimmenden Meßzeiten ist aber ein exakter Vergleich ohne weiteres nicht gegeben, da die Wassertemperaturen durch die Eigenbewegung des Wassers, vor allem durch die Gezeitenströmungen beeinflußt sind, deren Ausbildung und Auswirkung bei den einzelnen Feuerschiffen verschieden ist und wechselt. Die Feststellung der Größenordnung der mittleren Wassertemperaturen und der meteorologisch wirksamen Differenz Luft minus — minus Wassertemperatur ist aber notwendig.

Zur Statistik der Stürme an der deutschen Küste

Vorbemerkungen

Als mit dem Jahre 1878 die Deutsche Seewarte die Herausgabe der „Meteorologischen Beobachtungen in Deutschland" übernahm, die 1887 zum „Deutschen Meteorologischen Jahrbuch" ausgebaut wurden, erschien zum erstenmal als Erweiterung des Inhalts ein Teil III: „Zur Statistik der Stürme an der Deutschen Küste." Dieser dritte Teil, der — wie das Vorwort zu dem Bande sagt — „unter den sonst gebräuchlichen Veröffentlichungen eine besondere Stellung einnimmt", diente der Aufgabe der Seewarte: Der Nutzbarmachung meteorologischer Beobachtungen an der Küste für die deutsche Schiffahrt. In lückenloser Folge wurden diese Statistiken bis zum Jahre 1912 veröffentlicht. Sie waren die wichtigsten Unterlagen für die zusammenfassenden Arbeiten: E. Herrmann:[1]) „Die stürmischen Winde an der Deutschen Küste in den Jahren 1878—1887" und L. Großmann:[2]) „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1886—1895" und „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1896—1905."

Der Weltkrieg und seine Folgen zwangen die Seewarte, die Veröffentlichung vom Beobachtungsjahr 1913 ab einzustellen. Erst die Beobachtungen des Jahres 1933 wurden wieder bearbeitet und veröffentlicht in einer Sonderarbeit, die unter dem Titel erschien: „Zur Statistik der Stürme an der Deutschen Küste. Beobachtungsjahr 1933. 1. Jahrgang. Tägliche höchste Windstärke und zugehörige Windrichtung an den deutschen Küstenstationen und auf deutschen Feuerschiffen." Hamburg 1934. Die Untersuchung wurde hier im Gegensatz zu den früheren Bearbeitungen außer auf die Sturmwarnungsstellen auch auf sämtliche meteorologische Beobachtungsstationen an den deutschen Küsten sowie auf die Feuerschiffe ausgedehnt. Wie der Untertitel sagt, wurden für jeden Tag des Jahres — gleichgültig ob Sturmtag oder windschwacher Tag — die höchste Windstärke und die zugehörige Windrichtung für jede Station verzeichnet.

Die vorliegende Bearbeitung für das Jahr 1934 beschränkt sich wieder auf die wirklichen Sturmtage und Sturmperioden. Sie ist so angelegt, daß das meteorologisch und praktisch Bedeutsame in klarer Übersicht hervortritt und die geeignete Grundlage geschaffen ist für spätere zusammenfassende Bearbeitungen.

Einteilung der deutschen Küste und Stationsauswahl

Das Küstengebiet der Nordsee wurde als Einheit für sich genommen. In dem ausgedehnten Küstengebiet der Ostsee bildet die Insel Rügen eine natürliche Klimascheide, was schon E. Herrmann[3]) erkannte, der für die Untersuchung der Stürme die Ostseeküste in die beiden Bezirke westlich und östlich von Rügen unterteilte. Der Küstenteil Ostpreußens muß außerdem als eigener Bezirk genommen werden. Für die vorliegende Statistik ist die deutsche Küste daher in folgende **4 Teilgebiete** unterteilt worden (vgl. die nachstehende Übersichtskarte):

Nordsee: Die ganze deutsche Nordseeküste.
Ostsee I: Ostseeküste von der Flensburger Förde bis Arkona auf Rügen.
Ostsee II: Ostseeküste von Arkona auf Rügen bis Stilo.
Ostsee III: Ostpreußische Küste.

