Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamts für Wetterdienst in Potsdam werden die im Deutschen Meteorologischen Jahrbuch 1935, Teil IV, Heft 1, veröffentlichten „Beobachtungen des Observatoriums Potsdam" fortgesetzt. Inhalt und Umfang sind gegen die Vorjahre nahezu unverändert.

Die Beobachtungstermine sind 7^h, 14^h und 21^h Ortszeit. Die Gesamtsummen des Niederschlages und der Verdunstung werden um 7^h, die Temperaturextreme um 21^h für die vorhergehenden 24 Stunden bestimmt und dem Datum des Meßtages zugeschrieben. Die Regen- und Schneemessungen werden auf der Beobachtungswiese, letztere auf einem Zementfeld, durchgeführt; die Schneehöhen sind Mittelwerte aus mehreren Messungen. Die Bewölkungsmengen werden 2-stündlich zur vollen Stunde mittlerer Ortszeit geschätzt.

Von den hier veröffentlichten Registrierungen beziehen sich Luftdruck, Lufttemperatur und Luftfeuchtigkeit auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte ab 1936 nach der Formel:

$$(0^h + 1^h + \ldots\ldots\ldots\ldots + 23^h) : 24.$$

Die Werte für Windrichtung, Windgeschwindigkeit und luftelektrisches Potentialgefälle sind Stundenmittel, diejenigen für Niederschlag, Sonnenscheindauer und Wärmesummen der Sonnenstrahlung Stundensummen. Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck. Die Werte sind dem Sprungschen Waagebarographen entnommen und werden durch Vergleichsbeobachtungen täglich einmal auf das Gefäßheberbarometer Wild-Fueß Nr. 248 reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Die Meßgeräte sind auf der Beobachtungswiese in der großen englischen Hütte, 2,1 m über dem Erdboden, aufgestellt. Die Terminwerte der Temperatur und Feuchtigkeit sind Ablesungen an einer Thermometeraufstellung nach August mit einem Aspirator für das feuchte Thermometer. Alle Feuchteangaben sind auf das aspirierte Psychrometer reduziert. Die unter den Terminbeobachtungen veröffentlichten Tagesmittel der Lufttemperatur werden nach der Formel $(7^h + 14^h + 2 \times 21^h) : 4$, die des Luftdrucks und der Dampfspannung aus dem arithmetischen Mittel berechnet. Als Registriergeräte dienen ein Richardscher Thermograph mit 8tägigem Umlauf und ein Richardscher Hygrograph mit 1tägigem Umlauf.

3. Windmessung. Windrichtung und -geschwindigkeit werden mit einem mechanischen Schalenkreuz-Anemograph auf dem Turm des Observatoriums in 41.0 m Höhe über dem Erdboden registriert.

4. Niederschlags- und Verdunstungsmessung. Regenmenge und -dauer werden mit einer Sprung-Fueßschen Registrierwaage für Niederschlag und Verdunstung gemessen. Ferner ist noch ein mechanisch registrierender Regenmesser, System Hellmann-Fueß, mit 200 cm^2 Auffangfläche auf der Beobachtungswiese aufgestellt. Der Verdunstungsmessung dient ebenfalls noch ein Wildsches Evaporimeter mit 200 cm^2 Verdunstungsfläche, das in einer englischen Hütte auf der Beobachtungswiese beschattet, regensicher und windgeschützt aufgestellt ist.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit einem Sonnenscheinautographen Campbell-Stokes und mit einem Autographen nach Jordan (Zelloidinpapier), die auf dem Turm des Observatoriums in 34 m Höhe über dem Erdboden aufgestellt sind.

6. Erdbodentemperatur. Das Meßfeld befindet sich auf der Beobachtungswiese in kiesigem, humusfreiem Sand, dessen Oberfläche von Pflanzenwuchs und im Winter von Schnee frei gehalten wird. Für die Tiefen von 0,5 bis 12 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in Schutzröhren von Neusilber gesteckt werden. Abweichend von den Vorjahren werden für die Tiefen bis 50 cm die Terminablesungen 7^h, 14^h, 21^h mitgeteilt; für größere Tiefen werden die Ablesungen nur am 14^h-Termin ausgeführt.

7. Sonnenstrahlungsintensität: Die Messung der Sonnenintensität wird mit einem Bimetall-Lamellen-Aktinometer nach Michelson-Marten durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer und das Silverdisk-Aktinometer S I XII benutzt. Die Angaben sind auf die Smithsonian-Skala 1913 reduziert und die „Luftmassen" auf den zur Zeit der Beobachtungen herrschenden Barometerstand umgerechnet. Die mitgeteilten Wärmesummen sind nach den Aufzeichnungen eines thermoelektrischen Pyrheliographen, System Moll-Gorczynski, berechnet; die Summenbildung ist durch planimetrische Auswertung nach den Registrierungen eines Schlagbügelgalvanometers von Hartmann und Braun vorgenommen worden.

8. Luftelektrische Messungen. Auf der Beobachtungswiese wird das luftelektrische Potentialgefälle mit Benndorf-Elektrometern in 2 verschiedenen Empfindlichkeitsbereichen und Poloniumkollektor gemessen. Eine weitere Meßeinrichtung, jedoch mit Radiothorkollektor, befindet sich auf dem Turm des Observatoriums. Die veröffentlichten Werte sind auf die freie Ebene reduziert.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamtes für Wetterdienst in Wahnsdorf werden die im Meteorologischen Jahrbuch 1935, Teil IV, Heft 2, veröffentlichten „Beobachtungen des Observatoriums Wahnsdorf" fortgesetzt. Inhalt und Umfang sind gegen das Vorjahr etwas erweitert. Neu hinzugekommen sind:

1. die Niederschlagsmessungen auf Seite 30—33,
2. Angaben über die Luftmasse nach Bemporad bei den Messungen der Sonnenintensität auf den Seiten 58—64,
3. die Zusammenstellungen auf den Seiten 83—85.

Die Terminbeobachtungen sind im Teil I des Jahrbuches abgedruckt.

Von den hier veröffentlichten Registrierungen beziehen sich Luftdruck, Lufttemperatur, Luftfeuchtigkeit und elektrische Leitfähigkeit der Luft auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte nach der Formel

$$(1^h + 2^h + \ldots\ldots\ldots\ldots + 23^h + 24^h) : 24 \quad .$$

Die Werte für Windrichtung, Windgeschwindigkeit, Abkühlungsgröße und luftelektrisches Potentialgefälle sind Stundenmittel. Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden.

