der

Meteorologischen Beobachtungen des Observatoriums in Potsdam

im Jahre 1898.

Von

Professor Dr. A. Sprung.

Einleitung.

Die Bearbeitung des reichen, im »Internationalen Wolkenjahre« gewonnenen Beobachtungsmaterials wurde fortgesetzt, aber leider noch nicht beendigt.

Was den photogrammetrischen Wolkenautomaten anbetrifft, so wurde ein wesentlicher wissenschaftlicher Fortschritt dadurch erzielt, dass es im September des Berichtsjahres gelang, die im vorigen Jahrgange erwähnten Sternaufnahmen auszuführen, wobei der Apparat an beiden Stationen ungefähr 2 Stunden geöffnet blieb. Die genaue Bestimmung der Zeit zu Anfang und zu Ende des Versuches gestattet alsdann eine exakte Berechnung der Plattenkoordinaten des Anfangs und des Endes der Sternkurve, welche, verglichen mit den rohen Plattenkoordinaten, die Korrektionen der letzteren ergeben[1]). Aber auch ohne Anwendung dieses etwas umständlichen Verfahrens sind die Sternaufnahmen schon sehr wichtig, weil man nur die zwei identischen Kurvenstücke auf einander zu legen braucht, um den relativen Fehler der 2 Fadenkreuze gegeneinander zu erkennen und in Rechnung ziehen zu können.

Das Instrumentarium der meteorologischen Abtheilung des Observatoriums bereicherte sich um folgende Stücke:

1. Eine Präcisionswaage von Oscar Richter (früher Schickert) in Dresden, welche besonders zur Bestimmung der Luftfeuchtigkeit nach der chemischen Methode dienen soll.
2. Eine photographische Magazinkamera für Platten von 9×12 cm.
3. Zwei kleine Heissluftmotoren von Raab in Zeitz.
4. Ein in der Werkstatt des Observatoriums hergestelltes Modell zur Erläuterung des Kinemographen-Princips, wie es am mechanischen Windapparate Verwendung gefunden hat.
5. Eine Schutzhütte auf der Beobachtungswiese mit einem Apparate zur Aufzeichnung der winterlichen Niederschläge etc.; dieser wird im vorliegenden Hefte näher besprochen werden.

In die Tabellen wurden neu aufgenommen: Die von Woche zu Woche abzulesenden Stände eines Boden-Thermometers von 12 m Tiefe, dessen Einrichtung schon im vorigen Jahrgange beschrieben worden ist.

---

[1]) Vergl. A. Sprung: »Ueber den photogrammetrischen Wolkenautomaten und seine Justirung«. Zeitschr. für Instrumentenkunde XIX, 1899, S. 111 u. 129.

Zum Schlusse geben wir, wie gewöhnlich, noch folgende Erläuterungen zu den Tabellen:

Auf S. 10—57 sind die Tagesextreme durch fetten Druck hervorgehoben worden, und zwar die Maxima durch hohe, die Minima durch niedrige fette Ziffern. Bei der relativen Feuchtigkeit sind jedoch nur die Minima hervorgehoben.

Auch bei den Monatsmitteln dieser Tabellen ist allgemein in derselben Weise verfahren worden, so dass z. B. beim Luftdruck die sekundären Extreme nicht berücksichtigt sind.

In der Windtabelle sind die Calmen, d. h. diejenigen Fälle, in welchen das Schaalenkreuz im Laufe der betreffenden Stunde keine Bewegung zeigte, nicht mit 0 bezeichnet, sondern mit 0.5, als Mittel derjenigen Werthe von 0 bis 1.0, welche hierbei gleich wahrscheinlich sind; denn 1 m p. s. ist ungefähr diejenige Windgeschwindigkeit, bei welcher das Schaalenkreuz sich zu drehen beginnt. — In der Rubrik »Richtung« wird in diesen Fällen »C« gesetzt, anstatt der vom Apparat wirklich aufgezeichneten Richtung. — In der Tabelle d) auf S. 87 ist die Angabe 1.8 (km pro Stunde) gleichwerthig mit dem soeben erwähnten Betrage von 0.5 m p. s. — Die Angabe der Windrichtung bezieht sich auf das Ende des betreffenden Stunden-Interwalls.

Die Psychrometer-Angaben unter 0^0 (des feuchten Thermometers) sind zwar auch nach der den Wild-Jelinek'schen Tafeln zu Grunde liegenden Regnault'schen Formel berechnet, indessen wurde dabei — sobald die Wasserhülle gefroren war — die Spannkraft des Wasserdampfes über Eis verwendet, auf Grund der Tabellen von Juhlin in der Meteorol. Zeitschrift 1894 S. 98.

Am Fusse der Regen-Tabellen, S. 58—63, sind diejenigen Fälle näher bezeichnet, in welchen die Intensität des Regens grösser war als $^1/_5$ mm in 1 Minute.

In den Tabellen für die Bewölkung ist die Wolkenform kursiv angegeben und dahinter die Richtung, aus welcher die Wolken ziehen, in aufrechten grossen Buchstaben. Die Exponenten 0, 1, 2 an den die Menge der Bewölkung ausdrückenden Ziffern bezeichnen, wie allgemein üblich, die Intensität. — Die halbfett gesetzten Ziffern bedeuten — wie auch schon im Kopfe der Tabellen angegeben — die auf 1000 m Höhe berechnete Geschwindigkeit in m p. s. Diesen Angaben liegen Beobachtungen am Wolkenspiegel zu Grunde, wie dieselben in der »Instruktion«, S. 70, oder in der Zeitschrift für Instrumentenkunde 1891, S. 14, beschrieben worden sind; die dort angegebene Rechnung führt indessen zur sogenannten Winkelgeschwindigkeit, oder zu derjenigen Strecke, welche die Wolke in der Einheit der Entfernung, also in 1 m Höhe über dem Wolkenspiegel, in 1 Sekunde zurücklegen würde. Diese Werthe mussten mit 1000 multiplicirt werden, um dieselben in die in unserer Tabelle angegebenen Zahlen zu verwandeln. (Man vergl. auch Jahrg. 1893 dieser Beobachtungs-Ergebnisse, S. XXIII.)

Die graphischen Darstellungen des Sonnenscheins auf S. 76—81 geben ein Bild der Registrirung, so wie der Apparat sie lieferte: schwarz auf hellem Grunde. Eine vollständig mechanische Kopie der Brennspuren, etwa mit Hülfe der Photographie, verbietet sich leider deswegen, weil die Kartonstreifen theils gerade, theils aufwärts oder abwärts gebogen sind, so dass die Darstellung viel mehr Raum erfordern und auch nicht übersichtlich ausfallen würde. — Eine Strichelung der bei der Reproduktion durchweg bandförmig gehaltenen Brennspur bedeutet das Schmalerwerden derselben.

In den Monats- und Jahres-Uebersichten auf S. 82—90 sind die monatlichen Mittelwerthe für jede Stunde noch einmal vollständig zusammengestellt. Zur anschaulichen Darstellung des täglichen Ganges dienen die hinzugefügten »Abweichungen vom Tagesmittel«, mit fetten gedruckten +Zeichen.

Kursiv gedruckte Zahlen bedeuten, wie gebräuchlich, auf irgend eine Weise ergänzte, also wahrscheinliche Werthe, denen nur nicht ganz derselbe Grad von Sicherheit zuzuerkennen ist, wie den übrigen.

Die Maass-Einheiten sind diejenigen der internationalen Vereinbarungen; es ist angegeben: der Luftdruck in Millimetern Quecksilber, die Windstärke in Metern pro Sekunde bezw. in 12theiliger Skala, die Temperatur in Celsius-Graden, der Dunstdruck in Millimetern Quecksilber, die relative Feuchtigkeit in Procenten, die Niederschlagshöhe in Millimetern, die Bewölkung in 10theiliger Skala, die Sonnenscheindauer nach Stunden. — Die Niederschlagshöhe wird um 7^a gemessen und zum Messungstage notirt.

Die meteorologischen Terminbeobachtungen wurden in dreiwöchentlichem Turnus ausgeführt, und zwar ohne Betheiligung des Kastellans. Beobachter waren nach und neben einander die Herren Dr. Meinardus, Dr. Schwalbe, Kühl und Marten.

Ueber die Registrirung der winterlichen Niederschläge.

Von Prof. Dr. A. Sprung.

