Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamts für Wetterdienst in Potsdam werden die im Deutschen Meteorologischen Jahrbuch 1934, Teil IV, Heft 1, veröffentlichten „Beobachtungen des Observatoriums Potsdam" fortgesetzt. Inhalt und Umfang sind gegen die Vorjahre wenig verändert.

Die Beobachtungstermine sind 7^h, 14^h und 21^h Ortszeit. Die Gesamtsummen des Niederschlages und der Verdunstung werden um 8^h, die Temperaturextreme um 21^h für die vorhergehenden 24 Stunden bestimmt und dem Datum des Meßtages zugeschrieben. Die Regen- und Schneemessungen werden auf der Beobachtungswiese, letztere auf einem Zementfeld, durchgeführt; die Schneehöhen sind Mittelwerte aus mehreren Messungen. Die Bewölkungsmengen werden 2-stündlich zur vollen Stunde mittlerer Ortszeit geschätzt.

Von den hier veröffentlichten Registrierungen beziehen sich Luftdruck, Lufttemperatur und Luftfeuchtigkeit auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte nach der Formel:

$$(\tfrac{1}{2}0^h + 1^h + \ldots\ldots\ldots\ldots + 23^h + \tfrac{1}{2}24^h) : 24$$

Die Werte für Windrichtung, Windgeschwindigkeit und luftelektrisches Potentialgefälle sind Stundenmittel, diejenigen für Niederschlag, Sonnenscheindauer und Wärmesummen der Sonnenstrahlung Stundensummen. Alle Regiestrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck. Die Werte sind dem Sprungschen Waagebarographen entnommen und werden durch Vergleichsbeobachtungen täglich einmal auf das Gefäßheberbarometer Wild-Fueß Nr. 248 reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Die Meßgeräte sind auf der Beobachtungswiese in der großen englischen Hütte, 2,2 m über dem Erdboden, aufgestellt. Die Terminwerte der Temperatur und Feuchtigkeit sind Ablesungen an einer Thermometeraufstellung nach August mit einem Aspirator für das feuchte Thermometer. Alle Feuchteangaben sind auf das aspirierte Psychrometer reduziert. Die unter den Terminbeobachtungen veröffentlichten Tagesmittel der Lufttemperatur werden nach der Formel $(7^h + 14^h + 2 \times 21^h) : 4$, die des Luftdrucks und der Dampfspannung aus dem arithmetischen Mittel berechnet. Als Registriergeräte dienten ein Richardscher Thermograph mit 8-tägigem Umlauf und ein Richardscher Hygrograph mit 1tägigem Umlauf.

3. Windmessung. Windrichtung und -geschwindigkeit werden mit einem mechanischen Schalenkreuz-Anemograph auf dem Turm des Observatoriums in 41.0 m Höhe über dem Erdboden registriert.

4. Niederschlags- und Verdunstungsmessung. Regenmenge und -dauer werden mit einer Sprung-Fueßschen Registrierwaage für Niederschlag und Verdunstung gemessen. Ferner ist noch ein mechanisch registrierender Regenmesser, System Hellmann-Fueß, mit 200 cm^2 Auffangfläche auf der Beobachtungswiese aufgestellt. Der Verdunstungsmessung dient ebenfalls noch ein Wildsches Evaporimeter mit 200 cm^2 Verdunstungsfläche, das in einer englischen Hütte auf der Beobachtungswiese beschattet, regensicher und windgeschützt aufgestellt ist.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit einem Sonnenscheinautographen Campbell-Stokes und mit einem Autographen nach Jordan (Zelloidinpapier), die auf dem Turm des Observatoriums in 34 m Höhe über dem Erdboden aufgestellt sind.

6. Erdbodentemperatur. Das Meßfeld befindet sich auf der Beobachtungswiese in kiesigem, humusfreiem Sand, dessen Oberfläche von Pflanzenwuchs und im Winter von Schnee frei gehalten wird. Für die Tiefen von 0,5 bis 12 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in Schutzröhren von Neusilber gesteckt werden.

7. Sonnenstrahlungsintensität: Die Messung der Sonnenintensität wird mit einem Bimetall-Lamellen-Aktinometer nach Michelson-Marten durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer und das Silverdisk-Aktinometer S I XII benutzt. Die Angaben sind auf die Smithsonian-Skala 1913 reduziert und die „Luftmassen" auf den zur Zeit der Beobachtungen herrschenden Barometerstand umgerechnet. Die mitgeteilten Wärmesummen sind nach den Aufzeichnungen eines thermoelektrischen Pyrheliographen, System Moll-Gorczynski, berechnet; die Summenbildung ist durch planimetrische Auswertung nach den Registrierungen eines Schlagbügelgalvanometers von Hartmann und Braun vorgenommen worden.

8. Luftelektrische Messungen. Auf der Beobachtungswiese wird das luftelektrische Potentialgefälle mit Benndorf-Elektrometern in 2 verschiedenen Empfindlichkeitsbereichen und Poloniumkollektor gemessen. Eine weitere Meßeinrichtung, jedoch mit Radiothorkollektor, befindet sich auf dem Turm des Observatoriums. Die veröffentlichten Werte sind auf die freie Ebene reduziert.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamts für Wetterdienst in Wahnsdorf werden die im Deutschen Meteorologischen Jahrbuch 1934, Teil IV, Heft 2, veröffentlichten „Beobachtungen des Observatoriums Wahnsdorf" fortgesetzt. Inhalt und Umfang sind gegen das Vorjahr etwas erweitert. — Die Terminbeobachtungen sind im Teil I des Deutschen Meteorologischen Jahrbuchs abgedruckt.