Unsichere und interpolierte Werte sind kursiv gedruckt.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck. Die Stundenwerte des Luftdruckes sind dem Schreiberschen Waagebarographen entnommen und werden durch Vergleichsbeobachtungen (täglich 5mal) auf das Fueßsche Stationsbarometer Nr. 2294 reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Die Meßgeräte sind auf der Beobachtungswiese in einer Schreiberschen Hütte 2,5 m über dem Erdboden aufgestellt. Die Terminwerte von Temperatur und Feuchte werden mit einer Thermometeraufstellung bestimmt, deren feuchtes Thermometer seit 1936 mit künstlicher Ventilation versehen ist. Alle Feuchteangaben sind auf das aspirierte Psychrometer reduziert. An Registriergeräten waren vorhanden: 1 Fueßscher Thermograprah und 1 Lambrechtscher Hygrograph mit Tagesumlauf und 1 Fueßscher Thermograph und 1 Fueßscher Hygrograph mit Wochenumlauf.

3. Windmessung. Die Windmessungen auf dem Turme des Observatoriums sind im Jahre 1936 zunächst noch mit dem alten Instrumentarium durchgeführt worden, nämlich dem großen Schreiberschen Windapparat, dem Fueßschen Kontaktanemometer Nr. 2485, dem Schreiberschen Stauplattengerät und dem Böenschreiber Dines/Casella.

Im Frühjahr 1936 wurde auf dem Turm des Observatoriums als weiterer Windapparat der Fueßsche „Universalapparat" Nr. 28235 aufgestellt und am 22. Mai 1936 in Betrieb genommen. Sein Schalenkreuz befand sich in 28 m Höhe über dem Erdboden, also in gleicher Höhe mit dem Schreiberschen Schalenkreuz. Bis Ende Oktober 1936 konnten Vergleichsmessungen zwischen dem Schreiberschen Apparat und dem Universalapparat durchgeführt werden. Dann wurde mit dem Umbau des Turmes und mit dem Abbruch sämtlicher Schreiberscher Windgeräte begonnen. Vorher war der Universalapparat auf die Nordseite des Turmes gesetzt worden, und zwar so, daß sein Schalenkreuz 25 m über dem Erdboden zu stehen kam. Diese geringere Höhe konnte unbedenklich gewählt werden, da beim Turmumbau alle störenden Aufbauten auf dem Turm beseitigt wurden. Vom 15. November 1936 ab wurde zur Windregistrierung nur noch der Fueßsche Universalapparat benutzt. Daneben wurden auf einem provisorisch errichteten Mast gelegentlich noch Messungen mit Kontaktanemometern vorgenommen.

Die Untersuchungen über den Anschluß der alten Reihe an die neue sind noch nicht abgeschlossen; Näheres hierüber wird später mitgeteilt werden. Bei Benutzung der Windtabellen muß deshalb streng beachtet werden, daß die auf den Seiten 34—45 abgedruckten Windregistrierungen bis zum 14. November 1936 mit dem Schreiberschen Gerät und vom 15. November 1936 ab mit dem Universalapparat gewonnen sind.

Die Registrierung der Windgeschwindigkeit in 2,5 m über dem Boden erfolgte mit einem Fueßschen Kontaktanemometer, das auf der Instrumentenwiese aufgestellt und an einen Chronographen angeschlossen war.

4. Niederschlagsmessung. Seit 1936 liegen den veröffentlichten Niederschlagsmengen die Ergebnisse zu Grunde, die mit einem Hellmannschen Regenmesser von 200 qcm Auffangefläche und einem heizbaren registrierenden Regenmesser nach Hellmann, Bauart Fueß, gewonnen worden sind. Vorher sind lediglich die mit dem Schreiberschen Regenmesser mit 500 qcm Auffangefläche gemessenen Niederschläge veröffentlicht worden, die um etwa 10 % höher lagen. Die Vergleichsmessungen zwischen den beiden Niederschlagsmessern werden fortgesetzt.

Es ist versucht worden, die Niederschlagszeiten so genau wie möglich festzulegen. Zu diesem Zwecke wurden die Angaben des registrierenden Regenmessers, die bei schwachen Niederschlägen nicht mehr brauchbar sind, noch ergänzt durch Augenbeobachtungen und vor allem durch die Aufzeichnungen der luftelektrischen Leitfähigkeit, da in diesen Registrierungen selbst sehr schwache Niederschläge deutlich hervortreten.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit einem Sonnenscheinautographen nach Campbell/Stokes.

6. Erdbodentemperaturen. Das Meßfeld befindet sich auf der Instrumentenwiese in lehmigem Kies und wird von Pflanzenwuchs freigehalten. Im Winter wird eine etwa vorhandene Schneedecke nicht entfernt. Für die Tiefen von 0,5—2,5 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in eiserne Schutzröhren gesteckt werden.

7. Sonnenstrahlungsintensität. Die Messung der Sonnenintensität wird mit einem Aktinometer nach Michelson-Marten durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer Nr. 143 benutzt. Gemessen werden die Gesamtstrahlung und die Strahlung hinter dem Rotfilter RG 2 und dem Gelbfilter OG 1, beides Potsdamer Standard. An den mit Filtern ausgeführten Messungen sind keine Korrektionen angebracht. Die Angabe der Intensitäten erfolgt in cal cm^{-2} min^{-1}. Soweit es irgend möglich war, ist stets zur vollen Stunde wahrer Ortszeit gemessen worden. Mußte ausnahmsweise zu anderen Zeiten gemessen werden, so erfolgte, wenn es sich nur um geringe zeitliche Abweichungen handelte und keine anderen Bedenken dagegen sprachen, eine Reduktion der Intensitätswerte auf die volle Stunde wahrer Ortszeit.

8. Luftelektrische Messungen. Das luftelektrische Potentialgefälle wird mit Benndorf-Elektrometern in zwei verschiedenen Empfindlichkeitsbereichen und einem im Freien aufgestellten Radiothorkollektor gemessen. Veröffentlicht werden Stundenmittel in Volt/m. Der Reduktionsfaktor, dessen Einzelwerte zwischen 0,8 und 1,2 schwanken, ist zu 1,0 angenommen worden.

Die luftelektrische Leitfähigkeit wird nach der Scheringschen Methode gemessen. In einem Drahtkäfig von 17 m Länge und 1 m^2 Querschnitt ist ein Draht ausgespannt, der durch Uhrwerk und Relais in einem Wechsel von 10 Minuten entweder auf + 300 oder auf — 300 Volt aufgeladen wird. Aus den Kurven der Entladungsgeschwindigkeit, die von einem Benndorf-Elektrometer aufgezeichnet werden, wird unter Berücksichtigung des Isolationsfehlers für jede volle Stunde die positive und negative elektrische Leitfähigkeit der Luft berechnet. Die Angabe der Werte erfolgt in elektrostatischem Maß in 10^{-4} sec^{-1}.