I. Einleitung.

Nachdem ich 1877 in der Oesterr. Meteorol. Zeitschrift das Princip meines Laufgewichtsbarographen, 1880 in dem »Berichte über die wissenschaftlichen Instrumente auf der Berliner Gewerbeausstellung des Jahres 1879« die praktische Ausführung desselben durch Herrn Mechaniker R. Fuess beschrieben hatte, machte ich 1882 in der Oesterr. Meteorol. Zeitschr., S. 140, einen bestimmten Vorschlag, um das Princip der automatischen Laufgewichtswaage auch auf die Registrirung der Niederschläge in Anwendung zu bringen. Aber schon 1880 hatte ich ausgesprochen, dass das Princip des Laufgewichtsbarographen »offenbar auch zur Konstruktion anderer Registrirapparate mit Vortheil verwendet werden könne«.

Um die Fruchtbarkeit des Princips darzuthun, beschrieb ich 1888 in der Zeitschr. für Instrumentenkunde (S. 17) eine Anzahl von »Versuchen mit der registrirenden Laufgewichtswaage«[1]), nämlich 1. die Gewichtsänderungen der sogenannten Mariotte'schen Flasche, welche dazu diente, ein flaches Gefäss mit verdunstendem Alkohol immer wieder aufzufüllen; 2. die Gewichtsänderungen eines cylindrischen Gefässes, aus welchem vermöge eines engen Heberrohres destillirtes Wasser langsam in ein tieferstehendes cylindrisches Gefäss übertritt (elegant geschwungene Kurven); 3. Verdunstung von Wasser durch eine Thonzelle; 4. die Aenderungen des Auftriebes bei einer grossen hohlen (aber geschlossenen) Glaskugel, also: die Dichtigkeitsänderungen der umgebenden Luft vermöge der Aenderungen des Luftdrucks oder der Temperatur; 5. Anziehung oder Abstossung zweier Kupferdrahtrollen, welche von elektrischen Strömen durchflossen werden, also: Registrirung der Stromstärke!

Bei diesem letzten interessanten Versuche, in geringerem Grade aber auch noch bei den Versuchen 1. und 2., ist die Unveränderlichkeit der (horizontalen) Lage des Waagbalkens von besonderer Bedeutung, weil die Bedingungen des Versuches dadurch wesentlich vereinfacht werden; es handelt sich, genauer ausgesprochen, bei der Laufgewichtswaage um die automatische Aufzeichnung einer veränderlichen Kraft, ohne dass der Angriffspunkt derselben eine Verschiebung erleidet. Auch bei der hier zu besprechenden Aufzeichnung der Niederschläge ist diese Eigenthümlichkeit der Methode von gewisser Bedeutung, wie sich alsbald zeigen wird.

Bei dem oben erwähnten Vorschlage von 1882, in der Oesterr. Meteorol. Zeitschrift, hatte ich allgemein die Aufgabe zu lösen versucht, die Aufzeichnung und Verfolgung der Niederschläge bequemer zu machen, dadurch nämlich, dass der Beobachter nicht gezwungen sein sollte, zur Messung derselben ins Freie zu gehen — was ja gerade bei diesem Elemente, wenn es intensiv auftritt, mit gewissen Unbequemlichkeiten verbunden ist. Deshalb meinte ich, der Regenmesser solle das sich ansammelnde Wasser unmittelbar einem U-förmigen Rohre zuführen, dessen anderer Schenkel viel kürzer und mit Quecksilber gefüllt sei. Die Quecksilbersäule befindet sich etwa am Schreibtische des Beobachters, und kann auch dort durch Ablassen des gefallenen Regenwassers immer wieder auf »Null« gebracht werden. Bei Aufstellung des Regenmessers auf dem Dache — wobei natürlich nach Nipher ein Windschutztrichter aus Kupferdrahtgeflecht erforderlich wird — war die Schmelzung des Schnees durch warme Zimmerluft in Aussicht genommen. In dieser Form ist übrigens der Apparat von R. Fuess ausgeführt worden und hat z. B. an der deutschen Seewarte in Hamburg und an der Landwirthschaftlichen Hochschule in Berlin Aufstellung gefunden. Die Registrirung erfolgte dabei nicht nach dem Laufradprincip — was ja sehr leicht wäre auszuführen gewesen, die Skizze darüber ist sogar a. a. O. veröffentlicht — sondern in einfacherer Weise vermöge eines auf der Quecksilberoberfläche liegenden eisernen Schwimmers mit Schreibstift. Beiläufig sei noch bemerkt, dass auch für den

[1]) Diese Beschreibung ist mit Abänderungen, und unter Hinzufügung der Figur der Laufgewichtswaage, aufgenommen in die in Paris erscheinende Zeitschrift »La Lumière électrique«, T. XLIII (1892) pag. 170.

Fall, dass die Aufstellung des Regenmessers auf dem Dache doch noch Bedenken erregen sollte, die Möglichkeit des gleichen Verfahrens erörtert wurde; es handelt sich dann nicht um »kommunicirende Röhren«, sondern um einen »Heber«, so dass die Niveaudifferenz zwischen Regenmesser und Quecksilbersäule nun unbedingt unter 10 m bleiben muss. In dieser Form lässt sich übrigens die betreffende Einrichtung auch als Mareograph verwenden.

Bei der Erbauung des Meteorologischen Observatoriums in Potsdam im Jahre 1892 wurde daselbst der inzwischen entstandene Sprung-Fuess'sche Regenmesser mit elektrischer Registrirung zur Aufstellung gebracht, welcher sich im ersten Jahrgange unserer Veröffentlichungen, 1893, auf S. XIX—XXII, beschrieben findet, und ganz besonders als Fernregistrirapparat vorzügliche Dienste zu leisten verspricht. Man vergl. hierüber die Einleitung des vorigen Jahrganges (1897) unserer »Ergebnisse«, sowie besonders die Meteorol. Zeitschrift 1897, S. 385.

Neben der Möglichkeit der Fernregistrirung sind die Hauptvortheile dieses Apparates: Die ausserordentlich grosse Bequemlichkeit der Bedienung desselben und die Sicherheit der Zeitbestimmung; letztere vermöge der Aufstellung der Uhr in einem ganz beliebigen, gut geeigneten Raum, und infolge der grossen Zeitskala: 30 bezw. 60 mm in 1 Stunde. Die Bequemlichkeit aber liegt darin, dass nicht, wie bei den meisten übrigen Apparaten, Tag für Tag — und noch dazu im Freien — ein Registrirblatt neu aufgelegt zu werden braucht, sondern die Aufzeichnung im Zimmer auf einem sogenannten unendlichen Papierstreifen erfolgt, von welchem nur eine dem Regen vollkommen entsprechende Menge verbraucht und aufgerollt wird. Die Breite des Papierstreifens richtet sich nach der beabsichtigten Genauigkeit der Zeitbestimmung und beträgt 45 bezw. 80 mm. Der Papierverbrauch erreicht im Jahre nur ungefähr 9 m, während die Vorrathsrolle 30 m lang ist. Die Bedienung des Aussentheiles des Apparates beschränkt sich auf die einmal täglich erfolgende Messung des angesammelten Regenwassers, und auch diese könnte noch unterbleiben, wo man auf die Genauigkeit der Mengenbestimmung kein allzu grosses Gewicht legt, oder wo etwa so wie so schon ein gewöhnlicher Regenmesser aufgestellt ist. Man darf aber umgekehrt sagen: Wo bisher ein gewöhnlicher Regenmesser zu ein- oder dreimaliger täglicher Messung der Niederschläge vorhanden war, da wird derselbe durch Aufstellung eines elektrisch registrirenden Regenmessers nach dem System Sprung-Fuess überflüssig, weil die durch das elektrische Princip bedingte Diskontinuität von so geringem Betrage ist, ($^1/_{20}$ mm Regenhöhe), dass dieselbe praktisch gar nicht in Betracht kommt. Man ist also in der Lage, die bis dahin gefallene Regenmenge zu jeder beliebigen Zeit direkt messen zu können. Dieser kleine Vortheil ist beispielsweise bei den Pluviographen Hottinger, Richard, Hellmann-Fuess nicht vorhanden.

Die genannten drei sind übrigens ausgesprochene Sommerapparate; während der Monate, in denen Schnee zu erwarten ist, werden sie der Regel nach ausser Betrieb gesetzt. Man könnte nun versucht sein, für den in Rede stehenden elektrischen Regenautomaten als besonderen Vorzug den Umstand in Anspruch zu nehmen, dass sich der Apparat durch eine Schneeschmelz-Einrichtung leicht zu einem echten Winterapparate gestalten lässt, denn eine solche Einrichtung ist im Jahrgange 1893 unserer »Ergebnisse« bereits beschrieben worden. Man muss sogar behaupten, dass sich diese Einrichtung — eine Warmwasserheizung, deren Intensität sich selbstthätig der Aussentemperatur anpasst — im ganzen vortrefflich bewährt hat. Man sieht draussen lebhaft schneien, man geht zum Registrirapparat im Zimmer und wird finden, dass derselbe trotz des festen Aggregatzustandes der Niederschläge lebhaft und regelmässig arbeitet!