Von den hier veröffentlichten Registrierungen beziehen sich Luftdruck, Lufttemperatur, Luftfeuchtigkeit und elektrische Leitfähigkeit der Luft auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte nach der Formel

$$(1^h + 2^h + \ldots\ldots\ldots\ldots + 23^h + 24^h) : 24.$$

Die Werte für Windrichtung, Windgeschwindigkeit, Abkühlungsgröße und luftelektrisches Potentialgefälle sind Stundenmittel. Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck: Die Stundenwerte des Luftdruckes sind dem Schreiberschen Waagebarographen entnommen und werden durch Vergleichsbeobachtungen (täglich 5mal) auf das Fueßsche Stationsbarometer Nr. 2294 reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Die Meßgeräte sind auf der Beobachtungswiese in einer Schreiberschen Hütte in 2,5 m über dem Erdboden aufgestellt. Im Jahre 1935 war das Psychrometer noch ohne künstliche Ventilation. Die Werte für Dampfdruck und relative Feuchtigkeit sind der Jelinekschen Psychrometertafel unter Annahme einer mittleren Windgeschwindigkeit entnommen. Bei Temperaturen unter 0° wurden der Feuchtigkeitsbestimmung die Angaben des Hygrographen und des Hygrometers zugrunde gelegt. Als Registriergerät dienten ein Fueßscher Thermograph und ein Lambrechtscher Hygrograph; beide Instrumente mit eintägigem Umlauf.

3. Windmessung. Windrichtung und Windgeschwindigkeit werden mit einem Schreiberschen Windmeßgerät registriert. Das Schalenkreuz (großes Schreibersches Modell) befindet sich auf dem Turm in 274 m Seehöhe 28 m über dem Erdboden. Als Kontrollinstrument dient ein Fueßsches Schalenkreuz in annähernd gleicher Höhe mit Chronographenregistrierung. Die Registrierung der Windgeschwindigkeit in 2,5 m Höhe über dem Erdboden erfolgt mit einem Fueßschen Schalenkreuz, das auf der Instrumentenwiese aufgestellt und gleichfalls an einen Chronographen angeschlossen ist.

4. Niederschlagsmessung. Als Meßgeräte wurden 2 Schreibersche Regenmesser mit 500 cm² Auffangfläche und 1 registrierender Regenmesser nach Hellmann mit 200 cm² Auffangfläche benutzt. Der Betrieb des registrierenden Regenmessers ist auch in der kalten Jahreszeit durch Einfüllen eines Spiritus-Wasser-Gemisches in das Schwimmergefäß nach Möglichkeit aufrechterhalten worden.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit 2 Sonnenscheinautographen Campbell-Stokes, wovon das zweite Instrument Kontrollmessungen diente.

6. Erdbodentemperaturen. Das Meßfeld befindet sich auf der Instrumentenwiese in lehmigem Kies und wird von Pflanzenwuchs freigehalten. Im Winter wird eine etwa vorhandene Schneedecke nicht entfernt. Für die Tiefen von 0,5 bis 2,5 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in eiserne Schutzröhren gesteckt werden.

7. Sonnenstrahlungsintensität. Die Messung der Sonnenintensität wird mit einem Aktinometer nach Michelson-Marten durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer Nr. 143 benutzt. Gemessen werden die Gesamtstrahlung und die Strahlung hinter dem Rotfilter RG 2 und dem Gelbfilter OG 1, beides Potsdamer Standard. An den mit Filtern ausgeführten Messungen sind keine Korrektionen angebracht. Die Angabe der Intensitäten erfolgt in cal cm^{-2} min^{-1}. Soweit es irgend möglich war, ist stets zur vollen Stunde wahrer Ortszeit gemessen worden. Mußte ausnahmsweise zu anderen Zeiten gemessen werden, so erfolgte, wenn es sich nur um geringe zeitliche Abweichungen handelte und keine anderen Bedenken dagegen sprachen, eine Reduktion der Intensitätswerte auf die volle Stunde wahrer Ortszeit.

Im Sommer 1936 ist das Wahnsdorfer Michelson-Marten-Aktinometer mit neuen, geeichten Filtern versehen worden. Die bisher benutzten Filter wurden zur Nacheichung an das Meteorologische Observatorium in Potsdam gesandt. Die Eichung ergab für das alte Gelbfilter OG 1 die Korrektion O, während für das alte Rollfilter RG 2 durch Vergleichsmessungen vor Sonne infolge nicht ganz einwandfreier Oberflächenbeschaffenheit eine um 3% zu niedrige Durchlässigkeit ermittelt wurde. Es müssen daher alle in Wahnsdorf vor Juni 1936 ausgeführten Rotfiltermessungen um 3% erhöht werden.

8. Luftelektrische Messungen. Das luftelektrische Potentialgefälle wird mit Benndorf-Elektrometern in zwei verschiedenen Empfindlichkeitsbereichen und einem im Freien aufgestellten Radiothorkollektor gemessen. Veröffentlicht werden Stundenmittelwerte in Volt/m. Der Reduktionsfaktor, dessen Einzelwerte zwischen 0,8 und 1,2 schwanken, ist zu 1,0 angenommen worden.

Die luftelektrische Leitfähigkeit wird nach der Scheringschen Methode gemessen. In einem Drahtkäfig von 17 m Länge und 1 m^2 Querschnitt ist ein Draht ausgespannt, der durch Uhrwerk und Relais in einem Wechsel von 10 Minuten entweder auf + 300 oder auf — 300 Volt aufgeladen wird. Aus den Kurven der Entladungsgeschwindigkeit, die von einem Benndorf-Elektrometer aufgezeichnet werden, wird unter Berücksichtigung des Isolationsfehlers für jede volle Stunde die positive und negative elektrische Leitfähigkeit der Luft berechnet. Die Angabe der Werte erfolgt in elektrostatischem Maß in 10^{-4} sec^{-1}.

9. Abkühlungsgröße. Zur Bestimmung der Abkühlungsgröße wird ein Davoser Frigorimeter benutzt, dessen Kupferkugel auf der Instrumentenwiese in 2,5 m Höhe über dem Erdboden in der Nähe der Thermometerhütte aufgestellt ist. Daneben befindet sich in gleicher Höhe ein Fueßsches Kontaktanemometer. Die Aufzeichnung der Stundenmittel der Abkühlungsgröße erfolgt mit einem Registriergerät eigener Bauweise. Zur Kontrolle der Registrierungen werden an der Frigorimeteruhr täglich 4—5 Augenablesungen vorgenommen. Gemessen wird die Abkühlungsgröße in mcal $cm^{-2}sec^{-1}$.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Berichtigung!