9. Abkühlungsgröße. Zur Bestimmung der Abkühlungsgröße wird ein Davoser Frigorimeter benutzt, dessen Kupferkugel auf der Instrumentenwiese in 2,5 m Höhe über dem Erdboden in der Nähe der Thermometerhütte aufgestellt ist. Daneben befindet sich in gleicher Höhe ein Fueßsches Kontaktanemometer. Die Aufzeichnung der Stundenmittel der Abkühlungsgröße erfolgt mit einem Registriergerät eigener Bauweise. Zur Kontrolle der Registrierungen werden an der Frigorimeteruhr täglich 4—5 Augenablesungen vorgenommen. Gemessen wird die Abkühlungsgröße in mcal $cm^{-2}sec^{-1}$.

10. Koordinaten des Observatoriums

Geographische Breite: $\varphi = 51°7'$ N
Geographische Länge: $\lambda = 13°41'$ E
Höhe des Geländes über Normal-Null: H = 246 m

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Einleitung

Mit der vorliegenden Veröffentlichung der Beobachtungen und Registrierungen am Meteorologischen Observatorium des Reichsamtes für Wetterdienst in Aachen werden die im Deutschen Meteorologischen Jahrbuch 1935, Teil IV. Heft 3, veröffentlichten „Beobachtungen des Observatoriums Aachen" fortgesetzt. Inhalt und Umfang sind gegen das Vorjahr erweitert. — Die Terminbeobachtungen sind im Teil I des Deutschen Meteorologischen Jahrbuchs abgedruckt.

Von den hier abgedruckten Registrierungen beziehen sich Luftdruck, Lufttemperatur und Luftfeuchtigkeit auf die Angaben zur vollen Stunde. Die Berechnung der Tagesmittel dieser Elemente erfolgte nach der Formel:

$$(1^h + \ldots\ldots 24^h) : 24$$

Die Werte für Windrichtung und Windgeschwindigkeit sind Stundenmittel, die der Niederschlagsmengen Stundensummen; Niederschlagsdauer und Sonnenscheindauer sind in Stunden angegeben. Alle Registrierungen sind, soweit nichts anderes vermerkt ist, nach mittlerer Ortszeit ausgewertet worden.

Zur Erläuterung der Registrierungen und Beobachtungen dienen die nachstehenden Hinweise:

1. Luftdruck. Die Werte sind einem Richardschen Wochenbarographen entnommen und werden durch Vergleichsbeobachtungen auf ein Fueßsches Gefäßbarometer reduziert.

2. Lufttemperatur und Luftfeuchtigkeit. Der Fueßsche Tagesthermograph und der Fueßsche Tageshygrograph stehen auf der Wiese in einer englischen Hütte in 2,1 m Höhe über dem Erdboden. Die Werte werden durch Vergleich mit einem Normalthermometer und einem aspirierten Psychrometer korrigiert.

3. Windmessung. Windrichtung und -geschwindigkeit werden mit einem Fueßschen Schalenkreuz-Anemographen auf dem Turm des Observatoriums in 27,0 m Höhe über dem Erdboden registriert.

4. Niederschlagsmessung. Als Meßgerät wird ein auf der Wiese aufgestellter registrierender Regenmesser nach Hellmann benutzt, dessen Auffangfläche von 200 cm^2 sich 1 m über dem Erdboden befindet.

5. Sonnenscheindauer. Die Aufzeichnung der Sonnenscheindauer erfolgt mit einem Sonnenscheinautographen Campbell-Stokes, der auf dem Turm des Observatoriums in 22,5 m Höhe über dem Erdboden aufgestellt ist.

6. Erdbodentemperatur. Als Meßfeld dient ein auf der Beobachtungswiese befindliches künstliches Sandfeld, dessen Oberfläche von Pflanzenwuchs freigehalten wird.

7. Sonnenstrahlungsintensität. Die Messung der Sonnenintensität wird mit einem Michelson-Büttner-Bimetall-Aktinometer auf der Plattform des Observatoriums (214 m über N. N.) durchgeführt. Für Vergleichsmessungen wird das Angströmsche Kompensationspyrheliometer benutzt. Die Intensitätsmessungen in 3 Spektralbereichen sind in cal cm^{-2} min^{-1} auf wahre Ortszeit bezogen. Die Angaben sind auf die Smithsonian-Skala 1913 reduziert.

8. Koordinaten des Observatoriums

Geographische Breite $\varphi = 50^0\ 47'$ N
Geographische Länge $\lambda = 6^0\ 6'$ E
Höhe des Stationsgeländes über Normal Null H = 202 m.

Nähere Erklärungen zum Tabelleninhalt und zu den internationalen Zeichen sind aus dem Teil I des Deutschen Meteorologischen Jahrbuchs ersichtlich.

Wetterkundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee

Einleitung

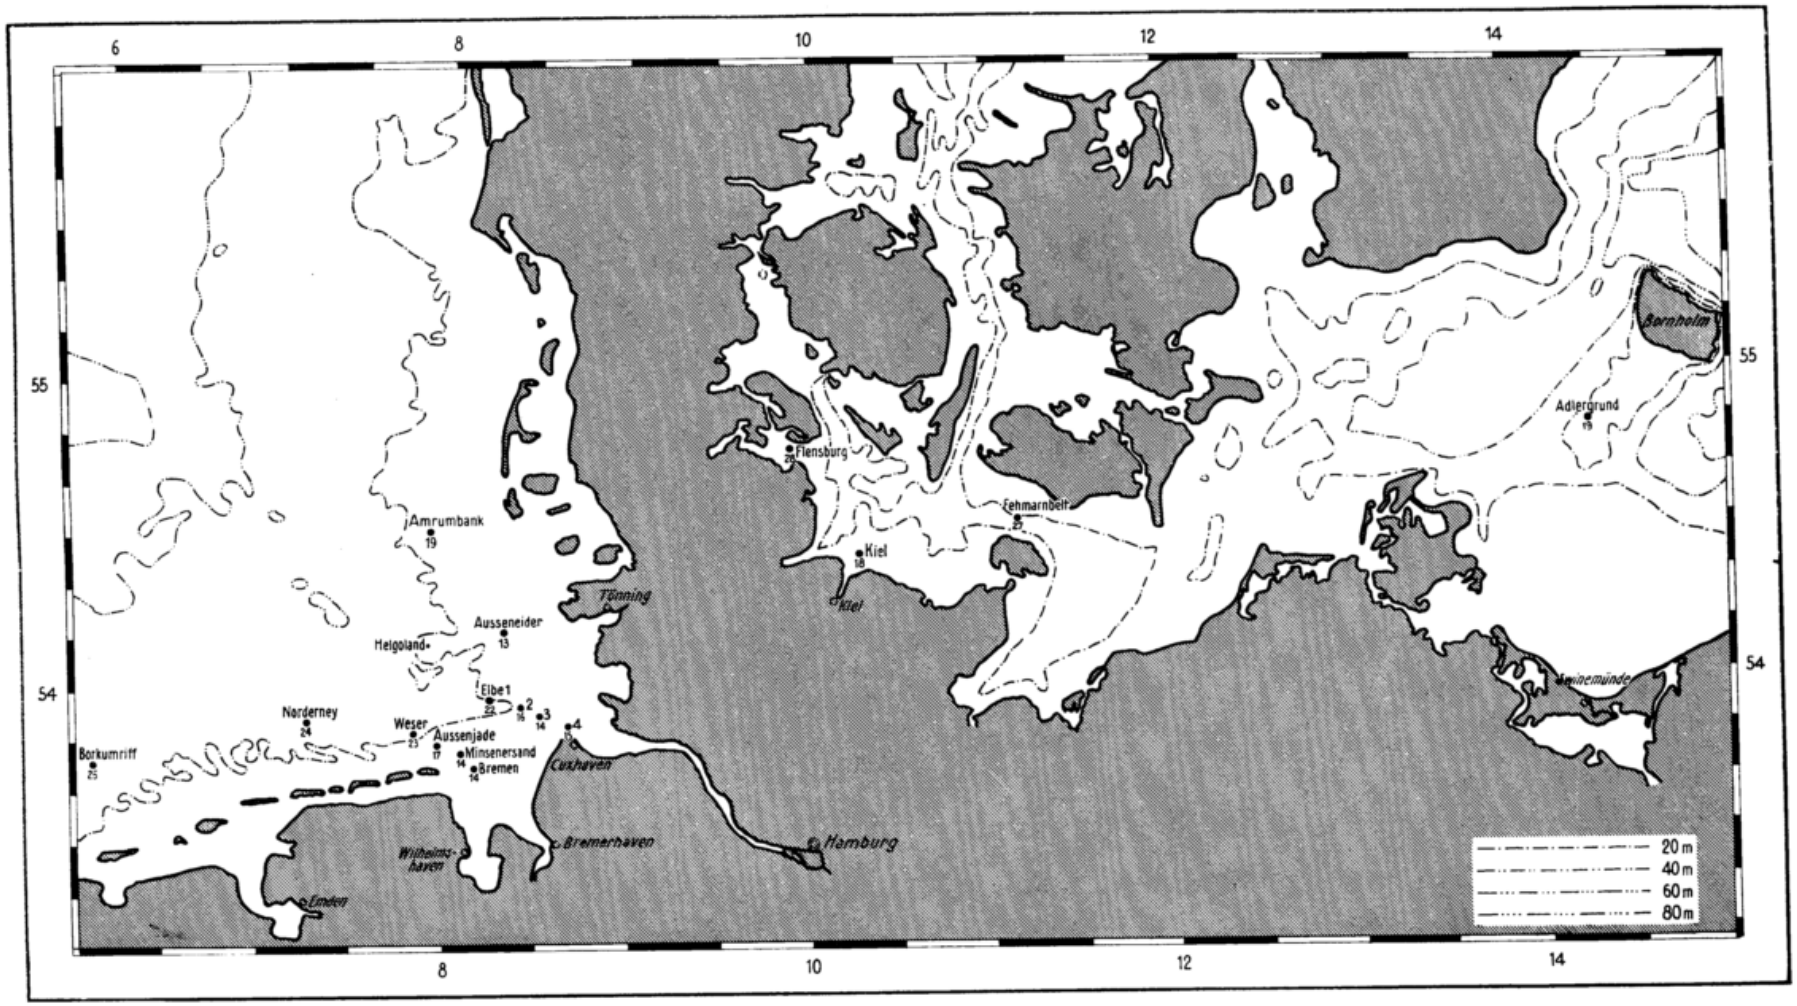

Schon frühzeitig erkannte man, daß die vor der Küste verankerten Feuerschiffe sehr wichtige und geeignete Punkte für regelmäßige meeres- und wetterkundliche Beobachtungen sind. Bereits 1872 richtete daher die Preußische Kommission zur Erforschung der deutschen Meere einen regelmäßigen Beobachtungsdienst ein, und zwar auf den Feuerschiffen „Borkum" und „Außenjade", 1875 auch auf dem Feuerschiff „Weser". Die Beobachtungen, die regelmäßig veröffentlicht wurden, hörten jedoch mit dem Jahrgang 1893 auf.

Nach dem Kriege richtete die Deutsche Seewarte nach und nach auf 12 Nordsee- und 4 Ostsee-Feuerschiffen einen regelmäßigen Beobachtungsdienst ein. Die Veröffentlichung der Beobachtungsergebnisse war allerdings wegen der Inflations- und Deflations-Jahre zunächst nicht möglich. Erst 1928 konnte ein Teil der meereskundlichen Beobachtungen gedruckt werden, nämlich die Jahrgänge 1924 und 1925, in der zu diesem Zweck von der Seewarte gegründeten Veröffentlichung „Meereskundliche Beobachtungen auf deutschen Feuerschiffen der Nord- und Ostsee". Als weitere Hefte dieser Reihe sind inzwischen erschienen: 1929 die Beobachtungsjahrgänge 1926 und 1927, dann 1930 – 1937 in je einem Heft die Beobachtungsjahrgänge 1928—1936, außerdem 1932 in einem Ergänzungsheft die Beobachtungsjahrgänge 1924—1928 der Feuerschiffe „Weser", „Bremen" und „Elbe 4" sowie die Tiefenbeobachtungsjahrgänge 1924—1929 vom Feuerschiff „Fehmarnbelt".

Nachstehende Tabelle zählt die deutschen Feuerschiffe auf, die sich 1936 an den meeres- und wetterkundlichen Beobachtungen beteiligt haben und gibt gleichzeitig ihre wichtigsten Daten. Die Abbildung (S. V) zeigt die Lage der Feuerschiffe in der Nord- und Ostsee.

Lage der deutschen Feuerschiffe der Nord- und Ostsee.

Die Zahlen geben die Wassertiefe in m an.

Die Bearbeitung der wetterkundlichen Beobachtungen konnte erst 1933 aufgenommen werden. Erschienen sind bisher die Jahrgänge 1932 und 1933 als Beihefte zum Deutschen Meteorologischen Jahrbuch (Beobachtungs-System der Deutschen Seewarte) und die Jahrgänge 1934 und 1935 in Teil IV, Heft 4 des Deutschen Meteorologischen Jahrbuches 1934 und 1935. Die vorliegende Veröffentlichung enthält den Beobachtungsjahrgang 1936.

Im Jahre 1936 wurden 2 weitere Ostsee-Feuerschiffe Beobachtungsstationen der Seewarte, nämlich „Kiel" und „Flensburg". Seit 1. Juli 1936 beobachten diese zunächst zu den Terminen 2, 8, 14 und 19 Uhr. Bei den übrigen 6 Feuerschiffen hat sich die Zahl der täglichen Terminbeobachtungen gegenüber dem Vorjahr nicht geändert.