Was ist nun also daran auszusetzen? Es ist die Regenmenge, welche von der Schmelzeinrichtung gefälscht wird, indem ein Theil des Schnees an der relativ warmen Auffangfläche verdunstet.

Indessen ist bereits im Jahrgange 1893 dieser »Ergebnisse« ein Hülfsmittel beschrieben worden, um diesem Uebelstande abzuhelfen. Dasselbe besteht darin, dass man in genau gleicher Höhe mit der Auffangfläche des Registrirapparates einen gewöhnlichen ungeheizten Regenmesser anbringt, und mit Hülfe desselben die vom Registrirapparate angezeigten Stundenmengen sämmtlich in dem Verhältnisse vergrössert, in welchem die am gewöhnlichen Regenmesser abgelesene Tagessumme diejenige des Registrirapparates übertrifft. Dieses Verfahren ist beispielsweise für technische Zwecke unbedingt ausreichend[1]); indessen von streng wissenschaftlichem Standpunkte aus darf dasselbe nicht ohne Weiteres gebilligt werden. In Wirklichkeit ist nämlich der Vorgang meistens nicht genau in der Weise verlaufen, wie er nach diesem Verfahren sich darstellt; will sagen: es gingen der Registrirung einige Stunden voraus, und folgten auch wohl einige nach, in denen

[1]) Für technische Zwecke würde ich vorschlagen, die Auffangfläche fortan nicht mehr 1000, sondern nur 500 qcm gross zu wählen. Die Empfindlichkeit ist dann nur halb so gross, d. h. es würde ein Umschlagen der Wippe erst nach je $^1/_{10}$ mm Regenhöhe erfolgen. Das wäre aber hier vollkommen ausreichend; der Apparat aber würde noch handlicher ausfallen, und — was wichtiger ist — so gut wie gar nicht mehr dem Vorwurfe ausgesetzt sein, dass der Wasserverbrauch für eine Kippung bei schwachem und starkem Regen etwas verschieden sei. (Man wolle übrigens die Bemerkungen über die »Horner'sche Wippe« im ersten Jahrgange, 1893, dieser »Ergebnisse« S. XXII nachlesen.)

geringe aber doch beachtenswerthe Mengen Schnee gefallen sind. Es wird also auf diese Weise nicht nur die Anzahl der Stunden mit Regen (bezw. Schnee), sondern auch die wirkliche Niederschlagsdauer zu klein gefunden. Nur in den Fällen, in welchen der Schneefall sogleich kräftig anhebt und schliesst, wird das Ergebniss der Registrirung mit dem wirklichen Vorgange vollkommen übereinstimmen. Aber ich fürchte, man hat Grund anzunehmen, dass solche Fälle gerade im Winter die Minderheit bilden.

In Erkenntniss dieser Sachlage bin ich von vornherein bemüht gewesen, für den Winter die Registrirung der Niederschläge auch noch nach der Wägungsmethode durchzuführen. Zu dem Ende wurde zunächst nach dem Vorgange des leider so früh verstorbenen eifrigen Meteorologen Pfarrer Richter in Schlesien, ein Hottinger'scher Pluviograph dem Zwecke der Schneeregistrirung angepasst. Das ist hier möglich, weil es sich bei diesem Apparate auch im Sommer um eine Art Wägung handelt und zwar vermittelst einer Federwaage. Das in einer grossen Wippe sich ansammelnde Regenwasser zieht 3 lange messingene Spiralfedern mehr und mehr auseinander und bewegt sich dabei nach unten, und zwar um ungefähr 10 mm auf 20 mm Regenhöhe. Diese Abwärtsbewegung der »Axe« mit Wassergefäss ist es eben, durch welche die Registrirung erfolgt. Herr Pfarrer Richter hat nun die als Wasserreservoir dienende grosse Wippe durch ein cylindrisches, unten ganz geschlossenes Gefäss ersetzt, welches oben einen zweckentsprechenden Umbau erhielt, ähnlich demjenigen in der weiter unten folgenden Fig. 2.

Die Wägung vermöge einer Federwaage, deren Spannung sogar in nicht geringem Grade von der Temperatur abhängt, lässt nun schon an sich zu wünschen übrig. Ferner erkannte ich in der starken Abwärtsbewegung eine Quelle der Unsicherheit. Ausserdem hängt die feine Einstellung von der zarten Führung der Axe durch entsprechende Rollen ab. Kurz, die Leistungen des Apparates befriedigten auf die Dauer keineswegs, und deshalb benutzte ich eine sich darbietende Gelegenheit, um einen Barographen ohne Barometerrohr in den Dienst der Schneemessung zu stellen.

II. Aufstellung und Einrichtung der Registrirwaage auf der Beobachtungswiese.

Ein Laufgewichtsbarograph erscheint von vornherein als ein zart konstituirter Apparat, der eigentlich in das Zimmer gehört; deshalb lag es nahe, auf der Beobachtungswiese wirklich ein kleines Häuschen für diesen Apparat zu erbauen. Der äussere Anblick der Anlage wird durch die beigegebene Tafel illustrirt; dieselbe enthält ausserdem noch eine Darstellung der Waage für sich, mit dem zugehörigen Auffanggefässe. Man erkennt, dass das Häuschen halb in die Erde hineingebaut ist, indem links unten die 3 Stufen ersichtlich sind, auf denen man bis zum Fussboden des Häuschens hinabsteigt. Auf dem Dache ist zur Kontrolle ein Hellmann'scher Regenmesser aufgestellt; man bemerkt denselben hinter dem Oberlichtfenster.

Zur weiteren Erläuterung diene der schematisch ausgeführte Vertikalschnitt Fig. 1. Man ersieht aus demselben deutlich das Princip der Anlage: Die innere Wandung des Häuschens ist aus gut verlöthetem Zinkwellblech hergestellt, um den Apparat thunlichst luftdicht gegen die Umgebung abzuschliessen, wobei die Thür sorgfältigst mit Filz abgedichtet wurde. Ringsherum aussen folgt einfaches Mauerwerk, welches indessen nicht unmittelbar das Zinkhäuschen berührt, sondern einen Zwischenraum von 20 cm übrig lässt, in welchem am Grunde, links und rechts, 2 Gasheizröhren angebracht sind. Es sollte auf diese Weise für den Apparat eine Art Zimmertemperatur hergestellt werden, ohne dass derselbe dabei den Verbrennungsgasen ausgesetzt sei.

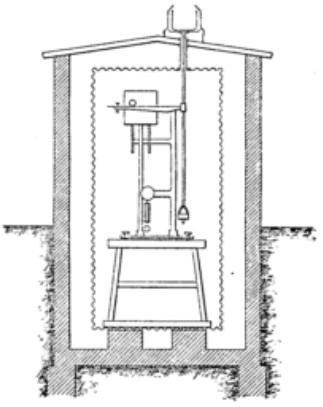

Fig. 1.

Die Heizung ist auch recht gut gelungen, der Abschluss des Apparates gegen die Heizgase aber weniger gut. Weil nämlich begreiflicherweise zur Wärmeersparung nur eine bescheidene Ventilation des Zwischenraumes vorgesehen war, blieb derselbe mit Verbrennungsgasen stark erfüllt, und diese vermochten doch zum Theil in das Zinkhäuschen einzutreten. Eine kleine Verunreinigung der Innenluft mit Verbrennungsgasen sollte nun aber überhaupt dem Apparate nichts schaden, weil ja die Verbrennung des Gases eigentlich nur Kohlensäure und Wasserdampf liefern müsste. Es trat aber eine merkliche Aetzung der nicht lackirten Metalloberflächen ein, und diese hat — wie die Gasanstalt auf Anfrage mittheilte — ihren Grund darin, dass sich dem Rohgase nur der in Form von Schwefelwasserstoff vorhandene Schwefel leicht entziehen lässt, der andere an Kohlenstoff gebundene Schwefel aber leider nicht. Es tritt deshalb auch bei der Verbrennung des gereinigten Leuchtgases Schweflige Säure auf, die natürlich den Metallen schädlich ist.

Im zweiten Winter habe ich deshalb die Heizung lieber ganz unterlassen, und es ist auch so ganz gut gegangen; allerdings war dieser Winter (1898 auf 99) ungewöhnlich mild.