In den Jahren 1934 und 1935 sind in den Tabellen der Sonnenintensität in Wahnsdorf die hinter dem Rotfilter RG 2 gemessenen Intensitäten um 3% zu erhöhen.

Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamtes für Wetterdienst in Aachen werden die im Deutschen Meteorologischen Jahrbuch 1934, Teil IV, Heft 3, veröffentlichten „Beobachtungen des Observatoriums Aachen" fortgesetzt. Inhalt und Umfang sind gegen das Vorjahr wenig verändert. — Die Terminbeobachtungen sind im Teil I des Deutschen Meteorologischen Jahrbuchs abgedruckt.

Von den hier abgedruckten Registrierungen beziehen sich Luftdruck und Lufttemperatur auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte nach der Formel:

$$(\tfrac{1}{2}\,0^h + 1^h + \ldots\ldots + 23^h + \tfrac{1}{2}\,24^h) : 24$$

Die Werte für Windgeschwindigkeit sind Stundenmittel, die der Niederschlagsmengen Stundensummen; Niederschlagsdauer und Sonnenscheindauer sind in Stunden angegeben. Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortzeit ausgewertet worden.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck. Die Werte sind einem Richardschen Wochenbarographen entnommen und werden durch Vergleichsbeobachtungen auf ein Fueßsches Gefäßbarometer reduziert.

2. Lufttemperatur. Der Fueßsche Tagesthermograph steht auf der Wiese in einer englischen Hütte in 2,1 m Höhe über dem Erdboden. Die Werte werden durch dreistündigen Vergleich mit einem Normalthermometer kontrolliert.

3. Windmessung. Windrichtung und -geschwindigkeit werden mit einem Fueßschen Schalenkreuz-Anemographen auf dem Turm des Observatoriums in 27,0 m Höhe über dem Erdboden registriert.

4. Niederschlagsmessung. Als Meßgerät wird ein auf der Wiese aufgestellter registrierender Regenmesser nach Hellmann benutzt, dessen Auffangfläche von 200 cm^2 sich 1 m über dem Erdboden befindet.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit einem Sonnenscheinautographen Campbell-Stokes, der auf dem Turm des Observatoriums in 22,5 m Höhe über dem Erdboden aufgestellt ist.

6. Sonnenstrahlungsintensität. Die Messung der Sonnenintensität wird mit einem Bimetall-Lamellen-Aktinometer nach Michelson-Marten auf der Plattform des Observatoriums (214 m über N. N.) durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer benutzt. Die Intensitätsmessungen in 3 Spektralbereichen sind in cal cm^{-2} min^{-1} auf wahre Ortszeit bezogen. Die Angaben sind auf die Smithsonian-Skala 1913 reduziert.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Wetterkundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee

Einleitung

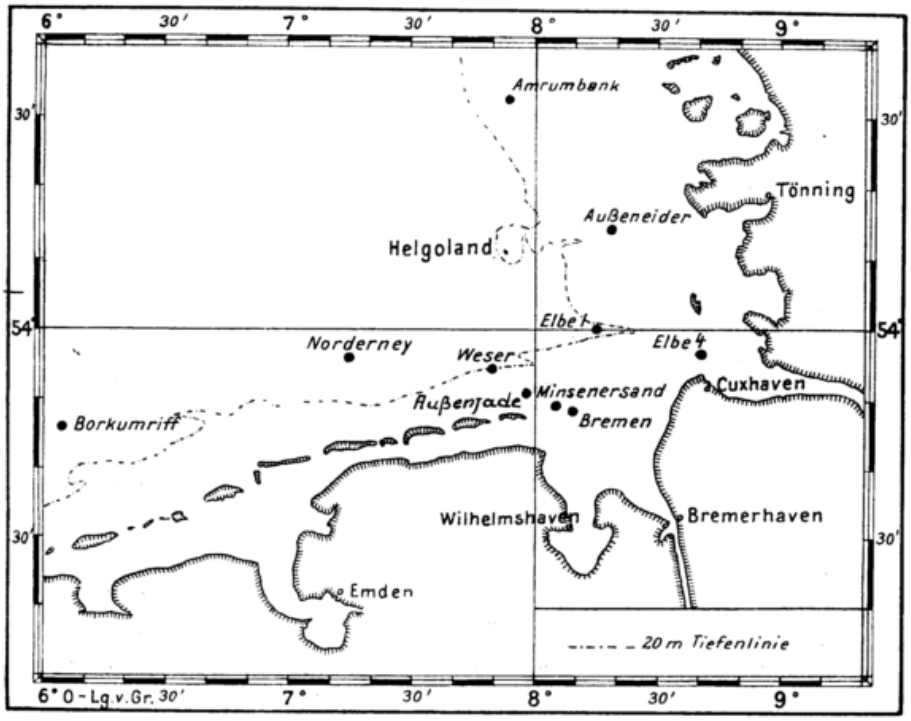

Schon frühzeitig erkannte man, daß die vor der Küste verankerten Feuerschiffe sehr wichtige und sehr geeignete Punkte für regelmäßige meeres- und wetterkundliche Beobachtungen sind. Bereits 1872 richtete daher die Preußische Kommission zur Erforschung der deutschen Meere einen regelmäßigen Beobachtungsdienst ein, und zwar auf den Feuerschiffen „Borkum" und „Außenjade", 1875 auch auf dem Feuerschiff „Weser". Die Beobachtungen, die regelmäßig veröffentlicht wurden, hörten jedoch mit dem Jahrgang 1893 auf.

