Einleitung.

Die Veröffentlichung der Beobachtungen und Aufzeichnungen am Meteorologischen Observatorium erfolgt für 1926 in demselben Umfang wie für die vorhergegangenen zwei Jahre.

Die Terminwerte der Temperatur und Feuchtigkeit sind Ablesungen oder Registrierungen in der großen »englischen Hütte« auf der Beobachtungswiese (Höhe über dem Erdboden 2.1 m) mit Aßmannscher Aspirationsvorrichtung für das feuchte Thermometer. Alle Feuchtigkeitsangaben sind auf das aspirierte Psychrometer reduziert.

Die Ablesungen beziehen sich alle auf die volle Stunde des Beobachtungstermins (Ortszeit). Die Extremtemperaturen werden von Extremthermometern in der Hütte auf der Beobachtungswiese erhalten, ihre Daten gelten für den Tag von 9^p des Vortages bis 9^p des Beobachtungstages. Hydrometeore und Sonnenschein im Moment der Terminbeobachtung sind den Bewölkungsangaben in den internationalen Zeichen als Indices hinzugefügt. Die Regen- und Schneemessungen wurden auf der Beobachtungswiese, letztere auf einem Zementfeld gemacht. Die Schneehöhen sind Mittelwerte aus mehreren Messungen. Der Regenmesser Hellmann steht auf der Beobachtungswiese (Höhe über dem Boden 1.3 m).

Von den hier veröffentlichten Registrierungen beziehen sich die für Luftdruck, Temperatur und Feuchtigkeit auf die Angaben der vollen Stunden; ihre Tagesmittel sind gebildet nach der Formel:

$$(\frac{1}{2} \cdot 12^p + 1^a + 2^a + \dots + 11^p + \frac{1}{2} \cdot 12^p) : 24.$$

Die Werte von Windgeschwindigkeit, Windrichtung und luftelektrischem Potentialgefälle sind Stundenmittel, diejenigen für Niederschlag und Sonnenscheindauer Stundensummen.

Die Luftdruckwerte werden den Aufzeichnungen des Sprung-Fueßschen Wagebarographen im Instrumentenzimmer entnommen und durch einmal tägliche Vergleichung auf das in der Nähe hängende Gefäßheberbarometer Wild-Fueß Nr. 248 bezogen. Die Angaben der Lufttemperatur liefert ein großer Richardscher Thermograph mit achttägigem Umlauf, der in einem Ausbau der großen Englischen Hütte (Ostseite) auf der Wiese aufgestellt ist. Die Registrierungen werden durch die Terminbeobachtungen auf das Thermometer in der Hütte so reduziert, daß die Korrekturen zwischen den Terminen linear interpoliert werden. Zur Registrierung der relativen Luftfeuchtigkeit wird ein Richardscher Hygrograph mit eintägiger Umlaufzeit benutzt, der dicht unter dem Dache der Thermometerhütte auf der Wiese aufgehängt ist.

Die Windwerte sind der mechanischen Registrierung des großen Schalenkreuz-Anemographen auf dem Turme des Observatoriums (41 m über dem Boden, 7 m oberhalb der Plattform des Turmes) entnommen. Für die Umrechnung der Geschwindigkeitsaufzeichnungen in m/s galten im Jahre 1926 die Formeln:

$$1. \text{ Jan. } - 30. \text{ Sept.: } v = 0.36 + 0.1009 n$$

$$1. \text{ Okt. } - 31. \text{ Dez.: } v = 0.44 + 0.1079 n,$$

wobei v die Windgeschwindigkeit in m/s, n die Länge des Papierablaufs (mm) in einer Stunde bezeichnet.

Die Werte der Regenmenge und Regendauer sind teils der Sprung-Fueßschen Registrierwage für Niederschlag und Verdunstung, teils dem mechanisch registrierenden Regenmesser, System Hellmann-Fueß, entnommen. Beide haben eine Auffangfläche von 200 cm², der Sprung-Fueßsche Apparat befindet sich 1 $\frac{1}{4}$ m, der Hellmann-Fueßsche, welcher nur zur Ergänzung dient, 1 $\frac{1}{4}$ m über dem Boden.