Diese Gebietseinteilung der Küste ist also unabhängig von der — früher auch für die Statistik benutzten — Gruppeneinteilung (I—VIII) nach Sturm**warnungs**bezirken!

Von den vorhandenen Stationen wurden diejenigen ausgewählt, deren Beobachtungen für das eigentliche **Küstenwetter** als „repräsentativ" anzusehen sind (es wurden also die an den Flüssen landeinwärts oder an Haffküsten gelegenen Stationen fortgelassen); auch wurden nur solche Beobachtungsstellen genommen, von denen möglichst häufige, regelmäßige und einwandfreie Beobachtungen vorliegen. Nach Fortfall der für die Zwecke der vorliegenden Untersuchung nicht geeignet erachteten Stationen blieben für die Nordsee 27, für Ostsee I 12, für Ostsee II 19 und für Ostsee III 10 Beobachtungsstellen, die im folgenden aufgezählt und in die nachstehende Übersichtskarte eingezeichnet sind. Von diesen 69 Beobachtungsstationen der Küste sind **54 Sturmwarnungsstellen (St)** und **13 Feuerschiffe (F)**, die übrigen andere meteorologische Stationen.

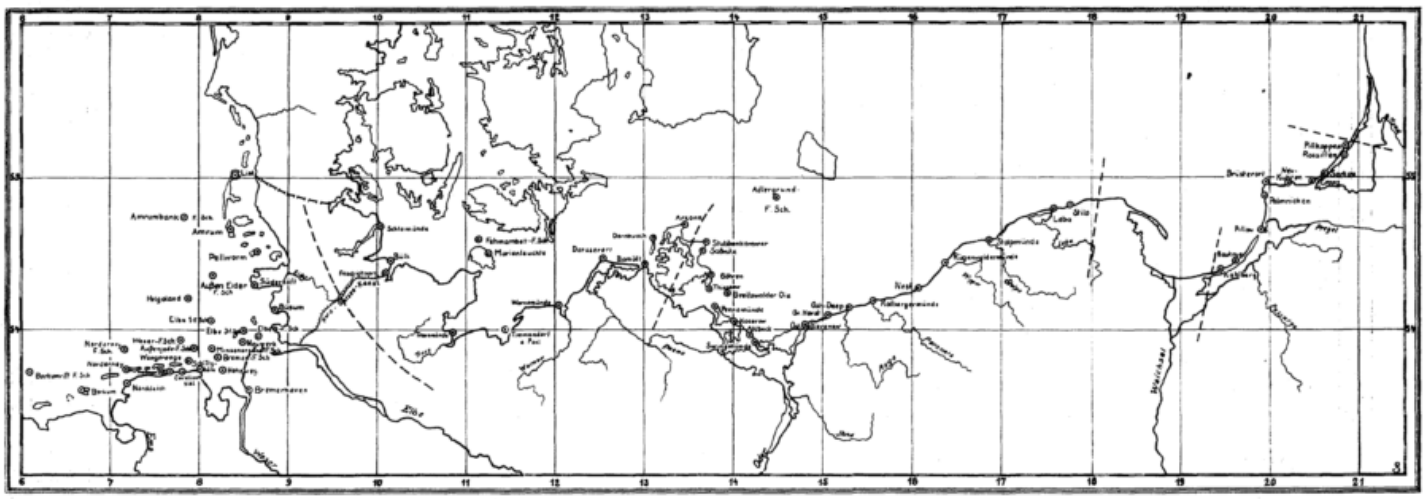
Übersichtskarte



Ausgewählte Beobachtungsstellen

Einteilung der deutschen Küste in die Bezirke Nordsee, Ostsee I, Ostsee II, Ostsee III

(69 Stationen, davon 54 Sturmwarnungsstellen der Deutschen Seewarte und 13 Feuerschiffe [F.-Sch.] vergl. Übersichtsliste, Seite 47)