Nach dem Kriege richtete die Deutsche Seewarte nach und nach auf 12 Nordsee- und 2 Ostsee-Feuerschiffen einen regelmäßigen Beobachtungsdienst ein. Die Veröffentlichung der Beobachtungsergebnisse war allerdings wegen der Inflations- und Deflations-Jahre zunächst nicht möglich. Erst 1928 konnte ein Teil der meereskundlichen Beobachtungen gedruckt werden, nämlich die Jahrgänge 1924 und 1925, in der zu diesem Zweck von der Seewarte gegründeten Veröffentlichung „Meereskundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee". Als weitere Hefte sind inzwischen erschienen: 1929 die Beobachtungsjahrgänge 1926 und 1927, dann 1930 – 1936 in je einem Heft die Beobachtungsjahrgänge 1928—1935, außerdem 1932 in einem Ergänzungsheft die Beobachtungsjahrgänge 1924—1928 der Feuerschiffe „Weser", „Bremen" und „Elbe 4" sowie die Tiefenbeobachtungsjahrgänge 1924—1929 vom Feuerschiff „Fehmarnbelt".

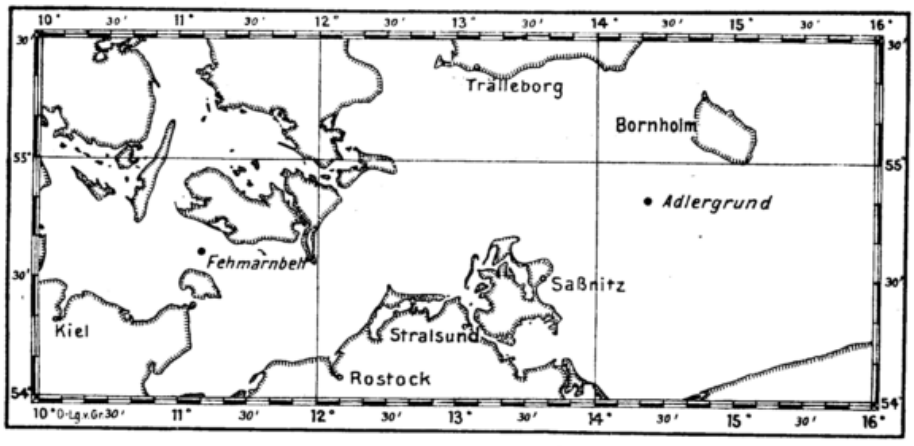

Nachstehende Tabelle zählt die deutschen Feuerschiffe auf, die sich 1935 an den meeres- und wetterkundlichen Beobachtungen beteiligt haben und gibt gleichzeitig ihre wichtigsten Daten. Zwei Kartenskizzen zeigen die Lage der Feuerschiffe in der Nord- und Ostsee.

E. Mühlthaler's Buch- und Kunstdruckerei G.m.b.H., München 2 NW

Die Bearbeitung der wetterkundlichen Beobachtungen konnte erst 1933 aufgenommen werden. Erschienen sind bisher die Jahrgänge 1932 und 1933 als Beihefte zum Deutschen Meteorologischen Jahrbuch (Beobachtungs-System der Deutschen Seewarte) und der Jahrgang 1934 in Teil IV, Heft 4 des Deutschen Meteorologischen Jahrbuches 1934. Die vorliegende Veröffentlichung enthält den Beobachtungsjahrgang 1935.

Die Zahl der täglichen Terminbeobachtungen hat sich gegenüber dem Vorjahr nicht geändert. Bei der Durchführung des Beobachtungsdienstes fand die Deutsche Seewarte volles Verständnis und wirksame Unterstützung von seiten der Besatzungen der Feuerschiffe sowie ihrer vorgesetzten Dienststellen, nämlich der Wasserbauämter Emden, Tönning und Kiel, des Schiffahrtsamtes Cuxhaven, des Seezeichen- und Lotsenamts der Jade in Wilhelmshaven, der Wasserstraßendirektion Bremen und des Hafenbauamts Swinemünde. Allen diesen Stellen sei hier der wärmste Dank der Deutschen Seewarte ausgesprochen.

Deutsche Seewarte.

Vorbemerkungen

Zeitangaben stets nach mitteleuropäischer Zeit.

Da die auf See vor Anker liegenden Feuerschiffe fast immer mehr oder weniger stark ausgeprägten Schwankungen in Seegang und Dünnung unterworfen sind, sind die Luftdruckbestimmungen hier infolge des „Pumpens" des Quecksilbers im Schiffsbarometer zumeist weniger genau als an Landstationen; von einer Veröffentlichung der Luftdruckangaben der Feuerschiffe wurde daher im Rahmen des meteorologischen Jahrbuchs abgesehen.

Lufttemperatur, Luftfeuchtigkeit: Zur Aufstellung der Thermometer sind Thermometerhütten verwendet, deren lichte Höhe, Breite und Tiefe ungefähr betragen: bei Modell I 33, 15.5, 7.5 cm — bei Modell II 40, 18, 15 cm — bei Modell III 40, 49, 30 cm. (Modell III wurde auf Außenjade-Feuerschiff mit Bordmitteln hergestellt, nachdem die vorher dort vorhandene Thermometerhütte durch Wellenschlag zertrümmert worden war). Die feuchten Thermometer sind mit einem Aßmannschen Aspirator versehen.

Es wurde für ausreichend erachtet, von dem Dampfdruck und der relativen Feuchtigkeit nur die Monats- und Jahresmittel zu bringen. Diese Monatswerte sind für die zugehörigen Monatsmittel der am trockenen und feuchten Thermometer abgelesenen Temperaturen den Aspirations-Psychrometer-Tafeln (herausgegeben vom Reichsamt für Wetterdienst) entnommen. Die durch dieses Verfahren bedingten Abweichungen sind nicht von praktischer Bedeutung. Die Jahresmittel wurden dann aus den zugehörigen 12 Monatsmitteln errechnet.