Dahingegen trat im Sommer besonders stark eine unwillkommene Erscheinung auf: Beträchtliche Volumenänderungen der Papiertafel durch die Feuchtigkeit. Beobachtungen ergaben nun, dass die Temperatur noch im Innern des Häuschens infolge der Strahlungswirkungen fast stärker schwankte als die Lufttemperatur, und hierdurch wurden die unliebsamen Aenderungen der relativen Feuchtigkeit hervorgerufen. Aus diesem Grunde liess ich den ganzen Zwischenraum, welcher ursprünglich geheizt wurde, mit Heu und Werg ausfüllen, und erzielte dadurch in der That eine Verringerung der Tagesschwankung der Temperatur auf ungefähr die Hälfte, und das »Werfen« der Papiertafel ist nun — wenn auch nicht vollkommen beseitigt — so doch wenigstens ausserordentlich verringert.

Dieses war im Sommer 1899.

In dem soeben verflossenen Winter (1899 auf 1900) ist die Lufttemperatur einmal auf -20^0 herabgegangen, und am Apparate selbst wurden als Minimum ungefähr -12^0 konstatirt. Trotzdem hat derselbe vollkommen befriedigend gearbeitet. Die Bedienung desselben ist natürlich bei einer solchen Kälte etwas unangenehmer als bei 15^0 über Null, wie ursprünglich beabsichtigt und erreicht war. Im Ganzen befriedigt mich aber der gegenwärtige Zustand doch wesentlich mehr als der ursprüngliche mit der Gasheizung. — Wegen der langsamen Temperaturänderungen kommt ein Beschlagen des Registrirapparates mit Feuchtigkeit so gut wie gar nicht vor, so dass sich derselbe vollkommen gut erhält.

Mit dem Aufgeben der Gasheizung war indessen noch ein anderer kleiner Vortheil verbunden. Es ist natürlich unerlässlich, das Dach des Zinkkastens und des eigentlichen Häuschens zu durchbrechen, um die Verbindung des Schneegefässes mit der Waage herzustellen. An dieser Durchbruchstelle sammelte sich in der ersten Zeit eine unleidliche Menge Kondensationswasser an, und deshalb wurde hier sehr bald ein Glycerinverschluss angelegt, wie derselbe in Fig. 2 angedeutet ist.

Der beabsichtigte Zweck wurde auch vollkommen erreicht, und ungefähr 2 Jahre hindurch habe ich an dieser Einrichtung Nichts geändert, bis ich dahinter kam, dass der Glycerinverschluss an einer unwillkommenen Eigenthümlichkeit der Kurven schuld war. Der Apparat zeigte sich nämlich empfindlich gegen alle Besuche, indem dabei fast immer eine merkbare Versetzeng der Kurve eintrat, und stets in gleichem Sinne, nämlich einer Vergrösserung des Gewichtes entsprechend.

Da Glycerinverschlüsse auch schon anderswo bei Schneewaagen zur Anwendung gekommen sind, würde es mich interessiren zu erfahren, ob man damit auch wohl schon ähnliche Erfahrungen gemacht hat? Den eigentlichen Grund der Gewichtsänderung aufzufinden ist mir nämlich noch nicht gelungen. Zunächst meinte ich, dass die Luftdruckänderung bei schnellem Oeffnen der Thür eine Verlagerung der Glycerinmassen erzeuge, welche dann erst allmählich wieder verschwinde. Dann aber hätte ein von mir absichtlich angelegter zweiter Wanddurchbruch — noch grösser als der erste — den Uebelstand beseitigen müssen, was aber leider in merkbarer Weise nicht eintrat. Aus diesem Grunds habe ich fürs Erste den Glycerinverschluss ganz aufgegeben; wenn trotzdem die Kondensationsprodukte des Wasserdampfes sich an der Durchbruchstelle im Allgemeinen durchaus nicht auffällig bemerkbar machen[1]), so ist das offenbar eine Folge der aufgegebenen Heizung und der daraus entsprungenen geringen Temperaturdifferenz zwischen Innenraum und Umgebung; denn ersterer folgt allen länger anhaltenden Temperaturänderungen der Umgebung vollkommen.

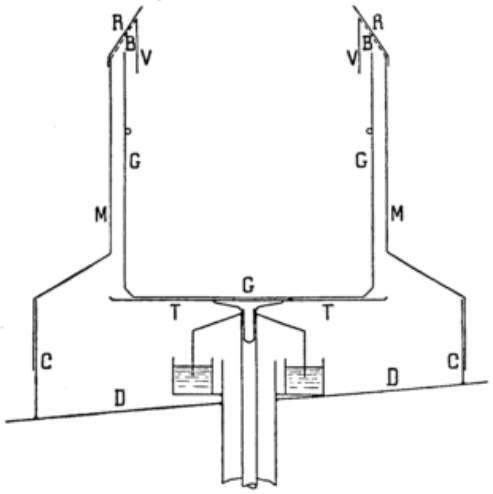

Fig. 2.

Besonders wichtig erscheint nun noch die Gestaltung des Auffangkopfes, welcher dazu bestimmt ist, den Schnee oder Regen in sicherer Weise dem Gefässe, in welchem derselbe gewogen wird, zuzuleiten. Hat man es nur mit Regen zu thun, so ist das Problem sehr einfach; die in Fig. 2 dargestellte Form genügt dann unbedingt. Für das eigentliche Gefäss kann dabei nur noch in Frage kommen,

[1]) Bei Temperaturen über Null fand sich in der That von Tropfwasser gar keine Spur. Am Schlusse von etwa 6 Tagen leichten Frostes zeigte sich auch so gut wie Nichts. Dahingegen war nach etwa 10 Tagen mit starkem Frost (bis zu -16^0) eine nicht zu vernachlässigende Menge kondensirten Wasserdampfes zu konstatiren. Letztere Wahrnehmung wurde indessen nur einmal gemacht.

ob man versuchen soll, die am Boden sich ansammelnde Wassermenge durch einen nur an einzelnen Stellen durchbrochenen Deckel gegen Verdunstung zu schützen. Ich habe das in zwei verschiedenen Formen versucht, bin aber schliesslich wieder ganz davon zurückgekommen. Gänzlich wird die Verdunstung doch nicht vermieden, und als lästig erweist sich der relativ starke Zurückgang der Kurve am Schlusse eines jeden Regenfalles, welcher durch die Verdunstung des an der Oberfläche des Deckels hängen gebliebenen Wassers hervorgerufen wird. Indessen mag sich ja der Verdunstungsschutz in der eigentlichen warmen Jahreszeit einigermassen bewähren; in den Uebergangsjahreszeiten jedoch kommt es vor, dass eine Schneedecke Tage lang auf dem Schutzdeckel liegen bleibt und nun ganz der stärkeren Verdunstung ausgesetzt bleibt, während schon am folgenden Tage der zu Wasser gewordene Inhalt wieder geschützt ist. Im eigentlichen Winter wird der Deckel so wie so entfernt werden, und der Schnee liegt nun wesentlich tiefer als bei den gelegentlichen Schneefällen des Frühjahrs und Herbstes, ist also der Verdunstung weniger stark ausgesetzt.

Aus diesen Gründen habe ich vorgezogen, den Verdunstungsschutz ganz fortzulassen, und immer eine Wasserhöhe von 1—2 cm in dem Sammelgefässe zu halteu. Da der Abstand der Wasseroberfläche vom Auffangrande 22 cm beträgt, so kann man annehmen, dass die Verdunstung stets unter gleichen Verhältnissen erfolgt; bei der grossen Empfindlichkeit der Registrirwaage (die Bewegung der Schreibfeder beträgt 23 mm für 1 mm Regenhöhe) werden auf diese Weise in den regen- und schneefreien Zeiten recht willkommene Aufzeichnungen der Verdunstung gewonnen.

Was nun den in Fig. 2 dargestellten Auffangkopf anbetrifft, so hat derselbe folgende Einrichtung.

Aus dem Innern des Häuschens steigt eine auf der rechts gelegenen Waagebalkenschneide reitende Messingstange frei beweglich herauf (man wolle auch die Lichtdrucktafel vergleichen) und trägt oben den Aluminiumteller T. Das auf diesem ruhende Sammelgefäss G ist aus dünnem Messingblech hergestellt und in ungefähr $^2/_3$ seiner Höhe durch einen eingelötheten Messingreifen versteift. Sammelgefäss G und Teller T sind von einem aus Zink hergestellten Schutzmantel M umgeben, der sich bequem, aber sicher, über einen kurzen Zinkcylinder C hinüberschieben lässt. Letzterer ist an seinem oberen Rande horizontal, während der untere sich der schwachen Steigung des Daches D anpasst, und an die Zinkhaut desselben angelöthet ist.