Bei der Durchführung des Beobachtungsdienstes fand die Deutsche Seewarte volles Verständnis und wirksame Unterstützung von seiten der Besatzungen der Feuerschiffe sowie ihrer vorgesetzten Dienststellen, nämlich der Wasserbauämter Emden, Tönning und Kiel, des Wasserstraßenamtes Cuxhaven, des Seezeichen- und Lotsenamts der Jade in Wilhelmshaven, der Wasserstraßendirektion Bremen und des Hafenbauamts Swinemünde. Allen diesen Stellen sei hier der wärmste Dank der Deutschen Seewarte ausgesprochen.

Die starken Stürme im letzten Viertel des Jahres brachten teilweise einen Ausfall der Beobachtungen mit sich, da die Nordsee-Feuerschiffe „Borkumriff", „Außenjade" und „Elbe 1" gezwungen waren, zeitweise ihre Stationen zu verlassen. „Elbe 1" ist am 27. Oktober bei orkanartigem Sturm gekentert, wobei die gesamte Besatzung den Seemannstod fand. Der tapferen pflichtreuen Besatzung, die bis zum letzten Augenblick ihre Beobachtungstätigkeit versah, sei auch an dieser Stelle in Ehren und Dankbarkeit gedacht.

Vorbemerkungen

Zeitangaben stets nach mitteleuropäischer Zeit.

Da die auf See vor Anker liegenden Feuerschiffe fast immer mehr oder weniger stark ausgeprägten Schwankungen in Seegang und Dünung unterworfen sind, sind die Luftdruckbestimmungen infolge des „Pumpens" des Quecksilbers im Schiffsbarometer hier zumeist weniger genau als an Landstationen; von einer Veröffentlichung der Luftdruckangaben der Feuerschiffe wurde daher im Rahmen des meteorologischen Jahrbuchs abgesehen.

Lufttemperatur, Luftfeuchtigkeit: Zur Aufstellung der Thermometer sind Thermometerhütten verwendet, deren lichte Höhe, Breite und Tiefe ungefähr betragen: bei Modell I 33, 15.5, 7.5 cm — bei Modell II 40, 18, 15 cm — bei Modell III 40, 49, 30 cm. (Modell III wurde auf Außenjade-Feuerschiff mit Bordmitteln hergestellt, nachdem die vorher dort vorhandene Thermometerhütte durch Wellenschlag zertrümmert worden war). Die feuchten Thermometer sind mit einem Aspirator versehen.

Es wurde für ausreichend erachtet, von dem Dampfdruck und der relativen Feuchtigkeit nur die Monats- und Jahresmittel zu bringen.

Um festzustellen, inwieweit die an Bord der Feuerschiffe in den Thermometerhütten gemessenen Lufttemperaturen gefälscht sein können, wurden in den Monaten August bis Dezember 1936 Vergleichsmessungen durchgeführt unter Benutzung eines strahlungsgeschützten Schleuderthermometers, mit dem die Temperatur der frischen Außenluft auf der Luvseite des Feuerschiffs gemessen wurde. In ungünstigem Fall, nämlich bei starker Sonneneinstrahlung und gleichzeitig schwacher Luftbewegung ($\leq$ 3 Bft.) ergab sich die Größenordnung des Fehlers der Thermometerhütte im Mittel zu den Terminen 11, 14, 17 Uhr im August zu + 0.5 bis + 1.0° C, im September um 11 Uhr und 17 Uhr meist kleiner als + 0.5° C und um 14 Uhr ebenfalls zu + 0.5 bis 1.0° C; in den Monaten Oktober bis Dezember sinkt der Fehler auch um 14 Uhr im Mittel unter 0.3° C. Maximale Fehler traten im August vereinzelt auf bis zu + 5° C, im September bis zu + 2.5° C, in den Monaten Oktober bis Dezember zu + 2° bis + 1° C.

Dies muß bei der Benutzung der in den folgenden Tabellen enthaltenen Extenso- und Mittelwerte der Lufttemperatur und entsprechend auch der Luftfeuchtigkeit und der Differenz Luft- minus Wassertemperatur berücksichtigt werden.

Zur Vermeidung dieser Fehler sind die Feuerschiffe „Kiel" und „Flensburg" bei ihrem erstmaligen Einsatz nur mit dem „Schleuderthermometer" ausgerüstet worden, desgl. „Elbe 1" bei der Wiedereinrichtung. Beschreibung des Schleuderthermometers siehe Annalen d. Hydr. u. marit. Met. 1936, S. 57/60. Ab Januar 1937 beobachten alle Feuerschiffe die Lufttemperatur nur mit dem Schleuderthermometer (hierbei fällt die Bestimmung der Luftfeuchte bis auf weiteres fort).

Wind: Die Windrichtung ist mißweisend angegeben. Die Deviation, die in den Original-Tagebüchern der Feuerschiffe stets vermerkt wird, hält sich innerhalb der Grenzen der Beobachtungsgenauigkeit und wurde deshalb nicht berücksichtigt. Die Windstärken sind nach der Beaufort-Skala geschätzt worden. Die Windrichtung ist in der im Wetterdienst üblichen Strich-Skala 00—32 gegeben.

00 Still	07 EzN	14 SSE	21 SWzW	28 NW
01 NzE	08 E	15 SzE	22 WSW	29 NWzN
02 NNE	09 EzS	16 S	23 WzS	30 NNW
03 NEzN	10 ESE	17 SzW	24 W	31 NzW
04 NE	11 SEzE	18 SSW	25 WzN	32 N
05 NEzE	12 SE	19 SWzS	26 WNW	
06 ENE	13 SEzS	20 SW	27 NWzW	

Die Windrichtungen mit ungeraden Strichnummern sind nur sehr selten angegeben worden. Die Windstärken $\geq$ 6 sind im Druck hervorgehoben, und zwar Windstärke 6 und 7 durch kleine fette, Windstärke 8—12 durch große fette Typen.

Seit August 1936 sind die Feuerschiffe „Borkumriff" und „Amrumbank" versuchsweise mit Schalenkreuz-Kontakt-Anemometern ausgerüstet; die Registrierstreifen werden der Seewarte eingesandt. Zur Windbestimmung an Bord bei den laufenden Terminbeobachtungen sind diese Anemometer jedoch nicht benutzt worden, vielmehr wird die Windstärke nach wie vor nur geschätzt.

Die Bewölkung ist in Zehnteln des Himmels geschätzt worden. Erstmalig wurde dem Grad der Bewölkung (0—10) die Witterung zum Termin mit den Zeichen für ● ✳ △ ▲ ≡ ⛆ ⊤ ≤ beigefügt.

Bemerkungen: Die in dieser Spalte enthaltenen Beobachtungen über den Ablauf der Witterung sind wieder so ausführlich wie im Vorjahr gegeben. Als Zeichen und Abkürzungen wurden die in Teil I des Deutschen Meteorologischen Jahrbuchs unter „Erläuterungen zu den Tabellen" aufgeführten verwendet.