Um festzustellen, inwieweit die an Bord der Feuerschiffe in den Thermometerhütten gemessenen Lufttemperaturen gefälscht sein können, wurden in den Monaten August und September 1936 Vergleichsmessungen durchgeführt unter Benutzung eines strahlungsgeschützten Schleuderthermometers, mit dem die Temperatur der frischen Außenluft auf der Luvseite des Feuerschiffes gemessen wurde. In ungünstigem Fall, nämlich bei starker Sonneneinstrahlung und gleichzeitig schwacher Luftbewegung ($\leq$ 3 Bft) ergab sich die Größenordnung des Fehlers der Thermometerhütte im Mittel zu den Terminen 11, 14, 17 Uhr im August zu + 0.5 bis + 1.0° C, im September um 11 Uhr und 17 Uhr meist kleiner als + 0.5° C und um 14 Uhr ebenfalls zu + 0.5 bis 1.0° C (maximale Fehler traten im August vereinzelt auf bis zu + 5° C und im September bis zu + 2.5° C.)

Dies muß bei der Benutzung der in den folgenden Tabellen enthaltenen Extenso- und Mittelwerte der Lufttemperatur und entsprechend auch der Luftfeuchtigkeit und der Differenz Luft-minus Wassertemperatur berücksichtigt werden.

Wind: Die Windrichtung ist mißweisend angegeben. Die Deviation, die in den Original-Tagebüchern der Feuerschiffe stets vermerkt wird, hält sich innerhalb der Grenzen der Beobachtungsgenauigkeit und wurde deshalb nicht berücksichtigt. Die Windstärken sind nach der Beaufort-Skala geschätzt worden. Die Windrichtung ist in der im Wetterdienst üblichen Strich-Skala 00—32 gegeben.

05 NEzE	12 SE	19 SWzS	26 WNW

Die Windrichtungen mit ungeraden Strichnummern sind nur sehr selten angegeben worden. Die Windstärken $\geq$ 6 sind im Druck hervorgehoben, und zwar Windstärke 6 und 7 durch kleine fette, Windstärke 8—12 durch große fette Typen.

Die Bewölkung ist in Zehnteln des Himmelsgewölbes geschätzt worden.

Bemerkungen: Die in dieser Spalte enthaltenen Beobachtungen über den Ablauf der Witterung sind, soweit es möglich war, ausführlicher als im Vorjahre angegeben. Über die hierbei verwendeten internationalen Zeichen und Abkürzungen siehe „Erläuterungen zu den Tabellen" in Teil I des Deutschen Meteorologischen Jahrbuches.

Messungen des Niederschlags in kardanisch aufgehängten Regenmessern sind zwar auf den Feuerschiffen durchgeführt worden, jedoch wird von einer Veröffentlichung hier abgesehen, weil bei der bekannten Schwierigkeit der Aufstellung von Regenmessern an Bord die einzelnen Meßwerte nicht sicher genug erscheinen. Es wird aber in der Zusammenstellung der Monats- und Jahresmittel, Tabelle Zahl der Tage, wenigstens die Zahl der Tage mit Niederschlag ($\geq$ 10.0 mm, $\geq$ 1.0 mm, $\geq$ 0.1 mm) angegeben.

Die Auszählung der „Tage mit ..." wurde auf Regen, Schnee, Graupel, Hagel, Nebel, Gewitter (mit Donner), Wetterleuchten und Sturm beschränkt.

Die Reihenfolge der Feuerschiffe ist stets wie folgt gegeben (im allgemeinen von West nach Ost fortschreitend): Zuerst die 4 Feuerschiffe in der Nordsee: Borkumriff, Außenjade, Elbe 1, Amrumbank; dann die 2 Feuerschiffe in der Ostsee: Fehmarnbelt und Adlergrund. Seite 1—36 enthält die Extenso-Beobachtungen von Lufttemperatur, Richtung und Stärke des Windes, Bewölkung und „Bemerkungen". Auf Seite 37—41 folgt die Zusammenstellung der Monats- und Jahresmittel für Lufttemperatur, Dampfdruck, Relative Feuchtigkeit, Windstärke, Bewölkung, dazu „Häufigkeit der Windrichtungen in Prozenten" und „Zahl der Tage"; und zwar als Mittelwerte der durchgeführten einzelnen meteorologischen Termine, deren Zahl bei den verschiedenen Feuerschiffen verschieden ist. Diese Verschiedenheit der Beobachtungstermine macht eine gesonderte Zusammenstellung von Gesamtmittelwerten der Monate und des Jahres notwendig (Seite 42 ff.).

Zum Schlusse folgt eine Tabelle, welche gleichzeitig gemessene Luft- und Wassertemperaturen bei den 6 Feuerschiffen in Beziehung setzt (Seite 44).

Allen Feuerschiffen gemeinsam sind aber die *5* Beobachtungszeiten *8, 11, 14, 17, 19h*. Die Gesamt-Monats- und Jahresmittel sind daher, um die unmittelbare Vergleichbarkeit untereinander zu gewährleisten, auf Grund dieser gemeinsamen 5 Termine berechnet worden. Die Mittelbildung geschah arithmetisch, da eine besondere Formel zur Annäherung an das „wahre" (24stündige) Mittel für diese 5 Beobachtungszeiten noch nicht festgestellt ist.

Bei den 3 Feuerschiffen mit Terminen zur Nachtzeit wurden auch die Mittelwerte für *alle* Beobachtungszeiten berechnet (ebenso arithmetisch) und der nachstehenden Tabelle in *Schrägdruck* zum Vergleich hinzugefügt. Diese letzteren Mittelwerte werden bei der Gleichmäßigkeit der Verteilung über die 24 Stunden dem wahren Mittel sehr nahe kommen.

Bei einem Vergleich der Ergebnisse der Feuerschiffsbeobachtungen mit denen der Landstationen ist auf den Unterschied der Mittelbildungen zu achten. **Außerdem ist auch das in den Vorbemerkungen über die Temperaturmessung an Bord Gesagte zu beachten.**

Die Häufigkeit der Windrichtungen im Monats- und Jahresmittel enthält bereits die vorangehende Tabelle.