Der Mantel M trägt an seinem oberen Rande vermöge der Brücke B den »Vorhang« V: einen kurzen Cylinder aus dünnem, glattem Messingblech. Abweichend von sonstigen Konstruktionen ist indessen die Brücke B nicht ein ringsherum laufendes Stück Kegelmantel, dessen oberer Rand zugleich die Auffangfläche bestimmt, sondern es besteht dieselbe nur aus 4 einzelnen Bänden von ca. $1^1/_2$ cm Breite, so dass man von oben hereinschauen und die Lage des Gefässrandes gegen Mantel und Vorhang kontrolliren kann. Natürlich darf der Zwischenraum für die Benutzung nicht offen bleiben, und deshalb wird der starke messingene Auffangring R als Deckel mit übergreifendem Rande darübergeschoben.

Wie oben schon erwähnt, bewährt sich dieser Auffangkopf bei Regen vollkommen gut, und dasselbe kann man auch von trockenem Schnee behaupten; bei feuchtem, klebrigem Schnee indessen gelangt nicht — wie es sein muss — Alles, was die Auffangfläche passirt hat, in das Gefäss G: es bleibt ein Theil des Schnees an dem Vorhang V hängen und wird der Wägung entzogen, bis etwa eine mitleidige Hand denselben nach unten befördert. Die hierdurch bedingte unrichtige Steigung der Kurve betrug bei dem zu Mittag beginnenden Schneefall vom 30. auf den 31. Januar 1900 um 4^p: 0.4 mm, um 8^p: 0.3 mm und um 9^a (am 31.): 1.1 mm Regenhöhe; da der ganze Schneefall bis 9^a 13 mm erreichte, so ist immerhin ungefähr $^1/_7$ des Ganzen auf diese Weise unterschlagen worden[1]). Und dabei ist der »Vorhang« bei unserem Apparate nur $4^1/_2$ cm hoch! Ihn noch ein wenig zu verkürzen, erscheint nach der Figur zwar zulässig, indessen wurde einmal bei starkem Nordwest doch beobachtet, dass Spuren von Schnee an der Leeseite auf den Tellerrand gelangten. 3—4 cm wird somit wohl als Minimum bei der Höhe des Vorhanges anzunehmen sein.

Wo nun aber die Registrirung überhaupt nicht vermöge der Laufgewichtswaage erfolgt, da muss natürlich die Höhe des Vorhanges noch bedeutend grösser genommen werden, und zwar genau um so viel, wie sich das Gefäss zu senken vermag. Bei dem Hottinger'schen Regenmesser z. B. sind das 10 cm, hier würde also der Vorhang 3—4 mal so viel Schnee aufzufangen vermögen als bei unserem Apparate!

Dieses Ergebniss spricht sicherlich sehr zu Gunsten der Verwendung der Laufgewichtswaage bei der Registrirung des Schneefalles. Es kommt aber noch hinzu, dass dabei der »Vorhang« allenfalls auch ganz entbehrt werden kann; in der That hat unser Apparat längere Zeit ohne, als mit Vorhang gearbeitet. Die Dimensionen und Verhältnisse waren dabei denen der Fig. 2 ganz

[1]) Ein anderes Mal, am 19. März, ereignete es sich, dass kurz vor der Bedienung des Apparates, um 9 Uhr Morgens, der am »Vorhang« hängen gebliebene Schnee zum Abthauen gelangte, wobei die Kurve bei vollkommen niederschlagsfreiem Wetter schnell um 7 mm (= 0.3 mm Regenhöhe) anstieg.

ähnlich, so dass also der konstante Abstand des oberen Gefässrandes vom Auffangring ungefähr 1 cm betrug. Bei feinem, trockenem Schnee und starkem Winde wird dann allerdings ein geringes Hinüberwehen über den Gefässrand eintreten können; aber man wird im Stande sein, diesen Verlust unschädlich zu machen, und zwar durch eine entsprechende Vergrösserung des Tellers. Diese Form des Auffangkopfes ist in kleinerem Maasstabe in Fig. 3 noch einmal dargestellt worden.

Ich will nicht verschweigen, dass auch sie noch nicht als ideal bezeichnet werden darf; tadelnswerth ist z. B. die besondere Grösse des Auffangringes, welche bei klebrigem Schnee leicht eine grössere Ansammlung desselben und damit verbundene Verkleinerung der Auffangfläche zur Folge hat. Man könnte deshalb darauf verfallen, den eigentlichen Auffangring dünn und ganz cylindrisch, statt kegelförmig zu

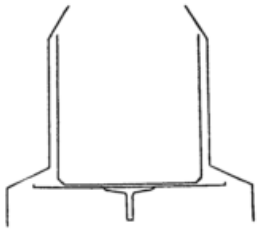

Fig. 3.

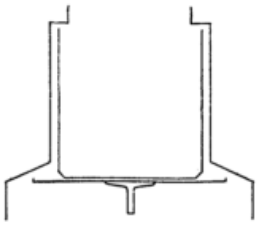

Fig. 4.

gestalten, wobei sich dann das Gefäss in dem weiteren Mantel recht gut würde unterbringen lassen: Fig. 4. Aber es wird dann wieder der Auffangring wie vorher der »Vorhang« wirken können, und auf der ringförmigen ganz horizontalen Fläche, welche zum Schutze des oberen Gefässrandes dient, mag sich der Schnee noch leichter ansammeln als auf der schrägen, wenn auch grösseren Fläche in Fig. 3. Versucht ist diese Form von mir nicht. Andere, noch zweckmässigere Formen des Auffangkopfes zu ersinnen, erscheint mir fast unmöglich.

Recht komplicirt ist z. B. der Auffangkopf bei dem »verbessersten Ombrographen und Atmographen« des Constantinow'schen Observatoriums zu Pawlowsk, beschrieben von H. Wild im Bull. de l'Acad. Imp. de St. Petersbourg 1896, Décembre T. V, No. 5. Mir will es aber scheinen, als ob dabei die Auffangfläche keineswegs genügend scharf definirt sei; die Bemerkung des Autors am Schlusse des Artikels deutet übrigens auch darauf hin. — Die dann noch vorschlagsweise mitgetheilte Gestaltung des Auffangkopfes ist in dieser Beziehung besser; sie stimmt mit der von mir in Fig. 2 dargestellten Form im Princip überein, nur dass natürlich der »Vorhang« wesentlich höher ist, und für den Sommer in den untersten Theil desselben ein Verdunstungsschutz eingehängt wird. Der Nachtheil des Vorhangs wird übrigens auch vom Verfasser anerkannt.

Man könnte vielleicht den Vorhang ganz schwach heizen, wodurch das Ankleben des Schnees natürlich sicher verhindert, aber dafür wieder ein Verdunstungsverlust herbeigeführt werden würde.

III. Einige weitere Erfahrungen mit der Registrirwaage.

Ist mit der Verwendung der Laufgewichtswaage zur Registrirung des Schneefalles auch schon recht viel gewonnen, so bleiben gewisse kleine Schwierigkeiten doch noch bestehen. Dazu gehört z. B. der störende Einfluss des Windes. Die Kurve fällt eigentlich nur bei vollkommener Windstille ganz dünn und glatt aus; der Regel nach zeigt sie sich verbreitert und mit Fransen besetzt. Letztere finden sich aber zum Glück nur an einer Seite, so dass man den Gang der Kurve doch verhältnissmässig sicher zu erkennen vermag. Und nur sehr selten erreichen die Störungen solche Beträge, dass die Entzifferung der Niederschlagskurve darunter unbedingt zu leiden hat. Hierbei kommt allerdings ein wenig zu statten, dass bei sehr starkem Winde nur selten merkliche Niederschläge auftreten. Möglicherweise liessen sich die Windstörungen verringern durch den sogenannten Nipher'schen Trichter oder durch hohe Schutzwände, welche den Apparat allseitig umgeben. Keines von beiden ist bisher von mir versucht worden. —

Noch eine Schwierigkeit muss erwähnt werden. Nichts erscheint im ersten Augenblick selbstverständlicher und einfacher als der Gedanke, im Winter, wo die übrigen Methoden der Regenregistrirung grösstentheils versagen, zur Methode der Wägung überzugehen, denn dabei erfolgt ja eben unmittelbar das, was man haben will: die Massenbestimmung der festen Niederschläge.