Die Anzahl der Beobachtungen ist bei den Beobachtungsstellen je nach ihrer Art recht verschieden. Die Sturmwarnungsstellen beobachten Wind und Wetter 3 mal täglich, führen außerdem aber zu **Sturmzeiten besondere Zwischenbeobachtungen** (Zw.-Beob.) im Zeitabstand von 2 Stunden aus, so daß gerade die hier untersuchten Sturmzeiten gut besetzt sind. Als ein Mangel erweist sich, daß diese Zwischenbeobachtungen der Sturmsignalisten sich auf die **Tageszeit** beschränken (zwischen 8 und 20 Uhr, höchstens bis 22 Uhr); es wird angestrebt werden, daß die Signalisten künftig auch Merkmale des Sturmverlaufs während der Nacht im meteorologischen Tagebuch notieren. Von den Feuerschiffen liegen die meisten Beobachtungen vor (bis zu 13 täglich), da sie zumeist jede 3. Stunde Meldungen für den Wetterdienst abgeben. Das über Tag und Nacht lückenlos ausgedehnte meteorologische Beobachtungsmaterial der Feuerschiffe kommt der vorliegenden Arbeit sehr zu statten.

Für die Erfassung der Sturmphänomene wurden von den gewählten Stationen alle Beobachtungen systematisch verwertet. Zunächst wurden für jede Beobachtungsstelle die Tage ausgesucht, an denen Windstärke 6 (Beaufort) erreicht oder überschritten wurde; die an dem Tage aufgetretene **höchste** Windstärke wurde dann in Tabellen aufgezeichnet.

Als „Sturmtage" wurden diejenigen Tage bezeichnet, an denen innerhalb eines Bezirkes an mindestens 3 Beobachtungsorten Windstärke 8 Beaufort oder mehr (also Sturm) beobachtet worden ist.

Diese Definition des „Sturmtages" entspricht derjenigen, die bereits 1887 erstmalig gegeben wurde („es müssen stürmische Winde auf größerem Gebiet mindestens an 3 Stationen auftreten").

Für jeden dieser „Sturmtage" wurden für alle Beobachtungsorte die Wind- und Wetterbeobachtungen ausgezogen und zusammengestellt, getrennt für jeden Bezirk. Nach diesen Zusammenstellungen erfolgte die Bestimmung der Merkmale und des Verlaufs eines jeden Sturms bezw. einer Sturmperiode. Für jeden Bezirk wurde die mittlere (vorherrschende) Richtung und Stärke des Sturms, die Art der Verbreitung, Beginn und Ende, die Anfangs- und Endrichtung des Sturmes, seine größte Stärke und in Kürze auch der Witterungsverlauf ermittelt.

Diese Angaben wurden dann in **gleicher** Reihenfolge zusammengestellt, für jeden Sturm in der folgenden Übersicht: „Verlauf und Merkmale der Stürme."

Bezüglich der Verbreitung innerhalb eines Bezirks wurde ein dreifacher Unterschied gemacht:

„Örtlicher" Sturm: mindestens 3, aber weniger als die Hälfte aller Beobachtungsorte haben Windstärke ≥ 8 Beaufort (Bft.).

„Verbreiteter" Sturm: gleich oder mehr als die Hälfte aller Beobachtungsorte Windstärke ≥ 8 Bft.

„Allgemeiner" Sturm: alle Beobachtungsorte Windstärke ≥ 8 Bft.

Sachbearbeiter: Dr **J. Wittenbecher** und Dr. **P. Pummerer.**

Der Sturm am 12. bis 13. Januar

Ostsee I und II: **SSE 8**

Lage: Das am 12. 8^h mit Kerndruck 945 mb südlich Island gelegene Sturmtief zieht langsam nordostwärts; Kern 965 mb am 13. 8^h bei Faröer. Ein nordostwärtsschwenkender Ausläufer ruft im Bereiche der Ostseeküste ein zeitweiliges Auffrischen der Winde bis Sturmstärke hervor.

Ostsee I: 12. I. **Nur** Barhöft bis Arkona / zwischen 18^h und 22^h zeitweise Sturm / SE oder SSE — SSW (Barhöft 22^h) / Bft. 8 / ab Spätnachmittag vielfach leichter ●, abends örtlich ✳, meist bedeckt, allgemein diesig.