Mittelwerte von Luft- und Wassertemperaturen und deren Unterschiede nach ausgewählten Terminen.

Im folgenden werden die zu einigen meteorologischen Terminen auf den Feuerschiffen gemessenen Wassertemperaturen in Beziehung zu den gleichzeitigen Lufttemperaturen gesetzt.

Für folgende Beobachtungszeiten sind gleichzeitige regelmäßige Messungen beider Temperaturen vorhanden:

Feuerschiff:	*Beobachtungszeiten:*
Borkumriff	3 Termine: 8 14 19h
Außenjade	2 „ : 8 19h
Elbe 1	5 „ : 8 11 14 17 19h
Amrumbank	5 „ : 8 11 14 17 19h
Fehmarnbelt	5 „ : 8 11 14 17 19h
Adlergrund	2 Termine: 8 19h

Es wurde über diese Termine arithmetisch gemittelt. Wegen der verschiedenen Zahl der Beobachtungstermine ist das Material inhomogen, und die Mittelwerte erlauben daher keinen unmittelbaren Vergleich.

Selbst bei übereinstimmenden Meßzeiten ist aber ein exakter Vergleich ohne weiteres nicht möglich, da die Wassertemperaturen durch die Eigenbewegung des Wassers, vor allem durch die Gezeitenströmungen beeinflußt sind, deren Ausbildung und Auswirkung bei den einzelnen Feuerschiffen verschieden ist und wechselt. Man beachte auch hier das in den Vorbemerkungen über die Messung der Lufttemperatur an Bord Gesagte.

Die Feststellung der Größenordnung der mittleren Wassertemperaturen und der meteorologisch wirksamen Differenz Luft- minus Wassertemperatur ist aber notwendig.

Zur Statistik der Stürme an der deutschen Küste

Vorbemerkungen

Als mit dem Jahre 1878 die Deutsche Seewarte die Herausgabe der „Meteorologischen Beobachtungen in Deutschland" übernahm, die 1887 zum „Deutschen Meteorologischen Jahrbuch" ausgebaut wurden, erschien zum erstenmal als Erweiterung des Inhalts ein Teil III: „Zur Statistik der Stürme an der Deutschen Küste." Dieser dritte Teil, der — wie das Vorwort zu dem Bande sagt — „unter den sonst gebräuchlichen Veröffentlichungen eine besondere Stellung einnimmt", diente der Aufgabe der Seewarte: der Nutzbarmachung meteorologischer Beobachtungen an der Küste für die deutsche Schiffahrt. In lückenloser Folge wurden diese Statistiken bis zum Jahre 1912 veröffentlicht. Sie waren die wichtigsten Unterlagen für die zusammenfassenden Arbeiten: E. Herrmann:[1]) „Die stürmischen Winde an der Deutschen Küste in den Jahren 1878—1887" und L. Großmann:[2]) „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1886—1895" und „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1896—1905."

Der Weltkrieg und seine Folgen zwangen die Seewarte, die Veröffentlichung vom Beobachtungsjahr 1913 ab einzustellen. Erst die Beobachtungen des Jahres 1933 wurden wieder bearbeitet und veröffentlicht in einer Sonderarbeit, die unter dem Titel erschien: „Zur Statistik der Stürme an der Deutschen Küste. Beobachtungsjahr 1933. 1. Jahrgang. Tägliche höchste Windstärke und zugehörige Windrichtung an den deutschen Küstenstationen und auf deutschen Feuerschiffen." Hamburg 1934. Die Untersuchung wurde hier im Gegensatz zu den früheren Bearbeitungen außer auf die Sturmwarnungsstellen auch auf sämtliche meteorologische Beobachtungsstationen an den deutschen Küsten sowie auf die Feuerschiffe ausgedehnt. Wie der Untertitel sagt, wurden für jeden Tag des Jahres — gleichgültig ob Sturmtag oder windschwacher Tag — die höchste Windstärke und die zugehörige Windrichtung für jede Station verzeichnet.

Die vorliegende Bearbeitung für das Jahr 1935 beschränkt sich ebenso wie die für das Jahr 1934 wieder auf die wirklichen Sturmtage und Sturmperioden. Sie ist so angelegt, daß das meteorologisch und praktisch Bedeutsame in klarer Übersicht hervortritt und die geeignete Grundlage geschaffen ist für spätere zusammenfassende Bearbeitungen.

Einteilung der deutschen Küste und Stationsauswahl

Das Küstengebiet der Nordsee wurde als Einheit für sich genommen. In dem ausgedehnten Küstengebiet der Ostsee bildet die Insel Rügen eine natürliche Klimascheide, was schon E. Herrmann[3]) erkannte, der für die Untersuchung der Stürme die Ostseeküste in die beiden Bezirke westlich und östlich von Rügen unterteilte. Der Küstenteil Ostpreußens muß außerdem als eigener Bezirk genommen werden. Für die vorliegende Statistik ist die deutsche Küste daher in folgende **4 Teilgebiete** unterteilt worden (vgl. die nachstehende Übersichtskarte):

Nordsee: Die ganze deutsche Nordseeküste.
Ostsee I: Ostseeküste von der Flensburger Förde bis Arkona auf Rügen.
Ostsee II: Ostseeküste von Arkona auf Rügen bis Stilo.
Ostsee III: Ostpreußische Küste.

Diese Gebietseinteilung der Küste ist also unabhängig von der — früher auch für die Statistik benutzten — Gruppeneinteilung (I—VIII) nach Sturm**warnungs**bezirken!