Man irrt indessen, wenn man annimmt, dass ein jeder Niederschlag sich durch ein Ansteigen der Kurven verrathen müsse. Es kann ganze Tage hindurch ununterbrochen schneien, ohne dass die Kurve ansteigt; ja die Kurve kann dabei sogar einen unausgesetzten Rückgang zeigen! Der Grund dieser unwillkommenen Erscheinung liegt in der wohlbekannten Thatsache, dass die Luft am Erdboden bei Regen und Schnee nur selten mit Feuchtigkeit ganz gesättigt ist. Die Wassertropfen zumal reissen beim Fallen die Luft zum Theil mit herab und beim Absteigen der letzteren tritt dynamische Erwärmung und Austrocknung ein. Es verschwinden dabei die kleinsten Wasserkügelchen, und der Regen ist deshalb verhältnissmässig durchsichtig.

Bei Schneefall werden ähnliche Verhältnisse obwalten müssen, wenn auch in weniger ausgeprägtem Maassstabe. Jedenfalls ist Thatsache, dass auch bei Schneefall die Luft meistens nicht ganz mit Wasserdampf gesättigt ist, und dass deshalb auch hier die Verdunstung in geringem Betrage ihren Fortgang nimmt. Geringfügige Regen- und Schneefälle werden deshalb von der Registrirwaage nicht aufgezeichnet werden, auch wenn dieselbe im Uebrigen die erforderliche Empfindlichkeit dafür besässe.

Um diesem Uebelstande zum Theil zu begegnen, müsste man das Auffanggefäss ausserordentlich tief wählen, was indessen wieder mit anderen Schwierigkeiten verknüpft sein mag; ganz wird sich der Uebelstand indessen nicht vermeiden lassen, und schon aus diesem Grunde werden auch die auf unmittelbarer Wägung beruhenden Pluviographen nicht geeignet sein, die Niederschläge vollkommen korrekt zur Aufzeichnung zu bringen. Da ungünstigerweise bei uns gerade die schwächsten Niederschläge recht lange währen (besonders im Winter), so erscheint die Regendauer nach den gebräuchlichen Registrirapparaten viel kleiner als sie in Wirklichkeit ist[1]).

Zuweilen tritt nun aber — und zwar vielleicht gerade am meisten bei den recht empfindlichen Registrirwaagen — auch der entgegengesetzte Uebelstand auf: Die Kurven zeigen ein deutliches Ansteigen, ohne dass mit den Regenmessern eine merkbare Niederschlagsmenge sich nachweisen lässt!

Wenn dabei die Luft mit Nebel erfüllt ist, so erscheint der Vorgang von vornherein einigermaassen verständlich, denn die Bedingungen des Nebels, welcher an der Erdoberfläche auftritt, sind denen der Niederschläge eigentlich ganz entgegengesetzt; es ist der anticyklone Witterungscharakter, bei welchem die oberen Schichten durch besondere Klarheit sich auszeichnen, so dass der Boden kräftig auszustrahlen vermag; die untersten Schichten erreichen dabei sehr leicht den Thaupunkt, es tritt Nebel ein und nun hört die Verdunstung vollkommen auf. Kein Wunder, wenn dabei der Inhalt des Gefässes der Registrirwaage aus der Luft unmittelbar Feuchtigkeit aufnimmt. Es sind indessen von mir ganz sicher Fälle beobachtet worden, in denen die Gewichtsvermehrung auch ohne Nebel eingetreten ist. In der Nacht vom 17. bis 18. April z. B. erfolgte, nachdem die Regenböen um 6^{p} aufgehört hatten, bis 11^{p} ein sehwacher Rückgang der Kurve durch Verdunstung, dann aber bis $8^{1}/_{2}{}^{a}$ ein ungefähr ebenso starkes Ansteigen der Kurve, nämlich um $2^{1}/_{2}$ mm, was ungefähr einer Regenhöhe von 0.1 mm entsprechen würde. Der Betrag ist ja nur klein, aber in der Kurve sehr deutlich zu erkennen, so dass bei rein mechanischer Interpretation der Aufzeichnungen ein Niederschlag von 9 Stunden Dauer hätte konstatirt werden können. Die Nacht war schwach bewölkt und sternklar bei schwachem Winde, die Luft der Sättigung zwar nahegekommen, Nebel indessen, wie gesagt, nicht aufgetreten, wohl aber war an günstigen Stellen Reif beobachtet. Der Verdunstungsmesser in der Holzhütte zeigte eine ganz geringe Verdunstung. Zur grösseren Sicherheit wurde die »Durchbruchstelle« bei der Registrirwaage genau untersucht; es zeigte sich von kondensirter Feuchtigkeit nicht die leiseste Spur. Zur Erklärung der Gewichtszunahme bleibt nichts anderes übrig als die Annahme einer etwas stärkeren Abkühlung des Gefässes gegen die meist wolkenlose Zenithalregion, so dass es sich also um eine Art Thau- oder Reifbildung handeln würde.

Wie aber sollte man wohl solche Vorkommnisse vermeiden? Wenn man eventuelle Niederschläge auffangen will, muss man doch schlechterdings das Gefäss unbedeckt lassen. Es ergiebt sich hieraus die Lehre, dass man selbst bei einem so einfachen Problem, wie die Registrirung der Niederschläge im ersten Augenblicke zu sein scheint, sich nicht blindlings auf seinen Apparat verlassen darf, wenn anders man es mit der Lösung solcher Aufgaben einigermaassen genau nehmen will. Die Ergebnisse der unmittelbaren Beobachtung der Phänomene müssen mit zu Rathe gezogen werden. Auch ist es unerlässlich, den Apparat nicht nur einmal am Tage, sondern mehrmals zu kontrolliren.

[1]) Man vergleiche meinen Artikel: Die Regendauer in Deutschland nach der Köppen'schen Stichprobenmethode. Jahresbericht 1900 des Berliner Zweigvereins der Deutschen Meteorol. Gesellschaft. Oder früher: »Ueber Regendauer und Regenstunden« in »Das Wetter« 1898, S. 97.

Des Weiteren erscheint die gleichzeitige Verwendung ganz anderer Instrumente, wie z. B. des registrirenden Pluvioskops von Hervé Mangon empfehlenswerth. Eine Beschreibung desselben findet sich in »La Nature« 1888, zweites Halbjahr, S. 212. Es ist mir nicht bekannt, ob die Aufzeichnungen desselben benutzt, bezw. bearbeitet worden sind; in Potsdam soll indessen ein ähnlicher Apparat zur Aufstellung gelangen.

IV. Herrn Professor Marvin's Apparate.

Erst im Laufe des verflossenen Winters ist mir zur Gewissheit geworden, dass das Princip meiner Laufgewichtswaage schon vor mir zur Registrirung der Niederschläge verwendet ist, und zwar von Prof. Marvin in Washington. Ich ersah das aus einem kurzen Artikel von H. H. Kimball: »Automatic records of a thunderstorm« in der Monthly Weather Review vom August 1899. Dort wird auf S. 356 zunächst »Professor Marvin's normal mercurial barograph« kurz erläutert als: »having a barometer tube suspended from the short arm of a balance beam. A change in the air pressure causes a slight movement of the beam, thereby closing an electric circuit. The movement of the magnet armature turns a screw and shifts a weight on the long arm of the beam, and the movement of this weight, which restores the equilibrium of the beam, is recorded by a pen; each movement of the weight or pen represents a change in air pressure of 0.0001 inch.« Nach dieser Beschreibung dürfte Prof. Marvin's Normal-Quecksilber-Barograph mit dem meinigen im Princip vollkommen identisch sein[1]).

Die nun folgende Beschreibung von »Professor Marvin's weighing rain and snow gage« setzt ebenfalls die Verwendung der Laufradwaage ausser Zweifel, doch kommen hier wenigstens noch ergänzende Konstruktionen hinzu, wie man, trotz ihrer Kürze, aus dem Wortlaute der hier folgenden Beschreibung ersehen mag. »The rain falling into a collector 8 inches in diameter flows into a receiver resting on a balance, and the counterpoise on the arm of the balance is moved electrically for every 0.001 inch of rainfall. The recording pen is made to move simultaneously with this weight when a double-threaded screw is turned by the motion of the magnet armature on the register, and the thread of the screw advances the pen either down or up the record sheet, depending upon the amount of rain that has fallen. Once across the sheet represents 0.50 inch of rainfall«.