Ostsee II: 12./13. I. **Örtlich** / Adlergrund: 12. 17^h—19^h, 13. 2^h—11^h, an Küste: 12. 20^h, 13. 6^h—8^h, Stilo: 13. 14^h—16^h zeitweise Sturm / Richtung schwankend zwischen SE und S / 13. 2^h und 8^h örtlich Bft. 9 / am 12. nur örtlich leichter, am 13. verbreitet ● und ✳, allgemein diesig, am 13. zwischen Arkona und Swinemünde zeitweise ≡.

Bemerkungen: In Ostsee III hat am 12. nur Pillkoppen Windstärke 8, am 13. Pillkoppen 8^h und 12^h SE 8, 20^h SE 9, Palmnicken 12^h und 14^h SSE 8 beobachtet.

Der Sturm am 14. Januar

Nordsee und Ostsee I: **SSE 8**

Lage: Am Südrande des das ganze europäische Nordmeer und den nordöstlichen Nordatlantischen Ozean bedeckenden Tiefdruckgebietes entstand am 13. ein Teiltief, das sich schnell den Britischen Inseln näherte. Am 14. 8^h liegt der Kern des Tiefs mit 975 mb über Südengland, um 19^h über der mittleren Nordsee und am 15. 8^h in gleicher Stärke vor der südwestnorwegischen Küste.

Nordsee: **Verbreitet** / 12^h—14^h, nur in der Elbmündung erst gegen 20^h — allgemein bis gegen 22^h, örtlich bis Mitternacht / schwankend zwischen SE — S / zwischen 17^h—19^h Helgoland, Süderhöft, List und Amrumbank zeitweise Bft. 9 / fast den ganzen Tag leichter bis mäßiger ●, z. T. schauerartig, vielfach diesig.

Ostsee I: **Verbreitet** / Kieler Bucht bis Fehmarnsund zwischen 14^h—17^h, sonst 17^h—19^h — Ende meist gegen 20^h, nur Friedrichsort bis Mitternacht noch Sturmböen / schwankend zwischen SE und S / Friedrichsort zeitweise Bft. 9 / ab Spätnachmittag vielfach zeitweise leichter ●, z. T. schauerartig.

Bemerkungen: Ostsee II: Adlergrund: 24^h S 8, 15. 4^h SSE 9, Nest: 14. 22^h SSE 8.

Die Sturmwetterlage vom 17. bis 19. Januar

Nordsee: am 17. **SW 8,** 18. **WSW 8,** Ostsee I: am 17. **SSW 8**, 19. **WSW 8,** Ostsee II: am 19. **WSW 8**

Lage Dem von den Azoren bis zu den Ostalpen reichenden Hochdruckgebiet mit dem Hauptkern 1035 mb über Spanien und einem Teilkern von 1030 mb über den Mittelalpen liegt ein ausgedehntes, den Nordostteil des Atlantischen Ozeans und das europäische Nordmeer bedeckendes Tiefdruckgebiet gegenüber. Dessen Haupttief befindet sich am 17. 8^h mit 970 mb westlich von Nordschottland, um 14^h auf 955 mb vertieft zwischen den Faröern und Nordschottland, am 18. 8^h mit 960 mb nordöstlich von den Shetlandinseln und am 19. 8^h auf 975 mb aufgefüllt über Mittelskandinavien. Seine Randstörungen rufen an der Nordseeküste sowie in der mittleren und westlichen Ostsee eine Verschärfung des Druckgradienten hervor, so daß die Winde dort zeitweise mit Sturmstärke wehen.