Messungen des Niederschlags in kardanisch aufgehängten Regenmessern sind zwar auf den Feuerschiffen (mit Ausnahme von „Kiel" und „Flensburg") durchgeführt worden, jedoch wird von einer Veröffentlichung hier abgesehen, weil bei der bekannten Schwierigkeit der Aufstellung von Regenmessern an Bord die einzelnen Meßwerte nicht sicher genug erscheinen. Es wird aber in der Zusammenstellung der Monats- und Jahresmittel, Tabelle Zahl der Tage, wenigstens die Zahl der Tage mit Niederschlag (≧ 10.0 mm, ≧ 1.0 mm, ≧ 0.1 mm) angegeben.

Die Auszählung der „Tage mit ..." wurde auf Regen, Schnee, Graupel, Hagel, Nebel, Gewitter (mit Donner), Wetterleuchten und Sturm beschränkt, wobei unter Schneetagen auch alle jene Tage gezählt sind, an denen Regen und Schnee gleichzeitig gefallen sind.

Die Reihenfolge der Feuerschiffe ist stets wie folgt gegeben (im allgemeinen von West nach Ost fortschreitend): Zuerst die 4 Feuerschiffe in der Nordsee: Borkumriff, Außenjade, Elbe 1, Amrumbank; dann die 4 Feuerschiffe in der Ostsee: Flensburg, Kiel, Fehmarnbelt und Adlergrund. Seite 1—42 enthält die Extenso-Beobachtungen von Lufttemperatur, Richtung und Stärke des Windes, Bewölkung und „Bemerkungen". Auf Seite 43—49 folgt die Zusammenstellung der Monats- und Jahresmittel für Lufttemperatur, Dampfdruck, Relative Feuchtigkeit, Windstärke, Bewölkung, dazu „Häufigkeit der Windrichtungen in Prozenten", „Häufigkeit der Windstärken (Bft.) in Prozenten" und „Zahl der Tage"; und zwar als Mittelwerte der durchgeführten einzelnen meteorologischen Termine, deren Zahl bei den verschiedenen Feuerschiffen verschieden ist.

Bei den Feuerschiffen „Kiel" und „Flensburg" fehlen die Angaben über Dampfdruck und Relative Feuchtigkeit sowie die Zahl der Niederschlags- und Schneetage.

Die Verschiedenheit der Beobachtungstermine macht eine gesonderte Zusammenstellung von Gesamtmittelwerten der Monate und des Jahres notwendig (Seite 50 u. 51).

Zum Schlusse folgt eine Tabelle, welche gleichzeitig gemessene Luft- und Wassertemperaturen bei den 8 Feuerschiffen in Beziehung setzt (Seite 52).

den Monatsmittel (und auch die Jahresmittel) eingeklammert; für Elbe 1 ist kein Jahresmittel gebildet. Für Flensburg und Kiel, die beide erst im Juli zu beobachten begannen, sind ebenfalls Jahresmittel nicht gebildet.

Den bisherigen 6 Feuerschiffen gemeinsam sind die 5 Beobachtungszeiten *8, 11, 14, 17, 19h*. Die Gesamt-Monats- und -Jahresmittel sind für diese 6 Feuerschiffe, um eine unmittelbare Vergleichbarkeit untereinander zu gewährleisten, auf Grund dieser gemeinsamen 5 Termine berechnet worden. Für die neu hinzugekommenen Feuerschiffe Flensburg und Kiel wurden die Mittelwerte aus den 4 vorhandenen Terminen genommen. Die Mittelbildung geschah arithmetisch, da eine besondere Formel zur Annäherung an das „wahre" (24 stündige) Mittel für diese Beobachtungszeiten noch nicht festgestellt ist.

Bei den 3 Feuerschiffen mit Terminen zur Nachtzeit wurden auch die Mittelwerte für *alle* Beobachtungszeiten berechnet (ebenso arithmetisch) und der nachstehenden Tabelle in *Schrägdruck* zum Vergleich hinzugefügt. Diese letzteren Mittelwerte werden bei der Gleichmäßigkeit der Verteilung über die 24 Stunden dem wahren Mittel sehr nahe kommen.

Bei einem Vergleich der Ergebnisse der Feuerschiffsbeobachtungen mit denen der Landstationen ist auf den Unterschied der Mittelbildungen zu achten. **Außerdem ist auch das in den Vorbemerkungen über die Temperaturmessung an Bord Gesagte zu beachten.**

Den Monats- und Jahresmitteln ist für 1936 erstmalig auch eine Tabelle für die „häufigste Windrichtung" beigefügt. Zu ihrer Bestimmung sowie zur Auszählung der Häufigkeit der einzelnen Windrichtungen in der vorangehenden Tabelle sind sämtliche Beobachtungen des Tages herangezogen.

Mittelwerte von Luft- und Wassertemperaturen und deren Unterschiede nach ausgewählten Terminen.

Im folgenden werden die zu einigen meteorologischen Terminen auf den Feuerschiffen gemessenen Temperaturen des Oberflächenwassers in Beziehung zu den gleichzeitigen Lufttemperaturen gesetzt.

Für folgende Beobachtungszeiten sind gleichzeitige regelmäßige Messungen beider Temperaturen vorhanden:

Feuerschiff:	*Beobachtungszeiten:*
Borkumriff	3 Termine: 8 14 19h
Außenjade	2 „ : 8 19h
Elbe 1	5 „ : 8 11 14 17 19h
Amrumbank	5 „ : 8 11 14 17 19h
Flensburg	4 „ : 2 8 14 19h
Kiel	4 „ : 2 8 14 19h
Fehmarnbelt	5 „ : 8 11 14 17 19h
Adlergrund	2 „ : 8 19h

Es wurde über diese Termine arithmetisch gemittelt. Wegen der verschiedenen Zahl der Beobachtungstermine ist das Material inhomogen, und die Mittelwerte erlauben daher keinen unmittelbaren Vergleich.

Selbst bei übereinstimmenden Meßzeiten ist aber ein exakter Vergleich ohne weiteres nicht möglich, da die Wassertemperaturen durch die Eigenbewegung des Wassers, vor allem durch die Gezeitenströmungen beeinflußt sind, deren Ausbildung und Auswirkung bei den einzelnen Feuerschiffen verschieden ist und wechselt. Man beachte auch hier das in den Vorbemerkungen über die Messung der Lufttemperatur an Bord Gesagte.

Die Feststellung der Größenordnung der mittleren Wassertemperaturen und der meteorologisch wirksamen Differenz Luft- minus Wassertemperatur ist aber notwendig.