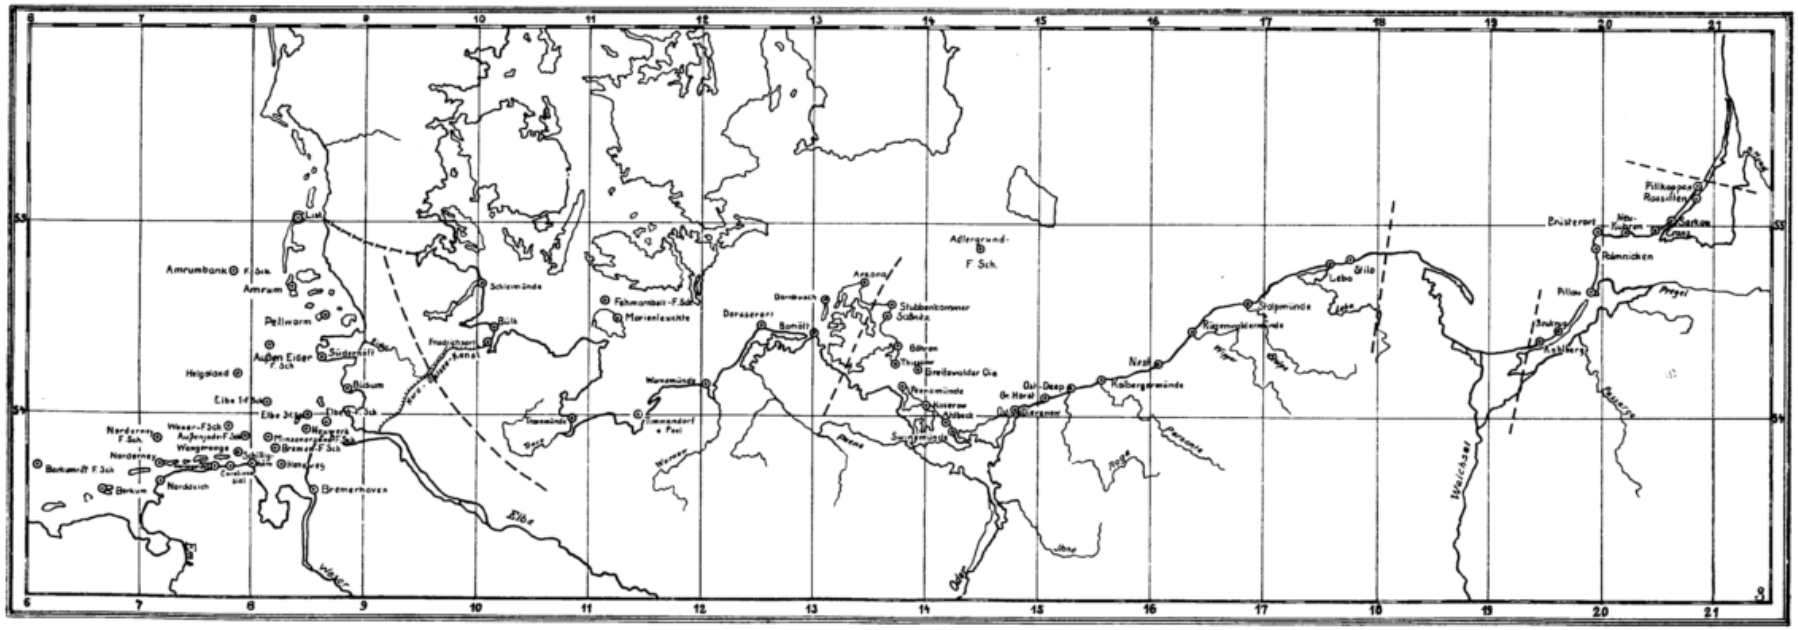

Von den vorhandenen Stationen wurden diejenigen ausgewählt, deren Beobachtungen für das eigentliche **Küstenwetter** als „repräsentativ" anzusehen sind (es wurden also die an den Flüssen landeinwärts oder an Haffküsten gelegenen Stationen fortgelassen); auch wurden nur solche Beobachtungsstellen genommen, von denen möglichst häufige, regelmäßige und einwandfreie Beobachtungen vorliegen. Nach Fortfall der für die Zwecke der vorliegenden Untersuchung nicht geeignet erachteten Stationen blieben für die Nordsee 27, für Ostsee I 12, für Ostsee II 19 und für Ostsee III 10 Beobachtungsstellen, die im folgenden aufgezählt und in die nachstehende Übersichtskarte eingezeichnet sind. Von diesen 69 Beobachtungsstationen der Küste sind **54 Sturmwarnungsstellen** (St) und **13 Feuerschiffe (F),** die übrigen andere meteorologische Stationen.

Ausgewählte Beobachtungsstellen

Einteilung der deutschen Küste in die Bezirke Nordsee, Ostsee I, Ostsee II, Ostsee III

(69 Stationen, davon 54 Sturmwarnungsstellen der Deutschen Seewarte und 13 Feuerschiffe [F.-Sch.]; vergl. Übersichtsliste, Seite 47)

Die Anzahl der Beobachtungen ist bei den Beobachtungsstellen je nach ihrer Art recht verschieden. Die Sturmwarnungsstellen beobachten Wind und Wetter 3 mal täglich, führen außerdem aber zu **Sturmzeiten besondere Zwischenbeobachtungen** (Zw.-Beob.) im Zeitabstand von 2 Stunden aus, so daß gerade die hier untersuchten Sturmzeiten gut besetzt sind. Als ein Mangel erweist sich, daß diese Zwischenbeobachtungen der Sturmsignalisten sich auf die **Tageszeit** beschränken (zwischen 8 und 20 Uhr, höchstens bis 22 Uhr); es wird angestrebt, daß die Signalisten künftig auch Merkmale des Sturmverlaufs während der Nacht im meteorologischen Tagebuch notieren. Von den Feuerschiffen liegen die meisten Beobachtungen vor (bis zu 17 täglich), da sie zumeist jede 3. Stunde Meldungen für den Wetterdienst abgeben und seit dem 1. Januar 1935 alle Nordsee-Feuerschiffe im Rahmen des hydrographischen Beobachtungsdienstes jede zweite Stunde Windrichtung und Windstärke beobachten. Das über Tag und Nacht lückenlos ausgedehnte meteorologische Beobachtungsmaterial der Feuerschiffe kommt der vorliegenden Arbeit sehr zu statten.