An einer anderen Stelle des Artikels von Herrn Kimball ist darauf hingewiesen, dass eine vollständige Beschreibung der angewandten Instrumente zu finden sei: in den Cirkularen C, E, F und G der Instrumentenabtheilung, sowie im I. Theile des »Report of the Chief of the Weather Bureau« 1891—92. An letzterer Stelle habe ich nachgesehen, und finde dort u. A. drei den Apparat erläuternde Figuren, aber keine specielle Auskunft über die Art und Weise, wie am Ende seines Weges das Laufrad sofort zurückgeleitet wird, NB. wenn der Niederschlag fortdauert; ja es geht diese wichtige Eigenthümlichkeit der Kon-

---

[1]) Kurz vor Abschluss dieses Artikels bietet sich mir zum ersten Male Gelegenheit, Marvin's Barograph abgebildet zu sehen und zwar in einem umfangreichen Prachtwerke: »Maryland Weather Service« Vol. One. (Baltimore, the John Hopkins Press, 1899) auf S. 324. Die Beschreibung folgt auf S. 327 und beginnt in folgender Weise: »In the Marvin barograph, shown in Plate XXXI, the idea of a standard barometer, which can be read by the observer at any time, and that of a standard recording apparatus which gives a continous record of absolute or standard pressures, are both realized.« Nun folgt eine Erörterung des Mechanismus, welche mit der oben im Text von mir wiedergegebenen im Wesentlichen übereinstimmt. Der Schluss lautet: »This barograph by Professor Marvin is the most sensitive and accurate of all that have yet been constructed for the U. S. Weather Bureau, and it preserves a record of the most minute changes in atmospheric pressure, such as those that accompany thunderstorms and gusts of wind«. Einen wesentlichen Unterschied gegen meinen Apparat vermag ich nicht zu entdecken, denn dass z. B. die Aufzeichnung auf einer Trommel erfolgt, anstatt auf einer ebenen Tafel, ist doch natürlich ganz unwesentlich. Sonst erstreckt sich aber die Uebereinstimmung sogar auf Einzelheiten, indem z. B. bei beiden das Barometerrohr an der rechten Seite hängt und an dem kürzeren Arme des Waagebalkens. Ein wesentlicherer Punkt der Uebereinstimmung ist dann aber noch die Skala zur direkten Ablesung der Höhe der Quecksilbersäule des Barographen, wie sie in der ursprünglichen und mehrfach wiederholten Abbildung meines Apparates deutlich zu erkennen ist. Dieselbe ergiebt sich aber auch aus der überaus eingehenden Besprechung meiner Laufgewichtsapparate in Prof. Cleveland Abbe's »Treatise on Meteorological Apparatus and Methods« (Washington 1888), wo sich auf S. 161 in Bezug auf »Sprung's balance barograph with sliding weight« Folgendes findet: »but in order that a special barometer may not be needed for the control of the registrating apparatus, a scale, m, divided into millimeters (whose steel zero point can be pushed by a screw into the lower mercury surface), is placed on the barometer tube B. As the diameter of the column amounts to 2 centimeters this arrangement must represent a good normal barometer.«

Die in Rede stehende Beschreibung von Marvin's Barograph in »Maryland Weather Service« rührt anscheinend ebenfalls von Herrn Prof. Cleveland Abbe her und doch wird auch von ihm der eigentliche Erfinder dieses Apparates nicht erwähnt.

struktion aus der Beschreibung nicht einmal hervor, so dass dieselbe möglicherweise später noch hinzugefügt sein mag.

Ausführlicher wird indessen eine andere Eigenthümlichkeit erörtert: eine elektrische Uebertragung der Aufzeichnungen nach dem Hause! Fürwahr, einfach scheint der Apparat nicht zu sein, aber wenn er trotzdem befriedigend arbeitet, so muss man ja den Fortschritt mit Freuden begrüssen. Nichtsdestoweniger möchte ich mir noch einige kleine Einwendungen erlauben. In der Beschreibung heisst es:

»The weighing mechanism consists of the usual balance on knife-edges with a beam and sliding counterpoise. The movement of this counterpoise is effected by means of a long screw set parallel to the beam upon which the weight slides. This screw is caused to revolve and move the weight by the vibratory action of the armature of an electromagnet. The balance, with the receiving vessel in position, is adjusted by hand to a condition of equilibrium. No action ensues untill the end with the receptacle becomes heavier, whereupon the deflection of the beam of the balance closes an electric circuit through the electromagnet.«

Hiernach scheint der Apparat nur auf eine Gewichts-Vermehrung des Gefässes zu reagiren, und nicht, wie meine Waage, jede beliebige Gewichts-Aenderung der Last zu verzeichnen. Wenn nun aber bis zum nächsten Regen oder Schneefall ein Theil des Gefässinhalts verdunstet, so würde ja der Regen die verdunstete Menge erst auffüllen müssen, ehe er selbst zur Registrirung gelangte! (Nach der Figur würde die Form des Auffanggefässes von den gebräuchlichen nicht abweichen. Aber auch wenn ein Verdunstungsschutz im Gefässe vorhanden wäre, so müsste derselbe, wie oben erörtert, im Winter zeitweise doch unwirksam werden.) Ferner scheint mir überhaupt die vollständige Ruhe des Waagebalkens, welche derselbe konservirt, so lange keine Gewichtsvermehrung der Last erfolgt, kein Fortschritt zu sein, weil dabei leicht ein Ankleben des Waagebalkens an der Anschlagstelle stattfinden kann. Nach meinen Erfahrungen ist es besser, wenn der Waagebalken fortwährend frei spielt und dabei womöglich die 2 Anschlagstellen oben und unten gar nicht berührt.

Drittens möchte ich behaupten, dass häufig auch der Wind ein Neigen des Waagebalkens bis zum Kontakt desselben zu Stande bringen wird; sollte hierdurch die Uebertragung der Aufzeichnung nach dem Hause gar nicht gestört werden? Ich möchte hier nur diese Frage aufwerfen, da ich nach der Beschreibung nicht vollständig durchschaue, ob der Apparat hiergegen gesichert ist.

Rekapitulirend möchte ich betonen, dass hier am Observatorium in Potsdam die Verwendung der unveränderten Laufgewichtswaage zur Registrirung der Niederschläge (und gleichzeitig der Verdunstung) nicht sehr grosse Schwierigkeiten hervorruft, weil im grösseren wärmeren Theile des Jahres der oben S. VI besprochene elektrische Registrirapparat in vollkommen ungestörter Thätigkeit ist. Im Winter aber hat man es meistens nur mit geringeren Niederschlägen zu thun, so dass nur selten die Schreibfeder unvorhergesehen an den Rand der Schreibtafel gelangt. Bequemer wäre es freilich, wenn alsdann trotzdem die Registrirung von selber ihren Fortgang nähme.

Während der sommerlichen Monate wird von uns die betreffende Laufgewichtswaage zur Registrirung der Verdunstung allein verwendet, indem die Verdunstungsschaale sich dann in einer »kleinen englischen Hütte« befindet. Zeitweilig wurden auch Versuche über Thaubildung angestellt; es diente hierzu eine Aluminiumschaale mit ganz niedrigem Rande. Als wesentliche Bedingung einer kräftigen Thaubildung ergab sich, wie vorauszusehen, eine gute thermische Isolirung der Schaale gegen die Metalltheile des Apparates.

V. Schlussbemerkungen.

Sämmtliche Registrirapparate, welche zur Aufzeichnung der Regenmenge bestimmt sind, liefern für die »Dauer des Regens« Resultate, welche hinter der wirklichen Regendauer bedeutend zurückbleiben: in Norddeutschland z. B. wird nach den Jahressummen ungefähr nur die Hälfte der wirklichen Regendauer von diesen Registrirapparaten erreicht. Das wird in der Natur der Sache begründet sein, indem (bei uns wenigstens) häufig Niederschläge auftreten, welche trotz ziemlich langer Dauer nur sehr geringe Mengen ergeben. Um so mehr wäre es unbillig, bei der Registrirung der winterlichen Niederschläge die Anforderung zu stellen, dass etwa die von ihnen verzeichnete Regendauer der wirklichen gleichkommen müsse; man wird auch hier höchstens die Hälfte erwarten dürfen. Aber man wird zu dem Anspruche berechtigt sein, dass, sobald die gewöhnlichen Regenmesser deutliche Mengen ergeben, dieses auch bei den Registrirapparaten der Fall sein müsse.

Von diesen Gesichtspunkten aus beurtheilt, möchte ich das Gesammtergebniss meiner Betrachtungen noch einmal in folgende Sätze zusammenfassen:

1) Die korrekte selbstthätige Registrirung der winterlichen Niederschläge gehört zu den schwierigsten Aufgaben der beobachtenden Meteorologie.

2) Von allen bekannten Principien muss hierbei dasjenige der Wägung als das am besten geeignete bezeichnet werden.

3) Ganz einwurfsfrei ist aber auch dieses nicht, so dass eine rein mechanische Deutung der Registrirkurven zu ernstlichen Irrthümern führen kann.