Von den beiden Sonnenschein-Autographen wird der nach dem System Campbell-Stokes gebaute seit dem 1. Juli 1915 benutzt (vergl. Ergebnisse der Met. Beob. Potsdam i. J. 1916 S. VII), der Jordansche Apparat wird seit 1915 nicht mehr mit Blauisenpapier, sondern mit einem mäßig empfindlichen Celloidinpapier beschiekt.

Die Bodentemperaturen gelten für kiesigen, von Humus befreiten Sand; die Oberfläche wird im Winter schneefrei gehalten. Für die Tiefen von 0.5 bis 12 m sind die Thermometer am unteren Ende von Holzstangen angebracht, die in Schutzröhren aus Neusilber gesteckt werden.

Die Verdunstungsangaben stammen von einem Wildschen Evaporimeter, der auf der Beobachtungswiese innerhalb einer großen Thermometerhütte, also beschattet, aufgestellt ist. Die Verdunstungsfläche befindet sich 2.3 m über dem Boden.

Die Messungen der Intensität der Sonnenstrahlung sind fast ausschließlich mit einem Bimetall-Lamellen-Aktinometer nach dem Prinzip von Michelson-Moskau ausgeführt, dessen Konstanten mit Angströms Kompensations-Pyrheliometer nachgeprüft wurden. Die Ablesungen sind auf die verbesserte pyrhelometrische Skala der Smithsonian Institution in Washington (1913) reduziert worden.

Die Aufzeichnung des luftelektrischen Potentialgefälles erfolgte bis zum 30. Juni 1926 in derselben Weise und mit derselben Empfindlichkeit wie im Vorjahre. Am 1. Juli wurde das bisher für luftelektrische Messungen benutzte Wellblechhaus abgebrochen, und die Registrierung des Potentialgefälles wurde in einen Neubau verlegt, der im Laufe der Jahre 1925 und 1926 im Westen der bisherigen Meßstelle errichtet worden war. Dieses neue, in einer Geländefalte gelegene luftelektrische Meßhaus, in dessen Umgebung eine große Zahl von Bäumen gefällt worden ist, ist mit einem großen weitmaschigen Messingdrahtnetz überdeckt worden, das sich in gleicher Höhe mit der großen ebenen Beobachtungswiese befindet. Dadurch ist ein einfacher Verlauf der Potentialflächen — gewissermaßen eine künstliche ebene Erdoberfläche — erreicht worden. Als Kollektor dient ein 60 cm senkrecht über dem Drahtnetz angebrachtes Radiothor-Präparat, das von einem frei durch das Dach des Meßhauses gehenden Metallrohr gehalten wird. Als Isolator dient ein Hartgummistab, auf den das Metallrohr gesetzt ist. Die ganze Vorrichtung ist, um Störungen durch Spinnen leicht beseitigen zu können, drehbar.

Im Innern des Meßhauses ist der Kollektor mit zwei Benndorf-Elektrometern verbunden, von denen das eine empfindliche, das zweite eine sehr unempfindliche Aufzeichnung des Spannungsverlaufs liefert. Als vorläufiger Reduktionsfaktor auf die freie Ebene wurde für die neue Aufstellung mit Hilfe von Parallelregistrierungen an der unveränderten Turmstation der Wert 1.24 bestimmt. Die normale, empfindliche Registrierung hatte dauernd die Volt-Empfindlichkeit von 7.0 Volt für 1 mm Ausschlag, während der Wert der unempfindlichen Anordnung stark gewechselt hat. Um auch die stärksten Ausschläge bei Böen und Gewittern zu erhalten, ist versuchsweise bis zu einer Volt-Empfindlichkeit von mehreren Hundert Volt pro mm heruntergegangen worden. Es zeigte sich jedoch, daß dann die Registrierung sehr unzuverlässig wurde, sodaß am Ende des Jahres die Empfindlichkeit wieder gesteigert wurde. Infolge dieser Versuche ist ein Teil der bei Niederschlag erhaltenen Werte unsicher.

Alle veröffentlichten luftelektrischen Werte sind auf die freie Ebene reduziert worden. Gemittelt wurden, wie bisher, nur die ruhigen Tage, d. h. niederschlags-, nebel- und ziemlich wolkenfreie Tage, an denen die Registrierkurven keine Störungen aufwiesen. Die sehr niedrigen Werte des zweiten Halbjahrs sind auf das überaus milde Wetter in dieser Zeit zurückzuführen.