Zur Statistik der Stürme an der deutschen Küste

Vorbemerkungen

Als mit dem Jahre 1878 die Deutsche Seewarte die Herausgabe der „Meteorologischen Beobachtungen in Deutschland" übernahm, die 1887 zum „Deutschen Meteorologischen Jahrbuch" ausgebaut wurden, erschien zum erstenmal als Erweiterung des Inhalts ein Teil III: „Zur Statistik der Stürme an der Deutschen Küste." Dieser dritte Teil, der — wie das Vorwort zu dem Bande sagt — „unter den sonst gebräuchlichen Veröffentlichungen eine besondere Stellung einnimmt", diente der Aufgabe der Seewarte: der Nutzbarmachung meteorologischer Beobachtungen an der Küste für die deutsche Schiffahrt. In lückenloser Folge wurden diese Statistiken bis zum Jahre 1912 veröffentlicht. Sie waren die wichtigsten Unterlagen für die zusammenfassenden Arbeiten: E. Herrmann:[1]) „Die stürmischen Winde an der Deutschen Küste in den Jahren 1878—1887" und L. Großmann:[2]) „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1886—1895" und „Die Stürme und die Sturmwarnungen an der Deutschen Küste in den Jahren 1896—1905."

Der Weltkrieg und seine Folgen zwangen die Seewarte, die Veröffentlichung vom Beobachtungsjahr 1913 ab einzustellen. Erst die Beobachtungen des Jahres 1933 wurden wieder bearbeitet und veröffentlicht in einer Sonderarbeit, die unter dem Titel erschien: „Zur Statistik der Stürme an der Deutschen Küste. Beobachtungsjahr 1933. 1. Jahrgang. Tägliche höchste Windstärke und zugehörige Windrichtung an den deutschen Küstenstationen und auf deutschen Feuerschiffen." Hamburg 1934.

Die vorliegende Bearbeitung für das Jahr 1936 beschränkt sich ebenso wie die für die Jahre 1934 und 1935 wieder auf die wirklichen Sturmtage und Sturmperioden. Sie ist so angelegt, daß das meteorologisch und praktisch Bedeutsame in klarer Übersicht hervortritt und die geeignete Grundlage geschaffen ist für spätere zusammenfassende Bearbeitungen.

Einteilung der deutschen Küste und Stationsauswahl

Das Küstengebiet der Nordsee wurde als Einheit für sich genommen. In dem ausgedehnten Küstengebiet der Ostsee bildet die Insel Rügen eine natürliche Klimascheide, was schon E. Herrmann[3]) erkannte, der für die Untersuchung der Stürme die Ostseeküste in die beiden Bezirke westlich und östlich von Rügen unterteilte. Der Küstenteil Ostpreußens muß außerdem als eigener Bezirk genommen werden. Für die vorliegende Statistik ist die deutsche Küste daher in folgende **4 Teilgebiete** unterteilt worden (vgl. die nachstehende Übersichtskarte):

Nordsee: Die ganze deutsche Nordseeküste.
Ostsee I: Ostseeküste von der Flensburger Förde bis Arkona auf Rügen.
Ostsee II: Ostseeküste von Arkona auf Rügen bis Stilo.
Ostsee III: Ostpreußische Küste.

Diese Gebietseinteilung der Küste ist also unabhängig von der — früher auch für die Statistik benutzten — Gruppeneinteilung (I—VIII) nach Sturm**warnungs**bezirken!

Von den vorhandenen Sturmwarnungsstellen der Seewarte wurden diejenigen ausgewählt, deren Beobachtungen für das eigentliche **Küstenwetter** als „repräsentativ" anzusehen sind (es wurden also die an den Flüssen landeinwärts oder an Haffküsten gelegenen Stellen fortgelassen); auch wurden nur solche Beobachtungsstellen genommen, von denen möglichst regelmäßige und einwandfreie Beobachtungen vorliegen. Nach Fortfall der für die Zwecke der vorliegenden Untersuchung nicht geeignet erachteten Stationen blieben für die Nordsee 28, für Ostsee I 14, für Ostsee II 20 und für Ostsee III 10 Beobachtungsstellen, die im folgenden aufgezählt sind. Von diesen 72 Beobachtungsstellen der Küste sind **56 Sturmwarnungsstellen (St)** und **16 Feuerschiffe (F).**

Einteilung der deutschen Küste in die Bezirke Nordsee, Ostsee I, Ostsee II, Ostsee III

(72 Stationen, davon 56 Sturmwarnungsstellen der Deutschen Seewarte und 16 Feuerschiffe [F.-Sch.]; vergl. Übersichtsliste, Seite 55)

Die Anzahl der Beobachtungen ist bei den Beobachtungsstellen je nach ihrer Art recht verschieden. Die Sturmwarnungsstellen beobachten Wind und Wetter 3 mal täglich, führen außerdem aber zu **Sturmzeiten besondere Zwischenbeobachtungen** (Zw.-Beob.) im Zeitabstand von 2 Stunden aus, so daß gerade die hier untersuchten Sturmzeiten gut besetzt sind. Als ein Mangel erweist sich, daß diese Zwischenbeobachtungen der Sturmsignalisten sich zumeist auf die Tageszeit beschränken (zwischen 8 und 20 Uhr, frühestens 6 Uhr und höchstens bis 22 Uhr). Diejenigen Sturmwarnungsstellen, an denen auch Angaben über den Sturmverlauf während der Nacht im meteorologischen Tagebuch notiert werden, sind in der vorstehenden Übersichtsliste durch * gekennzeichnet. Von den Feuerschiffen liegen die meisten Beobachtungen vor (bis zu 17 täglich), da sie zumeist jede 3. Stunde Meldungen für den Wetterdienst abgeben und alle Nordsee-Feuerschiffe im Rahmen des hydrographischen Beobachtungsdienstes jede zweite Stunde Windrichtung und Windstärke beobachten. Das über Tag und Nacht lückenlos ausgedehnte meteorologische Beobachtungsmaterial der Feuerschiffe kommt der vorliegenden Arbeit sehr zustatten.

Für die Erfassung der Sturmphänomene wurden von den gewählten Stationen alle Beobachtungen systematisch verwertet. Zunächst wurden für jede Beobachtungsstelle die Tage ausgesucht, an denen Windstärke 6 (Beaufort) erreicht oder überschritten wurde; die an dem Tage aufgetretene **höchste** Windstärke wurde dann in Tabellen aufgezeichnet.

Als „Sturmtage" wurden diejenigen Tage bezeichnet, an denen innerhalb eines Bezirkes an mindestens 3 Beobachtungsorten Windstärke 8 Beaufort oder mehr (also Sturm) beobachtet worden ist.

Diese Definition des „Sturmtages" entspricht derjenigen, die bereits 1887 erstmalig gegeben wurde („es müssen stürmische Winde auf größerem Gebiet mindestens an 3 Stationen auftreten").