Für die Erfassung der Sturmphänomene wurden von den gewählten Stationen alle Beobachtungen systematisch verwertet. Zunächst wurden für jede Beobachtungsstelle die Tage ausgesucht, an denen Windstärke 6 (Beaufort) erreicht oder überschritten wurde; die an dem Tage aufgetretene **höchste** Windstärke wurde dann in Tabellen aufgezeichnet.

Als „Sturmtage" wurden diejenigen Tage bezeichnet, an denen innerhalb eines Bezirkes an mindestens 3 Beobachtungsorten Windstärke 8 Beaufort oder mehr (also Sturm) beobachtet worden ist.

Diese Definition des „Sturmtages" entspricht derjenigen, die bereits 1887 erstmalig gegeben wurde („es müssen stürmische Winde auf größerem Gebiet mindestens an 3 Stationen auftreten").

Für jeden dieser „Sturmtage" wurden für alle Beobachtungsorte die Wind- und Wetterbeobachtungen ausgezogen und zusammengestellt, getrennt für jeden Bezirk. Nach diesen Zusammenstellungen erfolgte die Bestimmung der Merkmale und des Verlaufs eines jeden Sturms bezw. einer Sturmperiode. Für jeden Bezirk wurde die mittlere (vorherrschende) Richtung und Stärke des Sturms, die Art der Verbreitung, Beginn und Ende, die Anfangs- und Endrichtung des Sturmes, seine größte Stärke und in Kürze auch der Witterungsverlauf ermittelt.

Diese Angaben wurden dann in **gleicher** Reihenfolge zusammengestellt, für jeden Sturm in der folgenden Übersicht: „Verlauf und Merkmale der Stürme."

Bezüglich der Verbreitung innerhalb eines Bezirks wurde ein dreifacher Unterschied gemacht:

„Örtlicher" Sturm: mindestens 3, aber weniger als die Hälfte aller Beobachtungsorte haben Windstärke ≥ 8 Beaufort (Bft.).

„Verbreiteter" Sturm: gleich oder mehr als die Hälfte aller Beobachtungsorte Windstärke ≥ 8 Bft.

„Allgemeiner" Sturm: alle Beobachtungsorte Windstärke ≥ 8 Bft.

Der NW-Sturm am 13. April

Nordsee: **NW 8,** Ostsee I: **NW 8,** Ostsee II: **WNW 8**

Lage: Ein Tiefdruckgebiet mit zahlreichen Teilkernen erstreckt sich vom europäischen Nordmeer über die Ostsee und Polen bis nach den Donauländern und Oberitalien. Dem starken Druckfallgebiet, das am Nachmittag des 12. über Mittel- bzw. Südostdeutschland das am 13. 8^h über Nordpolen gelegene Tief (995 mb) entstehen ließ, folgte schnell ein sehr kräftiges Drucksteiggebiet. Dieses baute einen Hochdruckkeil auf, der schnell ostwärts vordrang und so die den Sturm hervorrufende Verschärfung der Druckgegensätze entstehen ließ.

Nordsee: 13. IV. **Örtlich,** Wesermündung bis Nordfriesische Inseln / zwischen 7^h und 10^h — 14^h oder 16^h / WNW, NW, NNW, meist NW / Bft. **8**, vereinzelt in Sturmböen Bft. **9** / ganzen Tag ❡, ❡, ❡, besonders vormittags und nachmittags.

Lage: Eine vom mittelrussischen Tiefdruckgebiet ausgehende und über die Karpathen, Schlesien und Jütland bis in den Raum nördlich von Island reichende Tiefdruckfurche trennt das britische Hoch von dem über der nördlichen Barentssee gelegenen. Aus dieser Tiefdruckfurche spalten sich zwei Teiltiefs ab. Das über Jütland befindliche vertieft sich (am 29. 19^h unter 1015 mb) und zieht in der Nacht vom 29. zum 30. zur Pommerschen Bucht. Am 30. 8^h liegt es, auf unter 1010 mb vertieft, nördlich der Odermündung und zieht im Laufe des Tages nach Südosten weiter. Auf seiner Rückseite dringt hoher Druck von Skandinavien aus südostwärts vor.

Zeitweise stürmischer NW in der Nordsee am 12. und 13. Mai

Nordsee: **NW 8**

Lage: Die bestehende Luftdruckverteilung — ein starkes Hoch über Nordwesteuropa und ein umfangreiches Tiefdruckgebiet mit zahlreichen Tiefkernen über Rußland — entspricht ganz dem Typus einer sommerlichen Monsun-Wetterlage. Druckfall- und Drucksteiggebiete, die die an der Ostflanke des nordwesteuropäischen Hochs nach Süden und Südosten vordringenden Staffeln der Kaltluft arktischen Ursprungs begleiten, rufen zeitweilig eine erhebliche Verschärfung der Druckgegensätze hervor. Diese wirkt sich in einem zeitweisen Auffrischen der nordwestlichen Winde bis zu Sturmstärke in der östlichen Nordsee aus.

Nordsee, Ostsee I: **SW 8**

Lage: Nur wenige Stunden hält die Wetterberuhigung, die der dem nach Mittelschweden abgezogenen Tief nachfolgende Hochdruckkeil bringt, an. Bereits am Abend des 30. wird das zwischen den Faröern und Nordschottland hindurch langsam zum europäischen Nordmeer vordringende Tief (30. 19^h 955 mb) wetterwirksam. Am 31. 8^h liegt der Kern (960 mb) des Tiefs dicht nordöstlich der Faröer. Im Laufe des Tages wird er aber rückläufig und verlagert sich in den Raum nordwestlich der Faröer. An der über der Nordsee nur langsam ostwärts vorrückenden und am 31. 8^h über Südskandinavien, Dänemark und Südengland in den Raum nördlich der Azoren verlaufenden Kaltfront bildet sich eine Wellenstörung, die sehr schnell nordostwärts zieht und abermals Sturm hervorruft.