4) Die registrirende Laufgewichtswaage erscheint — aus principiellen Gründen — allen anderen auf Wägung beruhenden Apparaten bedeutend überlegen. Störungen ihrer Thätigkeit durch Frost und sonstiges Unwetter sind nicht eingetreten.

5) Hierbei kann in ganz vortheilhafter Weise gleichzeitig eine Registrirung der Verdunstung gewonnen werden, wie es oben auf S. IX näher begründet wurde.

Berichtigungen.

Ergebnisse 1897.

Im Kopfe der Tabellen für Bodentemperaturen (Seite 100—112) muss als Tiefe des über dem Boden befindlichen Thermometers -0.008 m statt -0.08 m gesetzt werden.

Ergebnisse 1898.

Auf Seite 24. Am 9. Mai 7-8ª: **3.2** statt 3.2.
» » 25. Am 9. Mai 11-12ᵖ: **7.1** statt 7.1.
» » 41. Am 6. April 6ª: **-0.1** statt -0.4.
Am 6. April 7ª: 0.5 statt -0.5.
April, Mittel für 6ª: 4.76 statt 4.75.
» » » 7ª: 5.16 » 5.13.
Tagesmittel für 6. April: 5.44 statt 5.38.
» » 47. Am 6. April 7ª: 4.0 statt 3.7.
Am 6. April: Tagesmittel 3.54 statt 3.52.
April, Mittel für 7ª: 6.02 statt 6.01.

Einleitung III

Ueber die Registrirung der winterlichen Niederschläge. (Von Prof. A. Sprung) V

Tabellen.

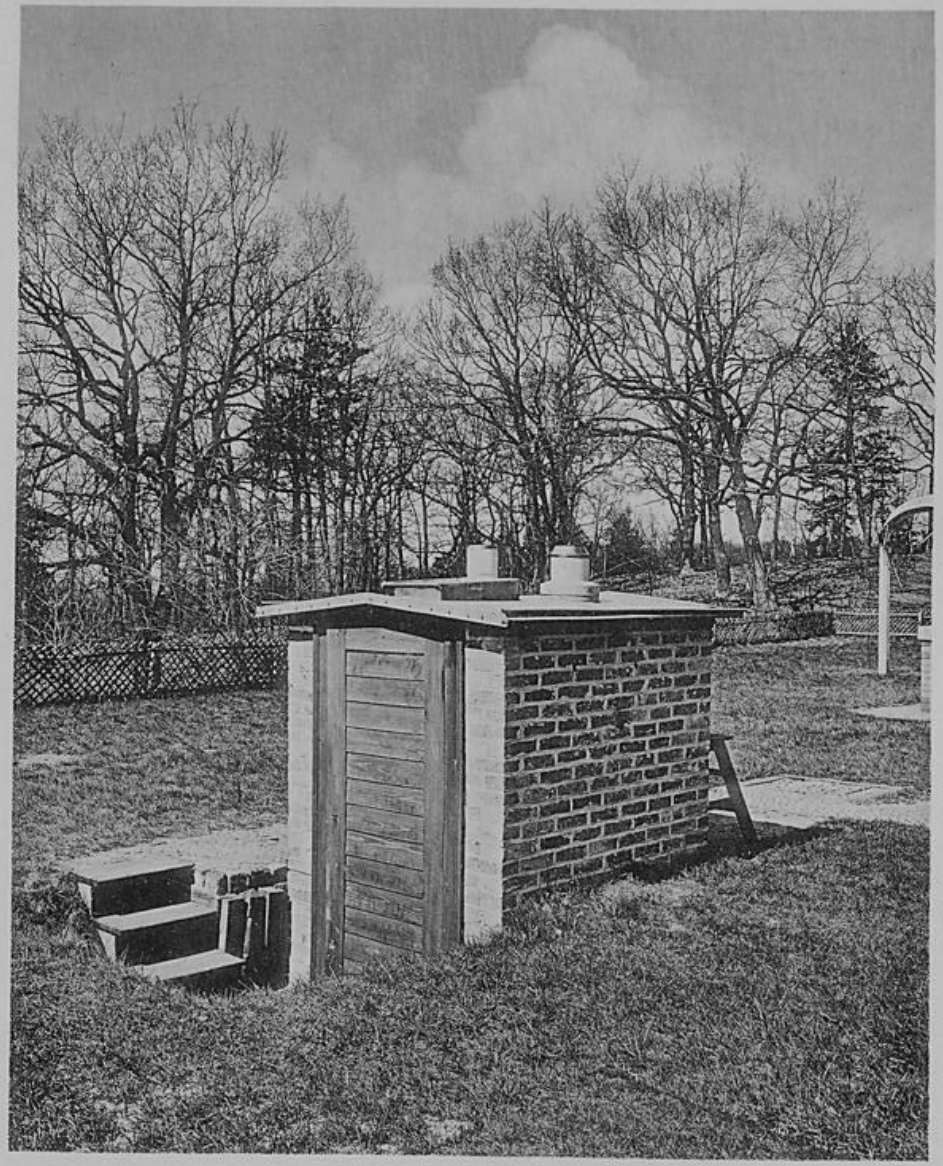
I. Termin-Beobachtungen 1

II. Stündliche Aufzeichnungen 9

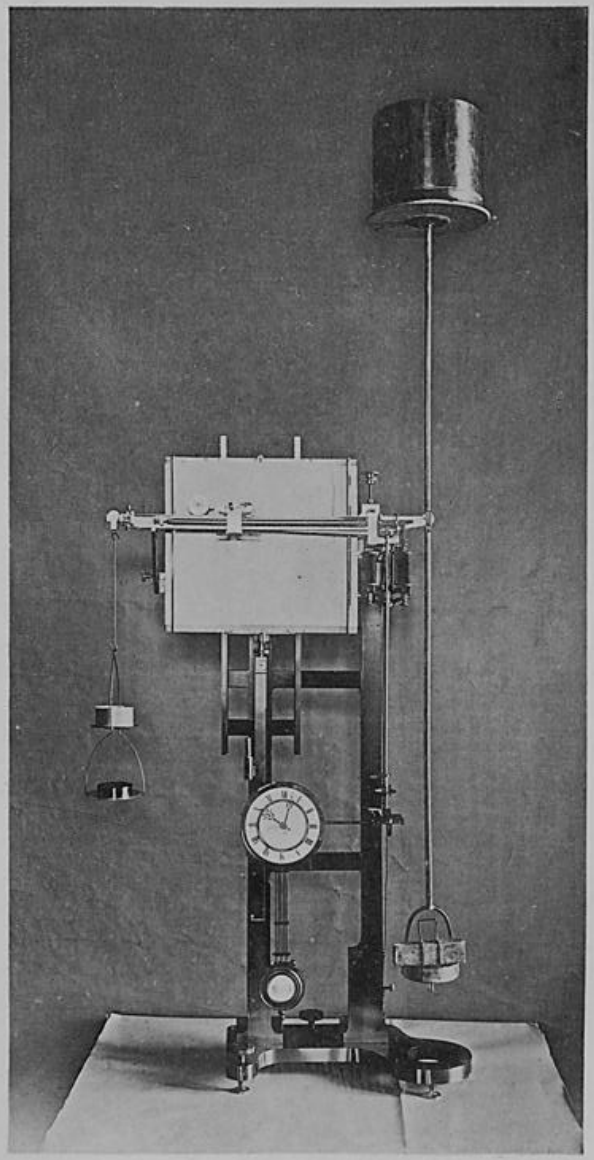
1. Luftdruck 10
2. Wind-Richtung und Geschwindigkeit 16
3. Lufttemperatur (Wiese) 40
4. Dunstdruck (Wiese) 46
5. Relative Feuchtigkeit (Wiese) 52
6. Niederschläge 58
7. Bewölkung 64
8. Sonnenscheindauer 76
9. Monats- und Jahresübersichten zu den Aufzeichnungen S. 10—81 82

III. Sonstige Aufzeichnungen 91

1. Temperatur auf dem Thurm und Differenz: Thurm minus Wiese 92
2. Relative Feuchtigkeit auf dem Thurm und Differenz: Thurm minus Wiese, Monatsübersicht . . . 99
3. Bodentemperaturen, beobachtet um 10 Uhr vormittags (alle Tiefen) 100
4. Bodentemperaturen, beobachtet zu den 3 Hauptterminen (geringe Tiefen) 106
5. Bodentemperaturen, Monats- und Jahresübersicht 112
6. Verdunstung 113
7. Gewitterbeobachtungen 114
8. Wassergehalt der Schneedecke 115
9. Nuthe-Station, Temperatur und Regen 116



Schutzhütte für die Laufgewichtswaage.



Laufgewichtswaage.