Lage: Das von den Azoren bis zur westlichen Nordsee und Frankreich reichende Hoch verlagert sich langsam nordnordostwärts. Vom 24. auf 25. aber zerfällt es. Seine Reste werden von dem Hoch aufgenommen, das jetzt ziemlich schnell von Westen her gegen den Kontinent vordringt. Das Kerngebiet dieses neuen Hochs, das am 26. westlich von Irland liegt, bewegt sich langsam südwärts. Dem Hoch liegt ein ausgedehntes Tiefdruckgebiet gegenüber, das das Europäische Nordmeer, Skandinavien, Finnland und Nordrußland bedeckt und von dem eine Tiefdruckrinne über Island hinweg zu dem westgrönländischen Tief führt. Von ihm lösen sich Teiltiefs ab, die zum Nordmeer vordringen und sich späterhin als Randstörung dem Strömungssystem des nordeuropäisch-nordrussischen Tiefdruckgebiets eingliedern. Auch über die Lofoten hinweg dringen zeitweise Störungen südwärts vor. Der Vorüberzug der Randstörungen ruft an der deutschen Küste an mehreren Tagen des betrachteten Zeitraumes ein Auffrischen der Winde bis Sturmstärke hervor.

Es ist vom Nordgrönlandhoch durch eine breite Tiefdruckfurche getrennt. In dieser wandern Teiltiefs ostwärts, die sich von dem Südgrönlandtief abspalten. Auf dem Wege zum Nordmeer vertiefen sie sich gewöhnlich, dort angelangt zerfallen sie aber meist schnell. Es lösen sich dann Teiltiefs ab, die über Mittelnorwegen hinweg nach Finnland vordringen und entweder selbst oder durch kräftige Randstörungen den Sturm hervorrufen.

Lage: Das am 13. 19h mit einem Kern von 1035 mb im Raume westlich von der Biskaya gelegene Hoch, das bisher ortsfest war, weicht westwärts zurück. Sein bis zum mittleren Nordmeer reichender Keil wird durch einen ausgeprägten Ausläufer des über Island hinweg ostwärts vordringenden Tiefs schnell abgebaut. Der Ausläufer ist am 14. 8h schon bis Jütland gelangt. In ihm ist vor der norwegischen Küste über der nördlichen Nordsee ein Teiltief von 990 mb entstanden und ein zweites vor dem Skagerrak in Bildung begriffen. Während das Haupttief über dem Nordmeer sich schnell auffüllt, vertiefen sich beide Teiltiefs und dringen schnell zur Ostsee vor. Am 15. 8h liegt je ein Tief von 975 mb über Lettland und dicht nördlich von Kopenhagen. Während das lettische Tief nur langsam nach Osten weiterzieht und sich dabei allmählich auffüllt, verliert das dänische Tief alsbald seine Selbständigkeit und schwenkt als Randstörung des lettischen Tiefs schnell südostwärts.

Lage: Von dem am 27. 8^h mit einem Kern von 955 mb dicht östlich von Island gelegenen Tief erstreckt sich ein Ausläufer über die Shetland-Inseln bis zum Westausgang des Kanals. Dieser schwenkt schnell ostwärts und zieht zwischen 19^h und 24^h über die Deutsche Bucht hinweg. Gleichzeitig dringt das Tief selbst nach Südosten vor. Am 28. 8^h liegt es, auf 970 mb aufgefüllt, etwas nordöstlich von den Shetland-Inseln. Die schon am Abend des 27. angedeutete Abspaltung eines Teiltiefs ist am Morgen des 28. fast vollzogen, und zwar liegt das Teiltief schon nördlich von Hernösand. Während nun das Teiltief sich weiter vertieft, verliert das jetzt vor der mittelnorwegischen Küste angelangte alte Haupttief schnell an Stärke. Am 29. 8^h weist es zwar noch einen Kern von 985 mb auf, hat aber keinen Einfluß mehr auf das Wettergeschehen in den deutschen Meeresgebieten. Dagegen erstreckt sich von dem nun über der Kola-Halbinsel angelangten Tief von 980 mb ein ausgeprägter Ausläufer in Richtung nach Nordschottland, der südostwärts vordringt und sich vertieft. Es bilden sich über Jütland und Südschweden und später über der mittleren Nordsee Teiltiefs, die langsam ostwärts ziehen. Am 31. abends kommt die deutsche Nordseeküste in den Bereich der Rückseitenströmung des letzten Teiltiefs.