Für jeden dieser „Sturmtage" wurden für alle Beobachtungsorte die Wind- und Wetterbeobachtungen ausgezogen und zusammengestellt, getrennt für jeden Bezirk. Nach diesen Zusammenstellungen erfolgte die Bestimmung der Merkmale und des Verlaufs eines jeden Sturms bezw. einer Sturmperiode. Für jeden Bezirk wurde die mittlere (vorherrschende) Richtung und Stärke des Sturms, die Art der Verbreitung, Beginn und Ende, die Anfangs- und Endrichtung des Sturmes, seine größte Stärke und in Kürze auch der Witterungsverlauf ermittelt.

Diese Angaben wurden dann in **gleicher** Reihenfolge zusammengestellt, für jeden Sturm in der folgenden Übersicht: „Verlauf und Merkmale der Stürme."

Bezüglich der Verbreitung innerhalb eines Bezirks wurde ein dreifacher Unterschied gemacht:

„Örtlicher" Sturm: mindestens 3, aber weniger als die Hälfte aller Beobachtungsorte haben Windstärke ≥ 8 Beaufort (Bft.).

„Verbreiteter" Sturm: gleich oder mehr als die Hälfte aller Beobachtungsorte Windstärke ≥ 8 Bft.

„Allgemeiner" Sturm: alle Beobachtungsorte Windstärke ≥ 8 Bft.

Lage: Das Haupttief (955 mb) des den mittleren und nordöstlichen Teil des Nordatlantischen Ozeans sowie das europäische Nordmeer bedeckenden Tiefdruckgebietes liegt am 9. 19^h im Raume westlich von Nordirland. Gleichzeitig befindet sich an der Nordwestspitze Irlands das von Südwesten vorgedrungene und schnell auf 955 mb vertiefte Teiltief. Dieses ist am 10. 8^h bis zur nördlichen Nordsee vorgedrungen und inzwischen zum Haupttief geworden, hat aber bereits den Höhepunkt seiner Entwicklung (nur noch 960 mb) überschritten. Das Tief zieht mit wesentlich verlangsamter Geschwindigkeit und unter weiterer Auffüllung zum europäischen Nordmeer. Zunächst läßt es einen kräftigen Ausläufer ostwärts schwenken, der am 10. 19^h bereits über Ostpreußen hinaus vorgedrungen ist. Dem Ausläufer folgt mit einer Staffel frischerer maritim-polaren Kaltluft eine Randstörung, die nach Passieren der südlichen Nordsee auf Südostkurs einschwenkt.

Bemerkungen:

Im Frischen und Kurischen Haff am 18. Sturm z. T. schon zwischen 7^h und 10^h zumeist erst nach 14^h einsetzend, und zwar zunächst aus SW, nach Durchzug der Kaltfront vorherrschend aus W; Windstärke erreicht im Frischen Haff zwischen 14^h und 24^h vielfach Bft. **10**; im Kurischen Haff überschreitet die Windstärke nur selten Bft. **9**.

Dieser Sturm gehört zu den schwersten, die an der deutschen Nordseeküste aufgetreten sind. Er rief eine außergewöhnlich hohe Sturmflut hervor — für Hamburg z. B. trat der seit 1885 höchste beobachtete Wasserstand ein —, die z. T. katastrophale Auswirkungen hatte. Die Vorländereien wurden überall meterhoch überschwemmt, allenthalben wurden an den Uferbefestigungen schwere Schäden angerichtet und vielerorts brachen Deiche oder wurden zumindest sehr schwer beschädigt. Auch durch den Sturm selbst sind auf den Inseln, an der ganzen Nord- und Ostseeküste und im angrenzenden Binnenland sehr schwere Schäden verursacht worden; von der Gewalt des Sturmes zeugt, daß z. B. der aus zwei Personenwagen, zwei Güterwagen und dem Packwagen bestehende Kleinbahnzug Bergen—Altenkirchen (Rügen) aus den Schienen geworfen worden ist. Die Schiffahrt wurde sehr stark behindert; in der Elbemündung lagen zeitweise bis zu 40 Schiffe aller Flaggen und in der Odermündung bei Swinemünde bis zu 15 Schiffe vor Anker, um ruhigeres Wetter abzuwarten. Auf See befindliche Schiffe erlitten schwere Beschädigungen und verloren vielfach einen Teil ihrer Deckslast. An den Küsten der Nord- und Ostsee kam es auch zu Strandungen (z. B. ein griechischer Dampfer an der holländischen Küste).

Das Feuerschiff „Norderney" mußte am 18. 8^{20h} die Station wegen Kettenbruches verlassen.

Der Sturm am 27. Oktober gehört ebenso wie der am 17. Oktober zu den schwersten Stürmen, die an der Nordseeküste aufgetreten sind. Beide übertrafen an Stärke noch die besonders schweren Oktoberstürme der Jahre 1921 und 1935. Der schwere bis orkanartige Sturm hielt im Emsgebiet fast 16 Stunden und vor der Elbemündung ungefähr 18 Stunden ohne Unterbrechung an. Er war im Bereiche der Ostfriesischen Inseln stärker als bei den Nordfriesischen Inseln. Glücklicherweise aber erreichte die Sturmflut an diesem Tage nicht die gleiche Höhe wie am 17. Oktober, da am 27. Oktober die vorherrschende Windrichtung W und nicht WNW und der Windstau auch geringer war. Trotzdem waren die angerichteten Schäden wieder sehr schwer, da die umfangreichen und schweren Beschädigungen der Uferbefestigungen und Deiche am 17. Oktober zumeist nur erst notdürftig hatten ausgebessert werden können und die aufgestauten und eingebrochenen Wassermassen noch nicht überall abgeflossen waren; der Bahndamm für die Inselbahn Westerland—Hörnum wurde südlich von Westerland an verschiedenen Stellen zerstört. Auch durch den Sturm selbst sind wiederum sehr schwere Schäden verursacht worden. Der ausgehende Schiffsverkehr ruhte am 27. in der Nordsee vollständig: 70 Schiffe aller Flaggen lagen in der Elbemündung vor Anker, um das Nachlassen des Sturmes abzuwarten. Die durch den schweren bis orkanartigen Sturm verursachten Schiffsunfälle waren schwerer und zahlreicher als am 17. Oktober. Das Feuerschiff „Elbe 1" kenterte um 13^{40h} und versank mit der ganzen Besatzung in den Fluten. Der Motorfischkutter „Fortuna" ist seit dem 27. Oktober verschollen. In den holländischen Gewässern gerieten mehrere Dampfer in Seenot, konnten aber geborgen werden. In der Deutschen Bucht und an der Ostseeküste strandeten mehrere kleinere und einige größere Schiffe, deren Besatzungen gerettet werden konnten.
Das Feuerschiff „Außenjade" mußte um 14^{30h} infolge Bruches des Ankerspills die Station verlassen.
